C++ Standard Library Reference

3/11/2019 • 2 minutes to read • [Edit Online](#)

A C++ program can call on a large number of functions from this conforming implementation of the C++ Standard Library. These functions perform essential services such as input and output and provide efficient implementations of frequently used operations.

For more information about Visual C++ run-time libraries, see [CRT Library Features](#).

In This Section

[C++ Standard Library Overview](#)

Provides an overview of the Microsoft implementation of the C++ Standard Library.

[iostream Programming](#)

Provides an overview of iostream programming.

[Header Files Reference](#)

Provides links to reference topics discussing the C++ Standard Library header files, with code examples.

C++ Standard Library Header Files

[Using C++ Library Headers](#)

[C++ Standard Library](#)

<algorithm>

10/31/2018 • 12 minutes to read • [Edit Online](#)

Defines C++ Standard Library container template functions that perform algorithms.

Syntax

(see relevant links below for specific algorithm syntax)

Remarks

The C++ Standard Library algorithms are generic because they can operate on a variety of data structures. The data structures that they can operate on include not only the C++ Standard Library container classes such as `vector` and `list`, but also program-defined data structures and arrays of elements that satisfy the requirements of a particular algorithm. C++ Standard Library algorithms achieve this level of generality by accessing and traversing the elements of a container indirectly through iterators.

C++ Standard Library algorithms process iterator ranges that are typically specified by their beginning or ending positions. The ranges referred to must be valid in the sense that all pointers in the ranges must be dereferenceable and, within the sequences of each range, the last position must be reachable from the first by incrementation.

The C++ Standard Library algorithms extend the actions supported by the operations and member functions of each C++ Standard Library container and allow working, for example, with different types of container objects at the same time. Two suffixes have been used to convey information about the purpose of the algorithms.

- The `_if` suffix indicates that the algorithm is used with function objects operating on the values of the elements rather than on the values of the elements themselves. The `find_if` algorithm looks for elements whose values satisfy the criterion specified by a function object, and the `find` algorithm searches for a particular value.
- The `_copy` suffix indicates that the algorithm not only manipulates the values of the elements but also copies the modified values into a destination range. The `reverse` algorithm reverses the order of the elements within a range, and the `reverse_copy` algorithm also copies the result into a destination range.

C++ Standard Library algorithms are often classified into groups that indicate something about their purpose or requirements. These include modifying algorithms that change the value of elements as compared with non-modifying algorithms that do not. Mutating algorithms change the order of elements, but not the values of their elements. Removing algorithms can eliminate elements from a range or a copy of a range. Sorting algorithms reorder the elements in a range in various ways and sorted range algorithms only act on ranges whose elements have been sorted in a particular way.

The C++ Standard Library numeric algorithms that are provided for numerical processing have their own header file `<numeric>`, and function objects and adaptors are defined in the header `<functional>`. Function objects that return Boolean values are known as predicates. The default binary predicate is the comparison `operator<`. In general, the elements being ordered need to be less than comparable so that, given any two elements, it can be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering among the nonequivalent elements.

Function templates

FUNCTION TEMPLATE	DESCRIPTION
<code>adjacent_find</code>	Searches for two adjacent elements that are either equal or satisfy a specified condition.
<code>all_of</code>	Returns true when a condition is present at each element in the given range.
<code>any_of</code>	Returns true when a condition is present at least once in the specified range of elements.
<code>binary_search</code>	Tests whether there is an element in a sorted range that is equal to a specified value or that is equivalent to it in a sense specified by a binary predicate.
<code>copy</code>	Assigns the values of elements from a source range to a destination range, iterating through the source sequence of elements and assigning them new positions in a forward direction.
<code>copy_backward</code>	Assigns the values of elements from a source range to a destination range, iterating through the source sequence of elements and assigning them new positions in a backward direction.
<code>copy_if</code>	Copy all elements in a given range that test true for a specified condition
<code>copy_n</code>	Copies a specified number of elements.
<code>count</code>	Returns the number of elements in a range whose values match a specified value.
<code>count_if</code>	Returns the number of elements in a range whose values match a specified condition.
<code>equal</code>	Compares two ranges element by element either for equality or equivalence in a sense specified by a binary predicate.
<code>equal_range</code>	Finds a pair of positions in an ordered range, the first less than or equivalent to the position of a specified element and the second greater than the element's position, where the sense of equivalence or ordering used to establish the positions in the sequence may be specified by a binary predicate.
<code>fill</code>	Assigns the same new value to every element in a specified range.
<code>fill_n</code>	Assigns a new value to a specified number of elements in a range starting with a particular element.
<code>find</code>	Locates the position of the first occurrence of an element in a range that has a specified value.

FUNCTION TEMPLATE	DESCRIPTION
<code>find_end</code>	Looks in a range for the last subsequence that is identical to a specified sequence or that is equivalent in a sense specified by a binary predicate.
<code>find_first_of</code>	Searches for the first occurrence of any of several values within a target range or for the first occurrence of any of several elements that are equivalent in a sense specified by a binary predicate to a specified set of the elements.
<code>find_if</code>	Locates the position of the first occurrence of an element in a range that satisfies a specified condition.
<code>find_if_not</code>	Returns the first element in the indicated range that does not satisfy a condition.
<code>for_each</code>	Applies a specified function object to each element in a forward order within a range and returns the function object.
<code>generate</code>	Assigns the values generated by a function object to each element in a range.
<code>generate_n</code>	Assigns the values generated by a function object to a specified number of element in a range and returns to the position one past the last assigned value.
<code>includes</code>	Tests whether one sorted range contains all the elements contained in a second sorted range, where the ordering or equivalence criterion between elements may be specified by a binary predicate.
<code>inplace_merge</code>	Combines the elements from two consecutive sorted ranges into a single sorted range, where the ordering criterion may be specified by a binary predicate.
<code>is_heap</code>	Returns true if the elements in the specified range form a heap.
<code>is_heap_until</code>	Returns true if the specified range forms a heap until the last element.
<code>is_partitioned</code>	Returns true if all the elements in the given range that test true for a condition come before any elements that test false .
<code>is_permutation</code>	Determines whether the elements in a given range form a valid permutation.
<code>is_sorted</code>	Returns true if the elements in the specified range are in sorted order.
<code>is_sorted_until</code>	Returns true if the elements in the specified range are in sorted order.
<code>iter_swap</code>	Exchanges two values referred to by a pair of specified iterators.

FUNCTION TEMPLATE	DESCRIPTION
lexicographical_compare	Compares element by element between two sequences to determine which is lesser of the two.
lower_bound	Finds the position of the first element in an ordered range that has a value greater than or equivalent to a specified value, where the ordering criterion may be specified by a binary predicate.
make_heap	Converts elements from a specified range into a heap in which the first element is the largest and for which a sorting criterion may be specified with a binary predicate.
max	Compares two objects and returns the larger of the two, where the ordering criterion may be specified by a binary predicate.
max_element	Finds the first occurrence of largest element in a specified range where the ordering criterion may be specified by a binary predicate.
merge	Combines all the elements from two sorted source ranges into a single, sorted destination range, where the ordering criterion may be specified by a binary predicate.
min	Compares two objects and returns the lesser of the two, where the ordering criterion may be specified by a binary predicate.
min_element	Finds the first occurrence of smallest element in a specified range where the ordering criterion may be specified by a binary predicate.
minmax	Compares two input parameters and returns them as a pair, in order of least to greatest.
minmax_element	Performs the work performed by min_element and max_element in one call.
mismatch	Compares two ranges element by element either for equality or equivalent in a sense specified by a binary predicate and locates the first position where a difference occurs.
<alg> move	Move elements associated with a specified range.
move_backward	Moves the elements of one iterator to another. The move starts with the last element in a specified range, and ends with the first element in that range.
next_permutation	Reorders the elements in a range so that the original ordering is replaced by the lexicographically next greater permutation if it exists, where the sense of next may be specified with a binary predicate.
none_of	Returns true when a condition is never present among elements in the given range.

FUNCTION TEMPLATE	DESCRIPTION
<code>nth_element</code>	Partitions a range of elements, correctly locating the n th element of the sequence in the range so that all the elements in front of it are less than or equal to it and all the elements that follow it in the sequence are greater than or equal to it.
<code>partial_sort</code>	Arranges a specified number of the smaller elements in a range into a nondescending order or according to an ordering criterion specified by a binary predicate.
<code>partial_sort_copy</code>	Copies elements from a source range into a destination range where the source elements are ordered by either less than or another specified binary predicate.
<code>partition</code>	Classifies elements in a range into two disjoint sets, with those elements satisfying a unary predicate preceding those that fail to satisfy it.
<code>partition_copy</code>	Copies elements for which a condition is true to one destination, and for which the condition is false to another. The elements must come from a specified range.
<code>partition_point</code>	Returns the first element in the given range that does not satisfy the condition. The elements are sorted so that those that satisfy the condition come before those that do not.
<code>pop_heap</code>	Removes the largest element from the front of a heap to the next-to-last position in the range and then forms a new heap from the remaining elements.
<code>prev_permutation</code>	Reorders the elements in a range so that the original ordering is replaced by the lexicographically next greater permutation if it exists, where the sense of next may be specified with a binary predicate.
<code>push_heap</code>	Adds an element that is at the end of a range to an existing heap consisting of the prior elements in the range.
<code>random_shuffle</code>	Rearranges a sequence of N elements in a range into one of $N!$ possible arrangements selected at random.
<code>remove</code>	Eliminates a specified value from a given range without disturbing the order of the remaining elements and returning the end of a new range free of the specified value.
<code>remove_copy</code>	Copies elements from a source range to a destination range, except that elements of a specified value are not copied, without disturbing the order of the remaining elements and returning the end of a new destination range.
<code>remove_copy_if</code>	Copies elements from a source range to a destination range, except that satisfying a predicate are not copied, without disturbing the order of the remaining elements and returning the end of a new destination range.

FUNCTION TEMPLATE	DESCRIPTION
remove_if	Eliminates elements that satisfy a predicate from a given range without disturbing the order of the remaining elements and returning the end of a new range free of the specified value.
replace	Examines each element in a range and replaces it if it matches a specified value.
replace_copy	Examines each element in a source range and replaces it if it matches a specified value while copying the result into a new destination range.
replace_copy_if	Examines each element in a source range and replaces it if it satisfies a specified predicate while copying the result into a new destination range.
replace_if	Examines each element in a range and replaces it if it satisfies a specified predicate.
reverse	Reverses the order of the elements within a range.
reverse_copy	Reverses the order of the elements within a source range while copying them into a destination range
rotate	Exchanges the elements in two adjacent ranges.
rotate_copy	Exchanges the elements in two adjacent ranges within a source range and copies the result to a destination range.
search	Searches for the first occurrence of a sequence within a target range whose elements are equal to those in a given sequence of elements or whose elements are equivalent in a sense specified by a binary predicate to the elements in the given sequence.
search_n	Searches for the first subsequence in a range that of a specified number of elements having a particular value or a relation to that value as specified by a binary predicate.
set_difference	Unites all of the elements that belong to one sorted source range, but not to a second sorted source range, into a single, sorted destination range, where the ordering criterion may be specified by a binary predicate.
set_intersection	Unites all of the elements that belong to both sorted source ranges into a single, sorted destination range, where the ordering criterion may be specified by a binary predicate.
set_symmetric_difference	Unites all of the elements that belong to one, but not both, of the sorted source ranges into a single, sorted destination range, where the ordering criterion may be specified by a binary predicate.

FUNCTION TEMPLATE	DESCRIPTION
set_union	Unites all of the elements that belong to at least one of two sorted source ranges into a single, sorted destination range, where the ordering criterion may be specified by a binary predicate.
sort	Arranges the elements in a specified range into a nondescending order or according to an ordering criterion specified by a binary predicate.
shuffle	Shuffles (rearranges) elements for a given range using a random number generator.
sort_heap	Converts a heap into a sorted range.
stable_partition	Classifies elements in a range into two disjoint sets, with those elements satisfying a unary predicate preceding those that fail to satisfy it, preserving the relative order of equivalent elements.
stable_sort	Arranges the elements in a specified range into a nondescending order or according to an ordering criterion specified by a binary predicate and preserves the relative ordering of equivalent elements.
swap	Exchanges the values of the elements between two types of objects, assigning the contents of the first object to the second object and the contents of the second to the first.
swap_ranges	Exchanges the elements of one range with the elements of another, equal sized range.
transform	Applies a specified function object to each element in a source range or to a pair of elements from two source ranges and copies the return values of the function object into a destination range.
unique	Removes duplicate elements that are adjacent to each other in a specified range.
unique_copy	Copies elements from a source range into a destination range except for the duplicate elements that are adjacent to each other.
upper_bound	Finds the position of the first element in an ordered range that has a value that is greater than a specified value, where the ordering criterion may be specified by a binary predicate.

adjacent_find

Searches for two adjacent elements that are either equal or satisfy a specified condition.

```
template<class ForwardIterator>
ForwardIterator adjacent_find(
    ForwardIterator first,
    ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
ForwardIterator adjacent_find(
    ForwardIterator first,
    ForwardIterator last,
    BinaryPredicate comp);
```

Parameters

first

A forward iterator addressing the position of the first element in the range to be searched.

last

A forward iterator addressing the position one past the final element in the range to be searched.

comp

The binary predicate giving the condition to be satisfied by the values of the adjacent elements in the range being searched.

Return Value

A forward iterator to the first element of the adjacent pair that are either equal to each other (in the first version) or that satisfy the condition given by the binary predicate (in the second version), provided that such a pair of elements is found. Otherwise, an iterator pointing to *last* is returned.

Remarks

The `adjacent_find` algorithm is a nonmutating sequence algorithm. The range to be searched must be valid; all pointers must be dereferenceable and the last position is reachable from the first by incrementation. The time complexity of the algorithm is linear in the number of elements contained in the range.

The `operator==` used to determine the match between elements must impose an equivalence relation between its operands.

Example

```

// alg_adj_fnd.cpp
// compile with: /EHsc
#include <list>
#include <algorithm>
#include <iostream>

// Returns whether second element is twice the first
bool twice (int elem1, int elem2 )
{
    return elem1 * 2 == elem2;
}

int main()
{
    using namespace std;
    list<int> L;
    list<int>::iterator Iter;
    list<int>::iterator result1, result2;

    L.push_back( 50 );
    L.push_back( 40 );
    L.push_back( 10 );
    L.push_back( 20 );
    L.push_back( 20 );

    cout << "L = ( " ;
    for ( Iter = L.begin( ) ; Iter != L.end( ) ; Iter++ )
        cout << *Iter << " ";
    cout << ")" << endl;

    result1 = adjacent_find( L.begin( ), L.end( ) );
    if ( result1 == L.end( ) )
        cout << "There are not two adjacent elements that are equal."
            << endl;
    else
        cout << "There are two adjacent elements that are equal."
            << "\n They have a value of "
            << *( result1 ) << "." << endl;

    result2 = adjacent_find( L.begin( ), L.end( ), twice );
    if ( result2 == L.end( ) )
        cout << "There are not two adjacent elements where the "
            << " second is twice the first." << endl;
    else
        cout << "There are two adjacent elements where "
            << "the second is twice the first."
            << "\n They have values of " << *(result2++);
        cout << " & " << *result2 << "." << endl;
}

```

```

L = ( 50 40 10 20 20 )
There are two adjacent elements that are equal.
They have a value of 20.
There are two adjacent elements where the second is twice the first.
They have values of 10 & 20.

```

all_of

Returns **true** when a condition is present at each element in the given range.

```
template<class InputIterator, class Predicate>
bool all_of(
    InputIterator first,
    InputIterator last,
    BinaryPredicate comp);
```

Parameters

first

An input iterator that indicates where to start to check for a condition. The iterator marks where a range of elements starts.

last

An input iterator that indicates the end of the range of elements to check for a condition.

comp

A condition to test for. This is a user-defined predicate function object that defines the condition to be satisfied by an element being checked. A predicate takes a single argument and returns **true** or **false**.

Return Value

Returns **true** if the condition is detected at each element in the indicated range, and **false** if the condition is not detected at least one time.

Remarks

The template function returns **true** only if, for each N in the range $[0, \text{last} - \text{first})$, the predicate `comp(*(_First + N))` is **true**.

any_of

Returns **true** when a condition is present at least once in the specified range of elements.

```
template<class InputIterator, class UnaryPredicate>
bool any_of(
    InputIterator first,
    InputIterator last,
    UnaryPredicate comp);
```

Parameters

first

An input iterator that indicates where to start checking a range of elements for a condition.

last

An input iterator that indicates the end of the range of elements to check for a condition.

comp

A condition to test for. This is provided by a user-defined predicate function object. The predicate defines the condition to be satisfied by the element being tested. A predicate takes a single argument and returns **true** or **false**.

Return Value

Returns **true** if the condition is detected at least once in the indicated range, **false** if the condition is never detected.

Remarks

The template function returns **true** only if, for some N in the range

$[0, \text{last} - \text{first})$, the predicate `comp(*(first + N))` is true.

binary_search

Tests whether there is an element in a sorted range that is equal to a specified value or that is equivalent to it in a sense specified by a binary predicate.

```
template<class ForwardIterator, class Type>
bool binary_search(
    ForwardIterator first,
    ForwardIterator last,
    const Type& value);

template<class ForwardIterator, class Type, class BinaryPredicate>
bool binary_search(
    ForwardIterator first,
    ForwardIterator last,
    const Type& value,
    BinaryPredicate comp);
```

Parameters

first

A forward iterator addressing the position of the first element in the range to be searched.

last

A forward iterator addressing the position one past the final element in the range to be searched.

value

The value required to be matched by the value of the element or that must satisfy the condition with the element value specified by the binary predicate.

comp

User-defined predicate function object that defines sense in which one element is less than another. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

true if an element is found in the range that is equal or equivalent to the specified value; otherwise, **false**.

Remarks

The sorted source range referenced must be valid; all pointers must be dereferenceable and, within the sequence, the last position must be reachable from the first by incrementation.

The sorted range must each be arranged as a precondition to the application of the `binary_search` algorithm in accordance with the same ordering as is to be used by the algorithm to sort the combined ranges.

The source ranges are not modified by `binary_search`.

The value types of the forward iterators need to be less-than comparable to be ordered, so that, given two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements

The complexity of the algorithm is logarithmic for random-access iterators and linear otherwise, with the number of steps proportional to $(\text{last} - \text{first})$.

Example

```
// alg_bin_srch.cpp
// compile with: /EHsc
#include <list>
#include <vector>
#include <algorithm>
#include <functional> // greater<int>()
```

```

#include <functional> // greater<int>()
#include <iostream>

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser( int elem1, int elem2 )
{
    if (elem1 < 0)
        elem1 = - elem1;
    if (elem2 < 0)
        elem2 = - elem2;
    return elem1 < elem2;
}

int main()
{
    using namespace std;

    list<int> List1;

    List1.push_back( 50 );
    List1.push_back( 10 );
    List1.push_back( 30 );
    List1.push_back( 20 );
    List1.push_back( 25 );
    List1.push_back( 5 );

    List1.sort();

    cout << "List1 = ( " ;
    for ( auto Iter : List1 )
        cout << Iter << " ";
    cout << ")" << endl;

    // default binary search for 10
    if ( binary_search(List1.begin(), List1.end(), 10) )
        cout << "There is an element in list List1 with a value equal to 10."
        << endl;
    else
        cout << "There is no element in list List1 with a value equal to 10."
        << endl;

    // a binary_search under the binary predicate greater
    List1.sort(greater<int>());
    if ( binary_search(List1.begin(), List1.end(), 10, greater<int>()) )
        cout << "There is an element in list List1 with a value greater than 10 "
        << "under greater than." << endl;
    else
        cout << "No element in list List1 with a value greater than 10 "
        << "under greater than." << endl;

    // a binary_search under the user-defined binary predicate mod_lesser
    vector<int> v1;

    for ( auto i = -2; i <= 4; ++i )
    {
        v1.push_back(i);
    }

    sort(v1.begin(), v1.end(), mod_lesser);

    cout << "Ordered using mod_lesser, vector v1 = ( " ;
    for ( auto Iter : v1 )
        cout << Iter << " ";
    cout << ")" << endl;

    if ( binary_search(v1.begin(), v1.end(), -3, mod_lesser) )
        cout << "There is an element with a value equivalent to -3 "
        << "under mod_lesser." << endl;
    else
        cout << "There is no element with a value equivalent to -3 "
        << "under mod_lesser." << endl;
}

```

```
    cout << "There is not an element with a value equivalent to -3 "
    << "under mod_lesser." << endl;
}
```

copy

Assigns the values of elements from a source range to a destination range, iterating through the source sequence of elements and assigning them new positions in a forward direction.

```
template<class InputIterator, class OutputIterator>
OutputIterator copy(
    InputIterator first,
    InputIterator last,
    OutputIterator destBeg);
```

Parameters

first

An input iterator addressing the position of the first element in the source range.

last

An input iterator addressing the position that is one past the final element in the source range.

destBeg

An output iterator addressing the position of the first element in the destination range.

Return Value

An output iterator addressing the position that is one past the final element in the destination range, that is, the iterator addresses `result + (last - first)`.

Remarks

The source range must be valid and there must be sufficient space at the destination to hold all the elements being copied.

Because the algorithm copies the source elements in order beginning with the first element, the destination range can overlap with the source range provided the *last* position of the source range is not contained in the destination range. `copy` can be used to shift elements to the left but not the right, unless there is no overlap between the source and destination ranges. To shift to the right any number of positions, use the [copy_backward](#) algorithm.

The `copy` algorithm only modifies values pointed to by the iterators, assigning new values to elements in the destination range. It cannot be used to create new elements and cannot insert elements into an empty container directly.

Example

```

// alg_copy.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1, v2;
    vector<int>::iterator Iter1, Iter2;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
        v1.push_back( 10 * i );

    int ii;
    for ( ii = 0 ; ii <= 10 ; ii++ )
        v2.push_back( 3 * ii );

    cout << "v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // To copy the first 3 elements of v1 into the middle of v2
    copy( v1.begin( ), v1.begin( ) + 3, v2.begin( ) + 4 );

    cout << "v2 with v1 insert = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // To shift the elements inserted into v2 two positions
    // to the left
    copy( v2.begin( )+4, v2.begin( ) + 7, v2.begin( ) + 2 );

    cout << "v2 with shifted insert = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;
}

```

```

v1 = ( 0 10 20 30 40 50 )
v2 = ( 0 3 6 9 12 15 18 21 24 27 30 )
v2 with v1 insert = ( 0 3 6 9 0 10 20 21 24 27 30 )
v2 with shifted insert = ( 0 3 0 10 20 10 20 21 24 27 30 )

```

copy_backward

Assigns the values of elements from a source range to a destination range, iterating through the source sequence of elements and assigning them new positions in a backward direction.

```
template<class BidirectionalIterator1, class BidirectionalIterator2>
BidirectionalIterator2 copy_backward(
    BidirectionalIterator1 first,
    BidirectionalIterator1 last,
    BidirectionalIterator2 destEnd);
```

Parameters

first

A bidirectional iterator addressing the position of the first element in the source range.

last

A bidirectional iterator addressing the position that is one past the final element in the source range.

destEnd

A bidirectional iterator addressing the position of one past the final element in the destination range.

Return Value

An output iterator addressing the position that is one past the final element in the destination range, that is, the iterator addresses *destEnd* - (*last* - *first*).

Remarks

The source range must be valid and there must be sufficient space at the destination to hold all the elements being copied.

The `copy_backward` algorithm imposes more stringent requirements than that the `copy` algorithm. Both its input and output iterators must be bidirectional.

The `copy_backward` and `move_backward` algorithms are the only C++ Standard Library algorithms designating the output range with an iterator pointing to the end of the destination range.

Because the algorithm copies the source elements in order beginning with the last element, the destination range can overlap with the source range provided the *first* position of the source range is not contained in the destination range. `copy_backward` can be used to shift elements to the right but not the left, unless there is no overlap between the source and destination ranges. To shift to the left any number of positions, use the `copy` algorithm.

The `copy_backward` algorithm only modifies values pointed to by the iterators, assigning new values to elements in the destination range. It cannot be used to create new elements and cannot insert elements into an empty container directly.

Example

```

// alg_copy_bkwd.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1, v2;
    vector<int>::iterator Iter1, Iter2;

    int i;
    for ( i = 0 ; i <= 5 ; ++i )
        v1.push_back( 10 * i );

    int ii;
    for ( ii = 0 ; ii <= 10 ; ++ii )
        v2.push_back( 3 * ii );

    cout << "v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; ++Iter1 )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; ++Iter2 )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // To copy_backward the first 3 elements of v1 into the middle of v2
    copy_backward( v1.begin( ), v1.begin( ) + 3, v2.begin( ) + 7 );

    cout << "v2 with v1 insert = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; ++Iter2 )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // To shift the elements inserted into v2 two positions
    // to the right
    copy_backward( v2.begin( )+4, v2.begin( ) + 7, v2.begin( ) + 9 );

    cout << "v2 with shifted insert = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; ++Iter2 )
        cout << *Iter2 << " ";
    cout << ")" << endl;
}

```

copy_if

In a range of elements, copies the elements that are **true** for the specified condition.

```

template<class InputIterator, class OutputIterator, class BinaryPredicate>
OutputIterator copy_if(
    InputIterator first,
    InputIterator last,
    OutputIterator dest,
    Predicate pred);

```

Parameters

first

An input iterator that indicates the start of a range to check for the condition.

last

An input iterator that indicates the end of the range.

dest

The output iterator that indicates the destination for the copied elements.

_Pred

The condition against which every element in the range is tested. This condition is provided by a user-defined predicate function object. A predicate takes one argument and returns **true** or **false**.

Return Value

An output iterator that equals *dest* incremented once for each element that fulfills the condition. In other words, the return value minus *dest* equals the number of copied elements.

Remarks

The template function evaluates

```
if (pred(*_First + N) * dest++ = *(_First + N))
```

once for each `N` in the range `[0, last - first)`, for strictly increasing values of `N` starting with the lowest value. If *dest* and *first* designate regions of storage, *dest* must not be in the range `[first, last)`.

copy_n

Copies a specified number of elements.

```
template<class InputIterator, class Size, class OutputIterator>
OutputIterator copy_n(
    InputIterator first,
    Size count,
    OutputIterator dest);
```

Parameters

first

An input iterator that indicates where to copy elements from.

count

A signed or unsigned integer type specifying the number of elements to copy.

dest

An output iterator that indicates where to copy elements to.

Return Value

Returns an output iterator where elements have been copied to. It is the same as the returned value of the third parameter, *dest*.

Remarks

The template function evaluates `*(dest + N) = *(first + N)` once for each `N` in the range `[0, count)`, for strictly increasing values of `N` starting with the lowest value. It then returns `dest + N`. If *dest* and *first* designate regions of storage, *dest* must not be in the range `[first, last)`.

count

Returns the number of elements in a range whose values match a specified value.

```
template<class InputIterator, class Type>
typename iterator_traits<InputIterator>::difference_type count(
    InputIterator first,
    InputIterator last,
    const Type& val);
```

Parameters

first

An input iterator addressing the position of the first element in the range to be traversed.

last

An input iterator addressing the position one past the final element in the range to be traversed.

val

The value of the elements to be counted.

Return Value

The difference type of the `InputIterator` that counts the number of elements in the range `[first, last)` that have value *val*.

Remarks

The `operator==` used to determine the match between an element and the specified value must impose an equivalence relation between its operands.

This algorithm is generalized to count elements that satisfy any predicate with the template function [count_if](#).

Example

```
// alg_count.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main()
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter;

    v1.push_back(10);
    v1.push_back(20);
    v1.push_back(10);
    v1.push_back(40);
    v1.push_back(10);

    cout << "v1 = ( " ;
    for (Iter = v1.begin(); Iter != v1.end(); Iter++)
        cout << *Iter << " ";
    cout << ")" << endl;

    vector<int>::iterator::difference_type result;
    result = count(v1.begin(), v1.end(), 10);
    cout << "The number of 10s in v2 is: " << result << "." << endl;
}
```

```
v1 = ( 10 20 10 40 10 )
The number of 10s in v2 is: 3.
```

count_if

Returns the number of elements in a range whose values satisfy a specified condition.

```
template<class InputIterator, class Predicate>
typename iterator_traits<InputIterator>::difference_type count_if(
    InputIterator first,
    InputIterator last,
    Predicate pred);
```

Parameters

first

An input iterator addressing the position of the first element in the range to be searched.

last

An input iterator addressing the position one past the final element in the range to be searched.

_Pred

User-defined predicate function object that defines the condition to be satisfied if an element is to be counted. A predicate takes single argument and returns **true** or **false**.

Return Value

The number of elements that satisfy the condition specified by the predicate.

Remarks

This template function is a generalization of the algorithm [count](#), replacing the predicate "equals a specific value" with any predicate.

Example

```

// alg_count_if.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

bool greater10(int value)
{
    return value > 10;
}

int main()
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter;

    v1.push_back(10);
    v1.push_back(20);
    v1.push_back(10);
    v1.push_back(40);
    v1.push_back(10);

    cout << "v1 = ( ";
    for (Iter = v1.begin(); Iter != v1.end(); Iter++)
        cout << *Iter << " ";
    cout << ")" << endl;

    vector<int>::iterator::difference_type result1;
    result1 = count_if(v1.begin(), v1.end(), greater10);
    cout << "The number of elements in v1 greater than 10 is: "
        << result1 << "." << endl;
}

```

```

v1 = ( 10 20 10 40 10 )
The number of elements in v1 greater than 10 is: 2.

```

equal

Compares two ranges element by element for equality or equivalence in a sense specified by a binary predicate.

Use `std::equal` when comparing elements in different container types (for example `vector` and `list`) or when comparing different element types, or when you need to compare sub-ranges of containers. Otherwise, when comparing elements of the same type in the same container type, use the non-member `operator==` that is provided for each container.

Use the dual-range overloads in C++14 code because the overloads that only take a single iterator for the second range will not detect differences if the second range is longer than the first range, and will result in undefined behavior if the second range is shorter than the first range.

```

template<class InputIterator1, class InputIterator2>
bool equal(
    InputIterator1 First1,
    InputIterator1 Last1,
    InputIterator2 First2);

template<class InputIterator1, class InputIterator2, class BinaryPredicate>
bool equal(
    InputIterator1 First1,
    InputIterator1 Last1,
    InputIterator2 First2,
    BinaryPredicate Comp); // C++14

template<class InputIterator1, class InputIterator2>
bool equal(
    InputIterator1 First1,
    InputIterator1 Last1,
    InputIterator2 First2,
    InputIterator2 Last2);

template<class InputIterator1, class InputIterator2, class BinaryPredicate>
bool equal(
    InputIterator1 First1,
    InputIterator1 Last1,
    InputIterator2 First2,
    InputIterator2 Last2,
    BinaryPredicate Comp);

```

Parameters

First1

An input iterator addressing the position of the first element in the first range to be tested.

Last1

An input iterator addressing the position one past the last element in the first range to be tested.

First2

An input iterator addressing the position of the first element in the second range to be tested.

First2

An input iterator addressing the position of one past the last element in the second range to be tested.

Comp

User-defined predicate function object that defines the condition to be satisfied if two elements are to be taken as equivalent. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

true if and only if the ranges are identical or equivalent under the binary predicate when compared element by element; otherwise, **false**.

Remarks

The range to be searched must be valid; all iterators must be dereferenceable and the last position is reachable from the first by incrementation.

If the two ranges are equal length, then the time complexity of the algorithm is linear in the number of elements contained in the range. Otherwise the function immediately returns **false**.

Neither the `operator==` nor the user-defined predicate is required to impose an equivalence relation that symmetric, reflexive and transitive between its operands.

Example

```

#include <iostream>
#include <vector>
#include <algorithm>

using namespace std;

int main()
{
    vector<int> v1 { 0, 5, 10, 15, 20, 25 };
    vector<int> v2 { 0, 5, 10, 15, 20, 25 };
    vector<int> v3 { 0, 5, 10, 15, 20, 25, 30, 35, 40, 45, 50 };

    // Using range-and-a-half equal:
    bool b = equal(v1.begin(), v1.end(), v2.begin());
    cout << "v1 and v2 are equal: "
         << b << endl; // true, as expected

    b = equal(v1.begin(), v1.end(), v3.begin());
    cout << "v1 and v3 are equal: "
         << b << endl; // true, surprisingly

    // Using dual-range equal:
    b = equal(v1.begin(), v1.end(), v3.begin(), v3.end());
    cout << "v1 and v3 are equal with dual-range overload: "
         << b << endl; // false

    return 0;
}

```

equal_range

Given an ordered range, finds the subrange in which all elements are equivalent to a given value.

```

template<class ForwardIterator, class Type>
pair<ForwardIterator, ForwardIterator> equal_range(
    ForwardIterator first,
    ForwardIterator last,
    const Type& val);

template<class ForwardIterator, class Type, class Predicate>
pair<ForwardIterator, ForwardIterator> equal_range(
    ForwardIterator first,
    ForwardIterator last,
    const Type& val,
    Predicate comp);

```

Parameters

first

A forward iterator addressing the position of the first element in the range to be searched.

last

A forward iterator addressing the position one past the final element in the range to be searched.

val

The value being searched for in the ordered range.

comp

User-defined predicate function object that defines the sense in which one element is less than another.

Return Value

A pair of forward iterators that specify a subrange, contained within the range searched, in which all of the

elements are equivalent to *val* in the sense defined by the binary predicate used (either *comp* or the default, less-than).

If no elements in the range are equivalent to *val*, the returned pair of forward iterators are equal and specify the point where *val* could be inserted without disturbing the order of the range.

Remarks

The first iterator of the pair returned by the algorithm is [lower_bound](#), and the second iterator is [upper_bound](#).

The range must be sorted according to the predicate provided to `equal_range`. For example, if you are going to use the greater-than predicate, the range must be sorted in descending order.

Elements in the possibly empty subrange defined by the pair of iterators returned by `equal_range` will be equivalent to *val* in the sense defined by the predicate used.

The complexity of the algorithm is logarithmic for random-access iterators and linear otherwise, with the number of steps proportional to (*last* - *first*).

Example

```
// alg_equal_range.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      // greater<int>()
#include <iostream>
#include <string>
using namespace std;

template<class T> void dump_vector( const vector<T>& v, pair<typename vector<T>::iterator, typename
vector<T>::iterator> range )
{
    // prints vector v with range delimited by [ and ]

    for ( typename vector<T>::const_iterator i = v.begin(); i != v.end(); ++i )
    {
        if ( i == range.first )
        {
            cout << "[ ";
        }
        if ( i == range.second )
        {
            cout << "] ";
        }

        cout << *i << " ";
    }
    cout << endl;
}

template<class T> void equal_range_demo( const vector<T>& original_vector, T val )
{
    vector<T> v(original_vector);

    sort( v.begin(), v.end() );
    cout << "Vector sorted by the default binary predicate <:" << endl << '\t';
    for ( vector<T>::const_iterator i = v.begin(); i != v.end(); ++i )
    {
        cout << *i << " ";
    }
    cout << endl << endl;

    pair<vector<T>::iterator, vector<T>::iterator> result
        = equal_range( v.begin(), v.end(), val );

    cout << "Result of equal_range with val = " << val << " " << endl << '\t';
```

```

    cout << "Result of equal_range with val = " << val << " : " << endl << '\t';
    dump_vector( v, result );
    cout << endl;
}

template<class T, class F> void equal_range_demo( const vector<T>& original_vector, T val, F pred, string
predname )
{
    vector<T> v(original_vector);

    sort( v.begin(), v.end(), pred );
    cout << "Vector sorted by the binary predicate " << predname << ":" << endl << '\t';
    for ( typename vector<T>::const_iterator i = v.begin(); i != v.end(); ++i )
    {
        cout << *i << " ";
    }
    cout << endl << endl;

    pair<typename vector<T>::iterator, typename vector<T>::iterator> result
        = equal_range( v.begin(), v.end(), val, pred );

    cout << "Result of equal_range with val = " << val << ":" << endl << '\t';
    dump_vector( v, result );
    cout << endl;
}

// Return whether absolute value of elem1 is less than absolute value of elem2
bool abs_lesser( int elem1, int elem2 )
{
    return abs(elem1) < abs(elem2);
}

// Return whether string l is shorter than string r
bool shorter_than(const string& l, const string& r)
{
    return l.size() < r.size();
}

int main()
{
    vector<int> v1;

    // Constructing vector v1 with default less than ordering
    for ( int i = -1; i <= 4; ++i )
    {
        v1.push_back(i);
    }

    for ( int i = -3; i <= 0; ++i )
    {
        v1.push_back( i );
    }

    equal_range_demo( v1, 3 );
    equal_range_demo( v1, 3, greater<int>(), "greater" );
    equal_range_demo( v1, 3, abs_lesser, "abs_lesser" );

    vector<string> v2;

    v2.push_back("cute");
    v2.push_back("fluffy");
    v2.push_back("kittens");
    v2.push_back("fun");
    v2.push_back("meowmeowmeow");
    v2.push_back("blah");

    equal_range_demo<string>( v2, "fred" );
    equal_range_demo<string>( v2, "fred", shorter_than, "shorter_than" );
}

```

fill

Assigns the same new value to every element in a specified range.

```
template<class ForwardIterator, class Type>
void fill(
    ForwardIterator first,
    ForwardIterator last,
    const Type& val);
```

Parameters

first

A forward iterator addressing the position of the first element in the range to be traversed.

last

A forward iterator addressing the position one past the final element in the range to be traversed.

val

The value to be assigned to elements in the range [*first*, *last*).

Remarks

The destination range must be valid; all pointers must be dereferenceable, and the last position is reachable from the first by incrementation. The complexity is linear with the size of the range.

Example

```
// alg_fill.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main()
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
    {
        v1.push_back( 5 * i );
    }

    cout << "Vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // Fill the last 5 positions with a value of 2
    fill( v1.begin( ) + 5, v1.end( ), 2 );

    cout << "Modified v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
}
```

```
Vector v1 = ( 0 5 10 15 20 25 30 35 40 45 )  
Modified v1 = ( 0 5 10 15 20 2 2 2 2 2 )
```

fill_n

Assigns a new value to a specified number of elements in a range beginning with a particular element.

```
template<class OutputIterator, class Size, class Type>  
OutputIterator fill_n(  
    OutputIterator First,  
    Size Count,  
    const Type& Val);
```

Parameters

First

An output iterator addressing the position of the first element in the range to be assigned the value *Val*.

Count

A signed or unsigned integer type specifying the number of elements to be assigned the value.

Val

The value to be assigned to elements in the range [*First*, *First* + *Count*).

Return Value

An iterator to the element that follows the last element filled if *Count* > zero, otherwise the first element.

Remarks

The destination range must be valid; all pointers must be dereferenceable, and the last position is reachable from the first by incrementation. The complexity is linear with the size of the range.

Example

```

// alg_fill_n.cpp
// compile using /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main()
{
    using namespace std;
    vector<int> v;

    for ( auto i = 0 ; i < 9 ; ++i )
        v.push_back( 0 );

    cout << " vector v = ( " ;
    for ( const auto &w : v )
        cout << w << " ";
    cout << ")" << endl;

    // Fill the first 3 positions with a value of 1, saving position.
    auto pos = fill_n( v.begin(), 3, 1 );

    cout << "modified v = ( " ;
    for ( const auto &w : v )
        cout << w << " ";
    cout << ")" << endl;

    // Fill the next 3 positions with a value of 2, using last position.
    fill_n( pos, 3, 2 );

    cout << "modified v = ( " ;
    for ( const auto &w : v )
        cout << w << " ";
    cout << ")" << endl;

    // Fill the last 3 positions with a value of 3, using relative math.
    fill_n( v.end()-3, 3, 3 );

    cout << "modified v = ( " ;
    for ( const auto &w : v )
        cout << w << " ";
    cout << ")" << endl;
}

```

find

Locates the position of the first occurrence of an element in a range that has a specified value.

```

template<class InputIterator, class T>
InputIterator find(
    InputIterator first,
    InputIterator last,
    const T& val);

```

Parameters

first

An input iterator addressing the position of the first element in the range to be searched for the specified value.

last

An input iterator addressing the position one past the final element in the range to be searched for the specified value.

val

The value to be searched for.

Return Value

An input iterator addressing the first occurrence of the specified value in the range being searched. If no element is found with an equivalent value, returns *last*.

Remarks

The `operator==` used to determine the match between an element and the specified value must impose an equivalence relation between its operands.

For a code example using `find()`, see [find_if](#).

find_end

Looks in a range for the last subsequence that is identical to a specified sequence or that is equivalent in a sense specified by a binary predicate.

```
template<class ForwardIterator1, class ForwardIterator2>
ForwardIterator1 find_end(
    ForwardIterator1 First1,
    ForwardIterator1 Last1,
    ForwardIterator2 First2,
    ForwardIterator2 Last2);

template<class ForwardIterator1, class ForwardIterator2, class Pred>
ForwardIterator1 find_end(
    ForwardIterator1 First1,
    ForwardIterator1 Last1,
    ForwardIterator2 First2,
    ForwardIterator2 Last2,
    Pred Comp);
```

Parameters

First1

A forward iterator addressing the position of the first element in the range to be searched.

Last1

A forward iterator addressing the position one past the last element in the range to be searched.

First2

A forward iterator addressing the position of the first element in the range to search for.

Last2

A forward iterator addressing the position one past the last element in the range to search for.

Comp

User-defined predicate function object that defines the condition to be satisfied if two elements are to be taken as equivalent. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

A forward iterator addressing the position of the first element of the last subsequence within [First1, Last1) that matches the specified sequence [First2, Last2).

Remarks

The `operator==` used to determine the match between an element and the specified value must impose an equivalence relation between its operands.

The ranges referenced must be valid; all pointers must be dereferenceable and, within each sequence, the last position is reachable from the first by incrementation.

Example

```
// alg_find_end.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <algorithm>
#include <iostream>

// Return whether second element is twice the first
bool twice ( int elem1, int elem2 )
{
    return 2 * elem1 == elem2;
}

int main()
{
    using namespace std;
    vector <int> v1, v2;
    list <int> L1;
    vector <int>::iterator Iter1, Iter2;
    list <int>::iterator L1_Iter, L1_inIter;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 5 * i );
    }
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 5 * i );
    }

    int ii;
    for ( ii = 1 ; ii <= 4 ; ii++ )
    {
        L1.push_back( 5 * ii );
    }

    int iii;
    for ( iii = 2 ; iii <= 4 ; iii++ )
    {
        v2.push_back( 10 * iii );
    }

    cout << "Vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "List L1 = ( " ;
    for ( L1_Iter = L1.begin( ) ; L1_Iter!= L1.end( ) ; L1_Iter++ )
        cout << *L1_Iter << " ";
    cout << ")" << endl;

    cout << "Vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Searching v1 for a match to L1 under identity
    vector <int>::iterator result1;
    result1 = find_end ( v1.begin( ), v1.end( ), L1.begin( ), L1.end( ) );

    if ( result1 == v1.end( ) )
```

```

    if ( result1 == v1.end( ) )
        cout << "There is no match of L1 in v1."
            << endl;
    else
        cout << "There is a match of L1 in v1 that begins at "
            << "position " << result1 - v1.begin( ) << "." << endl;

    // Searching v1 for a match to L1 under the binary predicate twice
    vector<int>::iterator result2;
    result2 = find_end ( v1.begin( ), v1.end( ), v2.begin( ), v2.end( ), twice );

    if ( result2 == v1.end( ) )
        cout << "There is no match of L1 in v1."
            << endl;
    else
        cout << "There is a sequence of elements in v1 that "
            << "are equivalent to those\n in v2 under the binary "
            << "predicate twice and that begins at position "
            << result2 - v1.begin( ) << "." << endl;
}

```

```

Vector v1 = ( 0 5 10 15 20 25 0 5 10 15 20 25 )
List L1 = ( 5 10 15 20 )
Vector v2 = ( 20 30 40 )
There is a match of L1 in v1 that begins at position 7.
There is a sequence of elements in v1 that are equivalent to those
in v2 under the binary predicate twice and that begins at position 8.

```

find_first_of

Searches for the first occurrence of any of several values within a target range or for the first occurrence of any of several elements that are equivalent in a sense specified by a binary predicate to a specified set of the elements.

```

template<class ForwardIterator1, class ForwardIterator2>
ForwardIterator1 find_first_of(
    ForwardIterator1 first1,
    ForwardIterator1 Last1,
    ForwardIterator2 first2,
    ForwardIterator2 Last2);

template<class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
ForwardIterator1 find_first_of(
    ForwardIterator1 first1,
    ForwardIterator1 Last1,
    ForwardIterator2 first2,
    ForwardIterator2 Last2,
    BinaryPredicate comp);

```

Parameters

first1

A forward iterator addressing the position of the first element in the range to be searched.

last1

A forward iterator addressing the position one past the final element in the range to be searched.

first2

A forward iterator addressing the position of the first element in the range to be matched.

last2

A forward iterator addressing the position one past the final element in the range to be matched.

comp

User-defined predicate function object that defines the condition to be satisfied if two elements are to be taken as equivalent. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

A forward iterator addressing the position of the first element of the first subsequence that matches the specified sequence or that is equivalent in a sense specified by a binary predicate.

Remarks

The `operator==` used to determine the match between an element and the specified value must impose an equivalence relation between its operands.

The ranges referenced must be valid; all pointers must be dereferenceable and, within each sequence, the last position is reachable from the first by incrementation.

Example

```
// alg_find_first_of.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <algorithm>
#include <iostream>

// Return whether second element is twice the first
bool twice ( int elem1, int elem2 )
{
    return 2 * elem1 == elem2;
}

int main()
{
    using namespace std;
    vector <int> v1, v2;
    list <int> L1;
    vector <int>::iterator Iter1, Iter2;
    list <int>::iterator L1_Iter, L1_inIter;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 5 * i );
    }
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 5 * i );
    }

    int ii;
    for ( ii = 3 ; ii <= 4 ; ii++ )
    {
        L1.push_back( 5 * ii );
    }

    int iii;
    for ( iii = 2 ; iii <= 4 ; iii++ )
    {
        v2.push_back( 10 * iii );
    }

    cout << "Vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
```

```

cout << "List L1 = ( " ;
for ( L1_Iter = L1.begin( ) ; L1_Iter!= L1.end( ) ; L1_Iter++ )
    cout << *L1_Iter << " ";
cout << ")" << endl;

cout << "Vector v2 = ( " ;
for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
    cout << *Iter2 << " ";
cout << ")" << endl;

// Searching v1 for first match to L1 under identity
vector<int>::iterator result1;
result1 = find_first_of ( v1.begin( ), v1.end( ), L1.begin( ), L1.end( ) );

if ( result1 == v1.end( ) )
    cout << "There is no match of L1 in v1."
        << endl;
else
    cout << "There is at least one match of L1 in v1"
        << "\n and the first one begins at "
        << "position "<< result1 - v1.begin( ) << "." << endl;

// Searching v1 for a match to L1 under the binary predicate twice
vector<int>::iterator result2;
result2 = find_first_of ( v1.begin( ), v1.end( ), v2.begin( ), v2.end( ), twice );

if ( result2 == v1.end( ) )
    cout << "There is no match of L1 in v1."
        << endl;
else
    cout << "There is a sequence of elements in v1 that "
        << "are equivalent\n to those in v2 under the binary "
        << "predicate twice\n and the first one begins at position "
        << result2 - v1.begin( ) << "." << endl;
}

```

```

Vector v1 = ( 0 5 10 15 20 25 0 5 10 15 20 25 )
List L1 = ( 15 20 )
Vector v2 = ( 20 30 40 )
There is at least one match of L1 in v1
and the first one begins at position 3.
There is a sequence of elements in v1 that are equivalent
to those in v2 under the binary predicate twice
and the first one begins at position 2.

```

find_if

Locates the position of the first occurrence of an element in a range that satisfies a specified condition.

```

template<class InputIterator, class Predicate>
InputIterator find_if(
    InputIterator first,
    InputIterator last,
    Predicate pred);

```

Parameters

first

An input iterator addressing the position of the first element in the range to be searched.

last

An input iterator addressing the position one past the final element in the range to be searched.

pred

User-defined predicate function object or [lambda expression](#) that defines the condition to be satisfied by the element being searched for. A predicate takes single argument and returns **true** (satisfied) or **false** (not satisfied). The signature of *pred* must effectively be `bool pred(const T& arg);`, where `T` is a type to which `InputIterator` can be implicitly converted when dereferenced. The **const** keyword is shown only to illustrate that the function object or lambda should not modify the argument.

Return Value

An input iterator that refers to the first element in the range that satisfies the condition specified by the predicate (the predicate results in **true**). If no element is found to satisfy the predicate, returns *last*.

Remarks

This template function is a generalization of the algorithm [find](#), replacing the predicate "equals a specific value" with any predicate. For the logical opposite (find the first element that does not satisfy the predicate), see [find_if_not](#).

Example

```
// cl.exe /W4 /nologo /EHsc /MTd
#include <vector>
#include <algorithm>
#include <iostream>
#include <string>

using namespace std;

template <typename S> void print(const S& s) {
    for (const auto& p : s) {
        cout << "(" << p << ") ";
    }
    cout << endl;
}

// Test std::find()
template <class InputIterator, class T>
void find_print_result(InputIterator first, InputIterator last, const T& value) {

    // call <algorithm> std::find()
    auto p = find(first, last, value);

    cout << "value " << value;
    if (p == last) {
        cout << " not found." << endl;
    } else {
        cout << " found." << endl;
    }
}

// Test std::find_if()
template <class InputIterator, class Predicate>
void find_if_print_result(InputIterator first, InputIterator last,
    Predicate Pred, const string& Str) {

    // call <algorithm> std::find_if()
    auto p = find_if(first, last, Pred);

    if (p == last) {
        cout << Str << " not found." << endl;
    } else {
        cout << "first " << Str << " found: " << *p << endl;
    }
}

// Function to use as the UnaryPredicate argument to find_if() in this example
```

```

bool is_odd_int(int i) {
    return ((i % 2) != 0);
}

int main()
{
    // Test using a plain old array.
    const int x[] = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 };
    cout << "array x[] contents: ";
    print(x);
    // Using non-member std::begin()/std::end() to get input iterators for the plain old array.
    cout << "Test std::find() with array..." << endl;
    find_print_result(begin(x), end(x), 10);
    find_print_result(begin(x), end(x), 42);
    cout << "Test std::find_if() with array..." << endl;
    find_if_print_result(begin(x), end(x), is_odd_int, "odd integer"); // function name
    find_if_print_result(begin(x), end(x), // lambda
        [](int i){ return ((i % 2) == 0); }, "even integer");

    // Test using a vector.
    vector<int> v;
    for (int i = 0; i < 10; ++i) {
        v.push_back((i + 1) * 10);
    }
    cout << endl << "vector v contents: ";
    print(v);
    cout << "Test std::find() with vector..." << endl;
    find_print_result(v.begin(), v.end(), 20);
    find_print_result(v.begin(), v.end(), 12);
    cout << "Test std::find_if() with vector..." << endl;
    find_if_print_result(v.begin(), v.end(), is_odd_int, "odd integer");
    find_if_print_result(v.begin(), v.end(), // lambda
        [](int i){ return ((i % 2) == 0); }, "even integer");
}

```

find_if_not

Returns the first element in the indicated range that does not satisfy a condition.

```

template<class InputIterator, class Predicate>
InputIterator find_if_not(
    InputIterator first,
    InputIterator last,
    Predicate pred);

```

Parameters

first

An input iterator addressing the position of the first element in the range to be searched.

last

An input iterator addressing the position one past the final element in the range to be searched.

pred

User-defined predicate function object or [lambda expression](#) that defines the condition to be not satisfied by the element being searched for. A predicate takes single argument and returns **true** (satisfied) or **false** (not satisfied).

The signature of *pred* must effectively be `bool pred(const T& arg);`, where `T` is a type to which `InputIterator` can be implicitly converted when dereferenced. The **const** keyword is shown only to illustrate that the function object or lambda should not modify the argument.

Return Value

An input iterator that refers to the first element in the range that does not satisfy the condition specified by the

predicate (the predicate results in **false**). If all elements satisfy the predicate (the predicate results in **true** for every element), returns *last*.

Remarks

This template function is a generalization of the algorithm [find](#), replacing the predicate "equals a specific value" with any predicate. For the logical opposite (find the first element that does satisfy the predicate), see [find_if](#).

For a code example readily adaptable to `find_if_not()`, see [find_if](#).

for_each

Applies a specified function object to each element in a forward order within a range and returns the function object.

```
template<class InputIterator, class Function>
Function for_each(
    InputIterator first,
    InputIterator last,
    Function func);
```

Parameters

first

An input iterator addressing the position of the first element in the range to be operated on.

last

An input iterator addressing the position one past the final element in the range operated on.

_Func

User-defined function object that is applied to each element in the range.

Return Value

A copy of the function object after it has been applied to all of the elements in the range.

Remarks

The algorithm `for_each` is very flexible, allowing the modification of each element within a range in different, user-specified ways. Templated functions may be reused in a modified form by passing different parameters. User-defined functions may accumulate information within an internal state that the algorithm may return after processing all of the elements in the range.

The range referenced must be valid; all pointers must be dereferenceable and, within the sequence, the last position must be reachable from the first by incrementation.

The complexity is linear with at most (*last* - *first*) comparisons.

Example

```
// alg_for_each.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

// The function object multiplies an element by a Factor
template <class Type>
class MultValue
{
private:
    Type Factor;    // The value to multiply by
public:
```

```

// Constructor initializes the value to multiply by
MultValue ( const Type& val ) : Factor ( val ) {
}

// The function call for the element to be multiplied
void operator( ) ( Type& elem ) const
{
    elem *= Factor;
}
};

// The function object to determine the average
class Average
{
private:
    long num;        // The number of elements
    long sum;        // The sum of the elements
public:
    // Constructor initializes the value to multiply by
    Average( ) : num ( 0 ) , sum ( 0 )
    {
    }

    // The function call to process the next element
    void operator( ) ( int elem ) \
    {
        num++;        // Increment the element count
        sum += elem;   // Add the value to the partial sum
    }

    // return Average
    operator double( )
    {
        return static_cast <double> (sum) /
            static_cast <double> (num);
    }
};

int main()
{
    using namespace std;
    vector <int> v1;
    vector <int>::iterator Iter1;

    // Constructing vector v1
    int i;
    for ( i = -4 ; i <= 2 ; i++ )
    {
        v1.push_back( i );
    }

    cout << "Original vector  v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Using for_each to multiply each element by a Factor
    for_each ( v1.begin( ), v1.end( ), MultValue<int> ( -2 ) );

    cout << "Multiplying the elements of the vector v1\n "
        << "by the factor -2 gives:\n v1mod1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // The function object is templatized and so can be
    // used again on the elements with a different Factor
    for_each (v1.begin( ), v1.end( ), MultValue<int> (5 ) );

```

```

cout << "Multiplying the elements of the vector v1mod\n "
    << "by the factor 5 gives:\n v1mod2 = ( " ;
for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
    cout << *Iter1 << " ";
cout << ")." << endl;

// The local state of a function object can accumulate
// information about a sequence of actions that the
// return value can make available, here the Average
double avemod2 = for_each ( v1.begin( ), v1.end( ),
    Average( ) );
cout << "The average of the elements of v1 is:\n Average ( v1mod2 ) = "
    << avemod2 << "." << endl;
}

```

```

Original vector  v1 = ( -4 -3 -2 -1 0 1 2 ).
Multiplying the elements of the vector v1
by the factor -2 gives:
v1mod1 = ( 8 6 4 2 0 -2 -4 ).
Multiplying the elements of the vector v1mod
by the factor 5 gives:
v1mod2 = ( 40 30 20 10 0 -10 -20 ).
The average of the elements of v1 is:
Average ( v1mod2 ) = 10.

```

generate

Assigns the values generated by a function object to each element in a range.

```

template<class ForwardIterator, class Generator>
void generate(
    ForwardIterator first,
    ForwardIterator last,
    Generator _Gen);

```

Parameters

first

A forward iterator addressing the position of the first element in the range to which values are to be assigned.

last

A forward iterator addressing the position one past the final element in the range to which values are to be assigned.

_Gen

A function object that is called with no arguments that is used to generate the values to be assigned to each of the elements in the range.

Remarks

The function object is invoked for each element in the range and does not need to return the same value each time it is called. It may, for example, read from a file or refer to and modify a local state. The generator's result type must be convertible to the value type of the forward iterators for the range.

The range referenced must be valid; all pointers must be dereferenceable and, within the sequence, the last position must be reachable from the first by incrementation.

The complexity is linear, with exactly (`last` - `first`) calls to the generator being required.

Example

```

// alg_generate.cpp
// compile with: /EHsc
#include <vector>
#include <deque>
#include <algorithm>
#include <iostream>
#include <ostream>

int main()
{
    using namespace std;

    // Assigning random values to vector integer elements
    vector<int> v1 ( 5 );
    vector<int>::iterator Iter1;
    deque<int> deq1 ( 5 );
    deque<int>::iterator d1_Iter;

    generate ( v1.begin( ), v1.end( ), rand );

    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Assigning random values to deque integer elements
    generate ( deq1.begin( ), deq1.end( ), rand );

    cout << "Deque deq1 is ( " ;
    for ( d1_Iter = deq1.begin( ) ; d1_Iter != deq1.end( ) ; d1_Iter++ )
        cout << *d1_Iter << " ";
    cout << ")." << endl;
}

```

```

Vector v1 is ( 41 18467 6334 26500 19169 ).
Deque deq1 is ( 15724 11478 29358 26962 24464 ).

```

generate_n

Assigns the values generated by a function object to a specified number of elements in a range and returns to the position one past the last assigned value.

```

template<class OutputIterator, class Diff, class Generator>
void generate_n(
    OutputIterator First,
    Diff Count,
    Generator Gen);

```

Parameters

First

An output iterator addressing the position of first element in the range to which values are to be assigned.

Count

A signed or unsigned integer type specifying the number of elements to be assigned a value by the generator function.

Gen

A function object that is called with no arguments that is used to generate the values to be assigned to each of the elements in the range.

Remarks

The function object is invoked for each element in the range and does not need to return the same value each time it is called. It may, for example, read from a file or refer to and modify a local state. The generator's result type must be convertible to the value type of the forward iterators for the range.

The range referenced must be valid; all pointers must be dereferenceable and, within the sequence, the last position must be reachable from the first by incrementation.

The complexity is linear, with exactly `Count` calls to the generator being required.

Example

```
// cl.exe /EHsc /nologo /W4 /MTd
#include <vector>
#include <deque>
#include <iostream>
#include <string>
#include <algorithm>
#include <random>

using namespace std;

template <typename C> void print(const string& s, const C& c) {
    cout << s;

    for (const auto& e : c) {
        cout << e << " ";
    }

    cout << endl;
}

int main()
{
    const int elemcount = 5;
    vector<int> v(elemcount);
    deque<int> dq(elemcount);

    // Set up random number distribution
    random_device rd;
    mt19937 engine(rd());
    uniform_int_distribution<int> dist(-9, 9);

    // Call generate_n, using a lambda for the third parameter
    generate_n(v.begin(), elemcount, [&]() { return dist(engine); });
    print("vector v is: ", v);

    generate_n(dq.begin(), elemcount, [&]() { return dist(engine); });
    print("deque dq is: ", dq);
}
```

includes

Tests whether one sorted range contains all the elements contained in a second sorted range, where the ordering or equivalence criterion between elements may be specified by a binary predicate.

```

template<class InputIterator1, class InputIterator2>
bool includes(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2);

template<class InputIterator1, class InputIterator2, class BinaryPredicate>
bool includes(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    BinaryPredicate comp );

```

Parameters

first1

An input iterator addressing the position of the first element in the first of two sorted source ranges to be tested for whether all the elements of the second are contained in the first.

last1

An input iterator addressing the position one past the last element in the first of two sorted source ranges to be tested for whether all the elements of the second are contained in the first.

first2

An input iterator addressing the position of the first element in second of two consecutive sorted source ranges to be tested for whether all the elements of the second are contained in the first.

last2

An input iterator addressing the position one past the last element in second of two consecutive sorted source ranges to be tested for whether all the elements of the second are contained in the first.

comp

User-defined predicate function object that defines sense in which one element is less than another. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

true if the first sorted range contains all the elements in the second sorted range; otherwise, **false**.

Remarks

Another way to think of this test is that it determined whether the second source range is a subset of the first source range.

The sorted source ranges referenced must be valid; all pointers must be dereferenceable and, within each sequence, the last position must be reachable from the first by incrementation.

The sorted source ranges must each be arranged as a precondition to the application of the algorithm `includes` in accordance with the same ordering as is to be used by the algorithm to sort the combined ranges.

The source ranges are not modified by the algorithm `merge`.

The value types of the input iterators need be less-than comparable to be ordered, so that, given two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. More precisely, the algorithm tests whether all the elements in the first sorted range under a specified binary predicate have equivalent ordering to those in the second sorted range.

The complexity of the algorithm is linear with at most $2 * ((last1 - first1) - (*last2 - first2*)) - 1$ comparisons for

nonempty source ranges.

Example

```
// alg_includes.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      // For greater<int>( )
#include <iostream>

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser (int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
}

int main()
{
    using namespace std;
    vector <int> v1a, v1b;
    vector <int>::iterator Iter1a, Iter1b;

    // Constructing vectors v1a & v1b with default less-than ordering
    int i;
    for ( i = -2 ; i <= 4 ; i++ )
    {
        v1a.push_back( i );
    }

    int ii;
    for ( ii = -2 ; ii <= 3 ; ii++ )
    {
        v1b.push_back( ii );
    }

    cout << "Original vector v1a with range sorted by the\n "
        << "binary predicate less than is v1a = ( " ;
    for ( Iter1a = v1a.begin( ) ; Iter1a != v1a.end( ) ; Iter1a++ )
        cout << *Iter1a << " ";
    cout << ")." << endl;

    cout << "Original vector v1b with range sorted by the\n "
        << "binary predicate less than is v1b = ( " ;
    for ( Iter1b = v1b.begin( ) ; Iter1b != v1b.end( ) ; Iter1b++ )
        cout << *Iter1b << " ";
    cout << ")." << endl;

    // Constructing vectors v2a & v2b with ranges sorted by greater
    vector <int> v2a ( v1a ) , v2b ( v1b );
    vector <int>::iterator Iter2a, Iter2b;
    sort ( v2a.begin( ), v2a.end( ), greater<int>( ) );
    sort ( v2b.begin( ), v2b.end( ), greater<int>( ) );
    v2a.pop_back( );

    cout << "Original vector v2a with range sorted by the\n "
        << "binary predicate greater is v2a = ( " ;
    for ( Iter2a = v2a.begin( ) ; Iter2a != v2a.end( ) ; Iter2a++ )
        cout << *Iter2a << " ";
    cout << ")." << endl;

    cout << "Original vector v2b with range sorted by the\n "
        << "binary predicate greater is v2b = ( " ;
    for ( Iter2b = v2b.begin( ) ; Iter2b != v2b.end( ) ; Iter2b++ )
```

```

        cout << *Iter2b << " ";
    cout << ")." << endl;

    // Constructing vectors v3a & v3b with ranges sorted by mod_lesser
    vector<int> v3a ( v1a ), v3b ( v1b );
    vector<int>::iterator Iter3a, Iter3b;
    reverse (v3a.begin( ), v3a.end( ) );
    v3a.pop_back( );
    v3a.pop_back( );
    sort ( v3a.begin( ), v3a.end( ), mod_lesser );
    sort ( v3b.begin( ), v3b.end( ), mod_lesser );

    cout << "Original vector v3a with range sorted by the\n "
        << "binary predicate mod_lesser is v3a = ( " ;
    for ( Iter3a = v3a.begin( ) ; Iter3a != v3a.end( ) ; Iter3a++ )
        cout << *Iter3a << " ";
    cout << ")." << endl;

    cout << "Original vector v3b with range sorted by the\n "
        << "binary predicate mod_lesser is v3b = ( " ;
    for ( Iter3b = v3b.begin( ) ; Iter3b != v3b.end( ) ; Iter3b++ )
        cout << *Iter3b << " ";
    cout << ")." << endl;

    // To test for inclusion under an ascending order
    // with the default binary predicate less<int>( )
    bool Result1;
    Result1 = includes ( v1a.begin( ), v1a.end( ),
        v1b.begin( ), v1b.end( ) );
    if ( Result1 )
        cout << "All the elements in vector v1b are "
            << "contained in vector v1a." << endl;
    else
        cout << "At least one of the elements in vector v1b "
            << "is not contained in vector v1a." << endl;

    // To test for inclusion under descending
    // order specify binary predicate greater<int>( )
    bool Result2;
    Result2 = includes ( v2a.begin( ), v2a.end( ),
        v2b.begin( ), v2b.end( ), greater<int>( ) );
    if ( Result2 )
        cout << "All the elements in vector v2b are "
            << "contained in vector v2a." << endl;
    else
        cout << "At least one of the elements in vector v2b "
            << "is not contained in vector v2a." << endl;

    // To test for inclusion under a user
    // defined binary predicate mod_lesser
    bool Result3;
    Result3 = includes ( v3a.begin( ), v3a.end( ),
        v3b.begin( ), v3b.end( ), mod_lesser );
    if ( Result3 )
        cout << "All the elements in vector v3b are "
            << "contained under mod_lesser in vector v3a."
            << endl;
    else
        cout << "At least one of the elements in vector v3b is "
            << " not contained under mod_lesser in vector v3a."
            << endl;
}

```

Original vector v1a with range sorted by the
binary predicate less than is v1a = (-2 -1 0 1 2 3 4).
Original vector v1b with range sorted by the
binary predicate less than is v1b = (-2 -1 0 1 2 3).
Original vector v2a with range sorted by the
binary predicate greater is v2a = (4 3 2 1 0 -1).
Original vector v2b with range sorted by the
binary predicate greater is v2b = (3 2 1 0 -1 -2).
Original vector v3a with range sorted by the
binary predicate mod_less is v3a = (0 1 2 3 4).
Original vector v3b with range sorted by the
binary predicate mod_less is v3b = (0 -1 1 -2 2 3).
All the elements in vector v1b are contained in vector v1a.
At least one of the elements in vector v2b is not contained in vector v2a.
At least one of the elements in vector v3b is not contained under mod_less in vector v3a.

inplace_merge

Combines the elements from two consecutive sorted ranges into a single sorted range, where the ordering criterion may be specified by a binary predicate.

```
template<class BidirectionalIterator>
void inplace_merge(
    BidirectionalIterator first,
    BidirectionalIterator middle,
    BidirectionalIterator last);

template<class BidirectionalIterator, class Predicate>
void inplace_merge(
    BidirectionalIterator first,
    BidirectionalIterator middle,
    BidirectionalIterator last,
    Predicate comp);
```

Parameters

first

A bidirectional iterator addressing the position of the first element in the first of two consecutive sorted ranges to be combined and sorted into a single range.

middle

A bidirectional iterator addressing the position of the first element in the second of two consecutive sorted ranges to be combined and sorted into a single range.

last

A bidirectional iterator addressing the position one past the last element in the second of two consecutive sorted ranges to be combined and sorted into a single range.

comp

User-defined predicate function object that defines the sense in which one element is greater than another. The binary predicate takes two arguments and should return **true** when the first element is less than the second element and **false** otherwise.

Remarks

The sorted consecutive ranges referenced must be valid; all pointers must be dereferenceable and, within each sequence, the last position must be reachable from the first by incrementation.

The sorted consecutive ranges must each be arranged as a precondition to the application of the `inplace_merge` algorithm in accordance with the same ordering as is to be used by the algorithm to sort the combined ranges. The

operation is stable as the relative order of elements within each range is preserved. When there are equivalent elements in both source ranges, the element from the first range precedes the element from the second in the combined range.

The complexity depends on the available memory as the algorithm allocates memory to a temporary buffer. If sufficient memory is available, the best case is linear with $(last - first) - 1$ comparisons; if no auxiliary memory is available, the worst case is $N \log(N)$, where $N = (last - first)$.

Example

```
// alg_inplace_merge.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      //For greater<int>( )
#include <iostream>

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser ( int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
}

int main()
{
    using namespace std;
    vector <int> v1;
    vector <int>::iterator Iter1, Iter2, Iter3;

    // Constructing vector v1 with default less-than ordering
    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( i );
    }

    int ii;
    for ( ii = -5 ; ii <= 0 ; ii++ )
    {
        v1.push_back( ii );
    }

    cout << "Original vector v1 with subranges sorted by the\n "
        << "binary predicate less than is  v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // Constructing vector v2 with ranges sorted by greater
    vector <int> v2 ( v1 );
    vector <int>::iterator break2;
    break2 = find ( v2.begin( ), v2.end( ), -5 );
    sort ( v2.begin( ), break2 , greater<int>( ) );
    sort ( break2 , v2.end( ), greater<int>( ) );
    cout << "Original vector v2 with subranges sorted by the\n "
        << "binary predicate greater is v2 = ( " ;

Merged inplace with binary predicate mod_lesser specified,
vector v3mod = ( 0 0 1 -1 2 -2 3 -3 4 -4 5 -5 )

```

is_heap

Returns **true** if the elements in the specified range form a heap.

```

template<class RandomAccessIterator>
bool is_heap(
    RandomAccessIterator first,
    RandomAccessIterator last);

template<class RandomAccessIterator, class BinaryPredicate>
bool is_heap(
    RandomAccessIterator first,
    RandomAccessIterator last,
    BinaryPredicate comp);

```

Parameters

first

A random access iterator that indicates the start of a range to check for a heap.

last

A random access iterator that indicates the end of a range.

comp

A condition to test to order elements. A binary predicate takes a single argument and returns **true** or **false**.

Return Value

Returns **true** if the elements in the specified range form a heap, **false** if they do not.

Remarks

The first template function returns `is_heap_until` (`first` , `last`) == `last` .

The second template function returns

```
is_heap_until(first, last, comp) == last .
```

is_heap_until

Returns an iterator positioned at the first element in the range [`begin` , `end`) that does not satisfy the heap ordering condition, or *end* if the range forms a heap.

```
template<class RandomAccessIterator>
RandomAccessIterator is_heap_until(
    RandomAccessIterator begin,
    RandomAccessIterator end);

template<class RandomAccessIterator, class BinaryPredicate>
RandomAccessIterator is_heap_until(
    RandomAccessIterator begin,
    RandomAccessIterator end,
    BinaryPredicate compare);
```

Parameters

begin

A random access iterator that specifies the first element of a range to check for a heap.

end

A random access iterator that specifies the end of the range to check for a heap.

compare

A binary predicate that specifies the strict weak ordering condition that defines a heap. The default predicate when *compare* is not specified is `std::less<>` .

Return Value

Returns *end* if the specified range forms a heap or contains one or fewer elements. Otherwise, returns an iterator for the first element found that does not satisfy the heap condition.

Remarks

The first template function returns the last iterator `next` in [`begin` , `end`] where [`begin` , `next`) is a heap ordered by the function object `std::less<>` . If the distance `end - begin < 2` , the function returns *end*.

The second template function behaves the same as the first, except that it uses the predicate `compare` instead of `std::less<>` as the heap ordering condition.

is_partitioned

Returns **true** if all the elements in the given range that test **true** for a condition come before any elements that test **false**.

```
template<class InputIterator, class BinaryPredicate>
bool is_partitioned(
    InputIterator first,
    InputIterator last,
    BinaryPredicate comp);
```

Parameters

first

An input iterator that indicates where a range starts to check for a condition.

last

An input iterator that indicates the end of a range.

comp

The condition to test for. This is provided by a user-defined predicate function object that defines the condition to be satisfied by the element being searched for. A predicate takes a single argument and returns **true** or **false**.

Return Value

Returns true when all of the elements in the given range that test **true** for a condition come before any elements that test **false**, and otherwise returns **false**.

Remarks

The template function returns **true** only if all elements in `[first , last)` are partitioned by *comp*; that is, all elements `x` in `[first , last)` for which `comp (x)` is true occur before all elements `y` for which `comp (y)` is **false**.

is_permutation

Returns true if both ranges contain the same elements, whether or not the elements are in the same order. Use the dual-range overloads in C++14 code because the overloads that only take a single iterator for the second range will not detect differences if the second range is longer than the first range, and will result in undefined behavior if the second range is shorter than the first range.

```

template<class ForwardIterator1, class ForwardIterator2>
bool is_permutation(
    ForwardIterator1 First1,
    ForwardIterator1 Last1,
    ForwardIterator2 First2);

template<class ForwardIterator1, class ForwardIterator2, class Predicate>
bool is_permutation(
    ForwardIterator1 First1,
    ForwardIterator1 Last1,
    ForwardIterator2 First2,
    Predicate Pred);

// C++14
template<class ForwardIterator1, class ForwardIterator2>
bool is_permutation(
    ForwardIterator1 First1,
    ForwardIterator1 Last1,
    ForwardIterator2 First2,
    ForwardIterator2 Last2);

template<class ForwardIterator1, class ForwardIterator2, class Predicate>
bool is_permutation(
    ForwardIterator1 First1,
    ForwardIterator1 Last1,
    ForwardIterator2 First2,
    ForwardIterator2 Last2,
    Predicate Pred);

```

Parameters

First1

A forward iterator that refers to the first element of the range.

Last1

A forward iterator that refers one past the last element of the range.

First2

A forward iterator that refers to the first element of a second range, used for comparison.

Last2

A forward iterator that refers to one past the last element of a second range, used for comparison.

Pred

A predicate that tests for equivalence and returns a **bool**.

Return Value

true when the ranges can be rearranged so as to be identical according to the comparator predicate; otherwise, **false**.

Remarks

`is_permutation` has quadratic complexity in the worst case.

The first template function assumes that there are as many elements in the range beginning at *First2* as there are in the range designated by [`First1`, `Last1`). If there are more elements in the second range, they are ignored; if there are less, undefined behavior will occur. The third template function (C++14 and later) does not make this assumption. Both return **true** only if, for each element *X* in the range designated by [`First1`, `Last1`) there are as many elements *Y* in the same range for which *X* == *Y* as there are in the range beginning at *First2* or [`First2`, `Last2`). Here, `operator==` must perform a pairwise comparison between its operands.

The second and fourth template functions behave the same, except that they replace `operator==(X, Y)` with

`Pred(X, Y)` . To behave correctly, the predicate must be symmetric, reflexive and transitive.

Example

The following example shows how to use `is_permutation` :

```
#include <vector>
#include <iostream>
#include <algorithm>
#include <string>

using namespace std;

int main()
{
    vector<int> vec_1{ 2, 3, 0, 1, 4, 5 };
    vector<int> vec_2{ 5, 4, 0, 3, 1, 2 };

    vector<int> vec_3{ 4, 9, 13, 3, 6, 5 };
    vector<int> vec_4{ 7, 4, 11, 9, 2, 1 };

    cout << "(1) Compare using built-in == operator: ";
    cout << boolalpha << is_permutation(vec_1.begin(), vec_1.end(),
        vec_2.begin(), vec_2.end()) << endl; // true

    cout << "(2) Compare after modifying vec_2: ";
    vec_2[0] = 6;
    cout << is_permutation(vec_1.begin(), vec_1.end(),
        vec_2.begin(), vec_2.end()) << endl; // false

    // Define equivalence as "both are odd or both are even"
    cout << "(3) vec_3 is a permutation of vec_4: ";
    cout << is_permutation(vec_3.begin(), vec_3.end(),
        vec_4.begin(), vec_4.end(),
        [](int lhs, int rhs) { return lhs % 2 == rhs % 2; }) << endl; // true

    // Initialize a vector using the 's' string literal to specify a std::string
    vector<string> animals_1{ "dog"s, "cat"s, "bird"s, "monkey"s };
    vector<string> animals_2{ "donkey"s, "bird"s, "meerkat"s, "cat"s };

    // Define equivalence as "first letters are equal":
    bool is_perm = is_permutation(animals_1.begin(), animals_1.end(), animals_2.begin(), animals_2.end(),
        [](const string& lhs, const string& rhs)
        {
            return lhs[0] == rhs[0]; //std::string guaranteed to have at least a null terminator
        });

    cout << "animals_2 is a permutation of animals_1: " << is_perm << endl; // true

    cout << "Press a letter" << endl;
    char c;
    cin >> c;

    return 0;
}
```

is_sorted

Returns **true** if the elements in the specified range are in sorted order.

```

template<class ForwardIterator>
bool is_sorted(
    ForwardIterator first,
    ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
bool is_sorted(
    ForwardIterator first,
    ForwardIterator last,
    BinaryPredicate comp);

```

Parameters

first

A forward iterator that indicates where the range to check begins.

last

A forward iterator that indicates the end of a range.

comp

The condition to test to determine an order between two elements. A predicate takes a single argument and returns **true** or **false**. This performs the same task as `operator<`.

Remarks

The first template function returns `is_sorted_until(first, last) == last`. The `operator<` function performs the order comparison.

The second template function returns `is_sorted_until(first, last , comp) == last`. The `comp` predicate function performs the order comparison.

is_sorted_until

Returns a `ForwardIterator` that is set to the last element that is in sorted order from a specified range.

The second version lets you provide a `BinaryPredicate` function that returns **true** when two given elements are in sorted order, and **false** otherwise.

```

template<class ForwardIterator>
ForwardIterator is_sorted_until(
    ForwardIterator first,
    ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
ForwardIterator is_sorted_until(
    ForwardIterator first,
    ForwardIterator last,
    BinaryPredicate comp);

```

Parameters

first

A forward iterator that indicates where the range to check starts.

last

A forward iterator that indicates the end of a range.

comp

The condition to test to determine an order between two elements. A predicate takes a single argument and returns **true** or **false**.

Return Value

Returns a `ForwardIterator` set to the last element in sorted order. The sorted sequence starts from *first*.

Remarks

The first template function returns the last iterator `next` in `[first , last]` so that `[first , next)` is a sorted sequence ordered by `operator<`. If `distance()` `< 2` the function returns *last*.

The second template function behaves the same, except that it replaces `operator<(X, Y)` with `comp (X, Y)`.

iter_swap

Exchanges two values referred to by a pair of specified iterators.

```
template<class ForwardIterator1, class ForwardIterator2>
void iter_swap( ForwardIterator1 left, ForwardIterator2 right );
```

Parameters

left

One of the forward iterators whose value is to be exchanged.

right

The second of the forward iterators whose value is to be exchanged.

Remarks

`swap` should be used in preference to `iter_swap`, which was included in the C++ Standard for backward compatibility. If `Fit1` and `Fit2` are forward iterators, then `iter_swap (Fit1 , Fit2)`, is equivalent to `swap (* Fit1 , * Fit2)`.

The value types of the input forward iterators must have the same value.

Example

```
// alg_iter_swap.cpp
// compile with: /EHsc
#include <vector>
#include <deque>
#include <algorithm>
#include <iostream>
#include <ostream>

using namespace std;
class CInt;
ostream& operator<<( ostream& osIn, const CInt& rhs );

class CInt
{
public:
    CInt( int n = 0 ) : m_nVal( n ){ }
    CInt( const CInt& rhs ) : m_nVal( rhs.m_nVal ){ }
    CInt& operator=( const CInt& rhs ) { m_nVal =
        rhs.m_nVal; return *this; }
    bool operator<( const CInt& rhs ) const
        { return ( m_nVal < rhs.m_nVal ); }
    friend ostream& operator<<( ostream& osIn, const CInt& rhs );

private:
    int m_nVal;
};

inline ostream& operator<<( ostream& osIn, const CInt& rhs )
{
    osIn << "CInt(" << rhs.m_nVal << ")";
```

```

    return osIn;
}

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser ( int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
};

int main()
{
    CInt c1 = 5, c2 = 1, c3 = 10;
    deque<CInt> deq1;
    deque<CInt>::iterator d1_Iter;

    deq1.push_back ( c1 );
    deq1.push_back ( c2 );
    deq1.push_back ( c3 );

    cout << "The original deque of CInts is deq1 = (" ;
    for ( d1_Iter = deq1.begin( ); d1_Iter != --deq1.end( ); d1_Iter++ )
        cout << " " << *d1_Iter << ", ";
    d1_Iter = --deq1.end( );
    cout << " " << *d1_Iter << " )." << endl;

    // Exchanging first and last elements with iter_swap
    iter_swap ( deq1.begin( ), --deq1.end( ) );

    cout << "The deque of CInts with first & last elements swapped is:\n deq1 = (" ;
    for ( d1_Iter = deq1.begin( ); d1_Iter != --deq1.end( ); d1_Iter++ )
        cout << " " << *d1_Iter << ", ";
    d1_Iter = --deq1.end( );
    cout << " " << *d1_Iter << " )." << endl;

    // Swapping back first and last elements with swap
    swap ( *deq1.begin( ), *(deq1.end( ) - 1 ) );

    cout << "The deque of CInts with first & last elements swapped back is:\n deq1 = (" ;
    for ( d1_Iter = deq1.begin( ); d1_Iter != --deq1.end( ); d1_Iter++ )
        cout << " " << *d1_Iter << ", ";
    d1_Iter = --deq1.end( );
    cout << " " << *d1_Iter << " )." << endl;

    // Swapping a vector element with a deque element
    vector<int> v1;
    vector<int>::iterator Iter1;
    deque<int> deq2;
    deque<int>::iterator d2_Iter;

    int i;
    for ( i = 0 ; i <= 3 ; i++ )
    {
        v1.push_back( i );
    }

    int ii;
    for ( ii = 4 ; ii <= 5 ; ii++ )
    {
        deq2.push_back( ii );
    }

    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ); Iter1 != v1.end( ); Iter1++ )
        cout << *Iter1 << " ";
    cout << " )." << endl;

```

```

cout << "Deque deq2 is ( " ;
for ( d2_Iter = deq2.begin( ) ; d2_Iter != deq2.end( ) ; d2_Iter++ )
    cout << *d2_Iter << " ";
cout << ")." << endl;

iter_swap ( v1.begin( ), deq2.begin( ) );

cout << "After exchanging first elements,\n vector v1 is: v1 = ( " ;
for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
    cout << *Iter1 << " ";
cout << ")." << endl << " & deque deq2 is: deq2 = ( " ;
for ( d2_Iter = deq2.begin( ) ; d2_Iter != deq2.end( ) ; d2_Iter++ )
    cout << *d2_Iter << " ";
cout << ")." << endl;
}

```

The original deque of CInts is deq1 = (CInt(5), CInt(1), CInt(10)).
 The deque of CInts with first & last elements swapped is:
 deq1 = (CInt(10), CInt(1), CInt(5)).
 The deque of CInts with first & last elements swapped back is:
 deq1 = (CInt(5), CInt(1), CInt(10)).
 Vector v1 is (0 1 2 3).
 Deque deq2 is (4 5).
 After exchanging first elements,
 vector v1 is: v1 = (4 1 2 3).
 & deque deq2 is: deq2 = (0 5).

lexicographical_compare

Compares element by element between two sequences to determine which is lesser of the two.

```

template<class InputIterator1, class InputIterator2>
bool lexicographical_compare(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2 );

template<class InputIterator1, class InputIterator2, class BinaryPredicate>
bool lexicographical_compare(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    BinaryPredicate comp );

```

Parameters

first1

An input iterator addressing the position of the first element in the first range to be compared.

last1

An input iterator addressing the position one past the final element in the first range to be compared.

first2

An input iterator addressing the position of the first element in the second range to be compared.

last2

An input iterator addressing the position one past the final element in the second range to be compared.

comp

User-defined predicate function object that defines sense in which one element is less than another. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

true if the first range is lexicographically less than the second range; otherwise **false**.

Remarks

A lexicographical comparison between sequences compares them element by element until:

- It finds two corresponding elements unequal, and the result of their comparison is taken as the result of the comparison between sequences.
- No inequalities are found, but one sequence has more elements than the other, and the shorter sequence is considered less than the longer sequence.
- No inequalities are found and the sequences have the same number of elements, and so the sequences are equal and the result of the comparison is false.

Example

```
// alg_lex_comp.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <algorithm>
#include <iostream>

// Return whether second element is twice the first
bool twice ( int elem1, int elem2 )
{
    return 2 * elem1 < elem2;
}

int main()
{
    using namespace std;
    vector <int> v1, v2;
    list <int> L1;
    vector <int>::iterator Iter1, Iter2;
    list <int>::iterator L1_Iter, L1_inIter;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 5 * i );
    }
    int ii;
    for ( ii = 0 ; ii <= 6 ; ii++ )
    {
        L1.push_back( 5 * ii );
    }

    int iii;
    for ( iii = 0 ; iii <= 5 ; iii++ )
    {
        v2.push_back( 10 * iii );
    }

    cout << "Vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "List L1 = ( " ;
    for ( L1_Iter = L1.begin( ) ; L1_Iter!= L1.end( ) ; L1_Iter++ )
```

```

        cout << *L1_Iter << " ";
    cout << ")" << endl;

    cout << "Vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Self lexicographical_comparison of v1 under identity
    bool result1;
    result1 = lexicographical_compare (v1.begin( ), v1.end( ),
                                       v1.begin( ), v1.end( ) );
    if ( result1 )
        cout << "Vector v1 is lexicographically_less than v1." << endl;
    else
        cout << "Vector v1 is not lexicographically_less than v1." << endl;

    // lexicographical_comparison of v1 and L2 under identity
    bool result2;
    result2 = lexicographical_compare (v1.begin( ), v1.end( ),
                                       L1.begin( ), L1.end( ) );
    if ( result2 )
        cout << "Vector v1 is lexicographically_less than L1." << endl;
    else
        cout << "Vector v1 is lexicographically_less than L1." << endl;

    bool result3;
    result3 = lexicographical_compare (v1.begin( ), v1.end( ),
                                       v2.begin( ), v2.end( ), twice );
    if ( result3 )
        cout << "Vector v1 is lexicographically_less than v2 "
              << "under twice." << endl;
    else
        cout << "Vector v1 is not lexicographically_less than v2 "
              << "under twice." << endl;
}

```

```

Vector v1 = ( 0 5 10 15 20 25 )
List L1 = ( 0 5 10 15 20 25 30 )
Vector v2 = ( 0 10 20 30 40 50 )
Vector v1 is not lexicographically_less than v1.
Vector v1 is lexicographically_less than L1.
Vector v1 is not lexicographically_less than v2 under twice.

```

lower_bound

Finds the position of the first element in an ordered range that has a value greater than or equivalent to a specified value, where the ordering criterion may be specified by a binary predicate.

```

template<class ForwardIterator, class Type>
ForwardIterator lower_bound(
    ForwardIterator first,
    ForwardIterator last,
    const Type& value );

template<class ForwardIterator, class Type, class BinaryPredicate>
ForwardIterator lower_bound(
    ForwardIterator first,
    ForwardIterator last,
    const Type& value,
    BinaryPredicate comp );

```

Parameters

first

A forward iterator addressing the position of the first element in the range to be searched.

last

A forward iterator addressing the position one past the final element in the range to be searched.

value

The value whose first position or possible first position is being searched for in the ordered range.

comp

User-defined predicate function object that defines sense in which one element is less than another. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

A forward iterator at the position of the first element in an ordered range with a value that is greater than or equivalent to a specified value, where the equivalence is specified with a binary predicate.

Remarks

The sorted source range referenced must be valid; all iterators must be dereferenceable and within the sequence the last position must be reachable from the first by incrementation.

A sorted range is a precondition of using `lower_bound` and where the ordering is the same as specified by with binary predicate.

The range is not modified by the algorithm `lower_bound`.

The value types of the forward iterators need be less-than comparable to be ordered, so that, given two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements

The complexity of the algorithm is logarithmic for random-access iterators and linear otherwise, with the number of steps proportional to $(\text{last} - \text{first})$.

Example

```
// alg_lower_bound.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      // greater<int>( )
#include <iostream>

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser( int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
}

int main()
{
    using namespace std;

    vector<int> v1;
    // Constructing vector v1 with default less-than ordering
    for ( auto i = -1 ; i <= 4 ; ++i )
    {
        v1.push_back( i );
    }
}
```

```

for ( auto ii =-3 ; ii <= 0 ; ++ii )
{
    v1.push_back( ii );
}

cout << "Starting vector v1 = ( " ;
for (const auto &Iter : v1)
    cout << Iter << " ";
cout << ")." << endl;

sort(v1.begin(), v1.end());
cout << "Original vector v1 with range sorted by the\n "
    << "binary predicate less than is v1 = ( " ;
for (const auto &Iter : v1)
    cout << Iter << " ";
cout << ")." << endl;

// Constructing vector v2 with range sorted by greater
vector<int> v2(v1);

sort(v2.begin(), v2.end(), greater<int>());

cout << "Original vector v2 with range sorted by the\n "
    << "binary predicate greater is v2 = ( " ;
for (const auto &Iter : v2)
    cout << Iter << " ";
cout << ")." << endl;

// Constructing vectors v3 with range sorted by mod_lesser
vector<int> v3(v1);
sort(v3.begin(), v3.end(), mod_lesser);

cout << "Original vector v3 with range sorted by the\n "
    << "binary predicate mod_lesser is v3 = ( " ;
for (const auto &Iter : v3)
    cout << Iter << " ";
cout << ")." << endl;

// Demonstrate lower_bound

vector<int>::iterator Result;

// lower_bound of 3 in v1 with default binary predicate less<int>()
Result = lower_bound(v1.begin(), v1.end(), 3);
cout << "The lower_bound in v1 for the element with a value of 3 is: "
    << *Result << "." << endl;

// lower_bound of 3 in v2 with the binary predicate greater<int>( )
Result = lower_bound(v2.begin(), v2.end(), 3, greater<int>());
cout << "The lower_bound in v2 for the element with a value of 3 is: "
    << *Result << "." << endl;

// lower_bound of 3 in v3 with the binary predicate mod_lesser
Result = lower_bound(v3.begin(), v3.end(), 3, mod_lesser);
cout << "The lower_bound in v3 for the element with a value of 3 is: "
    << *Result << "." << endl;
}

```

make_heap

Converts elements from a specified range into a heap in which the first element is the largest and for which a sorting criterion may be specified with a binary predicate.

```

template<class RandomAccessIterator>
void make_heap(
    RandomAccessIterator first,
    RandomAccessIterator last );

template<class RandomAccessIterator, class BinaryPredicate>
void make_heap(
    RandomAccessIterator first,
    RandomAccessIterator last,
    BinaryPredicate comp );

```

Parameters

first

A random-access iterator addressing the position of the first element in the range to be converted into a heap.

last

A random-access iterator addressing the position one past the final element in the range to be converted into a heap.

comp

User-defined predicate function object that defines sense in which one element is less than another. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Remarks

Heaps have two properties:

- The first element is always the largest.
- Elements may be added or removed in logarithmic time.

Heaps are an ideal way to implement priority queues and they are used in the implementation of the C++ Standard Library container adaptor [priority_queue Class](#).

The complexity is linear, requiring $3 * (*last - first)$ comparisons.

Example

```

// alg_make_heap.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1, v2;
    vector<int>::iterator Iter1, Iter2;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
        v1.push_back( i );

    random_shuffle( v1.begin( ), v1.end( ) );

    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Make v1 a heap with default less than ordering
    make_heap ( v1.begin( ), v1.end( ) );
    cout << "The heaped version of vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Make v1 a heap with greater than ordering
    make_heap ( v1.begin( ), v1.end( ), greater<int>( ) );
    cout << "The greater-than heaped version of v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
}

```

max

Compares two objects and returns the larger of the two, where the ordering criterion may be specified by a binary predicate.

```

template<class Type>
constexpr Type& max(
    const Type& left,
    const Type& right);
template<class Type, class Pr>
constexpr Type& max(
    const Type& left,
    const Type& right,
    BinaryPredicate comp);
template<class Type>
constexpr Type& max (
    initializer_list<Type> );
template<class Type, class Pr>
constexpr Type& max(
    initializer_list<Type> ,
    BinaryPredicate comp);

```

Parameters

left

The first of the two objects being compared.

right

The second of the two objects being compared.

comp

A binary predicate used to compare the two objects.

_lList

The initializer list that contains the objects to be compared.

Return Value

The greater of the two objects, unless neither is greater; in that case, it returns the first of the two objects. In the case of an initializer_list, it returns the greatest of the objects in the list.

Remarks

The `max` algorithm is unusual in having objects passed as parameters. Most C++ Standard Library algorithms operate on a range of elements whose position is specified by iterators passed as parameters. If you need a function that operates on a range of elements, use `max_element` instead. Visual Studio 2017 enables **constexpr** on the overloads that take an initializer_list.

Example

```
// alg_max.cpp
// compile with: /EHsc
#include <vector>
#include <set>
#include <algorithm>
#include <iostream>
#include <ostream>

using namespace std;
class CInt;
ostream& operator<< ( ostream& osIn, const CInt& rhs );

class CInt
{
public:
    CInt( int n = 0 ) : m_nVal( n ){}
    CInt( const CInt& rhs ) : m_nVal( rhs.m_nVal ){}
    CInt& operator=( const CInt& rhs ) {m_nVal =
        rhs.m_nVal; return *this;}
    bool operator<( const CInt& rhs ) const
        {return ( m_nVal < rhs.m_nVal );}
    friend ostream& operator<< ( ostream& osIn, const CInt& rhs );

private:
    int m_nVal;
};

inline ostream& operator<< ( ostream& osIn, const CInt& rhs )
{
    osIn << "CInt( " << rhs.m_nVal << " )";
    return osIn;
}

// Return whether absolute value of elem1 is greater than
// absolute value of elem2
bool abs_greater ( int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = -elem1;
    if ( elem2 < 0 )
        elem2 = -elem2;
```

```

    return elem1 < elem2;
};

int main()
{
    int a = 6, b = -7;
    // Return the integer with the larger absolute value
    const int& result1 = max(a, b, abs_greater);
    // Return the larger integer
    const int& result2 = max(a, b);

    cout << "Using integers 6 and -7..." << endl;
    cout << "The integer with the greater absolute value is: "
        << result1 << "." << endl;
    cout << "The integer with the greater value is: "
        << result2 << "." << endl;
    cout << endl;

    // Comparing the members of an initializer_list
    const int& result3 = max({ a, b });
    const int& result4 = max({ a, b }, abs_greater);

    cout << "Comparing the members of an initializer_list..." << endl;
    cout << "The member with the greater value is: " << result3 << endl;
    cout << "The integer with the greater absolute value is: " << result4 << endl;

    // using the max algorithm
    CInt c1 = 1, c2 = 2, c3 = 3;
    set<CInt> s1, s2, s3;
    set<CInt>::iterator s1_Iter, s2_Iter, s3_Iter;

    s1.insert ( c1 );
    s1.insert ( c2 );
    s2.insert ( c2 );
    s2.insert ( c3 );

    cout << "s1 = (" ;
    for ( s1_Iter = s1.begin( ); s1_Iter != --s1.end( ); s1_Iter++ )
        cout << " " << *s1_Iter << "," ;
    s1_Iter = --s1.end( );
    cout << " " << *s1_Iter << " )." << endl;

    cout << "s2 = (" ;
    for ( s2_Iter = s2.begin( ); s2_Iter != --s2.end( ); s2_Iter++ )
        cout << " " << *s2_Iter << "," ;
    s2_Iter = --s2.end( );
    cout << " " << *s2_Iter << " )." << endl;

    s3 = max ( s1, s2 );
    cout << "s3 = max ( s1, s2 ) = (" ;
    for ( s3_Iter = s3.begin( ); s3_Iter != --s3.end( ); s3_Iter++ )
        cout << " " << *s3_Iter << "," ;
    s3_Iter = --s3.end( );
    cout << " " << *s3_Iter << " )." << endl << endl;

    // Comparing vectors with integer elements using the max algorithm
    vector<int> v1, v2, v3, v4, v5;
    vector<int>::iterator Iter1, Iter2, Iter3, Iter4, Iter5;

    int i;
    for ( i = 0 ; i <= 2 ; i++ )
    {
        v1.push_back( i );
    }

    int ii;
    for ( ii = 0 ; ii <= 2 ; ii++ )
    {

```

```

        v2.push_back( ii );
    }

    int iii;
    for ( iii = 0 ; iii <= 2 ; iii++ )
    {
        v3.push_back( 2 * iii );
    }

    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    cout << "Vector v2 is ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")." << endl;

    cout << "Vector v3 is ( " ;
    for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
        cout << *Iter3 << " ";
    cout << ")." << endl;

    v4 = max ( v1, v2 );
    v5 = max ( v1, v3 );

    cout << "Vector v4 = max (v1,v2) is ( " ;
    for ( Iter4 = v4.begin( ) ; Iter4 != v4.end( ) ; Iter4++ )
        cout << *Iter4 << " ";
    cout << ")." << endl;

    cout << "Vector v5 = max (v1,v3) is ( " ;
    for ( Iter5 = v5.begin( ) ; Iter5 != v5.end( ) ; Iter5++ )
        cout << *Iter5 << " ";
    cout << ")." << endl;
}

```

Using integers 6 and -7...

The integer with the greater absolute value is: -7

The integer with the greater value is: 6.

Comparing the members of an initializer_list...The member with the greater value is: 6The integer wiht the greater absolute value is: -7

```

s1 = ( CInt( 1 ), CInt( 2 ) ).
s2 = ( CInt( 2 ), CInt( 3 ) ).
s3 = max ( s1, s2 ) = ( CInt( 2 ), CInt( 3 ) ).

```

Vector v1 is (0 1 2).

Vector v2 is (0 1 2).

Vector v3 is (0 2 4).

Vector v4 = max (v1,v2) is (0 1 2).

Vector v5 = max (v1,v3) is (0 2 4).

max_element

Finds the first occurrence of largest element in a specified range where the ordering criterion may be specified by a binary predicate.

```

template<class ForwardIterator>
constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last );

template<class ForwardIterator, class BinaryPredicate>
constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last, BinaryPredicate comp );

```

Parameters

first

A forward iterator addressing the position of the first element in the range to be searched for the largest element.

last

A forward iterator addressing the position one past the final element in the range to be searched for the largest element.

comp

User-defined predicate function object that defines the sense in which one element is greater than another. The binary predicate takes two arguments and should return **true** when the first element is less than the second element and **false** otherwise.

Return Value

A forward iterator addressing the position of the first occurrence of the largest element in the range searched.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within each sequence the last position is reachable from the first by incrementation.

The complexity is linear: $(\text{last} - \text{first}) - 1$ comparisons are required for a nonempty range.

Example

```
// alg_max_element.cpp
// compile with: /EHsc
#include <vector>
#include <set>
#include <algorithm>
#include <iostream>
#include <ostream>

using namespace std;
class CInt;
ostream& operator<< ( ostream& osIn, const CInt& rhs );

class CInt
{
public:
    CInt( int n = 0 ) : m_nVal( n ){}
    CInt( const CInt& rhs ) : m_nVal( rhs.m_nVal ){}
    CInt& operator=( const CInt& rhs ) {m_nVal =
        rhs.m_nVal; return *this;}
    bool operator<( const CInt& rhs ) const
        {return ( m_nVal < rhs.m_nVal );}
    friend ostream& operator<< ( ostream& osIn, const CInt& rhs );

private:
    int m_nVal;
};

inline ostream& operator<<(ostream& osIn, const CInt& rhs)
{
    osIn << "CInt( " << rhs.m_nVal << " )";
    return osIn;
}

// Return whether modulus of elem1 is greater than modulus of elem2
bool mod_lesser ( int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
```

```

    return elem1 < elem2;
};

int main()
{
    // Searching a set container with elements of type CInt
    // for the maximum element
    CInt c1 = 1, c2 = 2, c3 = -3;
    set<CInt> s1;
    set<CInt>::iterator s1_Iter, s1_R1_Iter, s1_R2_Iter;

    s1.insert ( c1 );
    s1.insert ( c2 );
    s1.insert ( c3 );

    cout << "s1 = (" ;
    for ( s1_Iter = s1.begin( ); s1_Iter != --s1.end( ); s1_Iter++ )
        cout << " " << *s1_Iter << ",";
    s1_Iter = --s1.end( );
    cout << " " << *s1_Iter << " )." << endl;

    s1_R1_Iter = max_element ( s1.begin( ), s1.end( ) );

    cout << "The largest element in s1 is: " << *s1_R1_Iter << endl;
    cout << endl;

    // Searching a vector with elements of type int for the maximum
    // element under default less than & mod_lesser binary predicates
    vector<int> v1;
    vector<int>::iterator v1_Iter, v1_R1_Iter, v1_R2_Iter;

    int i;
    for ( i = 0 ; i <= 3 ; i++ )
    {
        v1.push_back( i );
    }

    int ii;
    for ( ii = 1 ; ii <= 4 ; ii++ )
    {
        v1.push_back( - 2 * ii );
    }

    cout << "Vector v1 is ( " ;
    for ( v1_Iter = v1.begin( ) ; v1_Iter != v1.end( ) ; v1_Iter++ )
        cout << *v1_Iter << " ";
    cout << " )." << endl;

    v1_R1_Iter = max_element ( v1.begin( ), v1.end( ) );
    v1_R2_Iter = max_element ( v1.begin( ), v1.end( ), mod_lesser);

    cout << "The largest element in v1 is: " << *v1_R1_Iter << endl;
    cout << "The largest element in v1 under the mod_lesser"
        << "\n binary predicate is: " << *v1_R2_Iter << endl;
}

```

merge

Combines all of the elements from two sorted source ranges into a single, sorted destination range, where the ordering criterion may be specified by a binary predicate.

```

template<class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator merge(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    OutputIterator result );

template<class InputIterator1, class InputIterator2, class OutputIterator, class BinaryPredicate>
OutputIterator merge(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    OutputIterator result,
    BinaryPredicate comp );

```

Parameters

first1

An input iterator addressing the position of the first element in the first of two sorted source ranges to be combined and sorted into a single range.

last1

An input iterator addressing the position one past the last element in the first of two sorted source ranges to be combined and sorted into a single range.

first2

An input iterator addressing the position of the first element in second of two consecutive sorted source ranges to be combined and sorted into a single range.

last2

An input iterator addressing the position one past the last element in second of two consecutive sorted source ranges to be combined and sorted into a single range.

result

An output iterator addressing the position of the first element in the destination range where the two source ranges are to be combined into a single sorted range.

comp

User-defined predicate function object that defines the sense in which one element is greater than another. The binary predicate takes two arguments and should return **true** when the first element is less than the second element and **false** otherwise.

Return Value

An output iterator addressing the position one past the last element in the sorted destination range.

Remarks

The sorted source ranges referenced must be valid; all pointers must be dereferenceable and within each sequence the last position must be reachable from the first by incrementation.

The destination range should not overlap either of the source ranges and should be large enough to contain the destination range.

The sorted source ranges must each be arranged as a precondition to the application of the `merge` algorithm in accordance with the same ordering as is to be used by the algorithm to sort the combined ranges.

The operation is stable as the relative order of elements within each range is preserved in the destination range. The source ranges are not modified by the algorithm `merge`.

The value types of the input iterators need be less-than comparable to be ordered, so that, given two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. When there are equivalent elements in both source ranges, the elements in the first range precede the elements from the second source range in the destination range.

The complexity of the algorithm is linear with at most $(last1 - first1) - (last2 - first2) - 1$ comparisons.

The [list class](#) provides a member function "merge" to merge the elements of two lists.

Example

```
// alg_merge.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional> // For greater<int>( )
#include <iostream>

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser ( int elem1, int elem2 ) {
    if (elem1 < 0)
        elem1 = - elem1;
    if (elem2 < 0)
        elem2 = - elem2;
    return elem1 < elem2;
}

int main() {
    using namespace std;
    vector <int> v1a, v1b, v1 ( 12 );
    vector <int>::iterator Iter1a, Iter1b, Iter1;

    // Constructing vector v1a and v1b with default less than ordering
    int i;
    for ( i = 0 ; i <= 5 ; i++ )
        v1a.push_back( i );

    int ii;
    for ( ii = -5 ; ii <= 0 ; ii++ )
        v1b.push_back( ii );

    cout << "Original vector v1a with range sorted by the\n "
        << "binary predicate less than is  v1a = ( " ;
    for ( Iter1a = v1a.begin( ) ; Iter1a != v1a.end( ) ; Iter1a++ )
        cout << *Iter1a << " ";
    cout << ")." << endl;

    cout << "Original vector v1b with range sorted by the\n "
        << "binary predicate less than is  v1b = ( " ;
    for ( Iter1b = v1b.begin( ) ; Iter1b != v1b.end( ) ; Iter1b++ )
        cout << *Iter1b << " ";
    cout << ")." << endl;

    v2.begin( ), greater<int>( ) );
cout << "Merged inplace with binary predicate greater specified,\n "
    << "vector v2mod = ( " ;
for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
    cout << *Iter2 << " ";
cout << ")." << endl;

// Applying A user-defined (UD) binary predicate mod_lesser
merge ( v3a.begin( ), v3a.end( ), v3b.begin( ), v3b.end( ),
    v3.begin( ), mod_lesser );
cout << "Merged inplace with binary predicate mod_lesser specified,\n "
    << "vector v3mod = ( " ; ;
for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
    cout << *Iter3 << " ";
cout << ")." << endl;
}

```

min

Compares two objects and returns the lesser of the two, where the ordering criterion may be specified by a binary predicate.

```

template<class Type>
constexpr const Type& min(
    const Type& left,
    const Type& right);
template<class Type, class Pr>
constexpr const Type& min(
    const Type& left,
    const Type& right,
    BinaryPredicate comp);
template<class Type>
constexpr Type min(
    initializer_list<Type> );
template<class Type, class Pr>
constexpr Type min(
    initializer_list<Type>,
    BinaryPredicate comp);

```

Parameters

left

The first of the two objects being compared.

right

The second of the two objects being compared.

comp

A binary predicate used to compare the two objects.

_lList

The initializer_list that contains the members to be compared.

Return Value

The lesser of the two objects, unless neither is lesser; in that case, it returns the first of the two objects. In the case of an initializer_list, it returns the least of the objects in the list.

Remarks

The `min` algorithm is unusual in having objects passed as parameters. Most C++ Standard Library algorithms operate on a range of elements whose position is specified by iterators passed as parameters. If you need a function that uses a range of elements, use [min_element](#). `constexpr` was enabled on the `initializer_list` overloads in Visual Studio 2017.

Example

```

// alg_min.cpp
// compile with: /EHsc
#include <vector>
#include <set>
#include <algorithm>
#include <iostream>
#include <ostream>

using namespace std;
class CInt;
ostream& operator<< ( ostream& osIn, const CInt& rhs );

class CInt
{
public:
    CInt( int n = 0 ) : m_nVal( n ){}
    CInt( const CInt& rhs ) : m_nVal( rhs.m_nVal ){}
    CInt& operator=( const CInt& rhs ) {m_nVal =
        rhs.m_nVal; return *this;}
    bool operator/ ( const CInt& rhs ) const

```

```

bool operator<( const CInt& rhs ) const
{
    return ( m_nVal < rhs.m_nVal );
}

friend ostream& operator<<(ostream& osIn, const CInt& rhs);

private:
    int m_nVal;
};

inline ostream& operator<<( ostream& osIn, const CInt& rhs )
{
    osIn << "CInt( " << rhs.m_nVal << " )";
    return osIn;
}

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser ( int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
};

int main()
{
    // Comparing integers directly using the min algorithm with
    // binary predicate mod_lesser & with default less than
    int a = 6, b = -7, c = 7 ;
    const int& result1 = min ( a, b, mod_lesser );
    const int& result2 = min ( b, c );

    cout << "The mod_lesser of the integers 6 & -7 is: "
        << result1 << "." << endl;
    cout << "The lesser of the integers -7 & 7 is: "
        << result2 << "." << endl;
    cout << endl;

    // Comparing the members of an initializer_list
    const int& result3 = min({ a, c });
    const int& result4 = min({ a, b }, mod_lesser);

    cout << *Iter5 << " ";
cout << ")." << endl;
}

```

```

The mod_lesser of the integers 6 & -7 is: 6.
The lesser of the integers -7 & 7 is: -7.
The lesser of the integers 6 & 7 is: 6.The mod_lesser of the integers 6 & -7 is: 6.
s1 = ( CInt( 1 ), CInt( 2 ) ).
s2 = ( CInt( 2 ), CInt( 3 ) ).
s3 = min ( s1, s2 ) = ( CInt( 1 ), CInt( 2 ) ).

Vector v1 is ( 0 1 2 ).
Vector v2 is ( 0 1 2 ).
Vector v3 is ( 0 2 4 ).
Vector v4 = min ( v1,v2 ) is ( 0 1 2 ).
Vector v5 = min ( v1,v3 ) is ( 0 1 2 ).

```

min_element

Finds the first occurrence of smallest element in a specified range where the ordering criterion may be specified by a binary predicate.

```

template<class ForwardIterator>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last );

template<class ForwardIterator, class BinaryPredicate>
constexpr ForwardIterator min_element(
    ForwardIterator first,
    ForwardIterator last,
    BinaryPredicate comp);

```

Parameters

first

A forward iterator addressing the position of the first element in the range to be searched for the smallest element.

last

A forward iterator addressing the position one past the final element in the range to be searched for the smallest element.

comp

User-defined predicate function object that defines the sense in which one element is greater than another. The binary predicate takes two arguments and should return **true** when the first element is less than the second element and **false** otherwise.

Return Value

A forward iterator addressing the position of the first occurrence of the smallest element in the range searched.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within each sequence the last position is reachable from the first by incrementation.

The complexity is linear: $(\text{last} - \text{first}) - 1$ comparisons are required for a nonempty range.

Example

```

// alg_min_element.cpp
// compile with: /EHsc
#include <vector>
#include <set>
#include <algorithm>
#include <iostream>
#include <ostream>

```

```

using namespace std;
class CInt;
ostream& operator<<( ostream& osIn, const CInt& rhs );

class CInt
{
public:
    CInt( int n = 0 ) : m_nVal( n ){ }
    CInt( const CInt& rhs ) : m_nVal( rhs.m_nVal ){ }
    CInt& operator=( const CInt& rhs ) {m_nVal =
        rhs.m_nVal; return *this;}
    bool operator<( const CInt& rhs ) const
        {return ( m_nVal < rhs.m_nVal );}
    friend ostream& operator<<( ostream& osIn, const CInt& rhs );

private:
    int m_nVal;
};

inline ostream& operator<<( ostream& osIn, const CInt& rhs )
{
    osIn << "CInt( " << rhs.m_nVal << " )";
    return osIn;
}

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser ( int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
};

int main()
{
    // Searching a set container with elements of type CInt
    // for the minimum element
    CInt c1 = 1, c2 = 2, c3 = -3;
    set<CInt> s1;
    set<CInt>::iterator s1_Iter, s1_R1_Iter, s1_R2_Iter;

    s1.insert ( c1 );
    s1.insert ( c2 );
    s1.insert ( c3 );

    cout << "s1 = (" ;
    for ( s1_Iter = s1.begin( ); s1_Iter != --s1.end( ); s1_Iter++ )
        cout << " " << *s1_Iter << ",";
    s1_Iter = --s1.end( );
    cout << " " << *s1_Iter << " )." << endl;

    s1_R1_Iter = min_element ( s1.begin( ), s1.end( ) );

    cout << "The smallest element in s1 is: " << *s1_R1_Iter << endl;
    cout << endl;

    // Searching a vector with elements of type int for the maximum
    // element under default less than & mod_lesser binary predicates
    vector<int> v1;
    vector<int>::iterator v1_Iter, v1_R1_Iter, v1_R2_Iter;

    int i;
    for ( i = 0 ; i <= 3 ; i++ )
    {
        v1.push_back( i );
    }
}

```

```

int ii;
for ( ii = 1 ; ii <= 4 ; ii++ )
{
    v1.push_back( - 2 * ii );
}

cout << "Vector v1 is ( " ;
for ( v1_Iter = v1.begin( ) ; v1_Iter != v1.end( ) ; v1_Iter++ )
    cout << *v1_Iter << " ";
cout << ")." << endl;

v1_R1_Iter = min_element ( v1.begin( ), v1.end( ) );
v1_R2_Iter = min_element ( v1.begin( ), v1.end( ), mod_lesser);

cout << "The smallest element in v1 is: " << *v1_R1_Iter << endl;
cout << "The smallest element in v1 under the mod_lesser"
    << "\n binary predicate is: " << *v1_R2_Iter << endl;
}

```

```

s1 = ( CInt( -3 ), CInt( 1 ), CInt( 2 ) ).
The smallest element in s1 is: CInt( -3 )

Vector v1 is ( 0 1 2 3 -2 -4 -6 -8 ).
The smallest element in v1 is: -8
The smallest element in v1 under the mod_lesser
binary predicate is: 0

```

minmax_element

Performs the work performed by `min_element` and `max_element` in one call.

```

template<class ForwardIterator>
constexpr pair<ForwardIterator, ForwardIterator> minmax_element(
    ForwardIterator first,
    ForwardIterator last);
template<class ForwardIterator, class BinaryPredicate>
constexpr pair<ForwardIterator, ForwardIterator> minmax_element(
    ForwardIterator first,
    ForwardIterator last,
    BinaryPredicate comp);

```

Parameters

first

A forward iterator that indicates the beginning of a range.

last

A forward iterator that indicates the end of a range.

comp

An optional test used to order elements.

Return Value

Returns

```
pair<ForwardIterator, ForwardIterator>
```

```
( min_element (first, last), max_element (first, last)) .
```

Remarks

The first template function returns

```
pair<ForwardIterator, ForwardIterator>
```

```
(min_element(_First, Last), max_element(_First, Last)) .
```

The second template function behaves the same, except that it replaces `operator<(X, Y)` with `comp (X, Y)` .

If the sequence is non-empty, the function performs at most $3 * (last - first - 1) / 2$ comparisons.

minmax

Compares two input parameters and returns them as a pair, in order of lesser to greater.

```
template<class Type>
constexpr pair<const Type&, const Type&> minmax(
    const Type& left,
    const Type& right);
template<class Type, class BinaryPredicate>
constexpr pair<const Type&, const Type&> minmax(
    const Type& left,
    const Type& right,
    BinaryPredicate comp);
template<class Type>
constexpr pair<Type&, Type&> minmax(
    initializer_list<Type> );
template<class Type, class BinaryPredicate>
constexpr pair<Type&, Type&> minmax(
    initializer_list<Type>,
    BinaryPredicate comp);
```

Parameters

left

The first of the two objects being compared.

right

The second of the two objects being compared.

comp

A binary predicate used to compare the two objects.

_lList

The initializer_list that contains the members to be compared.

Remarks

The first template function returns `pair<const Type&, const Type&>(right , left)` if *right* is less than *left*.

Otherwise, it returns `pair<const Type&, const Type&>(left , right)` .

The second member function returns a pair where the first element is the lesser and the second is the greater when compared by the predicate *comp*.

The remaining template functions behave the same, except that they replace the *left* and *right* parameters with *_lList*.

The function performs exactly one comparison.

mismatch

Compares two ranges element by element and locates the first position where a difference occurs.

Use the dual-range overloads in C++14 code because the overloads that only take a single iterator for the second range will not detect differences if the second range is longer than the first range, and will result in undefined behavior if the second range is shorter than the first range.

```
template<class InputIterator1, class InputIterator2>
pair<InputIterator1, InputIterator2>>
mismatch(
    InputIterator1 First1,
    InputIterator1 Last1,
    InputIterator2 First2 );

template<class InputIterator1, class InputIterator2, class BinaryPredicate> pair<InputIterator1,
InputIterator2>>
mismatch(
    InputIterator1 First1,
    InputIterator1 Last1,
    InputIterator2 First2,
    BinaryPredicate Comp );

//C++14
template<class InputIterator1, class InputIterator2>
pair<InputIterator1, InputIterator2>>
mismatch(
    InputIterator1 First1,
    InputIterator1 Last1,
    InputIterator2 First2,
    InputIterator2 Last2 );

template<class InputIterator1, class InputIterator2, class BinaryPredicate> pair<InputIterator1,
InputIterator2>>
mismatch(
    InputIterator1 First1,
    InputIterator1 Last1,
    InputIterator2 First2,
    InputIterator2 Last2,
    BinaryPredicate Comp);
```

Parameters

First1

An input iterator addressing the position of the first element in the first range to be tested.

Last1

An input iterator addressing the position one past the last element in the first range to be tested.

First2

An input iterator addressing the position of the first element in the second range to be tested.

Last2

An input iterator addressing the position of one past the last element in the second range to be tested.

Comp

User-defined predicate function object that compares the current elements in each range and determines whether they are equivalent. It returns **true** when satisfied and **false** when not satisfied.

Return Value

A pair of iterators addressing the positions of the mismatch in the two ranges, the first component iterator to the position in the first range and the second component iterator to the position in the second range. If there is no difference between the elements in the ranges compared or if the binary predicate in the second version is satisfied by all element pairs from the two ranges, then the first component iterator points to the position one past the final element in the first range and the second component iterator to position one past the final element tested in the second range.

Remarks

The first template function assumes that there are as many elements in the range beginning at first2 as there are in the range designated by [first1, last1). If there are more in the second range, they are ignored; if there are less then undefined behavior will result.

The range to be searched must be valid; all iterators must be dereferenceable and the last position is reachable from the first by incrementation.

The time complexity of the algorithm is linear in the number of elements contained in the shorter range.

The user-defined predicate is not required to impose an equivalence relation that symmetric, reflexive and transitive between its operands.

Example

The following example demonstrates how to use mismatch. The C++03 overload is shown only in order to demonstrate how it can produce an unexpected result.

```
#include <vector>
#include <list>
#include <algorithm>
#include <iostream>
#include <string>
#include <utility>

using namespace std;

// Return whether first element is twice the second
// Note that this is not a symmetric, reflexive and transitive equivalence.
// mismatch and equal accept such predicates, but is_permutation does not.
bool twice(int elem1, int elem2)
{
    return elem1 == elem2 * 2;
}

void PrintResult(const string& msg, const pair<vector<int>::iterator, vector<int>::iterator>& result,
    const vector<int>& left, const vector<int>& right)
{
    // If either iterator stops before reaching the end of its container,
    // it means a mismatch was detected.
    if (result.first != left.end() || result.second != right.end())
    {
        string leftpos(result.first == left.end() ? "end" : to_string(*result.first));
        string rightpos(result.second == right.end() ? "end" : to_string(*result.second));
        cout << msg << "mismatch. Left iterator at " << leftpos
            << " right iterator at " << rightpos << endl;
    }
    else
    {
        cout << msg << " match." << endl;
    }
}

int main()
{
    vector<int> vec_1{ 0, 5, 10, 15, 20, 25 };
    vector<int> vec_2{ 0, 5, 10, 15, 20, 25, 30 };

    // Testing different length vectors for mismatch (C++03)
    auto match_vecs = mismatch(vec_1.begin(), vec_1.end(), vec_2.begin());
    bool is_mismatch = match_vecs.first != vec_1.end();
    cout << "C++03: vec_1 and vec_2 are a mismatch: " << boolalpha << is_mismatch << endl;

    // Using dual-range overloads:
```

```

// Testing different length vectors for mismatch (C++14)
match_vecs = mismatch(vec_1.begin(), vec_1.end(), vec_2.begin(), vec_2.end());
PrintResult("C++14: vec_1 and vec_2: ", match_vecs, vec_1, vec_2);

// Identify point of mismatch between vec_1 and modified vec_2.
vec_2[3] = 42;
match_vecs = mismatch(vec_1.begin(), vec_1.end(), vec_2.begin(), vec_2.end());
PrintResult("C++14 vec_1 v. vec_2 modified: ", match_vecs, vec_1, vec_2);

// Test vec_3 and vec_4 for mismatch under the binary predicate twice (C++14)
vector<int> vec_3{ 10, 20, 30, 40, 50, 60 };
vector<int> vec_4{ 5, 10, 15, 20, 25, 30 };
match_vecs = mismatch(vec_3.begin(), vec_3.end(), vec_4.begin(), vec_4.end(), twice);
PrintResult("vec_3 v. vec_4 with pred: ", match_vecs, vec_3, vec_4);

vec_4[5] = 31;
match_vecs = mismatch(vec_3.begin(), vec_3.end(), vec_4.begin(), vec_4.end(), twice);
PrintResult("vec_3 v. modified vec_4 with pred: ", match_vecs, vec_3, vec_4);

// Compare a vector<int> to a list<int>
list<int> list_1{ 0, 5, 10, 15, 20, 25 };
auto match_vec_list = mismatch(vec_1.begin(), vec_1.end(), list_1.begin(), list_1.end());
is_mismatch = match_vec_list.first != vec_1.end() || match_vec_list.second != list_1.end();
cout << "vec_1 and list_1 are a mismatch: " << boolalpha << is_mismatch << endl;

char c;
cout << "Press a key" << endl;
cin >> c;

}

/*
Output:
C++03: vec_1 and vec_2 are a mismatch: false

C++14: vec_1 and list_1 are a mismatch: false
Press a key
*/

```

<alg> move

Move elements associated with a specified range.

```

template<class InputIterator, class OutputIterator>
OutputIterator move(
    InputIterator first,
    InputIterator last,
    OutputIterator dest);

```

Parameters

first

An input iterator that indicates where to start the range of elements to move.

last

An input iterator that indicates the end of a range of elements to move.

dest

The output iterator that is to contain the moved elements.

Remarks

The template function evaluates `*(dest + N) = move(*(first + N))` once for each `N` in the range `[0, last - first)`, for strictly increasing values of `N` starting with the lowest value. It then returns `dest + N`. If `dest` and `first` designate regions of storage, `dest` must not be in the range `[first, last)`.

move_backward

Moves the elements of one iterator to another. The move starts with the last element in a specified range, and ends with the first element in that range.

```
template<class BidirectionalIterator1, class BidirectionalIterator2>
    BidirectionalIterator2 move_backward(
        BidirectionalIterator1 first,
        BidirectionalIterator1 last,
        BidirectionalIterator2 destEnd);
```

Parameters

first

An iterator that indicates the start of a range to move elements from.

last

An iterator that indicates the end of a range to move elements from. This element is not moved.

destEnd

A bidirectional iterator addressing the position of one past the final element in the destination range.

Remarks

The template function evaluates `*(destEnd - N - 1) = move(*(last - N - 1))` once for each `N` in the range `[0, last - first)`, for strictly increasing values of `N` starting with the lowest value. It then returns `destEnd - (last - first)`. If `destEnd` and `first` designate regions of storage, `destEnd` must not be in the range `[first, last)`.

`move` and `move_backward` are functionally equivalent to using `copy` and `copy_backward` with a move iterator.

next_permutation

Reorders the elements in a range so that the original ordering is replaced by the lexicographically next greater permutation if it exists, where the sense of next may be specified with a binary predicate.

```
template<class BidirectionalIterator>
    bool next_permutation(BidirectionalIterator first, BidirectionalIterator last);

template<class BidirectionalIterator, class BinaryPredicate>
    bool next_permutation(BidirectionalIterator first, BidirectionalIterator last, BinaryPredicate comp);
```

Parameters

first

A bidirectional iterator pointing to the position of the first element in the range to be permuted.

last

A bidirectional iterator pointing to the position one past the final element in the range to be permuted.

comp

User-defined predicate function object that defines the comparison criterion to be satisfied by successive elements in the ordering. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

true if the lexicographically next permutation exists and has replaced the original ordering of the range; otherwise **false**, in which case the ordering is transformed into the lexicographically smallest permutation.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The default binary predicate is less than and the elements in the range must be less than comparable to insure that the next permutation is well defined.

The complexity is linear with at most $(\text{last} - \text{first})/2$ swaps.

Example

```
// alg_next_perm.cpp
// compile with: /EHsc
#include <vector>
#include <deque>
#include <algorithm>
#include <iostream>
#include <ostream>

using namespace std;
class CInt;
ostream& operator<<( ostream& osIn, const CInt& rhs );

class CInt
{
public:
    CInt( int n = 0 ) : m_nVal( n ){}
    CInt( const CInt& rhs ) : m_nVal( rhs.m_nVal ){}

    // Reordering the elements of type CInt in a deque
    // using the prev_permutation algorithm
    CInt c1 = 5, c2 = 1, c3 = 10;
    bool deq1Result;
    deque<CInt> deq1, deq2, deq3;
    deque<CInt>::iterator d1_Iter;
```

```

deq1.push_back ( c1 );
deq1.push_back ( c2 );
deq1.push_back ( c3 );

cout << "The original deque of CInts is deq1 = (" ;
for ( d1_Iter = deq1.begin( ) ; d1_Iter != --deq1.end( ) ; d1_Iter++ )
    cout << " " << *d1_Iter << ", ";
d1_Iter = --deq1.end( ) ;
cout << " " << *d1_Iter << " )." << endl;

deq1Result = next_permutation ( deq1.begin( ), deq1.end( ) );

if ( deq1Result )
    cout << "The lexicographically next permutation "
        << "exists and has\nreplaced the original "
        << "ordering of the sequence in deq1." << endl;
else
    cout << "The lexicographically next permutation doesn't "
        << "exist\n and the lexicographically "
        << "smallest permutation\n has replaced the "
        << "original ordering of the sequence in deq1." << endl;

cout << "After one application of next_permutation,\n deq1 = (" ;
for ( d1_Iter = deq1.begin( ) ; d1_Iter != --deq1.end( ) ; d1_Iter++ )
    cout << " " << *d1_Iter << ", ";
d1_Iter = --deq1.end( ) ;
cout << " " << *d1_Iter << " )." << endl << endl;

// Permuting vector elements with binary function mod_lesser
vector <int> v1;
vector <int>::iterator Iter1;

int i;
for ( i = -3 ; i <= 3 ; i++ )
{
    v1.push_back( i );
}

cout << "Vector v1 is ( " ;
for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
    cout << *Iter1 << " ";
cout << " )." << endl;

next_permutation ( v1.begin( ), v1.end( ), mod_lesser );

cout << "After the first next_permutation, vector v1 is:\n v1 = ( " ;
for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )

cout << " )." << endl;

int iii = 1;
while ( iii <= 5 ) {
    next_permutation ( v1.begin( ), v1.end( ), mod_lesser );
    cout << "After another next_permutation of vector v1,\n v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << " )." << endl;
    iii++;
}
}

```

The original deque of CInts is `deq1 = (CInt(5), CInt(1), CInt(10))`.
The lexicographically next permutation exists and has replaced the original ordering of the sequence in `deq1`.
After one application of `next_permutation`,
`deq1 = (CInt(5), CInt(10), CInt(1))`.

Vector `v1` is `(-3 -2 -1 0 1 2 3)`.
After the first `next_permutation`, vector `v1` is:
`v1 = (-3 -2 -1 0 1 3 2)`.
After another `next_permutation` of vector `v1`,
`v1 = (-3 -2 -1 0 2 1 3)`.
After another `next_permutation` of vector `v1`,
`v1 = (-3 -2 -1 0 2 3 1)`.
After another `next_permutation` of vector `v1`,
`v1 = (-3 -2 -1 0 3 1 2)`.
After another `next_permutation` of vector `v1`,
`v1 = (-3 -2 -1 0 3 2 1)`.
After another `next_permutation` of vector `v1`,
`v1 = (-3 -2 -1 1 0 2 3)`.

nth_element

Partitions a range of elements, correctly locating the *n*th element of the sequence in the range so that all the elements in front of it are less than or equal to it and all the elements that follow it in the sequence are greater than or equal to it.

```
template<class RandomAccessIterator>
void nth_element( RandomAccessIterator first, RandomAccessIterator _Nth, RandomAccessIterator last);

template<class RandomAccessIterator, class BinaryPredicate>
void nth_element( RandomAccessIterator first, RandomAccessIterator _Nth, RandomAccessIterator last,
BinaryPredicate comp);
```

Parameters

first

A random-access iterator addressing the position of the first element in the range to be partitioned.

_Nth

A random-access iterator addressing the position of element to be correctly ordered on the boundary of the partition.

last

A random-access iterator addressing the position one past the final element in the range to be partitioned.

comp

User-defined predicate function object that defines the comparison criterion to be satisfied by successive elements in the ordering. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The `nth_element` algorithm does not guarantee that elements in the sub-ranges either side of the *n*th element are sorted. It thus makes fewer guarantees than `partial_sort`, which orders the elements in the range below some chosen element, and may be used as a faster alternative to `partial_sort` when the ordering of the lower range is not required.

Elements are equivalent, but not necessarily equal, if neither is less than the other.

The average of a sort complexity is linear with respect to $* \text{last} - \text{first} *$.

Example

```

// alg_nth_elem.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      // For greater<int>( )
#include <iostream>

// Return whether first element is greater than the second
bool UDgreater ( int elem1, int elem2 ) {
    return elem1 > elem2;
}

int main() {
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
        v1.push_back( 3 * i );

    int ii;
    for ( ii = 0 ; ii <= 5 ; ii++ )
        v1.push_back( 3 * ii + 1 );

    int iii;
    for ( iii = 0 ; iii <= 5 ; iii++ )
        v1.push_back( 3 * iii + 2 );

    cout << "Original vector:\n v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    nth_element(v1.begin( ), v1.begin( ) + 3, v1.end( ) );
    cout << "Position 3 partitioned vector:\n v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in descending order, specify binary predicate
    nth_element( v1.begin( ), v1.begin( ) + 4, v1.end( ),
        greater<int>( ) );
    cout << "Position 4 partitioned (greater) vector:\n v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    random_shuffle( v1.begin( ), v1.end( ) );
    cout << "Shuffled vector:\n v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // A user-defined (UD) binary predicate can also be used
    nth_element( v1.begin( ), v1.begin( ) + 5, v1.end( ), UDgreater );
    cout << "Position 5 partitioned (UDgreater) vector:\n v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
}

```

none_of

Returns **true** when a condition is never present among elements in the given range.

```
template<class InputIterator, class BinaryPredicate>
bool none_of(InputIterator first, InputIterator last, BinaryPredicate comp);
```

Parameters

first

An input iterator that indicates where to start to check a range of elements for a condition.

last

An input iterator that indicates the end of a range of elements.

comp

The condition to test for. This is provided by a user-defined predicate function object that defines the condition. A predicate takes a single argument and returns **true** or **false**.

Return Value

Returns **true** if the condition is not detected at least once in the indicated range, and **false** if the condition is detected.

Remarks

The template function returns **true** only if, for some `N` in the range `[0, last - first)`, the predicate `comp(*(first + N))` is always **false**.

partial_sort

Arranges a specified number of the smaller elements in a range into a nondescending order or according to an ordering criterion specified by a binary predicate.

```
template<class RandomAccessIterator>
void partial_sort(
    RandomAccessIterator first,
    RandomAccessIterator sortEnd,
    RandomAccessIterator last);

template<class RandomAccessIterator, class BinaryPredicate>
void partial_sort(
    RandomAccessIterator first,
    RandomAccessIterator sortEnd,
    RandomAccessIterator last,
    BinaryPredicate comp);
```

Parameters

first

A random-access iterator addressing the position of the first element in the range to be sorted.

sortEnd

A random-access iterator addressing the position one past the final element in the subrange to be sorted.

last

A random-access iterator addressing the position one past the final element in the range to be partially sorted.

comp

User-defined predicate function object that defines the comparison criterion to be satisfied by successive elements in the ordering. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

Elements are equivalent, but not necessarily equal, if neither is less than the other. The `sort` algorithm is not stable and does not guarantee that the relative ordering of equivalent elements will be preserved. The algorithm `stable_sort` does preserve this original ordering.

The average partial sort complexity is $O((\text{last} - \text{first}) \log (\text{sortEnd} - \text{first}))$.

Example

```

// alg_partial_sort.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      // For greater<int>( )
#include <iostream>

// Return whether first element is greater than the second
bool UDgreater ( int elem1, int elem2 )
{
    return elem1 > elem2;
}

int main()
{
    using namespace std;
    vector <int> v1;
    vector <int>::iterator Iter1;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 2 * i );
    }

    int ii;
    for ( ii = 0 ; ii <= 5 ; ii++ )
    {
        v1.push_back( 2 * ii + 1 );
    }

    cout << "Original vector:\n v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    partial_sort(v1.begin( ), v1.begin( ) + 6, v1.end( ) );
    cout << "Partially sorted vector:\n v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To partially sort in descending order, specify binary predicate
    partial_sort(v1.begin( ), v1.begin( ) + 4, v1.end( ), greater<int>( ) );
    cout << "Partially resorted (greater) vector:\n v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // A user-defined (UD) binary predicate can also be used
    partial_sort(v1.begin( ), v1.begin( ) + 8, v1.end( ),
UDgreater );
    cout << "Partially resorted (UDgreater) vector:\n v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
}

```

```
Original vector:
v1 = ( 0 2 4 6 8 10 1 3 5 7 9 11 )
Partially sorted vector:
v1 = ( 0 1 2 3 4 5 10 8 6 7 9 11 )
Partially resorted (greater) vector:
v1 = ( 11 10 9 8 0 1 2 3 4 5 6 7 )
Partially resorted (UDgreater) vector:
v1 = ( 11 10 9 8 7 6 5 4 0 1 2 3 )
```

partial_sort_copy

Copies elements from a source range into a destination range where the source elements are ordered by either less than or another specified binary predicate.

```
template<class InputIterator, class RandomAccessIterator>
RandomAccessIterator partial_sort_copy(
    InputIterator first1,
    InputIterator last1,
    RandomAccessIterator first2,
    RandomAccessIterator last2 );

template<class InputIterator, class RandomAccessIterator, class BinaryPredicate>
RandomAccessIterator partial_sort_copy(
    InputIterator first1,
    InputIterator last1,
    RandomAccessIterator first2,
    RandomAccessIterator last2,
    BinaryPredicate comp);
```

Parameters

first1

An input iterator addressing the position of the first element in the source range.

last1

An input iterator addressing the position one past the final element in the source range.

first2

A random-access iterator addressing the position of the first element in the sorted destination range.

last2

A random-access iterator addressing the position one past the final element in the sorted destination range.

comp

User-defined predicate function object that defines the condition to be satisfied if two elements are to be taken as equivalent. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

A random-access iterator addressing the element in the destination range one position beyond the last element inserted from the source range.

Remarks

The source and destination ranges must not overlap and must be valid; all pointers must be dereferenceable and within each sequence the last position must be reachable from the first by incrementation.

The binary predicate must provide a strict weak ordering so that elements that are not equivalent are ordered, but elements that are equivalent are not. Two elements are equivalent under less than, but not necessarily equal, if neither is less than the other.

Example

```
// alg_partial_sort_copy.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <algorithm>
#include <functional>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1, v2;
    list<int> list1;
    vector<int>::iterator iter1, iter2;
    list<int>::iterator list1_Iter, list1_inIter;

    int i;
    for (i = 0; i <= 9; i++)
        v1.push_back(i);

    random_shuffle(v1.begin(), v1.end());

    list1.push_back(60);
    list1.push_back(50);
    list1.push_back(20);
    list1.push_back(30);
    list1.push_back(40);
    list1.push_back(10);

    cout << "Vector v1 = ( " ;
    for (iter1 = v1.begin(); iter1 != v1.end(); iter1++)
        cout << *iter1 << " ";
    cout << ")" << endl;

    cout << "List list1 = ( " ;
    for (list1_Iter = list1.begin();
        list1_Iter != list1.end();
        list1_Iter++)
        cout << *list1_Iter << " ";
    cout << ")" << endl;

    // Copying a partially sorted copy of list1 into v1
    vector<int>::iterator result1;
    result1 = partial_sort_copy(list1.begin(), list1.end(),
        v1.begin(), v1.begin() + 3);

    cout << "List list1 Vector v1 = ( " ;
    for (iter1 = v1.begin(); iter1 != v1.end(); iter1++)
        cout << *iter1 << " ";
    cout << ")" << endl;
    cout << "The first v1 element one position beyond"
        << "\n the last 1 element inserted was " << *result1
        << "." << endl;

    // Copying a partially sorted copy of list1 into v2
    int ii;
    for (ii = 0; ii <= 9; ii++)
        v2.push_back(ii);

    random_shuffle(v2.begin(), v2.end());
    vector<int>::iterator result2;
    result2 = partial_sort_copy(list1.begin(), list1.end(),
        v2.begin(), v2.begin() + 6);

    cout << "List list1 into Vector v2 = ( " ;
    for (iter2 = v2.begin(); iter2 != v2.end(); iter2++)
        cout << *iter2 << " ";
```

```

    cout << ")" << endl;
    cout << "The first v2 element one position beyond"
        << "\n the last L 1 element inserted was " << *result2
        << "." << endl;
}

```

partition

Classifies elements in a range into two disjoint sets, with those elements satisfying a unary predicate preceding those that fail to satisfy it.

```

template<class BidirectionalIterator, class Predicate>
BidirectionalIterator partition(
    BidirectionalIterator first,
    BidirectionalIterator last,
    Predicate comp);

```

Parameters

first

A bidirectional iterator addressing the position of the first element in the range to be partitioned.

last

A bidirectional iterator addressing the position one past the final element in the range to be partitioned.

comp

User-defined predicate function object that defines the condition to be satisfied if an element is to be classified. A predicate takes a single argument and returns **true** or **false**.

Return Value

A bidirectional iterator addressing the position of the first element in the range to not satisfy the predicate condition.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

Elements a and b are equivalent, but not necessarily equal, if both $Pr(a, b)$ is false and $Pr(b, a)$ if false, where Pr is the parameter-specified predicate. The `partition` algorithm is not stable and does not guarantee that the relative ordering of equivalent elements will be preserved. The algorithm `stable_partition` does preserve this original ordering.

The complexity is linear: there are $(last - first)$ applications of *comp* and at most $(last - first)/2$ swaps.

Example

```

// alg_partition.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

bool greater5 ( int value ) {
    return value > 5;
}

int main() {
    using namespace std;
    vector<int> v1, v2;
    vector<int>::iterator Iter1, Iter2;

    int i;
    for ( i = 0 ; i <= 10 ; i++ )
    {
        v1.push_back( i );
    }
    random_shuffle( v1.begin( ), v1.end( ) );

    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Partition the range with predicate greater10
    partition ( v1.begin( ), v1.end( ), greater5 );
    cout << "The partitioned set of elements in v1 is: ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
}

```

partition_copy

Copies elements for which a condition is **true** to one destination, and for which the condition is **false** to another. The elements must come from a specified range.

```

template<class InputIterator, class OutputIterator1, class OutputIterator2, class Predicate>
pair<OutputIterator1, OutputIterator2>
partition_copy(
    InputIterator first,
    InputIterator last,
    OutputIterator1 dest1,
    OutputIterator2 dest2,
    Predicate pred);

```

Parameters

first

An input iterator that indicates the beginning of a range to check for a condition.

last

An input iterator that indicates the end of a range.

dest1

An output iterator used to copy elements that return true for a condition tested by using *_Pred*.

dest2

An output iterator used to copy elements that return false for a condition tested by using *_Pred*.

_Pred

The condition to test for. This is provided by a user-defined predicate function object that defines the condition to be tested. A predicate takes a single argument and returns **true** or **false**.

Remarks

The template function copies each element `x` in `[first,last)` to `*dest1++` if `_Pred(x)` is true, or to `*dest2++` if not. It returns `pair<OutputIterator1, OutputIterator2>(dest1, dest2)`.

partition_point

Returns the first element in the given range that does not satisfy the condition. The elements are sorted so that those that satisfy the condition come before those that do not.

```
template<class ForwardIterator, class Predicate>
ForwardIterator partition_point(
    ForwardIterator first,
    ForwardIterator last,
    Predicate comp);
```

Parameters

first

A `ForwardIterator` that indicates the start of a range to check for a condition.

last

A `ForwardIterator` that indicates the end of a range.

comp

The condition to test for. This is provided by a user-defined predicate function object that defines the condition to be satisfied by the element being searched for. A predicate takes a single argument and returns **true** or **false**.

Return Value

Returns a `ForwardIterator` that refers to the first element that does not fulfill the condition tested for by *comp*, or returns *last* if one is not found.

Remarks

The template function finds the first iterator `it` in `[first, last)` for which `comp(*it)` is **false**. The sequence must be ordered by *comp*.

pop_heap

Removes the largest element from the front of a heap to the next-to-last position in the range and then forms a new heap from the remaining elements.

```
template<class RandomAccessIterator>
void pop_heap( RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class BinaryPredicate>
void pop_heap(RandomAccessIterator first, RandomAccessIterator last, BinaryPredicate comp);
```

Parameters

first

A random-access iterator addressing the position of the first element in the heap.

last

A random-access iterator addressing the position one past the final element in the heap.

comp

User-defined predicate function object that defines sense in which one element is less than another. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Remarks

The `pop_heap` algorithm is the inverse of the operation performed by the `push_heap` algorithm, in which an element at the next-to-last position of a range is added to a heap consisting of the prior elements in the range, in the case when the element being added to the heap is larger than any of the elements already in the heap.

Heaps have two properties:

- The first element is always the largest.
- Elements may be added or removed in logarithmic time.

Heaps are an ideal way to implement priority queues and they are used in the implementation of the C++ Standard Library container adaptor [priority_queue Class](#).

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The range excluding the newly added element at the end must be a heap.

The complexity is logarithmic, requiring at most $\log(*last - first)$ comparisons.

Example

```

// alg_pop_heap.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1, Iter2;

    int i;
    for ( i = 1 ; i <= 9 ; i++ )
        v1.push_back( i );

    // Make v1 a heap with default less than ordering
    random_shuffle( v1.begin( ), v1.end( ) );
    make_heap ( v1.begin( ), v1.end( ) );
    cout << "The heaped version of vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Add an element to the back of the heap
    v1.push_back( 10 );
    push_heap( v1.begin( ), v1.end( ) );
    cout << "The reheaped v1 with 10 added is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Remove the largest element from the heap
    pop_heap( v1.begin( ), v1.end( ) );
    cout << "The heap v1 with 10 removed is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl << endl;

    // Make v1 a heap with greater-than ordering with a 0 element
    make_heap ( v1.begin( ), v1.end( ), greater<int>( ) );
    v1.push_back( 0 );
    push_heap( v1.begin( ), v1.end( ), greater<int>( ) );
    cout << "The 'greater than' reheaped v1 puts the smallest "
        << "element first:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Application of pop_heap to remove the smallest element
    pop_heap( v1.begin( ), v1.end( ), greater<int>( ) );
    cout << "The 'greater than' heaped v1 with the smallest element\n "
        << "removed from the heap is: ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
}

```

prev_permutation

Reorders the elements in a range so that the original ordering is replaced by the lexicographically previous greater permutation if it exists, where the sense of previous may be specified with a binary predicate.

```

template<class BidirectionalIterator>
bool prev_permutation(
    BidirectionalIterator first,
    BidirectionalIterator last);

template<class BidirectionalIterator, class BinaryPredicate>
bool prev_permutation(
    BidirectionalIterator first,
    BidirectionalIterator last,
    BinaryPredicate comp);

```

Parameters

first

A bidirectional iterator pointing to the position of the first element in the range to be permuted.

last

A bidirectional iterator pointing to the position one past the final element in the range to be permuted.

comp

User-defined predicate function object that defines the comparison criterion to be satisfied by successive elements in the ordering. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

true if the lexicographically previous permutation exists and has replaced the original ordering of the range; otherwise **false**, in which case the ordering is transformed into the lexicographically largest permutation.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The default binary predicate is less than and the elements in the range must be less-than comparable to ensure that the previous permutation is well defined.

The complexity is linear, with at most $(\text{last} - \text{first})/2$ swaps.

Example

```

// alg_prev_perm.cpp
// compile with: /EHsc
#include <vector>
#include <deque>
#include <algorithm>
#include <iostream>
#include <ostream>

using namespace std;
class CInt;
ostream& operator<< ( ostream& osIn, const CInt& rhs );

class CInt {
public:
    CInt( int n = 0 ) : m_nVal( n ){ }
    CInt( const CInt& rhs ) : m_nVal( rhs.m_nVal ){ }
    CInt& operator=( const CInt& rhs ) { m_nVal =
        rhs.m_nVal; return *this; }
    bool operator< ( const CInt& rhs ) const
        { return ( m_nVal < rhs.m_nVal ); }
    friend ostream& operator<< ( ostream& osIn, const CInt& rhs );

private:
    int m_nVal;

```

```

    int m_nVal;
};

inline ostream& operator<<( ostream& osIn, const CInt& rhs ) {
    osIn << "CInt( " << rhs.m_nVal << " )";
    return osIn;
}

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser (int elem1, int elem2 ) {
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
};

int main() {
    // Reordering the elements of type CInt in a deque
    // using the prev_permutation algorithm
    CInt c1 = 1, c2 = 5, c3 = 10;
    bool deq1Result;
    deque<CInt> deq1, deq2, deq3;
    deque<CInt>::iterator d1_Iter;

    deq1.push_back ( c1 );
    deq1.push_back ( c2 );
    deq1.push_back ( c3 );

    cout << "The original deque of CInts is deq1 = (" ;
    for ( d1_Iter = deq1.begin( ); d1_Iter != --deq1.end( ); d1_Iter++ )
        cout << " " << *d1_Iter << ",";
    d1_Iter = --deq1.end( );
    cout << " " << *d1_Iter << " )." << endl;

    deq1Result = prev_permutation ( deq1.begin( ), deq1.end( ) );

    if ( deq1Result )
        cout << "The lexicographically previous permutation "
            << "exists and has \nreplaced the original "
            << "ordering of the sequence in deq1." << endl;
    else
        cout << "The lexicographically previous permutation doesn't "
            << "exist\n and the lexicographically "
            << "smallest permutation\n has replaced the "
            << "original ordering of the sequence in deq1." << endl;

    cout << "After one application of prev_permutation,\n deq1 = (" ;
    for ( d1_Iter = deq1.begin( ); d1_Iter != --deq1.end( ); d1_Iter++ )
        cout << " " << *d1_Iter << ",";
    d1_Iter = --deq1.end( );
    cout << " " << *d1_Iter << " )." << endl << endl;

    // Permutating vector elements with binary function mod_lesser
    vector<int> v1;
    vector<int>::iterator Iter1;

    int i;
    for ( i = -3 ; i <= 3 ; i++ )
        v1.push_back( i );

    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ); Iter1 != v1.end( ); Iter1++ )
        cout << *Iter1 << " ";
    cout << " )." << endl;

    prev_permutation ( v1.begin( ), v1.end( ), mod_lesser );

    cout << "After the first prev_permutation, vector v1 is:\n v1 = ( " ;

```

```

for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
    cout << *Iter1 << " ";
cout << ")." << endl;

int iii = 1;
while ( iii <= 5 ) {
    prev_permutation ( v1.begin( ), v1.end( ), mod_lesser );
    cout << "After another prev_permutation of vector v1,\n v1 =  ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ;Iter1 ++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
    iii++;
}
}

```

The original deque of CInts is `deq1 = (CInt(1), CInt(5), CInt(10))`.
The lexicographically previous permutation doesn't exist
and the lexicographically smallest permutation
has replaced the original ordering of the sequence in `deq1`.
After one application of `prev_permutation`,
`deq1 = (CInt(10), CInt(5), CInt(1))`.

Vector `v1` is (-3 -2 -1 0 1 2 3).
After the first `prev_permutation`, vector `v1` is:
`v1 = (-3 -2 0 3 2 1 -1)`.
After another `prev_permutation` of vector `v1`,
`v1 = (-3 -2 0 3 -1 2 1)`.
After another `prev_permutation` of vector `v1`,
`v1 = (-3 -2 0 3 -1 1 2)`.
After another `prev_permutation` of vector `v1`,
`v1 = (-3 -2 0 2 3 1 -1)`.
After another `prev_permutation` of vector `v1`,
`v1 = (-3 -2 0 2 -1 3 1)`.
After another `prev_permutation` of vector `v1`,
`v1 = (-3 -2 0 2 -1 1 3)`.

push_heap

Adds an element that is at the end of a range to an existing heap consisting of the prior elements in the range.

```

template<class RandomAccessIterator>
void push_heap( RandomAccessIterator first, RandomAccessIterator last );

template<class RandomAccessIterator, class BinaryPredicate>
void push_heap( RandomAccessIterator first, RandomAccessIterator last, BinaryPredicate comp);

```

Parameters

first

A random-access iterator addressing the position of the first element in the heap.

last

A random-access iterator addressing the position one past the final element in the range to be converted into a heap.

comp

User-defined predicate function object that defines sense in which one element is less than another. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Remarks

The element must first be pushed back to the end of an existing heap and then the algorithm is used to add this

element to the existing heap.

Heaps have two properties:

- The first element is always the largest.
- Elements may be added or removed in logarithmic time.

Heaps are an ideal way to implement priority queues and they are used in the implementation of the C++ Standard Library container adaptor [priority_queue Class](#).

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The range excluding the newly added element at the end must be a heap.

The complexity is logarithmic, requiring at most $\log (last - first)$ comparisons.

Example

```

// alg_push_heap.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1, v2;
    vector<int>::iterator Iter1, Iter2;

    int i;
    for ( i = 1 ; i <= 9 ; i++ )
        v1.push_back( i );

    random_shuffle( v1.begin( ), v1.end( ) );

    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Make v1 a heap with default less than ordering
    make_heap ( v1.begin( ), v1.end( ) );
    cout << "The heaped version of vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Add an element to the heap
    v1.push_back( 10 );
    cout << "The heap v1 with 10 pushed back is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    push_heap( v1.begin( ), v1.end( ) );
    cout << "The reheaped v1 with 10 added is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl << endl;

    // Make v1 a heap with greater than ordering
    make_heap ( v1.begin( ), v1.end( ), greater<int>( ) );
    cout << "The greater-than heaped version of v1 is\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    v1.push_back(0);
    cout << "The greater-than heap v1 with 11 pushed back is\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    push_heap( v1.begin( ), v1.end( ), greater<int>( ) );
    cout << "The greater than reheaped v1 with 11 added is\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
}

```

random_shuffle

The `std::random_shuffle()` function is deprecated, replaced by [std::shuffle](#). For a code example and more information, see [<random>](#) and the Stack Overflow post [Why are std::random_shuffle methods being deprecated in C++14?](#).

remove

Eliminates a specified value from a given range without disturbing the order of the remaining elements and returning the end of a new range free of the specified value.

```
template<class ForwardIterator, class Type>
ForwardIterator remove(ForwardIterator first, ForwardIterator last, const Type& val);
```

Parameters

first

A forward iterator addressing the position of the first element in the range from which elements are being removed.

last

A forward iterator addressing the position one past the final element in the range from which elements are being removed.

val

The value that is to be removed from the range.

Return Value

A forward iterator addressing the new end position of the modified range, one past the final element of the remnant sequence free of the specified value.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The order of the elements not removed remains stable.

The `operator==` used to determine the equality between elements must impose an equivalence relation between its operands.

The complexity is linear; there are $(\text{last} - \text{first})$ comparisons for equality.

The [list class](#) has a more efficient member function version of `remove`, which also relinks pointers.

Example

```

// alg_remove.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1, Iter2, new_end;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
        v1.push_back( i );

    int ii;
    for ( ii = 0 ; ii <= 3 ; ii++ )
        v1.push_back( 7 );

    random_shuffle ( v1.begin( ), v1.end( ) );
    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Remove elements with a value of 7
    new_end = remove ( v1.begin( ), v1.end( ), 7 );

    cout << "Vector v1 with value 7 removed is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // To change the sequence size, use erase
    v1.erase (new_end, v1.end( ) );

    cout << "Vector v1 resized with value 7 removed is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
}

```

remove_copy

Copies elements from a source range to a destination range, except that elements of a specified value are not copied, without disturbing the order of the remaining elements and returning the end of a new destination range.

```

template<class InputIterator, class OutputIterator, class Type>
OutputIterator remove_copy(InputIterator first, InputIterator last, OutputIterator result, const Type& val);

```

Parameters

first

An input iterator addressing the position of the first element in the range from which elements are being removed.

last

An input iterator addressing the position one past the final element in the range from which elements are being removed.

result

An output iterator addressing the position of the first element in the destination range to which elements are being removed.

val

The value that is to be removed from the range.

Return Value

A forward iterator addressing the new end position of the destination range, one past the final element of the copy of the remnant sequence free of the specified value.

Remarks

The source and destination ranges referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

There must be enough space in the destination range to contain the remnant elements that will be copied after elements of the specified value are removed.

The order of the elements not removed remains stable.

The `operator==` used to determine the equality between elements must impose an equivalence relation between its operands.

The complexity is linear; there are $(\text{last} - \text{first})$ comparisons for equality and at most $(\text{last} - \text{first})$ assignments.

Example

```
// alg_remove_copy.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1, v2(10);
    vector<int>::iterator Iter1, Iter2, new_end;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
        v1.push_back( i );

    int ii;
    for ( ii = 0 ; ii <= 3 ; ii++ )
        v1.push_back( 7 );

    random_shuffle (v1.begin( ), v1.end( ) );
    cout << "The original vector v1 is:    ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Remove elements with a value of 7
    new_end = remove_copy ( v1.begin( ), v1.end( ), v2.begin( ), 7 );

    cout << "Vector v1 is left unchanged as ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    cout << "Vector v2 is a copy of v1 with the value 7 removed:\n ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")." << endl;
}
```

remove_copy_if

Copies elements from a source range to a destination range, except that satisfying a predicate are not copied, without disturbing the order of the remaining elements and returning the end of a new destination range.

```
template<class InputIterator, class OutputIterator, class Predicate>
OutputIterator remove_copy_if(InputIterator first, InputIterator last, OutputIterator result, Predicate pred);
```

Parameters

first

An input iterator addressing the position of the first element in the range from which elements are being removed.

last

An input iterator addressing the position one past the final element in the range from which elements are being removed.

result

An output iterator addressing the position of the first element in the destination range to which elements are being removed.

_Pred

The unary predicate that must be satisfied is the value of an element is to be replaced.

Return Value

A forward iterator addressing the new end position of the destination range, one past the final element of the remnant sequence free of the elements satisfying the predicate.

Remarks

The source range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

There must be enough space in the destination range to contain the remnant elements that will be copied after elements of the specified value are removed.

The order of the elements not removed remains stable.

The `operator==` used to determine the equality between elements must impose an equivalence relation between its operands.

The complexity is linear: there are $(last - first)$ comparisons for equality and at most $(last - first)$ assignments.

For information on how these functions behave, see [Checked Iterators](#).

Example

```

// alg_remove_copy_if.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

bool greater6 ( int value ) {
    return value > 6;
}

int main() {
    using namespace std;
    vector<int> v1, v2(10);
    vector<int>::iterator Iter1, Iter2, new_end;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
        v1.push_back( i );

    int ii;
    for ( ii = 0 ; ii <= 3 ; ii++ )
        v1.push_back( 7 );

    random_shuffle ( v1.begin( ), v1.end( ) );
    cout << "The original vector v1 is:      ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Remove elements with a value greater than 6
    new_end = remove_copy_if ( v1.begin( ), v1.end( ),
        v2.begin( ), greater6 );

    cout << "After the appliation of remove_copy_if to v1,\n "
        << "vector v1 is left unchanged as ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    cout << "Vector v2 is a copy of v1 with values greater "
        << "than 6 removed:\n ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != new_end ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")." << endl;
}

```

remove_if

Eliminates elements that satisfy a predicate from a given range without disturbing the order of the remaining elements and returning the end of a new range free of the specified value.

```

template<class ForwardIterator, class Predicate>
ForwardIterator remove_if(
    ForwardIterator first,
    ForwardIterator last,
    Predicate pred);

```

Parameters

first

A forward iterator pointing to the position of the first element in the range from which elements are being removed.

last

A forward iterator pointing to the position one past the final element in the range from which elements are being removed.

_Pred

The unary predicate that must be satisfied is the value of an element is to be replaced.

Return Value

A forward iterator addressing the new end position of the modified range, one past the final element of the remnant sequence free of the specified value.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The order of the elements not removed remains stable.

The `operator==` used to determine the equality between elements must impose an equivalence relation between its operands.

The complexity is linear: there are $(\text{last} - \text{first})$ comparisons for equality.

List has a more efficient member function version of remove which relinks pointers.

Example

```

// alg_remove_if.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

bool greater6 ( int value ) {
    return value > 6;
}

int main() {
    using namespace std;
    vector<int> v1, v2;
    vector<int>::iterator Iter1, Iter2, new_end;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
        v1.push_back( i );

    int ii;
    for ( ii = 0 ; ii <= 3 ; ii++ )
        v1.push_back( 7 );

    random_shuffle ( v1.begin( ), v1.end( ) );
    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Remove elements satisfying predicate greater6
    new_end = remove_if (v1.begin( ), v1.end( ), greater6 );

    cout << "Vector v1 with elements satisfying greater6 removed is\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // To change the sequence size, use erase
    v1.erase (new_end, v1.end( ) );

    cout << "Vector v1 resized elements satisfying greater6 removed is\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
}

```

replace

Examines each element in a range and replaces it if it matches a specified value.

```

template<class ForwardIterator, class Type>
void replace(
    ForwardIterator first,
    ForwardIterator last,
    const Type& oldVal,
    const Type& newVal);

```

Parameters

first

A forward iterator pointing to the position of the first element in the range from which elements are being replaced.

last

A forward iterator pointing to the position one past the final element in the range from which elements are being replaced.

_OldVal

The old value of the elements being replaced.

_NewVal

The new value being assigned to the elements with the old value.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The order of the elements not replaced remains stable.

The `operator==` used to determine the equality between elements must impose an equivalence relation between its operands.

The complexity is linear; there are $(\text{last} - \text{first})$ comparisons for equality and at most $(\text{last} - \text{first})$ assignments of new values.

Example

```
// alg_replace.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
        v1.push_back( i );

    int ii;
    for ( ii = 0 ; ii <= 3 ; ii++ )
        v1.push_back( 7 );

    random_shuffle (v1.begin( ), v1.end( ) );
    cout << "The original vector v1 is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Replace elements with a value of 7 with a value of 700
    replace (v1.begin( ), v1.end( ), 7 , 700);

    cout << "The vector v1 with a value 700 replacing that of 7 is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
}
```

replace_copy

Examines each element in a source range and replaces it if it matches a specified value while copying the result into a new destination range.

```
template<class InputIterator, class OutputIterator, class Type>
OutputIterator replace_copy(
    InputIterator first,
    InputIterator last,
    OutputIterator result,
    const Type& oldVal,
    const Type& newVal);
```

Parameters

first

An input iterator pointing to the position of the first element in the range from which elements are being replaced.

last

An input iterator pointing to the position one past the final element in the range from which elements are being replaced.

result

An output iterator pointing to the first element in the destination range to where the altered sequence of elements is being copied.

_OldVal

The old value of the elements being replaced.

_NewVal

The new value being assigned to the elements with the old value.

Return Value

An output iterator pointing to the position one past the final element in the destination range to where the altered sequence of elements is being copied.

Remarks

The source and destination ranges referenced must not overlap and must both be valid: all pointers must be dereferenceable and within the sequences the last position is reachable from the first by incrementation.

The order of the elements not replaced remains stable.

The `operator==` used to determine the equality between elements must impose an equivalence relation between its operands.

The complexity is linear: there are $(\text{last} - \text{first})$ comparisons for equality and at most $(\text{last} - \text{first})$ assignments of new values.

Example

```

// alg_replace_copy.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <algorithm>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1;
    list<int> L1 (15);
    vector<int>::iterator Iter1;
    list<int>::iterator L_Iter1;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
        v1.push_back( i );

    int ii;
    for ( ii = 0 ; ii <= 3 ; ii++ )
        v1.push_back( 7 );

    random_shuffle ( v1.begin( ), v1.end( ) );

    int iii;
    for ( iii = 0 ; iii <= 15 ; iii++ )
        v1.push_back( 1 );

    cout << "The original vector v1 is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Replace elements in one part of a vector with a value of 7
    // with a value of 70 and copy into another part of the vector
    replace_copy ( v1.begin( ), v1.begin( ) + 14, v1.end( ) - 15, 7 , 70);

    cout << "The vector v1 with a value 70 replacing that of 7 is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Replace elements in a vector with a value of 70
    // with a value of 1 and copy into a list
    replace_copy ( v1.begin( ), v1.begin( ) + 14, L1.begin( ), 7 , 1);

    cout << "The list copy L1 of v1 with the value 0 replacing "
        << "that of 7 is:\n ( " ;
    for ( L_Iter1 = L1.begin( ) ; L_Iter1 != L1.end( ) ; L_Iter1++ )
        cout << *L_Iter1 << " ";
    cout << ")." << endl;
}

```

replace_copy_if

Examines each element in a source range and replaces it if it satisfies a specified predicate while copying the result into a new destination range.

```
template<class InputIterator, class OutputIterator, class Predicate, class Type>
OutputIterator replace_copy_if(
    InputIterator first,
    InputIterator last,
    OutputIterator result,
    Predicate pred,
    const Type& val);
```

Parameters

first

An input iterator pointing to the position of the first element in the range from which elements are being replaced.

last

An input iterator pointing to the position one past the final element in the range from which elements are being replaced.

result

An output iterator pointing to the position of the first element in the destination range to which elements are being copied.

_Pred

The unary predicate that must be satisfied is the value of an element is to be replaced.

val

The new value being assigned to the elements whose old value satisfies the predicate.

Return Value

An output iterator pointing to the position one past the final element in the destination range to where the altered sequence of elements is being copied.

Remarks

The source and destination ranges referenced must not overlap and must both be valid: all pointers must be dereferenceable and within the sequences the last position is reachable from the first by incrementation.

The order of the elements not replaced remains stable.

The `operator==` used to determine the equality between elements must impose an equivalence relation between its operands.

The complexity is linear; there are $(\text{last} - \text{first})$ comparisons for equality and at most $(\text{last} - \text{first})$ assignments of new values.

Example

```

// alg_replace_copy_if.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <algorithm>
#include <iostream>

bool greater6 ( int value ) {
    return value > 6;
}

int main() {
    using namespace std;
    vector <int> v1;
    list <int> L1 (13);
    vector <int>::iterator Iter1;
    list <int>::iterator L_Iter1;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
        v1.push_back( i );

    int ii;
    for ( ii = 0 ; ii <= 3 ; ii++ )
        v1.push_back( 7 );

    random_shuffle ( v1.begin( ), v1.end( ) );

    int iii;
    for ( iii = 0 ; iii <= 13 ; iii++ )
        v1.push_back( 1 );

    cout << "The original vector v1 is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Replace elements with a value of 7 in the 1st half of a vector
    // with a value of 70 and copy it into the 2nd half of the vector
    replace_copy_if ( v1.begin( ), v1.begin( ) + 14, v1.end( ) - 14,
        greater6 , 70);

    cout << "The vector v1 with values of 70 replacing those greater"
        << "\n than 6 in the 1st half & copied into the 2nd half is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Replace elements in a vector with a value of 70
    // with a value of 1 and copy into a list
    replace_copy_if ( v1.begin( ), v1.begin( ) + 13, L1.begin( ),
        greater6 , -1 );

    cout << "A list copy of vector v1 with the value -1\n replacing "
        << "those greater than 6 is:\n ( " ;
    for ( L_Iter1 = L1.begin( ) ; L_Iter1 != L1.end( ) ; L_Iter1++ )
        cout << *L_Iter1 << " ";
    cout << ")." << endl;
}

```

replace_if

Examines each element in a range and replaces it if it satisfies a specified predicate.

```
template<class ForwardIterator, class Predicate, class Type>
void replace_if(
    ForwardIterator first,
    ForwardIterator last,
    Predicate pred,
    const Type& val);
```

Parameters

first

A forward iterator pointing to the position of the first element in the range from which elements are being replaced.

last

An iterator pointing to the position one past the final element in the range from which elements are being replaced.

_Pred

The unary predicate that must be satisfied is the value of an element is to be replaced.

val

The new value being assigned to the elements whose old value satisfies the predicate.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The order of the elements not replaced remains stable.

The algorithm `replace_if` is a generalization of the algorithm `replace`, allowing any predicate to be specified, rather than equality to a specified constant value.

The `operator==` used to determine the equality between elements must impose an equivalence relation between its operands.

The complexity is linear: there are $(\text{last} - \text{first})$ comparisons for equality and at most $(\text{last} - \text{first})$ assignments of new values.

Example

```

// alg_replace_if.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

bool greater6 ( int value ) {
    return value > 6;
}

int main() {
    using namespace std;
    vector <int> v1;
    vector <int>::iterator Iter1;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
        v1.push_back( i );

    int ii;
    for ( ii = 0 ; ii <= 3 ; ii++ )
        v1.push_back( 7 );

    random_shuffle ( v1.begin( ), v1.end( ) );
    cout << "The original vector v1 is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Replace elements satisfying the predicate greater6
    // with a value of 70
    replace_if ( v1.begin( ), v1.end( ), greater6 , 70);

    cout << "The vector v1 with a value 70 replacing those\n "
        << "elements satisfying the greater6 predicate is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
}

```

reverse

Reverses the order of the elements within a range.

```

template<class BidirectionalIterator>
void reverse(BidirectionalIterator first, BidirectionalIterator last);

```

Parameters

first

A bidirectional iterator pointing to the position of the first element in the range within which the elements are being permuted.

last

A bidirectional iterator pointing to the position one past the final element in the range within which the elements are being permuted.

Remarks

The source range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

Example

```

// alg_reverse.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
    {
        v1.push_back( i );
    }

    cout << "The original vector v1 is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Reverse the elements in the vector
    reverse (v1.begin( ), v1.end( ) );

    cout << "The modified vector v1 with values reversed is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
}

```

```

The original vector v1 is:
( 0 1 2 3 4 5 6 7 8 9 ).
The modified vector v1 with values reversed is:
( 9 8 7 6 5 4 3 2 1 0 ).

```

reverse_copy

Reverses the order of the elements within a source range while copying them into a destination range

```

template<class BidirectionalIterator, class OutputIterator>
OutputIterator reverse_copy(
    BidirectionalIterator first,
    BidirectionalIterator last,
    OutputIterator result);

```

Parameters

first

A bidirectional iterator pointing to the position of the first element in the source range within which the elements are being permuted.

last

A bidirectional iterator pointing to the position one past the final element in the source range within which the elements are being permuted.

result

An output iterator pointing to the position of the first element in the destination range to which elements are being copied.

Return Value

An output iterator pointing to the position one past the final element in the destination range to where the altered sequence of elements is being copied.

Remarks

The source and destination ranges referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

Example

```
// alg_reverse_copy.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1, v2( 10 );
    vector<int>::iterator Iter1, Iter2;

    int i;
    for ( i = 0 ; i <= 9 ; i++ )
    {
        v1.push_back( i );
    }

    cout << "The original vector v1 is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Reverse the elements in the vector
    reverse_copy( v1.begin( ), v1.end( ), v2.begin( ) );

    cout << "The copy v2 of the reversed vector v1 is:\n ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")." << endl;

    cout << "The original vector v1 remains unmodified as:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;
}
```

rotate

Exchanges the elements in two adjacent ranges.

```
template<class ForwardIterator>
void rotate(
    ForwardIterator first,
    ForwardIterator middle,
    ForwardIterator last);
```

Parameters

first

A forward iterator addressing the position of the first element in the range to be rotated.

middle

A forward iterator defining the boundary within the range that addresses the position of the first element in the second part of the range whose elements are to be exchanged with those in the first part of the range.

Last

A forward iterator addressing the position one past the final element in the range to be rotated.

Remarks

The ranges referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The complexity is linear with at most $(\text{last} - \text{first})$ swaps.

Example

```

// alg_rotate.cpp
// compile with: /EHsc
#include <vector>
#include <deque>
#include <algorithm>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1;
    deque<int> d1;
    vector<int>::iterator v1Iter1;
    deque<int>::iterator d1Iter1;

    int i;
    for ( i = -3 ; i <= 5 ; i++ )
    {
        v1.push_back( i );
    }

    int ii;
    for ( ii =0 ; ii <= 5 ; ii++ )
    {
        d1.push_back( ii );
    }

    cout << "Vector v1 is ( " ;
    for ( v1Iter1 = v1.begin( ) ; v1Iter1 != v1.end( ) ;v1Iter1 ++ )
        cout << *v1Iter1 << " ";
    cout << ")." << endl;

    rotate ( v1.begin( ), v1.begin( ) + 3 , v1.end( ) );
    cout << "After rotating, vector v1 is ( " ;
    for ( v1Iter1 = v1.begin( ) ; v1Iter1 != v1.end( ) ;v1Iter1 ++ )
        cout << *v1Iter1 << " ";
    cout << ")." << endl;

    cout << "The original deque d1 is ( " ;
    for ( d1Iter1 = d1.begin( ) ; d1Iter1 != d1.end( ) ;d1Iter1 ++ )
        cout << *d1Iter1 << " ";
    cout << ")." << endl;

    int iii = 1;
    while ( iii <= d1.end( ) - d1.begin( ) ) {
        rotate ( d1.begin( ), d1.begin( ) + 1 , d1.end( ) );
        cout << "After the rotation of a single deque element to the back,\n d1 is ( " ;
        for ( d1Iter1 = d1.begin( ) ; d1Iter1 != d1.end( ) ;d1Iter1 ++ )
            cout << *d1Iter1 << " ";
        cout << ")." << endl;
        iii++;
    }
}

```

Vector v1 is (-3 -2 -1 0 1 2 3 4 5).
After rotating, vector v1 is (0 1 2 3 4 5 -3 -2 -1).
The original deque d1 is (0 1 2 3 4 5).
After the rotation of a single deque element to the back,
d1 is (1 2 3 4 5 0).
After the rotation of a single deque element to the back,
d1 is (2 3 4 5 0 1).
After the rotation of a single deque element to the back,
d1 is (3 4 5 0 1 2).
After the rotation of a single deque element to the back,
d1 is (4 5 0 1 2 3).
After the rotation of a single deque element to the back,
d1 is (5 0 1 2 3 4).
After the rotation of a single deque element to the back,
d1 is (0 1 2 3 4 5).

rotate_copy

Exchanges the elements in two adjacent ranges within a source range and copies the result to a destination range.

```
template<class ForwardIterator, class OutputIterator>
OutputIterator rotate_copy(
    ForwardIterator first,
    ForwardIterator middle,
    ForwardIterator last,
    OutputIterator result );
```

Parameters

first

A forward iterator addressing the position of the first element in the range to be rotated.

middle

A forward iterator defining the boundary within the range that addresses the position of the first element in the second part of the range whose elements are to be exchanged with those in the first part of the range.

_Last A forward iterator addressing the position one past the final element in the range to be rotated.

result

An output iterator addressing the position of the first element in the destination range.

Return Value

An output iterator addressing the position one past the final element in the destination range.

Remarks

The ranges referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The complexity is linear with at most $(\text{last} - \text{first})$ swaps.

Example

```

// alg_rotate_copy.cpp
// compile with: /EHsc
#include <vector>
#include <deque>
#include <algorithm>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1 , v2 ( 9 );
    deque<int> d1 , d2 ( 6 );
    vector<int>::iterator v1Iter , v2Iter;
    deque<int>::iterator d1Iter , d2Iter;

    int i;
    for ( i = -3 ; i <= 5 ; i++ )
        v1.push_back( i );

    int ii;
    for ( ii =0 ; ii <= 5 ; ii++ )
        d1.push_back( ii );

    cout << "Vector v1 is ( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ;v1Iter ++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;

    rotate_copy ( v1.begin( ) , v1.begin( ) + 3 , v1.end( ) , v2.begin( ) );
    cout << "After rotating, the vector v1 remains unchanged as:\n v1 = ( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ;v1Iter ++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;

    cout << "After rotating, the copy of vector v1 in v2 is:\n v2 = ( " ;
    for ( v2Iter = v2.begin( ) ; v2Iter != v2.end( ) ;v2Iter ++ )
        cout << *v2Iter << " ";
    cout << ")." << endl;

    cout << "The original deque d1 is ( " ;
    for ( d1Iter = d1.begin( ) ; d1Iter != d1.end( ) ;d1Iter ++ )
        cout << *d1Iter << " ";
    cout << ")." << endl;

    int iii = 1;
    while ( iii <= d1.end( ) - d1.begin( ) )
    {
        rotate_copy ( d1.begin( ) , d1.begin( ) + iii , d1.end( ) , d2.begin( ) );
        cout << "After the rotation of a single deque element to the back,\n d2 is ( " ;
        for ( d2Iter = d2.begin( ) ; d2Iter != d2.end( ) ;d2Iter ++ )
            cout << *d2Iter << " ";
        cout << ")." << endl;
        iii++;
    }
}

```

search

Searches for the first occurrence of a sequence within a target range whose elements are equal to those in a given sequence of elements or whose elements are equivalent in a sense specified by a binary predicate to the elements in the given sequence.

```

template<class ForwardIterator1, class ForwardIterator2>
ForwardIterator1 search(
    ForwardIterator1 first1,
    ForwardIterator1 last1,
    ForwardIterator2 first2,
    ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2, class Predicate>
ForwardIterator1 search(
    ForwardIterator1 first1,
    ForwardIterator1 last1,
    ForwardIterator2 first2,
    ForwardIterator2 last2
    Predicate comp);

```

Parameters

first1

A forward iterator addressing the position of the first element in the range to be searched.

last1

A forward iterator addressing the position one past the final element in the range to be searched.

first2

A forward iterator addressing the position of the first element in the range to be matched.

last2

A forward iterator addressing the position one past the final element in the range to be matched.

comp

User-defined predicate function object that defines the condition to be satisfied if two elements are to be taken as equivalent. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

A forward iterator addressing the position of the first element of the first subsequence that matches the specified sequence or that is equivalent in a sense specified by a binary predicate.

Remarks

The `operator==` used to determine the match between an element and the specified value must impose an equivalence relation between its operands.

The ranges referenced must be valid; all pointers must be dereferenceable and within each sequence the last position is reachable from the first by incrementation.

Average complexity is linear with respect to the size of the searched range, and worst case complexity is also linear with respect to the size of the sequence being searched for.

Example

```

// alg_search.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <algorithm>
#include <iostream>

// Return whether second element is twice the first
bool twice (int elem1, int elem2 )
{
    return 2 * elem1 == elem2;
}

```

```

int main() {
    using namespace std;
    vector<int> v1, v2;
    list<int> L1;
    vector<int>::iterator Iter1, Iter2;
    list<int>::iterator L1_Iter, L1_inIter;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 5 * i );
    }
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 5 * i );
    }

    int ii;
    for ( ii = 4 ; ii <= 5 ; ii++ )
    {
        L1.push_back( 5 * ii );
    }

    int iii;
    for ( iii = 2 ; iii <= 4 ; iii++ )
    {
        v2.push_back( 10 * iii );
    }

    cout << "Vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "List L1 = ( " ;
    for ( L1_Iter = L1.begin( ) ; L1_Iter!= L1.end( ) ; L1_Iter++ )
        cout << *L1_Iter << " ";
    cout << ")" << endl;

    cout << "Vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Searching v1 for first match to L1 under identity
    vector<int>::iterator result1;
    result1 = search (v1.begin( ), v1.end( ), L1.begin( ), L1.end( ) );

    if ( result1 == v1.end( ) )
        cout << "There is no match of L1 in v1."
            << endl;
    else
        cout << "There is at least one match of L1 in v1"
            << "\n and the first one begins at "
            << "position "<< result1 - v1.begin( ) << "." << endl;

    // Searching v1 for a match to L1 under the binary predicate twice
    vector<int>::iterator result2;
    result2 = search (v1.begin( ), v1.end( ), v2.begin( ), v2.end( ), twice );

    if ( result2 == v1.end( ) )
        cout << "There is no match of L1 in v1."
            << endl;
    else
        cout << "There is a sequence of elements in v1 that "
            << "are equivalent\n to those in v2 under the binary "
            << "predicate twice\n and the first one begins at position "
            << result2 - v1.begin( ) << "." << endl;
}

```

```

Vector v1 = ( 0 5 10 15 20 25 0 5 10 15 20 25 )
List L1 = ( 20 25 )
Vector v2 = ( 20 30 40 )
There is at least one match of L1 in v1
and the first one begins at position 4.
There is a sequence of elements in v1 that are equivalent
to those in v2 under the binary predicate twice
and the first one begins at position 2.

```

search_n

Searches for the first subsequence in a range that of a specified number of elements having a particular value or a relation to that value as specified by a binary predicate.

```

template<class ForwardIterator1, class Diff2, class Type>
ForwardIterator1 search_n(
    ForwardIterator1 first1,
    ForwardIterator1 last1,
    Diff2 count,
    const Type& val);

template<class ForwardIterator1, class Diff2, class Type, class BinaryPredicate>
ForwardIterator1 search_n(
    ForwardIterator1 first1,
    ForwardIterator1 last1,
    Diff2 count,
    const Type& val,
    BinaryPredicate comp);

```

Parameters

first1

A forward iterator addressing the position of the first element in the range to be searched.

last1

A forward iterator addressing the position one past the final element in the range to be searched.

count

The size of the subsequence being searched for.

val

The value of the elements in the sequence being searched for.

comp

User-defined predicate function object that defines the condition to be satisfied if two elements are to be taken as equivalent. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

A forward iterator addressing the position of the first element of the first subsequence that matches the specified sequence or that is equivalent in a sense specified by a binary predicate.

Remarks

The `operator==` used to determine the match between an element and the specified value must impose an equivalence relation between its operands.

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

Complexity is linear with respect to the size of the searched.

Example

```
// alg_search_n.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <algorithm>
#include <iostream>

// Return whether second element is 1/2 of the first
bool one_half ( int elem1, int elem2 )
{
    return elem1 == 2 * elem2;
}

int main()
{
    using namespace std;
    vector <int> v1, v2;
    vector <int>::iterator Iter1;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 5 * i );
    }

    for ( i = 0 ; i <= 2 ; i++ )
    {
        v1.push_back( 5 );
    }

    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 5 * i );
    }

    for ( i = 0 ; i <= 2 ; i++ )
    {
        v1.push_back( 10 );
    }

    cout << "Vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // Searching v1 for first match to (5 5 5) under identity
    vector <int>::iterator result1;
    result1 = search_n ( v1.begin( ), v1.end( ), 3, 5 );

    if ( result1 == v1.end( ) )
        cout << "There is no match for a sequence ( 5 5 5 ) in v1."
              << endl;
    else
        cout << "There is at least one match of a sequence ( 5 5 5 )"
              << "\n in v1 and the first one begins at "
              << "position "<< result1 - v1.begin( ) << "." << endl;

    // Searching v1 for first match to (5 5 5) under one_half
    vector <int>::iterator result2;
    result2 = search_n (v1.begin( ), v1.end( ), 3, 5, one_half );

    if ( result2 == v1.end( ) )
        cout << "There is no match for a sequence ( 5 5 5 ) in v1"
              << " under the equivalence predicate one_half." << endl;
```

```

else
    cout << "There is a match of a sequence ( 5 5 5 ) "
        << "under the equivalence\n predicate one_half "
        << "in v1 and the first one begins at "
        << "position "<< result2 - v1.begin( ) << "." << endl;
}

```

```

Vector v1 = ( 0 5 10 15 20 25 5 5 5 0 5 10 15 20 25 10 10 10 )
There is at least one match of a sequence ( 5 5 5 )
in v1 and the first one begins at position 6.
There is a match of a sequence ( 5 5 5 ) under the equivalence
predicate one_half in v1 and the first one begins at position 15.

```

set_difference

Unites all of the elements that belong to one sorted source range, but not to a second sorted source range, into a single, sorted destination range, where the ordering criterion may be specified by a binary predicate.

```

template<class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator set_difference(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    OutputIterator result );

template<class InputIterator1, class InputIterator2, class OutputIterator, class BinaryPredicate>
OutputIterator set_difference(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    OutputIterator result,
    BinaryPredicate comp );

```

Parameters

first1

An input iterator addressing the position of the first element in the first of two sorted source ranges to be united and sorted into a single range representing the difference of the two source ranges.

last1

An input iterator addressing the position one past the last element in the first of two sorted source ranges to be united and sorted into a single range representing the difference of the two source ranges.

first2

An input iterator addressing the position of the first element in second of two consecutive sorted source ranges to be united and sorted into a single range representing the difference of the two source ranges.

last2

An input iterator addressing the position one past the last element in second of two consecutive sorted source ranges to be united and sorted into a single range representing the difference of the two source ranges.

result

An output iterator addressing the position of the first element in the destination range where the two source ranges are to be united into a single sorted range representing the difference of the two source ranges.

comp

User-defined predicate function object that defines the sense in which one element is greater than another. The

binary predicate takes two arguments and should return **true** when the first element is less than the second element and **false** otherwise.

Return Value

An output iterator addressing the position one past the last element in the sorted destination range representing the difference of the two source ranges.

Remarks

The sorted source ranges referenced must be valid; all pointers must be dereferenceable and within each sequence the last position must be reachable from the first by incrementation.

The destination range should not overlap either of the source ranges and should be large enough to contain the first source range.

The sorted source ranges must each be arranged as a precondition to the application of the `set_difference` algorithm in accordance with the same ordering as is to be used by the algorithm to sort the combined ranges.

The operation is stable as the relative order of elements within each range is preserved in the destination range. The source ranges are not modified by the algorithm merge.

The value types of the input iterators need be less-than-comparable to be ordered, so that, given two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. When there are equivalent elements in both source ranges, the elements in the first range precede the elements from the second source range in the destination range. If the source ranges contain duplicates of an element such that there are more in the first source range than in the second, then the destination range will contain the number by which the occurrences of those elements in the first source range exceed the occurrences of those elements in the second source range.

The complexity of the algorithm is linear with at most $2 * ((last1 - first1) - (last2 - first2)) - 1$ comparisons for nonempty source ranges.

Example

```
// alg_set_diff.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      // For greater<int>( )
#include <iostream>

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser (int elem1, int elem2 )
{
    if (elem1 < 0)
        elem1 = - elem1;
    if (elem2 < 0)
        elem2 = - elem2;
    return elem1 < elem2;
}

int main()
{
    using namespace std;
    vector <int> v1a, v1b, v1 ( 12 );
    vector <int>::iterator Iter1a, Iter1b, Iter1, Result1;

    // Constructing vectors v1a & v1b with default less-than ordering
    int i;
    for ( i = -1 ; i <= 4 ; i++ )
    {
        v1a.push_back( i );
    }
}
```

```

int ii;
for ( ii = -3 ; ii <= 0 ; ii++ )
{
    v1b.push_back( ii );
}

cout << "Original vector v1a with range sorted by the\n "
    << "binary predicate less than is v1a = ( " ;

```

```

cout << "Set_difference of source ranges with binary"
    << "predicate greater specified,\n vector v2mod = ( " ;
for ( Iter2 = v2.begin( ) ; Iter2 != Result2 ; Iter2++ )
    cout << *Iter2 << " ";
cout << ")." << endl;

// To combine into a difference applying a user
// defined binary predicate mod_lesser
Result3 = set_difference ( v3a.begin( ), v3a.end( ),
    v3b.begin( ), v3b.end( ), v3.begin( ), mod_lesser );
cout << "Set_difference of source ranges with binary "
    << "predicate mod_lesser specified,\n vector v3mod = ( " ; ;
for ( Iter3 = v3.begin( ) ; Iter3 != Result3 ; Iter3++ )
    cout << *Iter3 << " ";
cout << ")." << endl;
}

```

set_intersection

Unites all of the elements that belong to both sorted source ranges into a single, sorted destination range, where the ordering criterion may be specified by a binary predicate.

```

template<class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator set_intersection(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    OutputIterator result );

template<class InputIterator1, class InputIterator2, class OutputIterator, class BinaryPredicate>
OutputIterator set_intersection(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    OutputIterator result,
    BinaryPredicate comp );

```

Parameters

first1

An input iterator addressing the position of the first element in the first of two sorted source ranges to be united and sorted into a single range representing the intersection of the two source ranges.

last1

An input iterator addressing the position one past the last element in the first of two sorted source ranges to be united and sorted into a single range representing the intersection of the two source ranges.

first2

An input iterator addressing the position of the first element in second of two consecutive sorted source ranges to be united and sorted into a single range representing the intersection of the two source ranges.

last2

An input iterator addressing the position one past the last element in second of two consecutive sorted source ranges to be united and sorted into a single range representing the intersection of the two source ranges.

_Result An output iterator addressing the position of the first element in the destination range where the two source ranges are to be united into a single sorted range representing the intersection of the two source ranges.

comp

User-defined predicate function object that defines the sense in which one element is greater than another. The binary predicate takes two arguments and should return **true** when the first element is less than the second element and **false** otherwise.

Return Value

An output iterator addressing the position one past the last element in the sorted destination range representing the intersection of the two source ranges.

Remarks

The sorted source ranges referenced must be valid; all pointers must be dereferenceable and within each sequence the last position must be reachable from the first by incrementation.

The destination range should not overlap either of the source ranges and should be large enough to contain the destination range.

The sorted source ranges must each be arranged as a precondition to the application of the merge algorithm in accordance with the same ordering as is to be used by the algorithm to sort the combined ranges.

The operation is stable as the relative order of elements within each range is preserved in the destination range. The source ranges are not modified by the algorithm.

The value types of the input iterators need be less-than comparable to be ordered, so that, given two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. When there are equivalent elements in both source ranges, the elements in the first range precede the elements from the second source range in the destination range. If the source ranges contain duplicates of an element, then the destination range will contain the maximum number of those elements that occur in both source ranges.

The complexity of the algorithm is linear with at most $2 * ((last1 - first1) + (last2 - first2)) - 1$ comparisons for nonempty source ranges.

Example

```
// alg_set_intersection.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>    // For greater<int>( )
#include <iostream>

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser (int elem1, int elem2 ) {
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
}

int main() {
    using namespace std;
    vector<int> v1a, v1b, v1 ( 12 );
    vector<int>::iterator Iter1a, Iter1b, Iter1, Result1;

    // Constructing vectors v1a & v1b with default less than ordering
    int i;
    for ( i = -1 ; i <= 3 ; i++ )
        v1a.push_back( i );

    int ii;
    for ( ii = -3 ; ii <= 1 ; ii++ )
        v1b.push_back( ii );
```

```

cout << "Original vector v1a with range sorted by the\n "
    << "binary predicate less than is v1a = ( " ;
for ( Iter1a = v1a.begin( ) ; Iter1a != v1a.end( ) ; Iter1a++ )
    cout << *Iter1a << " ";
cout << ")." << endl;

cout << "Original vector v1b with range sorted by the\n "
    << "binary predicate less than is v1b = ( " ;

    v2b.begin( ) , v2b.end( ) , v2.begin( ) , greater <int>( ) );
cout << "Intersection of source ranges with binary predicate"
    << " greater specified,\n vector v2mod = ( " ;
for ( Iter2 = v2.begin( ) ; Iter2 != Result2 ; ++Iter2 )
    cout << *Iter2 << " ";
cout << ")." << endl;

```

```

// To combine into an intersection applying a user-defined
// binary predicate mod_lesser
Result3 = set_intersection ( v3a.begin( ), v3a.end( ),
    v3b.begin( ), v3b.end( ), v3.begin( ), mod_lesser );
cout << "Intersection of source ranges with binary predicate "
    << "mod_lesser specified,\n vector v3mod = ( " ; ;
for ( Iter3 = v3.begin( ) ; Iter3 != Result3 ; ++Iter3 )
    cout << *Iter3 << " ";
cout << ")." << endl;
}

```

set_symmetric_difference

Unites all of the elements that belong to one, but not both, of the sorted source ranges into a single, sorted destination range, where the ordering criterion may be specified by a binary predicate.

```

template<class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator set_symmetric_difference(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    OutputIterator result );

template<class InputIterator1, class InputIterator2, class OutputIterator, class BinaryPredicate>
OutputIterator set_symmetric_difference(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    OutputIterator result,
    BinaryPredicate comp );

```

Parameters

first1

An input iterator addressing the position of the first element in the first of two sorted source ranges to be united and sorted into a single range representing the symmetric difference of the two source ranges.

last1

An input iterator addressing the position one past the last element in the first of two sorted source ranges to be united and sorted into a single range representing the symmetric difference of the two source ranges.

first2

An input iterator addressing the position of the first element in second of two consecutive sorted source ranges to be united and sorted into a single range representing the symmetric difference of the two source ranges.

last2

An input iterator addressing the position one past the last element in second of two consecutive sorted source ranges to be united and sorted into a single range representing the symmetric difference of the two source ranges.

_Result An output iterator addressing the position of the first element in the destination range where the two source ranges are to be united into a single sorted range representing the symmetric difference of the two source ranges.

comp

User-defined predicate function object that defines the sense in which one element is greater than another. The binary predicate takes two arguments and should return **true** when the first element is less than the second element and **false** otherwise.

Return Value

An output iterator addressing the position one past the last element in the sorted destination range representing the symmetric difference of the two source ranges.

Remarks

The sorted source ranges referenced must be valid; all pointers must be dereferenceable and within each sequence the last position must be reachable from the first by incrementation.

The destination range should not overlap either of the source ranges and should be large enough to contain the destination range.

The sorted source ranges must each be arranged as a precondition to the application of the `merge*` algorithm in accordance with the same ordering as is to be used by the algorithm to sort the combined ranges.

The operation is stable as the relative order of elements within each range is preserved in the destination range. The source ranges are not modified by the algorithm `merge`.

The value types of the input iterators need be less-than comparable to be ordered, so that, given two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. When there are equivalent elements in both source ranges, the elements in the first range precede the elements from the second source range in the destination range. If the source ranges contain duplicates of an element, then the destination range will contain the absolute value of the number by which the occurrences of those elements in the one of the source ranges exceeds the occurrences of those elements in the second source range.

The complexity of the algorithm is linear with at most $2 * ((last1 - first1) - (last2 - first2)) - 1$ comparisons for nonempty source ranges.

Example

```
// alg_set_sym_diff.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      // For greater<int>( )
#include <iostream>

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser (int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
}

int main()
{
    using namespace std;
    vector<int> v1a, v1b, v1 ( 12 );
    vector<int>::iterator Iter1a, Iter1b, Iter1, Result1;

    // Constructing vectors v1a & v1b with default less-than ordering
    int i;
    for ( i = -1 ; i <= 4 ; i++ )
    {
        v1a.push_back( i );
    }

    int ii;
    for ( ii = -3 ; ii <= 0 ; ii++ )
    {
```

```

    v1b.push_back( ii );
}

cout << "Original vector v1a with range sorted by the\n "
    << "binary predicate less than is v1a = ( " ;
for ( Iter1a = v1a.begin( ) ; Iter1a != v1a.end( ) ; Iter1a++ )
    cout << *Iter1a << " ";
cout << ")." << endl;

cout << "Original vector v1b with range sorted by the\n "
    << "binary predicate less than is v1b = ( " ;
for ( Iter1b = v1b.begin( ) ; Iter1b != v1b.end( ) ; Iter1b++ )
    cout << *Iter1b << " ";
cout << ")." << endl;

// Constructing vectors v2a & v2b with ranges sorted by greater
vector<int> v2a ( v1a ) , v2b ( v1b ) , v2 ( v1 );
vector<int>::iterator Iter2a, Iter2b, Iter2, Result2;
sort ( v2a.begin( ) , v2a.end( ) , greater<int>( ) );
sort ( v2b.begin( ) , v2b.end( ) , greater<int>( ) );

for ( Iter3 = v3.begin( ) ; Iter3 != Result3 ; Iter3++ )
    cout << *Iter3 << " ";
cout << ")." << endl;
}

```

set_union

Unites all of the elements that belong to at least one of two sorted source ranges into a single, sorted destination range, where the ordering criterion may be specified by a binary predicate.

```

template<class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator set_union(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    OutputIterator result );

template<class InputIterator1, class InputIterator2, class OutputIterator, class BinaryPredicate>
OutputIterator set_union(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    InputIterator2 last2,
    OutputIterator result,
    BinaryPredicate comp );

```

Parameters

first1

An input iterator addressing the position of the first element in the first of two sorted source ranges to be united and sorted into a single range representing the union of the two source ranges.

last1

An input iterator addressing the position one past the last element in the first of two sorted source ranges to be united and sorted into a single range representing the union of the two source ranges.

first2

An input iterator addressing the position of the first element in second of two consecutive sorted source ranges to be united and sorted into a single range representing the union of the two source ranges.

last2

An input iterator addressing the position one past the last element in second of two consecutive sorted source ranges to be united and sorted into a single range representing the union of the two source ranges.

_ Result An output iterator addressing the position of the first element in the destination range where the two source ranges are to be united into a single sorted range representing the union of the two source ranges.

comp

User-defined predicate function object that defines the sense in which one element is greater than another. The binary predicate takes two arguments and should return **true** when the first element is less than the second element and **false** otherwise.

Return Value

An output iterator addressing the position one past the last element in the sorted destination range representing the union of the two source ranges.

Remarks

The sorted source ranges referenced must be valid; all pointers must be dereferenceable and within each sequence the last position must be reachable from the first by incrementation.

The destination range should not overlap either of the source ranges and should be large enough to contain the destination range.

The sorted source ranges must each be arranged as a precondition to the application of the `merge` algorithm in accordance with the same ordering as is to be used by the algorithm to sort the combined ranges.

The operation is stable as the relative order of elements within each range is preserved in the destination range. The source ranges are not modified by the algorithm `merge`.

The value types of the input iterators need be less-than comparable to be ordered, so that, given two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. When there are equivalent elements in both source ranges, the elements in the first range precede the elements from the second source range in the destination range. If the source ranges contain duplicates of an element, then the destination range will contain the maximum number of those elements that occur in both source ranges.

The complexity of the algorithm is linear with at most $2 * ((last1 - first1) - (last2 - first2)) - 1$ comparisons.

Example

```
// alg_set_union.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      // For greater<int>( )
#include <iostream>

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser ( int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
}

int main()
{
    using namespace std;
    vector <int> v1a, v1b, v1 ( 12 );
    vector <int>::iterator Iter1a, Iter1b, Iter1, Result1;

    // Constructing vectors v1a & v1b with default less than ordering
    int i;
    for ( i = -1 ; i <= 3 ; i++ )
    {
        v1a.push_back( i );
    }

    int ii;
    for ( ii = -3 ; ii <= 1 ; ii++ )
    {
        v1b.push_back( ii );
    }
}
```

```

cout << "Original vector v1a with range sorted by the\n "
    << "binary predicate less than is  v1a = ( " ;
for ( Iter1a = v1a.begin( ) ; Iter1a != v1a.end( ) ; Iter1a++ )
    cout << *Iter1a << " ";
cout << ")." << endl;

cout << "Original vector v1b with range sorted by the\n "
    << "binary predicate less than is  v1b = ( " ;
for ( Iter1b = v1b.begin( ) ; Iter1b != v1b.end( ) ; Iter1b++ )
    cout << *Iter1b << " ";
cout << ")." << endl;

// Constructing vectors v2a & v2b with ranges sorted by greater
vector <int> v2a ( v1a ) , v2b ( v1b ) , v2 ( v1 );
vector <int>::iterator Iter2a, Iter2b, Iter2, Result2;
sort ( v2a.begin( ) , v2a.end( ) , greater<int>( ) );
sort ( v2b.begin( ) , v2b.end( ) , greater<int>( ) );

cout << "Original vector v2a with range sorted by the\n "
    << "binary predicate greater is  v2a = ( " ;
for ( Iter2a = v2a.begin( ) ; Iter2a != v2a.end( ) ; Iter2a++ )
    cout << *Iter2a << " ";
cout << ")." << endl;

cout << "Original vector v2b with range sorted by the\n "
    << "binary predicate greater is  v2b = ( " ;
for ( Iter2b = v2b.begin( ) ; Iter2b != v2b.end( ) ; Iter2b++ )
    cout << *Iter2b << " ";
cout << ")." << endl;

// Constructing vectors v3a & v3b with ranges sorted by mod_lesser
vector <int> v3a ( v1a ) , v3b ( v1b ) , v3 ( v1 );
vector <int>::iterator Iter3a, Iter3b, Iter3, Result3;
sort ( v3a.begin( ) , v3a.end( ) , mod_lesser );
sort ( v3b.begin( ) , v3b.end( ) , mod_lesser );

cout << "Original vector v3a with range sorted by the\n "
    << "binary predicate mod_lesser is  v3a = ( " ;
for ( Iter3a = v3a.begin( ) ; Iter3a != v3a.end( ) ; Iter3a++ )
    cout << *Iter3a << " ";
cout << ")." << endl;

cout << "Original vector v3b with range sorted by the\n "
    << "binary predicate mod_lesser is  v3b = ( " ;
for ( Iter3b = v3b.begin( ) ; Iter3b != v3b.end( ) ; Iter3b++ )
    cout << *Iter3b << " ";
cout << ")." << endl;

// To combine into a union in ascending order with the default
// binary predicate less <int>( )
Result1 = set_union ( v1a.begin( ) , v1a.end( ) ,
    v1b.begin( ) , v1b.end( ) , v1.begin( ) );
cout << "Union of source ranges with default order,"
    << "\n vector v1mod = ( " ;
for ( Iter1 = v1.begin( ) ; Iter1 != Result1 ; Iter1++ )
    cout << *Iter1 << " ";
cout << ")." << endl;

// To combine into a union in descending order, specify binary
// predicate greater<int>( )
Result2 = set_union ( v2a.begin( ) , v2a.end( ) ,
    v2b.begin( ) , v2b.end( ) , v2.begin( ) , greater <int>( ) );
cout << "Union of source ranges with binary predicate greater "
    << "specified,\n vector v2mod = ( " ;
for ( Iter2 = v2.begin( ) ; Iter2 != Result2 ; Iter2++ )
    cout << *Iter2 << " ";
cout << ")." << endl;

```

```
// To combine into a union applying a user-defined
// binary predicate mod_lesser
Result3 = set_union ( v3a.begin( ), v3a.end( ),
    v3b.begin( ), v3b.end( ), v3.begin( ), mod_lesser );
cout << "Union of source ranges with binary predicate "
    << "mod_lesser specified,\n vector v3mod = ( " ; ;
for ( Iter3 = v3.begin( ) ; Iter3 != Result3 ; Iter3++ )
    cout << *Iter3 << " ";
cout << ")." << endl;
}
```

shuffle

Shuffles (rearranges) elements for a given range by using a random number generator.

```
template<class RandomAccessIterator, class UniformRandomNumberGenerator>
void shuffle(RandomAccessIterator first,
    RandomAccessIterator last,
    UniformRandomNumberGenerator&& gen);
```

Parameters

first

An iterator to the first element in the range to be shuffled, inclusive. Must meet the requirements of

`RandomAccessIterator` and `ValueSwappable`.

last

An iterator to the last element in the range to be shuffled, exclusive. Must meet the requirements of

`RandomAccessIterator` and `ValueSwappable`.

gen

The random number generator that the `shuffle()` function will use for the operation. Must meet the requirements of a `UniformRandomNumberGenerator`.

Remarks

For more information, and a code sample that uses `shuffle()`, see [<random>](#).

sort

Arranges the elements in a specified range into a nondescending order or according to an ordering criterion specified by a binary predicate.

```
template<class RandomAccessIterator>
void sort(
    RandomAccessIterator first,
    RandomAccessIterator last);

template<class RandomAccessIterator, class Predicate>
void sort(
    RandomAccessIterator first,
    RandomAccessIterator last,
    Predicate comp);
```

Parameters

first

A random-access iterator addressing the position of the first element in the range to be sorted.

last

A random-access iterator addressing the position one past the final element in the range to be sorted.

comp

User-defined predicate function object that defines the comparison criterion to be satisfied by successive elements in the ordering. This binary predicate takes two arguments and returns **true** if the two arguments are in order and **false** otherwise. This comparator function must impose a strict weak ordering on pairs of elements from the sequence. For more information, see [Algorithms](#).

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

Elements are equivalent, but not necessarily equal, if neither is less than the other. The `sort` algorithm is not stable and so does not guarantee that the relative ordering of equivalent elements will be preserved. The algorithm `stable_sort` does preserve this original ordering.

The average of a sort complexity is $O(N \log N)$, where $N = last - first$.

Example

```

// alg_sort.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      // For greater<int>( )
#include <iostream>

// Return whether first element is greater than the second
bool UDgreater ( int elem1, int elem2 )
{
    return elem1 > elem2;
}

int main()
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 2 * i );
    }

    int ii;
    for ( ii = 0 ; ii <= 5 ; ii++ )
    {
        v1.push_back( 2 * ii + 1 );
    }

    cout << "Original vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    sort( v1.begin( ), v1.end( ) );
    cout << "Sorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in descending order. specify binary predicate
    sort( v1.begin( ), v1.end( ), greater<int>( ) );
    cout << "Resorted (greater) vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // A user-defined (UD) binary predicate can also be used
    sort( v1.begin( ), v1.end( ), UDgreater );
    cout << "Resorted (UDgreater) vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
}

```

```

Original vector v1 = ( 0 2 4 6 8 10 1 3 5 7 9 11 )
Sorted vector v1 = ( 0 1 2 3 4 5 6 7 8 9 10 11 )
Resorted (greater) vector v1 = ( 11 10 9 8 7 6 5 4 3 2 1 0 )
Resorted (UDgreater) vector v1 = ( 11 10 9 8 7 6 5 4 3 2 1 0 )

```

sort_heap

Converts a heap into a sorted range.

```
template<class RandomAccessIterator>
void sort_heap(
    RandomAccessIterator first,
    RandomAccessIterator last);

template<class RandomAccessIterator, class Predicate>
void sort_heap(
    RandomAccessIterator first,
    RandomAccessIterator last,
    Predicate comp);
```

Parameters

first

A random-access iterator addressing the position of the first element in the target heap.

last

A random-access iterator addressing the position one past the final element in the target heap.

comp

User-defined predicate function object that defines sense in which one element is less than another. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Remarks

Heaps have two properties:

- The first element is always the largest.
- Elements may be added or removed in logarithmic time.

After the application of this algorithm, the range it was applied to is no longer a heap.

This is not a stable sort because the relative order of equivalent elements is not necessarily preserved.

Heaps are an ideal way to implement priority queues and they are used in the implementation of the C++ Standard Library container adaptor [priority_queue Class](#).

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

The complexity is at most $N \log N$, where $N = (last - first)$.

Example

```

// alg_sort_heap.cpp
// compile with: /EHsc
#include <algorithm>
#include <functional>
#include <iostream>
#include <ostream>
#include <string>
#include <vector>
using namespace std;

void print(const string& s, const vector<int>& v) {
    cout << s << ": ( ";

    for (auto i = v.begin(); i != v.end(); ++i) {
        cout << *i << " ";
    }

    cout << ")" << endl;
}

int main() {
    vector<int> v;
    for (int i = 1; i <= 9; ++i) {
        v.push_back(i);
    }
    print("Initially", v);

    random_shuffle(v.begin(), v.end());
    print("After random_shuffle", v);

    make_heap(v.begin(), v.end());
    print("    After make_heap", v);

    sort_heap(v.begin(), v.end());
    print("    After sort_heap", v);

    random_shuffle(v.begin(), v.end());
    print("        After random_shuffle", v);

    make_heap(v.begin(), v.end(), greater<int>());
    print("After make_heap with greater<int>", v);

    sort_heap(v.begin(), v.end(), greater<int>());
    print("After sort_heap with greater<int>", v);
}

```

stable_partition

Classifies elements in a range into two disjoint sets, with those elements satisfying a unary predicate preceding those that fail to satisfy it, preserving the relative order of equivalent elements.

```

template<class BidirectionalIterator, class Predicate>
BidirectionalIterator stable_partition(
    BidirectionalIterator first,
    BidirectionalIterator last,
    Predicate pred );

```

Parameters

first

A bidirectional iterator addressing the position of the first element in the range to be partitioned.

last

A bidirectional iterator addressing the position one past the final element in the range to be partitioned.

_Pred

User-defined predicate function object that defines the condition to be satisfied if an element is to be classified. A predicate takes single argument and returns **true** or **false**.

Return Value

A bidirectional iterator addressing the position of the first element in the range to not satisfy the predicate condition.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

Elements a and b are equivalent, but not necessarily equal, if both $Pr(a, b)$ is false and $Pr(b, a)$ if false, where Pr is the parameter-specified predicate. The `stable_partition` algorithm is stable and guarantees that the relative ordering of equivalent elements will be preserved. The algorithm `partition` does not necessarily preserve this original ordering.

Example

```
// alg_stable_partition.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

bool greater5 ( int value ) {
    return value > 5;
}

int main() {
    using namespace std;
    vector <int> v1, v2;
    vector <int>::iterator Iter1, Iter2, result;

    int i;
    for ( i = 0 ; i <= 10 ; i++ )
        v1.push_back( i );

    int ii;
    for ( ii = 0 ; ii <= 4 ; ii++ )
        v1.push_back( 5 );

    random_shuffle(v1.begin( ), v1.end( ) );

    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Partition the range with predicate greater10
    result = stable_partition (v1.begin( ), v1.end( ), greater5 );
    cout << "The partitioned set of elements in v1 is:\n ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    cout << "The first element in v1 to fail to satisfy the"
        << "\n predicate greater5 is: " << *result << "." << endl;
}
```

stable_sort

Arranges the elements in a specified range into a nondescending order or according to an ordering criterion specified by a binary predicate and preserves the relative ordering of equivalent elements.

```
template<class BidirectionalIterator>
void stable_sort( BidirectionalIterator first, BidirectionalIterator last );

template<class BidirectionalIterator, class BinaryPredicate>
void stable_sort(
    BidirectionalIterator first,
    BidirectionalIterator last,
    BinaryPredicate comp );
```

Parameters

first

A bidirectional iterator addressing the position of the first element in the range to be sorted.

last

A bidirectional iterator addressing the position one past the final element in the range to be sorted.

comp

User-defined predicate function object that defines the comparison criterion to be satisfied by successive elements in the ordering. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Remarks

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation.

Elements are equivalent, but not necessarily equal, if neither is less than the other. The `sort` algorithm is stable and guarantees that the relative ordering of equivalent elements will be preserved.

The run-time complexity of `stable_sort` depends on the amount of memory available, but the best case (given sufficient memory) is $O(N \log N)$ and the worst case is $O(N (\log N)^2)$, where $N = last - first$. Usually, the `sort` algorithm is significantly faster than `stable_sort`.

Example

```

// alg_stable_sort.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>      // For greater<int>( )
#include <iostream>

// Return whether first element is greater than the second
bool UDgreater (int elem1, int elem2 )
{
    return elem1 > elem2;
}

int main()
{
    using namespace std;
    vector <int> v1;
    vector <int>::iterator Iter1;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 2 * i );
    }

    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 2 * i );
    }

    cout << "Original vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    stable_sort(v1.begin( ), v1.end( ) );
    cout << "Sorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in descending order, specify binary predicate
    stable_sort(v1.begin( ), v1.end( ), greater<int>( ) );
    cout << "Resorted (greater) vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // A user-defined (UD) binary predicate can also be used
    stable_sort(v1.begin( ), v1.end( ), UDgreater );
    cout << "Resorted (UDgreater) vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
}

```

```

Original vector v1 = ( 0 2 4 6 8 10 0 2 4 6 8 10 )
Sorted vector v1 = ( 0 0 2 2 4 4 6 6 8 8 10 10 )
Resorted (greater) vector v1 = ( 10 10 8 8 6 6 4 4 2 2 0 0 )
Resorted (UDgreater) vector v1 = ( 10 10 8 8 6 6 4 4 2 2 0 0 )

```

swap

The first override exchanges the values of two objects. The second override exchanges the values between two

arrays of objects.

```
template<class Type>
    void swap(
        Type& left,
        Type& right);
template<class Type, size_t N>
    void swap(
        Type (& left)[N],
        Type (& right)[N]);\r
```

Parameters

left

For the first override, the first object to have its contents exchanged. For the second override, the first array of objects to have its contents exchanged.

right

For the first override, the second object to have its contents exchanged. For the second override, the second array of objects to have its contents exchanged.

Remarks

The first overload is designed to operate on individual objects. The second overload swaps the contents of objects between two arrays.

Example

```

// alg_swap.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <iostream>

int main()
{
    using namespace std;
    vector<int> v1, v2;
    vector<int>::iterator Iter1, Iter2, result;

    for ( int i = 0 ; i <= 10 ; i++ )
    {
        v1.push_back( i );
    }

    for ( int ii = 0 ; ii <= 4 ; ii++ )
    {
        v2.push_back( 5 );
    }

    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    cout << "Vector v2 is ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")." << endl;

    swap( v1, v2 );

    cout << "Vector v1 is ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    cout << "Vector v2 is ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")." << endl;
}

```

```

Vector v1 is ( 0 1 2 3 4 5 6 7 8 9 10 ).
Vector v2 is ( 5 5 5 5 5 ).
Vector v1 is ( 5 5 5 5 5 ).
Vector v2 is ( 0 1 2 3 4 5 6 7 8 9 10 ).

```

swap_ranges

Exchanges the elements of one range with the elements of another, equal sized range.

```

template<class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 swap_ranges(
    ForwardIterator1 first1,
    ForwardIterator1 last1,
    ForwardIterator2 first2 );

```

Parameters

first1

A forward iterator pointing to the first position of the first range whose elements are to be exchanged.

last1

A forward iterator pointing to one past the final position of the first range whose elements are to be exchanged.

first2

A forward iterator pointing to the first position of the second range whose elements are to be exchanged.

Return Value

A forward iterator pointing to one past the final position of the second range whose elements are to be exchanged.

Remarks

The ranges referenced must be valid; all pointers must be dereferenceable and within each sequence the last position is reachable from the first by incrementation. The second range has to be as large as the first range.

The complexity is linear with *last1* - *first1* swaps performed. If elements from containers of the same type are being swapped, then the `swap` member function from that container should be used, because the member function typically has constant complexity.

Example

```

// alg_swap_ranges.cpp
// compile with: /EHsc
#include <vector>
#include <deque>
#include <algorithm>
#include <iostream>

int main()
{
    using namespace std;
    vector<int> v1;
    deque<int> d1;
    vector<int>::iterator v1Iter1;
    deque<int>::iterator d1Iter1;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( i );
    }

    int ii;
    for ( ii =4 ; ii <= 9 ; ii++ )
    {
        d1.push_back( 6 );
    }

    cout << "Vector v1 is ( " ;
    for ( v1Iter1 = v1.begin( ) ; v1Iter1 != v1.end( ) ;v1Iter1 ++ )
        cout << *v1Iter1 << " ";
    cout << ")." << endl;

    cout << "Deque d1 is ( " ;
    for ( d1Iter1 = d1.begin( ) ; d1Iter1 != d1.end( ) ;d1Iter1 ++ )
        cout << *d1Iter1 << " ";
    cout << ")." << endl;

    swap_ranges ( v1.begin( ), v1.end( ), d1.begin( ) );

    cout << "After the swap_range, vector v1 is ( " ;
    for ( v1Iter1 = v1.begin( ) ; v1Iter1 != v1.end( ) ;v1Iter1 ++ )
        cout << *v1Iter1 << " ";
    cout << ")." << endl;

    cout << "After the swap_range deque d1 is ( " ;
    for ( d1Iter1 = d1.begin( ) ; d1Iter1 != d1.end( ) ;d1Iter1 ++ )
        cout << *d1Iter1 << " ";
    cout << ")." << endl;
}

```

```

Vector v1 is ( 0 1 2 3 4 5 ).
Deque d1 is ( 6 6 6 6 6 6 ).
After the swap_range, vector v1 is ( 6 6 6 6 6 6 ).
After the swap_range deque d1 is ( 0 1 2 3 4 5 ).

```

transform

Applies a specified function object to each element in a source range or to a pair of elements from two source ranges and copies the return values of the function object into a destination range.

```

template<class InputIterator, class OutputIterator, class UnaryFunction>
OutputIterator transform(
    InputIterator first1,
    InputIterator last1,
    OutputIterator result,
    UnaryFunction func );

template<class InputIterator1, class InputIterator2, class OutputIterator, class BinaryFunction>
OutputIterator transform(
    InputIterator1 first1,
    InputIterator1 last1,
    InputIterator2 first2,
    OutputIterator result,
    BinaryFunction func );

```

Parameters

first1

An input iterator addressing the position of the first element in the first source range to be operated on.

last1

An input iterator addressing the position one past the final element in the first source range operated on.

first2

An input iterator addressing the position of the first element in the second source range to be operated on.

result

An output iterator addressing the position of the first element in the destination range.

_Func

User-defined unary function object used in the first version of the algorithm that is applied to each element in the first source range or A user-defined (UD) binary function object used in the second version of the algorithm that is applied pairwise, in a forward order, to the two source ranges.

Return Value

An output iterator addressing the position one past the final element in the destination range that is receiving the output elements transformed by the function object.

Remarks

The ranges referenced must be valid; all pointers must be dereferenceable and within each sequence the last position must be reachable from the first by incrementation. The destination range must be large enough to contain the transformed source range.

If *result* is set equal to *first1* in the first version of the algorithm, then the source and destination ranges will be the same and the sequence will be modified in place. But the *result* may not address a position within the range [`first1 + 1, last1`).

The complexity is linear with at most (`last1 - first1`) comparisons.

Example

```

// alg_transform.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <iostream>

// The function object multiplies an element by a Factor
template <class Type>
class MultValue

```

```

{
    private:
        Type Factor;    // The value to multiply by
    public:
        // Constructor initializes the value to multiply by
        MultValue ( const Type& val ) : Factor ( val ) {
        }

        // The function call for the element to be multiplied
        Type operator( ) ( Type& elem ) const
        {
            return elem * Factor;
        }
};

int main()
{
    using namespace std;
    vector<int> v1, v2 ( 7 ), v3 ( 7 );
    vector<int>::iterator Iter1, Iter2 , Iter3;

    // Constructing vector v1
    int i;
    for ( i = -4 ; i <= 2 ; i++ )
    {
        v1.push_back( i );
    }

    cout << "Original vector  v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Modifying the vector v1 in place
    transform (v1.begin( ), v1.end( ), v1.begin( ), MultValue<int> ( 2 ) );
    cout << "The elements of the vector v1 multiplied by 2 in place gives:"
        << "\n v1mod = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")." << endl;

    // Using transform to multiply each element by a factor of 5
    transform ( v1.begin( ), v1.end( ), v2.begin( ), MultValue<int> ( 5 ) );

    cout << "Multiplying the elements of the vector v1mod\n "
        << "by the factor 5 & copying to v2 gives:\n v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")." << endl;

    // The second version of transform used to multiply the
    // elements of the vectors v1mod & v2 pairwise
    transform ( v1.begin( ), v1.end( ), v2.begin( ), v3.begin( ),
        multiplies<int>( ) );

    cout << "Multiplying elements of the vectors v1mod and v2 pairwise "
        << "gives:\n v3 = ( " ;
    for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
        cout << *Iter3 << " ";
    cout << ")." << endl;
}

```

```
Original vector v1 = ( -4 -3 -2 -1 0 1 2 ).
The elements of the vector v1 multiplied by 2 in place gives:
v1mod = ( -8 -6 -4 -2 0 2 4 ).
Multiplying the elements of the vector v1mod
by the factor 5 & copying to v2 gives:
v2 = ( -40 -30 -20 -10 0 10 20 ).
Multiplying elements of the vectors v1mod and v2 pairwise gives:
v3 = ( 320 180 80 20 0 20 80 ).
```

unique

Removes duplicate elements that are adjacent to each other in a specified range.

```
template<class ForwardIterator>
ForwardIterator unique(
    ForwardIterator first,
    ForwardIterator last);

template<class ForwardIterator, class Predicate>
ForwardIterator unique(
    ForwardIterator first,
    ForwardIterator last,
    Predicate comp);
```

Parameters

first

A forward iterator addressing the position of the first element in the range to be scanned for duplicate removal.

last

A forward iterator addressing the position one past the final element in the range to be scanned for duplicate removal.

comp

User-defined predicate function object that defines the condition to be satisfied if two elements are to be taken as equivalent. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

A forward iterator to the new end of the modified sequence that contains no consecutive duplicates, addressing the position one past the last element not removed.

Remarks

Both forms of the algorithm remove the second duplicate of a consecutive pair of equal elements.

The operation of the algorithm is stable so that the relative order of the undeleted elements is not changed.

The range referenced must be valid; all pointers must be dereferenceable and within the sequence the last position is reachable from the first by incrementation. The number of elements in the sequence is not changed by the algorithm `unique` and the elements beyond the end of the modified sequence are dereferenceable but not specified.

The complexity is linear, requiring $(\text{last} - \text{first}) - 1$ comparisons.

List provides a more efficient member function "unique", which may perform better.

These algorithms cannot be used on an associative container.

Example

```

// alg_unique.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <iostream>
#include <ostream>

using namespace std;

// Return whether modulus of elem1 is equal to modulus of elem2
bool mod_equal ( int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 == elem2;
};

int main()
{
    vector <int> v1;
    vector <int>::iterator v1_Iter1, v1_Iter2, v1_Iter3,
        v1_NewEnd1, v1_NewEnd2, v1_NewEnd3;

    int i;
    for ( i = 0 ; i <= 3 ; i++ )
    {
        v1.push_back( 5 );
        v1.push_back( -5 );
    }

    int ii;
    for ( ii = 0 ; ii <= 3 ; ii++ )
    {
        v1.push_back( 4 );
    }
    v1.push_back( 7 );

    cout << "Vector v1 is ( " ;
    for ( v1_Iter1 = v1.begin( ) ; v1_Iter1 != v1.end( ) ; v1_Iter1++ )
        cout << *v1_Iter1 << " ";
    cout << ")." << endl;

    // Remove consecutive duplicates
    v1_NewEnd1 = unique ( v1.begin( ), v1.end( ) );

    cout << "Removing adjacent duplicates from vector v1 gives\n ( " ;
    for ( v1_Iter1 = v1.begin( ) ; v1_Iter1 != v1_NewEnd1 ; v1_Iter1++ )
        cout << *v1_Iter1 << " ";
    cout << ")." << endl;

    // Remove consecutive duplicates under the binary predicate mod_equals
    v1_NewEnd2 = unique ( v1.begin( ), v1_NewEnd1 , mod_equal );

    cout << "Removing adjacent duplicates from vector v1 under the\n "
        << " binary predicate mod_equal gives\n ( " ;
    for ( v1_Iter2 = v1.begin( ) ; v1_Iter2 != v1_NewEnd2 ; v1_Iter2++ )
        cout << *v1_Iter2 << " ";
    cout << ")." << endl;

    // Remove elements if preceded by an element that was greater
    v1_NewEnd3 = unique ( v1.begin( ), v1_NewEnd2, greater<int>( ) );

    cout << "Removing adjacent elements satisfying the binary\n "
        << " predicate mod_equal from vector v1 gives ( " ;
    for ( v1_Iter3 = v1.begin( ) ; v1_Iter3 != v1_NewEnd3 ; v1_Iter3++ )
        cout << *v1_Iter3 << " ";

```

```
    cout << ")." << endl;
}
```

Vector v1 is (5 -5 5 -5 5 -5 5 -5 4 4 4 7).
Removing adjacent duplicates from vector v1 gives
(5 -5 5 -5 5 -5 5 -5 4 7).
Removing adjacent duplicates from vector v1 under the
binary predicate mod_equal gives
(5 4 7).
Removing adjacent elements satisfying the binary
predicate mod_equal from vector v1 gives (5 7).

unique_copy

Copies elements from a source range into a destination range except for the duplicate elements that are adjacent to each other.

```
template<class InputIterator, class OutputIterator>
OutputIterator unique_copy( InputIterator first,
    InputIterator last,
    OutputIterator result );

template<class InputIterator, class OutputIterator, class BinaryPredicate>
OutputIterator unique_copy( InputIterator first,
    InputIterator last,
    OutputIterator result,
    BinaryPredicate comp );
```

Parameters

first

A forward iterator addressing the position of the first element in the source range to be copied.

last

A forward iterator addressing the position one past the final element in the source range to be copied.

result

An output iterator addressing the position of the first element in the destination range that is receiving the copy with consecutive duplicates removed.

comp

User-defined predicate function object that defines the condition to be satisfied if two elements are to be taken as equivalent. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

An output iterator addressing the position one past the final element in the destination range that is receiving the copy with consecutive duplicates removed.

Remarks

Both forms of the algorithm remove the second duplicate of a consecutive pair of equal elements.

The operation of the algorithm is stable so that the relative order of the undeleted elements is not changed.

The ranges referenced must be valid; all pointers must be dereferenceable and within a sequence the last position is reachable from the first by incrementation.

The complexity is linear, requiring (`last` - `first`) comparisons.

Example

```

// alg_unique_copy.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <iostream>
#include <ostream>

using namespace std;

// Return whether modulus of elem1 is equal to modulus of elem2
bool mod_equal ( int elem1, int elem2 ) {
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 == elem2;
};

int main() {
    vector<int> v1;
    vector<int>::iterator v1_Iter1, v1_Iter2,
        v1_NewEnd1, v1_NewEnd2;

    int i;
    for ( i = 0 ; i <= 1 ; i++ ) {
        v1.push_back( 5 );
        v1.push_back( -5 );
    }

    int ii;
    for ( ii = 0 ; ii <= 2 ; ii++ )
        v1.push_back( 4 );
    v1.push_back( 7 );

    int iii;
    for ( iii = 0 ; iii <= 5 ; iii++ )
        v1.push_back( 10 );

    cout << "Vector v1 is\n ( " ;
    for ( v1_Iter1 = v1.begin( ) ; v1_Iter1 != v1.end( ) ; v1_Iter1++ )
        cout << *v1_Iter1 << " ";
    cout << ")." << endl;

    // Copy first half to second, removing consecutive duplicates
    v1_NewEnd1 = unique_copy ( v1.begin( ), v1.begin( ) + 8, v1.begin( ) + 8 );

    cout << "Copying the first half of the vector to the second half\n "
        << "while removing adjacent duplicates gives\n ( " ;
    for ( v1_Iter1 = v1.begin( ) ; v1_Iter1 != v1_NewEnd1 ; v1_Iter1++ )
        cout << *v1_Iter1 << " ";
    cout << ")." << endl;

    int iv;
    for ( iv = 0 ; iv <= 7 ; iv++ )
        v1.push_back( 10 );

    // Remove consecutive duplicates under the binary predicate mod_equals
    v1_NewEnd2 = unique_copy ( v1.begin( ), v1.begin( ) + 14,
        v1.begin( ) + 14 , mod_equal );

    cout << "Copying the first half of the vector to the second half\n "
        << " removing adjacent duplicates under mod_equals gives\n ( " ;
    for ( v1_Iter2 = v1.begin( ) ; v1_Iter2 != v1_NewEnd2 ; v1_Iter2++ )
        cout << *v1_Iter2 << " ";
    cout << ")." << endl;
}

```

upper_bound

Finds the position of the first element in an ordered range that has a value that is greater than a specified value, where the ordering criterion may be specified by a binary predicate.

```
template<class ForwardIterator, class Type>
ForwardIterator upper_bound(
    ForwardIterator first,
    ForwardIterator last,
    const Type& value);

template<class ForwardIterator, class Type, class Predicate>
ForwardIterator upper_bound(
    ForwardIterator first,
    ForwardIterator last,
    const Type& value,
    Predicate comp);
```

Parameters

first

The position of the first element in the range to be searched.

last

The position one past the final element in the range to be searched.

value

The value in the ordered range that needs to be exceeded by the value of the element addressed by the iterator returned.

comp

User-defined predicate function object that defines sense in which one element is less than another. A binary predicate takes two arguments and returns **true** when satisfied and **false** when not satisfied.

Return Value

A forward iterator to the position of the first element that has a value greater than a specified value.

Remarks

The sorted source range referenced must be valid; all iterators must be dereferenceable and within the sequence the last position must be reachable from the first by incrementation.

A sorted range is a precondition of the use of `upper_bound` and where the ordering criterion is the same as specified by the binary predicate.

The range is not modified by `upper_bound`.

The value types of the forward iterators need be less-than comparable to be ordered, so that, given two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements

The complexity of the algorithm is logarithmic for random-access iterators and linear otherwise, with the number of steps proportional to `(last - first)`.

Example

```
// alg_upper_bound.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
```

```

#include <functional>      // greater<int>( )
#include <iostream>

// Return whether modulus of elem1 is less than modulus of elem2
bool mod_lesser( int elem1, int elem2 )
{
    if ( elem1 < 0 )
        elem1 = - elem1;
    if ( elem2 < 0 )
        elem2 = - elem2;
    return elem1 < elem2;
}

int main()
{
    using namespace std;

    vector<int> v1;
    // Constructing vector v1 with default less-than ordering
    for ( auto i = -1 ; i <= 4 ; ++i )
    {
        v1.push_back( i );
    }

    for ( auto ii = -3 ; ii <= 0 ; ++ii )
    {
        v1.push_back( ii );
    }

    cout << "Starting vector v1 = ( " ;
    for (const auto &Iter : v1)
        cout << Iter << " ";
    cout << ")." << endl;

    sort(v1.begin(), v1.end());
    cout << "Original vector v1 with range sorted by the\n "
        << "binary predicate less than is v1 = ( " ;
    for (const auto &Iter : v1)
        cout << Iter << " ";
    cout << ")." << endl;

    // Constructing vector v2 with range sorted by greater
    vector<int> v2(v1);

    sort(v2.begin(), v2.end(), greater<int>());

    cout << "Original vector v2 with range sorted by the\n "
        << "binary predicate greater is v2 = ( " ;
    for (const auto &Iter : v2)
        cout << Iter << " ";
    cout << ")." << endl;

    // Constructing vectors v3 with range sorted by mod_lesser
    vector<int> v3(v1);
    sort(v3.begin(), v3.end(), mod_lesser);

    cout << "Original vector v3 with range sorted by the\n "
        << "binary predicate mod_lesser is v3 = ( " ;
    for (const auto &Iter : v3)
        cout << Iter << " ";
    cout << ")." << endl;

    // Demonstrate upper_bound

    vector<int>::iterator Result;

    // upper_bound of 3 in v1 with default binary predicate less<int>()
    Result = upper_bound(v1.begin(), v1.end(), 3);
    cout << "The upper_bound in v1 for the element with a value of 3 is: "

```

```

        << *Result << "." << endl;

// upper_bound of 3 in v2 with the binary predicate greater<int>( )
Result = upper_bound(v2.begin(), v2.end(), 3, greater<int>());
cout << "The upper_bound in v2 for the element with a value of 3 is: "
    << *Result << "." << endl;

// upper_bound of 3 in v3 with the binary predicate mod_lesser
Result = upper_bound(v3.begin(), v3.end(), 3, mod_lesser);
cout << "The upper_bound in v3 for the element with a value of 3 is: "
    << *Result << "." << endl;
}

```

[<algorithm>](#)

<allocators>

10/31/2018 • 5 minutes to read • [Edit Online](#)

Defines several templates that help allocate and free memory blocks for node-based containers.

Syntax

```
#include <allocators>
```

Remarks

The <allocators> header provides six allocator templates that can be used to select memory-management strategies for node-based containers. For use with these templates, it also provides several different synchronization filters to tailor the memory-management strategy to a variety of different multithreading schemes (including none). Matching a memory management strategy to the known memory usage patterns, and synchronization requirements, of a particular application can often increase the speed or reduce the overall memory requirements of an application.

The allocator templates are implemented with reusable components that can be customized or replaced to provide additional memory-management strategies.

The node-based containers in the C++ Standard Library (std::list, std::set, std::multiset, std::map and std::multimap) store their elements in individual nodes. All the nodes for a particular container type are the same size, so the flexibility of a general-purpose memory manager is not needed. Because the size of each memory block is known at compile time, the memory manager can be much simpler and faster.

When used with containers that are not node-based (such as the C++ Standard Library containers std::vector, std::deque, and std::basic_string), the allocator templates will work correctly, but are not likely to provide any performance improvement over the default allocator.

An allocator is a template class that describes an object that manages storage allocation and freeing for objects and arrays of objects of a designated type. Allocator objects are used by several container template classes in the C++ Standard Library.

The allocators are all templates of this type:

```
template<class Type>  
class allocator;
```

where the template argument `Type` is the type managed by the allocator instance. The C++ Standard Library provides a default allocator, template class `allocator`, which is defined in [<memory>](#). The <allocators> header provides the following allocators:

- [allocator_newdel](#)
- [allocator_unbounded](#)
- [allocator_fixed_size](#)
- [allocator_variable_size](#)
- [allocator_suballoc](#)

- [allocator_chunklist](#)

Use an appropriate instantiation of an allocator as the second type argument when creating a container, such as the following code example.

```
#include <list>
#include <allocators>
std::list<int, stdext::allocators::allocator_chunklist<int> > _List0;
```

_List0 allocates nodes with `allocator_chunklist` and the default synchronization filter.

Use the macro `ALLOCATOR_DECL` to create allocator templates with synchronization filters other than the default:

```
#include <list>
#include <allocators>
ALLOCATOR_DECL(CACHE_CHUNKLIST, stdext::allocators::sync_per_thread, Alloc);
std::list<int, alloc<int> > _List1;
```

_List1 allocates nodes with `allocator_chunklist` and the `sync_per_thread` synchronization filter.

A block allocator is a cache or a filter. A cache is a template class that takes one argument of type `std::size_t`. It defines a block allocator that allocates and deallocates memory blocks of a single size. It must obtain memory using operator **new**, but it need not make a separate call to operator **new** for each block. It may, for example, suballocate from a larger block or cache deallocated blocks for subsequent reallocation.

With a compiler that cannot compile rebind the value of the `std::size_t` argument used when the template was instantiated is not necessarily the value of the argument `_Sz` passed to a cache's member functions `allocate` and `deallocate`.

`<allocators>` provides the following cache templates:

- [cache_freelist](#)
- [cache_suballoc](#)
- [cache_chunklist](#)

A filter is a block allocator that implements its member functions using another block allocator which is passed to it as a template argument. The most common form of filter is a synchronization filter, which applies a synchronization policy to control access to the member functions of an instance of another block allocator.

`<allocators>` provides the following synchronization filters:

- [sync_none](#)
- [sync_per_container](#)
- [sync_per_thread](#)
- [sync_shared](#)

`<allocators>` also provides the filter `rts_alloc`, which holds multiple block allocator instances and determines which instance to use for allocation or deallocation at runtime instead of at compile time. It is used with compilers that cannot compile rebind.

A synchronization policy determines how an allocator instance handles simultaneous allocation and deallocation requests from multiple threads. The simplest policy is to pass all requests directly through to the underlying cache object, leaving synchronization management to the user. A more complex policy could be to use a mutex to serialize access to the underlying cache object.

If a compiler supports compiling both single-threaded and multi-threaded applications, the default synchronization filter for single-threaded applications is `sync_none`; for all other cases it is `sync_shared`.

The cache template `cache_freelist` takes a max class argument which determines the maximum number of elements to be stored in the free list.

<allocators> provides the following max classes:

- [max_none](#)
- [max_unbounded](#)
- [max_fixed_size](#)
- [max_variable_size](#)

Macros

MACRO	DESCRIPTION
ALLOCATOR_DECL	Yields an allocator template class.
CACHE_CHUNKLIST	Yields <code>stdext::allocators::cache_chunklist<sizeof(Type)></code> .
CACHE_FREELIST	Yields <code>stdext::allocators::cache_freelist<sizeof(Type), max></code> .
CACHE_SUBALLOC	Yields <code>stdext::allocators::cache_suballoc<sizeof(Type)></code> .
SYNC_DEFAULT	Yields a synchronization filter.

Operators

OPERATOR	DESCRIPTION
operator!= (<allocators>)	Tests for inequality between allocator objects of a specified class.
operator== (<allocators>)	Tests for equality between allocator objects of a specified class.

Classes

CLASS	DESCRIPTION
allocator_base	Defines the base class and common functions needed to create a user-defined allocator from a synchronization filter.
allocator_chunklist	Describes an object that manages storage allocation and freeing for objects using a cache of type cache_chunklist .
allocator_fixed_size	Describes an object that manages storage allocation and freeing for objects of type <code>Type</code> using a cache of type cache_freelist with a length managed by max_fixed_size .

CLASS	DESCRIPTION
allocator_newdel	Implements an allocator that uses operator delete to deallocate a memory block and operator new to allocate a memory block.
allocator_suballoc	Describes an object that manages storage allocation and freeing for objects of type <code>Type</code> using a cache of type cache_suballoc .
allocator_unbounded	Describes an object that manages storage allocation and freeing for objects of type <code>Type</code> using a cache of type cache_freelist with a length managed by max_unbounded .
allocator_variable_size	Describes an object that manages storage allocation and freeing for objects of type <code>Type</code> using a cache of type cache_freelist with a length managed by max_variable_size .
cache_chunklist	Defines a block allocator that allocates and deallocates memory blocks of a single size.
cache_freelist	Defines a block allocator that allocates and deallocates memory blocks of a single size.
cache_suballoc	Defines a block allocator that allocates and deallocates memory blocks of a single size.
freelist	Manages a list of memory blocks.
max_fixed_size	Describes a max class object that limits a freelist object to a fixed maximum length.
max_none	Describes a max class object that limits a freelist object to a maximum length of zero.
max_unbounded	Describes a max class object that does not limit the maximum length of a freelist object.
max_variable_size	Describes a max class object that limits a freelist object to a maximum length that is roughly proportional to the number of allocated memory blocks.
rts_alloc	The <code>rts_alloc</code> template class describes a filter that holds an array of cache instances and determines which instance to use for allocation and deallocation at runtime instead of at compile time.
sync_none	Describes a synchronization filter that provides no synchronization.
sync_per_container	Describes a synchronization filter that provides a separate cache object for each allocator object.
sync_per_thread	Describes a synchronization filter that provides a separate cache object for each thread.

CLASS	DESCRIPTION
sync_shared	Describes a synchronization filter that uses a mutex to control access to a cache object that is shared by all allocators.

<allocators> macros

10/31/2018 • 2 minutes to read • [Edit Online](#)

ALLOCATOR_DECL	CACHE_CHUNKLIST	CACHE_FREELIST
CACHE_SUBALLOC	SYNC_DEFAULT	

ALLOCATOR_DECL

Yields an allocator template class.

```
#define ALLOCATOR_DECL(cache, sync, name) <alloc_template>
```

Remarks

The macro yields a template definition `template <class Type> class name {.....}` and a specialization `template <> class name<void> {.....}` which together define an allocator template class that uses the synchronization filter `sync` and a cache of type `cache`.

For compilers that can compile `rebind`, the resulting template definition looks like this:

```
struct rebind
{
    /* convert a name<Type> to a name<Other> */
    typedef name<Other> other;
};
```

For compilers that cannot compile `rebind` the resulting template definition looks like this:

```
template <class Type> class name
: public stdext::allocators::allocator_base<Type,
    sync<stdext::allocators::rts_alloc<cache>>>
{
public:
    name() {}
    template <class Other>
    name(const name<Other>&) {}
    template <class Other>
    name& operator= (const name<Other>&)
    {
        return *this;
    }
};
```

CACHE_CHUNKLIST

Yields `stdext::allocators::cache_chunklist<sizeof(Type)>`.

```
#define CACHE_CHUNKLIST <cache_class>
```

Remarks

CACHE_FREELIST

Yields `stdext::allocators::cache_freelist<sizeof(Type), max>` .

```
#define CACHE_FREELIST(max) <cache_class>
```

Remarks

CACHE_SUBALLOC

Yields `stdext::allocators::cache_suballoc<sizeof(Type)>` .

```
#define CACHE_SUBALLOC <cache_class>
```

Remarks

SYNC_DEFAULT

Yields a synchronization filter.

```
#define SYNC_DEFAULT <sync_template>
```

Remarks

If a compiler supports compiling both single-threaded and multi-threaded applications, for single-threaded applications the macro yields `stdext::allocators::sync_none` ; in all other cases it yields

`stdext::allocators::sync_shared` .

[<allocators>](#)

<allocators> operators

10/31/2018 • 2 minutes to read • [Edit Online](#)

These are the global template operator functions defined in <allocators>. For class member operator functions, see the class documentation.

operator!=	operator==

operator!=

Tests for inequality between allocator objects of a specified class.

```
template <class Type, class Sync>
bool operator!=(
    const allocator_base<Type, Sync>& left,
    const allocator_base<Type, Sync>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	One of the allocator objects to be tested for inequality.
<i>right</i>	One of the allocator objects to be tested for inequality.

Return Value

true if the allocator objects are not equal; **false** if allocator objects are equal.

Remarks

The template operator returns `!(left == right)`.

operator==

Tests for equality between allocator objects of a specified class.

```
template <class Type, class Sync>
bool operator==(
    const allocator_base<Type, Sync>& left,
    const allocator_base<Type, Sync>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	One of the allocator objects to be tested for equality.
<i>right</i>	One of the allocator objects to be tested for equality.

Return Value

true if the allocator objects are equal; **false** if allocator objects are not equal.

Remarks

This template operator returns `left.equals(right)`.

[<allocators>](#)

allocator_base Class

10/31/2018 • 5 minutes to read • [Edit Online](#)

Defines the base class and common functions needed to create a user-defined allocator from a synchronization filter.

Syntax

```
template <class Type, class Sync>
class allocator_base
```

Parameters

PARAMETER	DESCRIPTION
<i>Type</i>	The type of elements allocated by the allocator.
<i>Sync</i>	The synchronization policy for the allocator, which is sync_none Class , sync_per_container Class , sync_per_thread Class , or sync_shared Class .

Constructors

CONSTRUCTOR	DESCRIPTION
allocator_base	Constructs an object of type <code>allocator_base</code> .

Typedefs

TYPE NAME	DESCRIPTION
const_pointer	A type that provides a constant pointer to the type of object managed by the allocator.
const_reference	A type that provides a constant reference to type of object managed by the allocator.
difference_type	A signed integral type that can represent the difference between values of pointers to the type of object managed by the allocator.
pointer	A type that provides a pointer to the type of object managed by the allocator.
reference	A type that provides a reference to the type of object managed by the allocator.
size_type	An unsigned integral type that can represent the length of any sequence that an object of template class <code>allocator_base</code> can allocate.

TYPE NAME	DESCRIPTION
<code>value_type</code>	A type that is managed by the allocator.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>_Charalloc</code>	Allocates storage for an array of type char .
<code>_Chardealloc</code>	Frees storage for the array containing elements of type char .
<code>address</code>	Finds the address of an object whose value is specified.
<code>allocate</code>	Allocates a block of memory large enough to store at least some specified number of elements.
<code>construct</code>	Constructs a specific type of object at a specified address that is initialized with a specified value.
<code>deallocate</code>	Frees a specified number of objects from storage beginning at a specified position.
<code>destroy</code>	Calls an objects destructor without deallocating the memory where the object was stored.
<code>max_size</code>	Returns the number of elements of type <i>Type</i> that could be allocated by an object of class allocator before the free memory is used up.

Requirements

Header: <allocators>

Namespace: stdext

allocator_base::_Charalloc

Allocates storage for an array of type **char**.

```
char *_Charalloc(size_type count);
```

Parameters

PARAMETER	DESCRIPTION
<code>count</code>	The number of elements in the array to be allocated.

Return Value

A pointer to the allocated object.

Remarks

This member function is used by containers when compiled with a compiler that cannot compile rebind. It implements `_Charalloc` for the user-defined allocator by returning the result of a call to the `allocate` function of

the synchronization filter.

allocator_base::_Chardealloc

Frees storage for the array containing elements of type **char**.

```
void _Chardealloc(void* ptr, size_type count);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the first object to be deallocated from storage.
<i>count</i>	The number of objects to be deallocated from storage.

Remarks

This member function is used by containers when compiled with a compiler that cannot compile rebind. It implements `_Chardealloc` for the user-defined allocator by calling the `deallocate` function of the synchronization filter. The pointer `ptr` must have been earlier returned by a call to `_Charalloc` for an allocator object that compares equal to `*this`, allocating an array object of the same size and type. `_Chardealloc` never throws an exception.

allocator_base::address

Finds the address of an object whose value is specified.

```
pointer address(reference val);

const_pointer address(const_reference val);
```

Parameters

val

The const or nonconst value of the object whose address is being searched for.

Return Value

A const or nonconst pointer to the object found of, respectively, const or nonconst value.

Remarks

This member function is implemented for the user-defined allocator by returning `&val`.

allocator_base::allocate

Allocates a block of memory large enough to store at least some specified number of elements.

```
template <class Other>
pointer allocate(size_type _Nx, const Other* _Hint = 0);

pointer allocate(size_type _Nx);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Nx</code>	The number of elements in the array to be allocated.
<code>_Hint</code>	This parameter is ignored.

Return Value

A pointer to the allocated object.

Remarks

The member function implements memory allocation for the user-defined allocator by returning the result of a call to the `allocate` function of the synchronization filter of type `Type *` if `_Nx == 1`, otherwise by returning the result of a call to `operator new(_Nx * sizeof(Type))` cast to `Type *`.

allocator_base::allocator_base

Constructs an object of type `allocator_base`.

```
allocator_base();

template <class Other>
allocator_base(const allocator_base<Other, Sync>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The allocator object to be copied.

Remarks

The first constructor constructs an `allocator_base` instance. The second constructor constructs an `allocator_base` instance such that for any `allocator_base<Type, _Sync>` instance `a`,
`allocator_base<Type, Sync>(allocator_base<Other, Sync>(a)) == a`.

allocator_base::const_pointer

A type that provides a constant pointer to the type of object managed by the allocator.

```
typedef const Type *const_pointer;
```

allocator_base::const_reference

A type that provides a constant reference to type of object managed by the allocator.

```
typedef const Type& const_reference;
```

allocator_base::construct

Constructs a specific type of object at a specified address that is initialized with a specified value.

```
void construct(pointer ptr, const Type& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the location where the object is to be constructed.
<i>val</i>	The value with which the object being constructed is to be initialized.

Remarks

This member function is implemented for the user-defined allocator by calling `new((void*)ptr Type(val))`.

allocator_base::deallocate

Frees a specified number of objects from storage beginning at a specified position.

```
void deallocate(pointer ptr, size_type _Nx);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the first object to be deallocated from storage.
<i>_Nx</i>	The number of objects to be deallocated from storage.

Remarks

This member function is implemented for the user-defined allocator by calling `deallocate(ptr)` on the synchronization filter `Sync` if `_Nx == 1`, otherwise by calling `operator delete(_Nx * ptr)`.

allocator_base::destroy

Calls an objects destructor without deallocating the memory where the object was stored.

```
void destroy(pointer ptr);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer designating the address of the object to be destroyed.

Remarks

This member function is implemented for the user-defined allocator by calling `ptr->~Type()`.

allocator_base::difference_type

A signed integral type that can represent the difference between values of pointers to the type of object managed

by the allocator.

```
typedef std::ptrdiff_t difference_type;
```

allocator_base::max_size

Returns the number of elements of type `Type` that could be allocated by an object of class allocator before the free memory is used up.

```
size_type max_size() const;
```

Return Value

The number of elements that could be allocated.

Remarks

This member function is implemented for the user-defined allocator by returning `(size_t)-1 / sizeof(Type)` if `0 < (size_t)-1 / sizeof(Type)`, otherwise `1`.

allocator_base::pointer

A type that provides a pointer to the type of object managed by the allocator.

```
typedef Type *pointer;
```

allocator_base::reference

A type that provides a reference to the type of object managed by the allocator.

```
typedef Type& reference;
```

allocator_base::size_type

An unsigned integral type that can represent the length of any sequence that an object of template class `allocator_base` can allocate.

```
typedef std::size_t size_type;
```

allocator_base::value_type

A type that is managed by the allocator.

```
typedef Type value_type;
```

allocator_newdel Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Implements an allocator that uses **operator delete** to deallocate a memory block and **operator new** to allocate a memory block.

Syntax

```
template <class Type>
class allocator_newdel;
```

Parameters

PARAMETER	DESCRIPTION
<i>Type</i>	The type of elements allocated by the allocator.

Remarks

The [ALLOCATOR_DECL](#) macro passes this class as the *name* parameter in the following statement:

```
ALLOCATOR_DECL(CACHE_FREELIST stdext::allocators::max_none), SYNC_DEFAULT, allocator_newdel);
```

allocator_unbounded Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an object that manages storage allocation and freeing for objects of type *Type* using a cache of type [cache_freelist](#) with a length managed by [max_unbounded](#).

Syntax

```
template <class Type>
class allocator_unbounded;
```

Parameters

PARAMETER	DESCRIPTION
<i>Type</i>	The type of elements allocated by the allocator.

Remarks

The [ALLOCATOR_DECL](#) macro passes this class as the *name* parameter in the following statement:

```
ALLOCATOR_DECL(CACHE_FREELIST(stdext::allocators::max_unbounded), SYNC_DEFAULT, allocator_unbounded);
```

[<allocators>](#)

cache_chunklist Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines a [block allocator](#) that allocates and deallocates memory blocks of a single size.

Syntax

```
template <std::size_t Sz, std::size_t Nelts = 20>
class cache_chunklist
```

Parameters

PARAMETER	DESCRIPTION
<code>Sz</code>	The number of elements in the array to be allocated.

Remarks

This template class uses **operator new** to allocate chunks of raw memory, suballocating blocks to allocate storage for a memory block when needed; it stores deallocated memory blocks in a separate free list for each chunk, and uses **operator delete** to deallocate a chunk when none of its memory blocks is in use.

Each memory block holds `Sz` bytes of usable memory and a pointer to the chunk that it belongs to. Each chunk holds `Nelts` memory blocks, three pointers, an int and the data that **operator new** and **operator delete** require.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>cache_chunklist</code>	Constructs an object of type <code>cache_chunklist</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>allocate</code>	Allocates a block of memory.
<code>deallocate</code>	Frees a specified number of objects from storage beginning at a specified position.

Requirements

Header: <allocators>

Namespace: stdext

cache_chunklist::allocate

Allocates a block of memory.

```
void *allocate(std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>count</i>	The number of elements in the array to be allocated.

Return Value

A pointer to the allocated object.

Remarks

cache_chunklist::cache_chunklist

Constructs an object of type `cache_chunklist`.

```
cache_chunklist();
```

Remarks

cache_chunklist::deallocate

Frees a specified number of objects from storage beginning at a specified position.

```
void deallocate(void* ptr, std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the first object to be deallocated from storage.
<i>count</i>	The number of objects to be deallocated from storage.

Remarks

See also

[<allocators>](#)

cache_freelist Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines a [block allocator](#) that allocates and deallocates memory blocks of a single size.

Syntax

```
template <std::size_t Sz, class Max>
class cache_freelist
```

Parameters

PARAMETER	DESCRIPTION
<i>Sz</i>	The number of elements in the array to be allocated.
<i>Max</i>	The max class representing the maximum size of the free list. This can be max_fixed_size , max_none , max_unbounded , or max_variable_size .

Remarks

The `cache_freelist` template class maintains a free list of memory blocks of size *Sz*. When the free list is full it uses **operator delete** to deallocate memory blocks. When the free list is empty it uses **operator new** to allocate new memory blocks. The maximum size of the free list is determined by the class max class passed in the *Max* parameter.

Each memory block holds *Sz* bytes of usable memory and the data that **operator new** and **operator delete** require.

Constructors

CONSTRUCTOR	DESCRIPTION
cache_freelist	Constructs an object of type <code>cache_freelist</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
allocate	Allocates a block of memory.
deallocate	Frees a specified number of objects from storage beginning at a specified position.

Requirements

Header: <allocators>

Namespace: stdext

cache_freelist::allocate

Allocates a block of memory.

```
void *allocate(std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>count</i>	The number of elements in the array to be allocated.

Return Value

A pointer to the allocated object.

Remarks

cache_freelist::cache_freelist

Constructs an object of type `cache_freelist`.

```
cache_freelist();
```

Remarks

cache_freelist::deallocate

Frees a specified number of objects from storage beginning at a specified position.

```
void deallocate(void* ptr, std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the first object to be deallocated from storage.
<i>count</i>	The number of objects to be deallocated from storage.

Remarks

See also

[<allocators>](#)

cache_suballoc Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines a [block allocator](#) that allocates and deallocates memory blocks of a single size.

Syntax

```
template <std::size_t Sz, size_t Nelts = 20>
class cache_suballoc
```

Parameters

PARAMETER	DESCRIPTION
Sz	The number of elements in the array to be allocated.

Remarks

The cache_suballoc template class stores deallocated memory blocks in a free list with unbounded length, using `freelist<sizeof(Type), max_unbounded>`, and suballocates memory blocks from a larger chunk allocated with **operator new** when the free list is empty.

Each chunk holds `Sz * Nelts` bytes of usable memory and the data that **operator new** and **operator delete** require. Allocated chunks are never freed.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>cache_suballoc</code>	Constructs an object of type <code>cache_suballoc</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>allocate</code>	Allocates a block of memory.
<code>deallocate</code>	Frees a specified number of objects from storage beginning at a specified position.

Requirements

Header: <allocators>

Namespace: stdext

cache_suballoc::allocate

Allocates a block of memory.

```
void *allocate(std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>count</i>	The number of elements in the array to be allocated.

Return Value

A pointer to the allocated object.

Remarks

cache_suballoc::cache_suballoc

Constructs an object of type `cache_suballoc`.

```
cache_suballoc();
```

Remarks

cache_suballoc::deallocate

Frees a specified number of objects from storage beginning at a specified position.

```
void deallocate(void* ptr, std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the first object to be deallocated from storage.
<i>count</i>	The number of objects to be deallocated from storage.

Remarks

See also

[<allocators>](#)

freelist Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Manages a list of memory blocks.

Syntax

```
template <std::size_t Sz, class Max>
class freelist : public Max
```

Parameters

PARAMETER	DESCRIPTION
<i>Sz</i>	The number of elements in the array to be allocated.
<i>Max</i>	The max class representing the maximum number of elements to be stored in the free list. The max class can be max_none , max_unbounded , max_fixed_size , or max_variable_size .

Remarks

This template class manages a list of memory blocks of size *Sz* with the maximum length of the list determined by the max class passed in *Max*.

Constructors

CONSTRUCTOR	DESCRIPTION
freelist	Constructs an object of type <code>freelist</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
pop	Removes the first memory block from the free list.
push	Adds a memory block to the list.

Requirements

Header: <allocators>

Namespace: stdext

freelist::freelist

Constructs an object of type `freelist`.

```
freelist();
```

Remarks

freelist::pop

Removes the first memory block from the free list.

```
void *pop();
```

Return Value

Returns a pointer to the memory block removed from the list.

Remarks

The member function returns NULL if the list is empty. Otherwise, it removes the first memory block from the list.

freelist::push

Adds a memory block to the list.

```
bool push(void* ptr);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the memory block to be added to the free list.

Return Value

true if the `full` function of the max class returns **false**; otherwise, the `push` function returns **false**.

Remarks

If the `full` function of the max class returns **false**, this member function adds the memory block pointed to by *ptr* to the head of the list.

[<allocators>](#)

max_fixed_size Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes a [max class](#) object that limits a [freelist](#) object to a fixed maximum length.

Syntax

```
template <std::size_t Max>
class max_fixed_size
```

Parameters

PARAMETER	DESCRIPTION
<i>Max</i>	The max class that determines the maximum number of elements to store in the <code>freelist</code> .

Constructors

CONSTRUCTOR	DESCRIPTION
<code>max_fixed_size</code>	Constructs an object of type <code>max_fixed_size</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>allocated</code>	Increments the count of allocated memory blocks.
<code>deallocated</code>	Decrements the count of allocated memory blocks.
<code>full</code>	Returns a value that specifies whether more memory blocks should be added to the free list.
<code>released</code>	Decrements the count of memory blocks on the free list.
<code>saved</code>	Increments the count of memory blocks on the free list.

Requirements

Header: `<allocators>`

Namespace: `stdext`

max_fixed_size::allocated

Increments the count of allocated memory blocks.

```
void allocated(std::size_t _Nx = 1);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Nx</code>	The increment value.

Remarks

The member function does nothing. This member function is called after each successful call by `cache_freelist::allocate` to operator **new**. The argument `_Nx` is the number of memory blocks in the chunk allocated by operator **new**.

`max_fixed_size::deallocated`

Decrements the count of allocated memory blocks.

```
void deallocated(std::size_t _Nx = 1);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Nx</code>	The increment value.

Remarks

The member function does nothing. This member function is called after each call by `cache_freelist::deallocate` to operator **delete**. The argument `_Nx` is the number of memory blocks in the chunk deallocated by operator **delete**.

`max_fixed_size::full`

Returns a value that specifies whether more memory blocks should be added to the free list.

```
bool full();
```

Return Value

true if `Max <= _Nblocks`; otherwise, **false**.

Remarks

This member function is called by `cache_freelist::deallocate`. If the call returns **true**, `deallocate` puts the memory block on the free list; if it returns false, `deallocate` calls operator **delete** to deallocate the block.

`max_fixed_size::max_fixed_size`

Constructs an object of type `max_fixed_size`.

```
max_fixed_size();
```

Remarks

This constructor initializes the stored value `_Nblocks` to zero.

`max_fixed_size::released`

Decrements the count of memory blocks on the free list.

```
void released();
```

Remarks

Decrements the stored value `_Nblocks`. The `released` member function of the current [max class](#) is called by `cache_freelist::allocate` whenever it removes a memory block from the free list.

max_fixed_size::saved

Increments the count of memory blocks on the free list.

```
void saved();
```

Remarks

This member function increments the stored value `_Nblocks`. This member function is called by `cache_freelist::deallocate` whenever it puts a memory block on the free list.

See also

[<allocators>](#)

max_none Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes a [max class](#) object that limits a [freelist](#) object to a maximum length of zero.

Syntax

```
template <std::size_t Max>
class max_none
```

Parameters

PARAMETER	DESCRIPTION
<i>Max</i>	The max class that determines the maximum number of elements to store in the <code>freelist</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
allocated	Increments the count of allocated memory blocks.
deallocated	Decrements the count of allocated memory blocks.
full	Returns a value that specifies whether more memory blocks should be added to the free list.
released	Decrements the count of memory blocks on the free list.
saved	Increments the count of memory blocks on the free list.

Requirements

Header: <allocators>

Namespace: stdext

max_none::allocated

Increments the count of allocated memory blocks.

```
void allocated(std::size_t _Nx = 1);
```

Parameters

PARAMETER	DESCRIPTION
<i>_Nx</i>	The increment value.

Remarks

This member function does nothing. It is called after each successful call by `cache_freelist::allocate` to operator **new**. The argument `_Nx` is the number of memory blocks in the chunk allocated by operator **new**.

max_none::deallocated

Decrements the count of allocated memory blocks.

```
void deallocated(std::size_t _Nx = 1);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Nx</code>	The increment value.

Remarks

The member function does nothing. This member function is called after each call by `cache_freelist::deallocate` to operator **delete**. The argument `_Nx` is the number of memory blocks in the chunk deallocated by operator **delete**.

max_none::full

Returns a value that specifies whether more memory blocks should be added to the free list.

```
bool full();
```

Return Value

This member function always returns **true**.

Remarks

This member function is called by `cache_freelist::deallocate`. If the call returns **true**, `deallocate` puts the memory block on the free list; if it returns false, `deallocate` calls operator **delete** to deallocate the block.

max_none::released

Decrements the count of memory blocks on the free list.

```
void released();
```

Remarks

This member function does nothing. The `released` member function of the current max class is called by `cache_freelist::allocate` whenever it removes a memory block from the free list.

max_none::saved

Increments the count of memory blocks on the free list.

```
void saved();
```

Remarks

This member function does nothing. It is called by `cache_freelist::deallocate` whenever it puts a memory block on the free list.

See also

[<allocators>](#)

max_unbounded Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes a [max class](#) object that does not limit the maximum length of a [freelist](#) object.

Syntax

```
class max_unbounded
```

Member functions

MEMBER FUNCTION	DESCRIPTION
allocated	Increments the count of allocated memory blocks.
deallocated	Decrements the count of allocated memory blocks.
full	Returns a value that specifies whether more memory blocks should be added to the free list.
released	Decrements the count of memory blocks on the free list.
saved	Increments the count of memory blocks on the free list.

Requirements

Header: <allocators>

Namespace: stdext

max_unbounded::allocated

Increments the count of allocated memory blocks.

```
void allocated(std::size_t _Nx = 1);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Nx</code>	The increment value.

Remarks

This member function does nothing. It is called after each successful call by `cache_freelist::allocate` to operator **new**. The argument `_Nx` is the number of memory blocks in the chunk allocated by operator **new**.

max_unbounded::deallocated

Decrements the count of allocated memory blocks.

```
void deallocated(std::size_t _Nx = 1);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Nx</code>	The increment value.

Remarks

The member function does nothing. This member function is called after each call by `cache_freelist::deallocate` to operator **delete**. The argument `_Nx` is the number of memory blocks in the chunk deallocated by operator **delete**.

max_unbounded::full

Returns a value that specifies whether more memory blocks should be added to the free list.

```
bool full();
```

Return Value

The member function always returns **false**.

Remarks

This member function is called by `cache_freelist::deallocate`. If the call returns **true**, `deallocate` puts the memory block on the free list; if it returns false, `deallocate` calls operator **delete** to deallocate the block.

max_unbounded::released

Decrements the count of memory blocks on the free list.

```
void released();
```

Remarks

This member function does nothing. The `released` member function of the current max class is called by `cache_freelist::allocate` whenever it removes a memory block from the free list.

max_unbounded::saved

Increments the count of memory blocks on the free list.

```
void saved();
```

Remarks

This member function does nothing. It is called by `cache_freelist::deallocate` whenever it puts a memory block on the free list.

See also

[<allocators>](#)

max_variable_size Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes a [max class](#) object that limits a [freelist](#) object to a maximum length that is roughly proportional to the number of allocated memory blocks.

Syntax

```
class max_variable_size
```

Constructors

CONSTRUCTOR	DESCRIPTION
max_variable_size	Constructs an object of type <code>max_variable_size</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
allocated	Increments the count of allocated memory blocks.
deallocated	Decrements the count of allocated memory blocks.
full	Returns a value that specifies whether more memory blocks should be added to the free list.
released	Decrements the count of memory blocks on the free list.
saved	Increments the count of memory blocks on the free list.

Requirements

Header: <allocators>

Namespace: stdext

max_variable_size::allocated

Increments the count of allocated memory blocks.

```
void allocated(std::size_t _Nx = 1);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Nx</code>	The increment value.

Remarks

This member function adds `_Nx` to the stored value `_Nallocs`. This member function is called after each successful call by `cache_freelist::allocate` to operator **new**. The argument `_Nx` is the number of memory blocks in the chunk allocated by operator **new**.

max_variable_size::deallocated

Decrements the count of allocated memory blocks.

```
void deallocated(std::size_t _Nx = 1);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Nx</code>	The increment value.

Remarks

The member function subtracts `_Nx` from the stored value `_Nallocs`. This member function is called after each call by `cache_freelist::deallocate` to operator **delete**. The argument `_Nx` is the number of memory blocks in the chunk deallocated by operator **delete**.

max_variable_size::full

Returns a value that specifies whether more memory blocks should be added to the free list.

```
bool full();
```

Return Value

true if `_Nallocs / 16 + 16 <= _Nblocks`.

Remarks

This member function is called by `cache_freelist::deallocate`. If the call returns **true**, `deallocate` puts the memory block on the free list; if it returns false, `deallocate` calls operator **delete** to deallocate the block.

max_variable_size::max_variable_size

Constructs an object of type `max_variable_size`.

```
max_variable_size();
```

Remarks

The constructor initializes the stored values `_Nblocks` and `_Nallocs` to zero.

max_variable_size::released

Decrements the count of memory blocks on the free list.

```
void released();
```

Remarks

This member function decrements the stored value `_Nblocks`. The `released` member function of the current `max` class is called by `cache_freelist::allocate` whenever it removes a memory block from the free list.

`max_variable_size::saved`

Increments the count of memory blocks on the free list.

```
void saved();
```

Remarks

This member function increments the stored value `_Nblocks`. This member function is called by `cache_freelist::deallocate` whenever it puts a memory block on the free list.

See also

[<allocators>](#)

rts_alloc Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The rts_alloc template class describes a [filter](#) that holds an array of cache instances and determines which instance to use for allocation and deallocation at runtime instead of at compile time.

Syntax

```
template <class Cache>
class rts_alloc
```

Parameters

PARAMETER	DESCRIPTION
<i>Cache</i>	The type of cache instances contained in the array. This can be cache_chunklist Class , cache_freelist , or cache_suballoc .

Remarks

This template class holds multiple block allocator instances and determines which instance to use for allocation or deallocation at runtime instead of at compile time. It is used with compilers that cannot compile rebind.

Member functions

MEMBER FUNCTION	DESCRIPTION
allocate	Allocates a block of memory.
deallocate	Frees a specified number of objects from storage beginning at a specified position.
equals	Compares two caches for equality.

Requirements

Header: <allocators>

Namespace: stdext

rts_alloc::allocate

Allocates a block of memory.

```
void *allocate(std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>count</i>	The number of elements in the array to be allocated.

Return Value

A pointer to the allocated object.

Remarks

The member function returns `caches[_IDX].allocate(count)`, where the index `_IDX` is determined by the requested block size *count*, or, if *count* is too large, it returns `operator new(count)`. `cache`, which represents the cache object.

rts_alloc::deallocate

Frees a specified number of objects from storage beginning at a specified position.

```
void deallocate(void* ptr, std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the first object to be deallocated from storage.
<i>count</i>	The number of objects to be deallocated from storage.

Remarks

The member function calls `caches[_IDX].deallocate(ptr, count)`, where the index `_IDX` is determined by the requested block size *count*, or, if *count* is too large, it returns `operator delete(ptr)`.

rts_alloc::equals

Compares two caches for equality.

```
bool equals(const sync<_Cache>& _Other) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>_Cache</i>	The cache object associated with the filter.
<i>_Other</i>	The cache object to compare for equality.

Remarks

true if the result of `caches[0].equals(other.caches[0])`; otherwise, **false**. `caches` represents the array of cache objects.

[ALLOCATOR_DECL](#)

<allocators>

sync_none Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes a [synchronization filter](#) that provides no synchronization.

Syntax

```
template <class Cache>
class sync_none
```

Parameters

PARAMETER	DESCRIPTION
<code>Cache</code>	The type of cache associated with the synchronization filter. This can be cache_chunklist , cache_freelist , or cache_suballoc .

Member functions

MEMBER FUNCTION	DESCRIPTION
allocate	Allocates a block of memory.
deallocate	Frees a specified number of objects from storage beginning at a specified position.
equals	Compares two caches for equality.

Requirements

Header: <allocators>

Namespace: stdext

sync_none::allocate

Allocates a block of memory.

```
void *allocate(std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>count</i>	The number of elements in the array to be allocated.

Remarks

The member function returns `cache.allocate(count)`, where `cache` is the cache object.

sync_none::deallocate

Frees a specified number of objects from storage beginning at a specified position.

```
void deallocate(void* ptr, std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the first object to be deallocated from storage.
<i>count</i>	The number of objects to be deallocated from storage.

Remarks

The member function calls `cache.deallocate(ptr, count)`, where `cache` represents the cache object.

sync_none::equals

Compares two caches for equality.

```
bool equals(const sync<Cache>& Other) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>Cache</i>	The cache object of the synchronization filter.
<i>Other</i>	The cache object to compare for equality.

Return Value

The member function always returns **true**.

Remarks

See also

[<allocators>](#)

sync_per_container Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes a [synchronization filter](#) that provides a separate cache object for each allocator object.

Syntax

```
template <class Cache>
class sync_per_container
    : public Cache
```

Parameters

PARAMETER	DESCRIPTION
<i>Cache</i>	The type of cache associated with the synchronization filter. This can be cache_chunklist , cache_freelist , or cache_suballoc .

Member functions

MEMBER FUNCTION	DESCRIPTION
equals	Compares two caches for equality.

Requirements

Header: <allocators>

Namespace: stdext

sync_per_container::equals

Compares two caches for equality.

```
bool equals(const sync_per_container<Cache>& Other) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>Cache</i>	The cache object of the synchronization filter.
<i>Other</i>	The cache object to compare for equality.

Return Value

The member function always returns **false**.

Remarks

See also

[<allocators>](#)

sync_per_thread Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes a [synchronization filter](#) that provides a separate cache object for each thread.

Syntax

```
template <class Cache>
class sync_per_thread
```

Parameters

PARAMETER	DESCRIPTION
<i>Cache</i>	The type of cache associated with the synchronization filter. This can be cache_chunklist , cache_freelist , or cache_suballoc .

Remarks

Allocators that use `sync_per_thread` can compare equal even though blocks allocated in one thread cannot be deallocated from another thread. When using one of these allocators memory blocks allocated in one thread should not be made visible to other threads. In practice this means that a container that uses one of these allocators should only be accessed by a single thread.

Member functions

MEMBER FUNCTION	DESCRIPTION
allocate	Allocates a block of memory.
deallocate	Frees a specified number of objects from storage beginning at a specified position.
equals	Compares two caches for equality.

Requirements

Header: <allocators>

Namespace: stdext

sync_per_thread::allocate

Allocates a block of memory.

```
void *allocate(std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>count</i>	The number of elements in the array to be allocated.

Remarks

The member function returns the result of a call to `cache::allocate(count)` on the cache object belonging to the current thread. If no cache object has been allocated for the current thread, it first allocates one.

sync_per_thread::deallocate

Frees a specified number of objects from storage beginning at a specified position.

```
void deallocate(void* ptr, std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the first object to be deallocated from storage.
<i>count</i>	The number of objects to be deallocated from storage.

Remarks

The member function calls `deallocate` on the cache object belonging to the current thread. If no cache object has been allocated for the current thread, it first allocates one.

sync_per_thread::equals

Compares two caches for equality.

```
bool equals(const sync<Cache>& Other) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>Cache</i>	The cache object of the synchronization filter.
<i>Other</i>	The cache object to compare for equality.

Return Value

false if no cache object has been allocated for this object or for *Other* in the current thread. Otherwise it returns the result of applying `operator==` to the two cache objects.

Remarks

See also

[<allocators>](#)

sync_shared Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes a [synchronization filter](#) that uses a mutex to control access to a cache object that is shared by all allocators.

Syntax

```
template <class Cache>
class sync_shared
```

Parameters

PARAMETER	DESCRIPTION
<i>Cache</i>	The type of cache associated with the synchronization filter. This can be cache_chunklist , cache_freelist , or cache_suballoc .

Member functions

MEMBER FUNCTION	DESCRIPTION
allocate	Allocates a block of memory.
deallocate	Frees a specified number of objects from storage beginning at a specified position.
equals	Compares two caches for equality.

Requirements

Header: <allocators>

Namespace: stdext

sync_shared::allocate

Allocates a block of memory.

```
void *allocate(std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>count</i>	The number of elements in the array to be allocated.

Return Value

A pointer to the allocated object.

Remarks

The member function locks the mutex, calls `cache.allocate(count)`, unlocks the mutex, and returns the result of the earlier call to `cache.allocate(count)`. `cache` represents the current cache object.

`sync_shared::deallocate`

Frees a specified number of objects from storage beginning at a specified position.

```
void deallocate(void* ptr, std::size_t count);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the first object to be deallocated from storage.
<i>count</i>	The number of objects to be deallocated from storage.

Remarks

This member function locks the mutex, calls `cache.deallocate(ptr, count)`, where `cache` represents the cache object, and then unlocks the mutex.

`sync_shared::equals`

Compares two caches for equality.

```
bool equals(const sync_shared<Cache>& Other) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>Cache</i>	The type of cache associated with the synchronization filter.
<i>Other</i>	The cache to compare for equality.

Return Value

true if the result of `cache.equals(Other.cache)`, where `cache` represents the cache object, is **true**; otherwise, **false**.

Remarks

See also

[<allocators>](#)

<array>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template class **array** and several supporting templates.

Syntax

```
#include <array>
```

Classes

CLASS	DESCRIPTION
array	Stores a fixed-length sequence of elements.
tuple_element	Wraps the type of an array element.
tuple_size	Wraps the size of an array element.

Operators

OPERATOR	DESCRIPTION
operator==	array comparison, equal
operator!=	array comparison, not equal
operator<	array comparison, less than
operator>=	array comparison, greater than or equal
operator>	array comparison, greater than
operator<=	array comparison, less than or equal

Functions

FUNCTION	DESCRIPTION
get	Get specified array element.
swap	Exchanges the contents of one array with the contents of another array.

See also

[<tuple>](#)

[Header Files Reference](#)

<array> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

The <array> header includes two non-member functions, `get` and `swap`, that operate on **array** objects.

<code>get</code>	<code>swap</code>

get

Returns a reference to the specified element of the array.

```
template <int Index, class T, size_t N>
constexpr T& get(array<T, N>& arr) noexcept;

template <int Index, class T, size_t N>
constexpr const T& get(const array<T, N>& arr) noexcept;

template <int Index, class T, size_t N>
constexpr T&& get(array<T, N>&& arr) noexcept;
```

Parameters

Index

The element offset.

T

The type of an element.

N

The number of elements in the array.

arr

The array to select from.

Example

```

#include <array>
#include <iostream>

using namespace std;

typedef array<int, 4> MyArray;

int main()
{
    MyArray c0 { 0, 1, 2, 3 };

    // display contents " 0 1 2 3"
    for (const auto& e : c0)
    {
        cout << " " << e;
    }
    cout << endl;

    // display odd elements " 1 3"
    cout << " " << get<1>(c0);
    cout << " " << get<3>(c0) << endl;
}

```

```

0 1 2 3
1 3

```

swap

A non-member template specialization of `std::swap` that swaps two **array** objects.

```

template <class Ty, std::size_t N>
void swap(array<Ty, N>& left, array<Ty, N>& right);

```

Parameters

Ty

The type of an element.

N

The size of the array.

left

The first array to swap.

right

The second array to swap.

Remarks

The template function executes `left.swap(right)`.

Example

```

// std__array__swap.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = { 0, 1, 2, 3 };

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1 = { 4, 5, 6, 7 };
    c0.swap(c1);

    // display swapped contents " 4 5 6 7"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    swap(c0, c1);

    // display swapped contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
4 5 6 7
0 1 2 3

```

See also

[<array>](#)

<array> operators

11/9/2018 • 5 minutes to read • [Edit Online](#)

The <array> header includes these **array** non-member comparison template functions.

operator!=	operator>	operator>=
operator<	operator<=	operator==

operator!=

Array comparison, not equal.

```
template <Ty, std::size_t N>
bool operator!=(
    const array<Ty, N>& left,
    const array<Ty, N>& right);
```

Parameters

Ty

The type of an element.

N

The size of the array.

left

Left container to compare.

right

Right container to compare.

Remarks

The template function returns `!(left == right)`.

Example

```

// std_array_operator_ne.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1 = {4, 5, 6, 7};

    // display contents " 4 5 6 7"
    for (Myarray::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 != c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c0 != c1);
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
4 5 6 7
false
true

```

operator<

Array comparison, less than.

```

template <Ty, std::size_t N>
bool operator<(
    const array<Ty, N>& left,
    const array<Ty, N>& right);

```

Parameters

Ty

The type of an element.

N

The size of the array.

left

Left container to compare.

right

Right container to compare.

Remarks

The template function overloads `operator<` to compare two objects of template class [array Class](#). The function returns `lexicographical_compare(left.begin(), left.end(), right.begin())`.

Example

```
// std_array_operator_lt.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1 = {4, 5, 6, 7};

    // display contents " 4 5 6 7"
    for (Myarray::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 < c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c0 < c1);
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
4 5 6 7
false
true
```

operator<=

Array comparison, less than or equal.

```
template <Ty, std::size_t N>
bool operator<=(
    const array<Ty, N>& left,
    const array<Ty, N>& right);
```

Parameters

Ty

The type of an element.

N

The size of the array.

left

Left container to compare.

right

Right container to compare.

Remarks

The template function returns `!(right < left)`.

Example

```
// std__array__operator_le.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1 = {4, 5, 6, 7};

    // display contents " 4 5 6 7"
    for (Myarray::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 <= c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c1 <= c0);
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
4 5 6 7
true
false
```

operator==

Array comparison, equal.

```
template <Ty, std::size_t N>
bool operator==(
    const array<Ty, N>& left,
    const array<Ty, N>& right);
```

Parameters

Ty

The type of an element.

N

The size of the array.

left

Left container to compare.

right

Right container to compare.

Remarks

The template function overloads `operator==` to compare two objects of template class [array Class](#). The function returns `equal(left.begin(), left.end(), right.begin())`.

Example

```
// std_array_operator_eq.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1 = {4, 5, 6, 7};

    // display contents " 4 5 6 7"
    for (Myarray::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 == c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c0 == c1);
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
4 5 6 7
true
false
```

operator>

Array comparison, greater than.

```
template <Ty, std::size_t N>
bool operator>(
    const array<Ty, N>& left,
    const array<Ty, N>& right);
```

Parameters

Ty

The type of an element.

N

The size of the array.

left

Left container to compare.

right

Right container to compare.

Remarks

The template function returns `(right < left)`.

Example

```
// std_array_operator_gt.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1 = {4, 5, 6, 7};

    // display contents " 4 5 6 7"
    for (Myarray::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 > c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c1 > c0);
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
4 5 6 7
false
true
```

operator>=

Array comparison, greater than or equal.

```
template <Ty, std::size_t N>
bool operator>=(
    const array<Ty, N>& left,
    const array<Ty, N>& right);
```

Parameters

Ty

The type of an element.

N

The size of the array.

left

Left container to compare.

right

Right container to compare.

Remarks

The template function returns `!(left < right)`.

Example

```
// std__array__operator_ge.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1 = {4, 5, 6, 7};

    // display contents " 4 5 6 7"
    for (Myarray::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 >= c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c0 >= c1);
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
4 5 6 7
true
false
```

[`<array>`](#)

array Class (C++ Standard Library)

12/20/2018 • 21 minutes to read • [Edit Online](#)

Describes an object that controls a sequence of length `N` of elements of type `Ty`. The sequence is stored as an array of `Ty`, contained in the `array<Ty, N>` object.

Syntax

```
template <class Ty, std::size_t N>
class array;
```

Parameters

PARAMETER	DESCRIPTION
<code>Ty</code>	The type of an element.
<code>N</code>	The number of elements.

Members

TYPE DEFINITION	DESCRIPTION
<code>const_iterator</code>	The type of a constant iterator for the controlled sequence.
<code>const_pointer</code>	The type of a constant pointer to an element.
<code>const_reference</code>	The type of a constant reference to an element.
<code>const_reverse_iterator</code>	The type of a constant reverse iterator for the controlled sequence.
<code>difference_type</code>	The type of a signed distance between two elements.
<code>iterator</code>	The type of an iterator for the controlled sequence.
<code>pointer</code>	The type of a pointer to an element.
<code>reference</code>	The type of a reference to an element.
<code>reverse_iterator</code>	The type of a reverse iterator for the controlled sequence.
<code>size_type</code>	The type of an unsigned distance between two elements.
<code>value_type</code>	The type of an element.

MEMBER FUNCTION	DESCRIPTION
<code>array</code>	Constructs an array object.
<code>assign</code>	Replaces all elements.
<code>at</code>	Accesses an element at a specified position.
<code>back</code>	Accesses the last element.
<code>begin</code>	Designates the beginning of the controlled sequence.
<code>cbegin</code>	Returns a random-access const iterator to the first element in the array.
<code>cend</code>	Returns a random-access const iterator that points just beyond the end of the array.
<code>crbegin</code>	Returns a const iterator to the first element in a reversed array.
<code>crend</code>	Returns a const iterator to the end of a reversed array.
<code>data</code>	Gets the address of the first element.
<code>empty</code>	Tests whether elements are present.
<code>end</code>	Designates the end of the controlled sequence.
<code>fill</code>	Replaces all elements with a specified value.
<code>front</code>	Accesses the first element.
<code>max_size</code>	Counts the number of elements.
<code>rbegin</code>	Designates the beginning of the reversed controlled sequence.
<code>rend</code>	Designates the end of the reversed controlled sequence.
<code>size</code>	Counts the number of elements.
<code>swap</code>	Swaps the contents of two containers.
OPERATOR	DESCRIPTION
<code>array::operator=</code>	Replaces the controlled sequence.
<code>array::operator[]</code>	Accesses an element at a specified position.

Remarks

The type has a default constructor `array()` and a default assignment operator `operator=`, and satisfies the

requirements for an `aggregate`. Therefore, objects of type `array<Ty, N>` can be initialized by using an aggregate initializer. For example,

```
array<int, 4> ai = { 1, 2, 3 };
```

creates the object `ai` that holds four integer values, initializes the first three elements to the values 1, 2, and 3, respectively, and initializes the fourth element to 0.

Requirements

Header: `<array>`

Namespace: `std`

`array::array`

Constructs an array object.

```
array();  
  
array(const array& right);
```

Parameters

right

Object or range to insert.

Remarks

The default constructor `array()` leaves the controlled sequence uninitialized (or default initialized). You use it to specify an uninitialized controlled sequence.

The copy constructor `array(const array& right)` initializes the controlled sequence with the sequence [*right*.begin(), *right*.end()). You use it to specify an initial controlled sequence that is a copy of the sequence controlled by the array object *right*.

Example

```

// std__array__array_array.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1(c0);

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3

```

array::assign

Obsolete in C++11, replaced by [fill](#). Replaces all elements.

```
void assign(const Ty& val);
```

Parameters

val

The value to assign.

Remarks

The member function replaces the sequence controlled by `*this` with a repetition of `N` elements of value *val*.

Example

```

// std_array_array_assign.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1;
    c1.assign(4);

    // display contents " 4 4 4 4"
    for (Myarray::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
4 4 4 4

```

array::at

Accesses an element at a specified position.

```

reference at(size_type off);

constexpr const_reference at(size_type off) const;

```

Parameters

off

Position of element to access.

Remarks

The member functions return a reference to the element of the controlled sequence at position *off*. If that position is invalid, the function throws an object of class `out_of_range`.

Example

```

// std_array_array_at.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display odd elements " 1 3"
    std::cout << " " << c0.at(1);
    std::cout << " " << c0.at(3);
    std::cout << std::endl;

    return (0);
}

```

array::back

Accesses the last element.

```

reference back();

constexpr const_reference back() const;

```

Remarks

The member functions return a reference to the last element of the controlled sequence, which must be non-empty.

Example

```

// std_array_array_back.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display last element " 3"
    std::cout << " " << c0.back();
    std::cout << std::endl;

    return (0);
}

```

```
0 1 2 3
3
```

array::begin

Designates the beginning of the controlled sequence.

```
iterator begin() noexcept;
const_iterator begin() const noexcept;
```

Remarks

The member functions return a random-access iterator that points at the first element of the sequence (or just beyond the end of an empty sequence).

Example

```
// std__array__array_begin.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display first element " 0"
    Myarray::iterator it2 = c0.begin();
    std::cout << " " << *it2;
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
0
```

array::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const noexcept;
```

Return Value

A **const** random-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin` , the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

`array::cend`

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const noexcept;
```

Return Value

A random-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

`array::const_iterator`

The type of a constant iterator for the controlled sequence.

```
typedef implementation-defined const_iterator;
```

Remarks

The type describes an object that can serve as a constant random-access iterator for the controlled sequence.

Example

```

// std_array_array_const_iterator.cpp
// compile with: /EHsc /W4
#include <array>
#include <iostream>

typedef std::array<int, 4> MyArray;

int main()
{
    MyArray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    std::cout << "it1:";
    for ( MyArray::const_iterator it1 = c0.begin();
          it1 != c0.end();
          ++it1 ) {
        std::cout << " " << *it1;
    }
    std::cout << std::endl;

    // display first element " 0"
    MyArray::const_iterator it2 = c0.begin();
    std::cout << "it2:";
    std::cout << " " << *it2;
    std::cout << std::endl;

    return (0);
}

```

```

it1: 0 1 2 3
it2: 0

```

array::const_pointer

The type of a constant pointer to an element.

```

typedef const Ty *const_pointer;

```

Remarks

The type describes an object that can serve as a constant pointer to elements of the sequence.

Example

```

// std__array__array_const_pointer.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display first element " 0"
    Myarray::const_pointer ptr = &c0.begin();
    std::cout << " " << *ptr;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0

```

array::const_reference

The type of a constant reference to an element.

```

typedef const Ty& const_reference;

```

Remarks

The type describes an object that can serve as a constant reference to an element of the controlled sequence.

Example

```

// std__array__array_const_reference.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display first element " 0"
    Myarray::const_reference ref = *c0.begin();
    std::cout << " " << ref;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0

```

array::const_reverse_iterator

The type of a constant reverse iterator for the controlled sequence.

```

typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

```

Remarks

The type describes an object that can serve as a constant reverse iterator for the controlled sequence.

Example

```
// std_array_array_const_reverse_iterator.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display last element " 3"
    Myarray::const_reverse_iterator it2 = c0.rbegin();
    std::cout << " " << *it2;
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
3
```

array::crbegin

Returns a const iterator to the first element in a reversed array.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse random-access iterator addressing the first element in a reversed array or addressing what had been the last element in the unreversed array.

Remarks

With the return value of `crbegin`, the array object cannot be modified.

Example

```
// array_crbegin.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

int main( )
{
    using namespace std;
    array<int, 2> v1 = {1, 2};
    array<int, 2>::iterator v1_Iter;
    array<int, 2>::const_reverse_iterator v1_rIter;

    v1_Iter = v1.begin( );
    cout << "The first element of array is "
         << *v1_Iter << "." << endl;

    v1_rIter = v1.crbegin( );
    cout << "The first element of the reversed array is "
         << *v1_rIter << "." << endl;
}
```

```
The first element of array is 1.
The first element of the reversed array is 2.
```

array::crend

Returns a const iterator that addresses the location succeeding the last element in a reversed array.

```
const_reverse_iterator crend() const noexcept;
```

Return Value

A const reverse random-access iterator that addresses the location succeeding the last element in a reversed array (the location that had preceded the first element in the unreversed array).

Remarks

`crend` is used with a reversed array just as `array::cend` is used with a array.

With the return value of `crend` (suitably decremented), the array object cannot be modified.

`crend` can be used to test to whether a reverse iterator has reached the end of its array.

The value returned by `crend` should not be dereferenced.

Example

```
// array_crend.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

int main( )
{
    using namespace std;
    array<int, 2> v1 = {1, 2};
    array<int, 2>::const_reverse_iterator v1_rIter;

    for ( v1_rIter = v1.rbegin( ) ; v1_rIter != v1.rend( ) ; v1_rIter++ )
        cout << *v1_rIter << endl;
}
```

```
2
1
```

array::data

Gets the address of the first element.

```
Ty *data();

const Ty *data() const;
```

Remarks

The member functions return the address of the first element in the controlled sequence.

Example

```
// std__array__array_data.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display first element " 0"
    Myarray::pointer ptr = c0.data();
    std::cout << " " << *ptr;
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
0
```

array::difference_type

The type of a signed distance between two elements.

```
typedef std::ptrdiff_t difference_type;
```

Remarks

The signed integer type describes an object that can represent the difference between the addresses of any two elements in the controlled sequence. It is a synonym for the type `std::ptrdiff_t`.

Example

```
// std_array_array_difference_type.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display distance first-last " -4"
    Myarray::difference_type diff = c0.begin() - c0.end();
    std::cout << " " << diff;
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
-4
```

array::empty

Tests whether no elements are present.

```
constexpr bool empty() const;
```

Remarks

The member function returns true only if `N == 0`.

Example

```

// std__array__array_empty.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display whether c0 is empty " false"
    std::cout << std::boolalpha << " " << c0.empty();
    std::cout << std::endl;

    std::array<int, 0> c1;

    // display whether c1 is empty " true"
    std::cout << std::boolalpha << " " << c1.empty();
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
false
true

```

array::end

Designates the end of the controlled sequence.

```

reference end();

const_reference end() const;

```

Remarks

The member functions return a random-access iterator that points just beyond the end of the sequence.

Example

```
// std__array__array_end.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display last element " 3"
    Myarray::iterator it2 = c0.end();
    std::cout << " " << *--it2;
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
3
```

array::fill

Erases a array and copies the specified elements to the empty array.

```
void fill(const Type& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value of the element being inserted into the array.

Remarks

`fill` replaces each element of the array with the specified value.

Example

```

// array_fill.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

int main( )
{
    using namespace std;
    array<int, 2> v1 = {1, 2};
    array<int, 2>::iterator iter;

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    v1.fill(3);
    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << *iter << " ";
    cout << endl;
}

```

array::front

Accesses the first element.

```

reference front();

constexpr const_reference front() const;

```

Remarks

The member functions return a reference to the first element of the controlled sequence, which must be non-empty.

Example

```

// std_array_array_front.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display first element " 0"
    std::cout << " " << c0.front();
    std::cout << std::endl;

    return (0);
}

```

```
0 1 2 3
0
```

array::iterator

The type of an iterator for the controlled sequence.

```
typedef implementation-defined iterator;
```

Remarks

The type describes an object that can serve as a random-access iterator for the controlled sequence.

Example

```
// std_array_array_iterator.cpp
// compile with: /EHsc /W4
#include <array>
#include <iostream>

typedef std::array<int, 4> MyArray;

int main()
{
    MyArray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    std::cout << "it1:";
    for ( MyArray::iterator it1 = c0.begin();
          it1 != c0.end();
          ++it1 ) {
        std::cout << " " << *it1;
    }
    std::cout << std::endl;

    // display first element " 0"
    MyArray::iterator it2 = c0.begin();
    std::cout << "it2:";
    std::cout << " " << *it2;
    std::cout << std::endl;

    return (0);
}
```

```
it1: 0 1 2 3

it2: 0
```

array::max_size

Counts the number of elements.

```
constexpr size_type max_size() const;
```

Remarks

The member function returns `N`.

Example

```
// std_array_array_max_size.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display (maximum) size " 4"
    std::cout << " " << c0.max_size();
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
4
```

array::operator[]

Accesses an element at a specified position.

```
reference operator[](size_type off);

constexpr const_reference operator[](size_type off) const;
```

Parameters

off

Position of element to access.

Remarks

The member functions return a reference to the element of the controlled sequence at position *off*. If that position is invalid, the behavior is undefined.

There is also a non-member [get](#) function available to get a reference to an element of an **array**.

Example

```
// std__array__array_operator_sub.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display odd elements " 1 3"
    std::cout << " " << c0[1];
    std::cout << " " << c0[3];
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
1 3
```

array::operator=

Replaces the controlled sequence.

```
array<Value> operator=(array<Value> right);
```

Parameters

right

Container to copy.

Remarks

The member operator assigns each element of *right* to the corresponding element of the controlled sequence, then returns `*this`. You use it to replace the controlled sequence with a copy of the controlled sequence in *right*.

Example

```

// std__array__array_operator_as.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1;
    c1 = c0;

    // display copied contents " 0 1 2 3"
    for (Myarray::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3

```

array::pointer

The type of a pointer to an element.

```
typedef Ty *pointer;
```

Remarks

The type describes an object that can serve as a pointer to elements of the sequence.

Example

```

// std__array__array_pointer.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display first element " 0"
    Myarray::pointer ptr = &c0.begin();
    std::cout << " " << *ptr;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0

```

array::rbegin

Designates the beginning of the reversed controlled sequence.

```

reverse_iterator rbegin()noexcept;
const_reverse_iterator rbegin() const noexcept;

```

Remarks

The member functions return a reverse iterator that points just beyond the end of the controlled sequence. Hence, it designates the beginning of the reverse sequence.

Example

```

// std__array__array_rbegin.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display last element " 3"
    Myarray::const_reverse_iterator it2 = c0.rbegin();
    std::cout << " " << *it2;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
3

```

array::reference

The type of a reference to an element.

```

typedef Ty& reference;

```

Remarks

The type describes an object that can serve as a reference to an element of the controlled sequence.

Example

```

// std__array__array_reference.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display first element " 0"
    Myarray::reference ref = *c0.begin();
    std::cout << " " << ref;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0

```

array::rend

Designates the end of the reversed controlled sequence.

```

reverse_iterator rend()noexcept;
const_reverse_iterator rend() const noexcept;

```

Remarks

The member functions return a reverse iterator that points at the first element of the sequence (or just beyond the end of an empty sequence)). Hence, it designates the end of the reverse sequence.

Example

```

// std__array__array_rend.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display first element " 0"
    Myarray::const_reverse_iterator it2 = c0.rend();
    std::cout << " " << *--it2;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0

```

array::reverse_iterator

The type of a reverse iterator for the controlled sequence.

```

typedef std::reverse_iterator<iterator> reverse_iterator;

```

Remarks

The type describes an object that can serve as a reverse iterator for the controlled sequence.

Example

```

// std__array__array_reverse_iterator.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display last element " 3"
    Myarray::reverse_iterator it2 = c0.rbegin();
    std::cout << " " << *it2;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
3

```

array::size

Counts the number of elements.

```
constexpr size_type size() const;
```

Remarks

The member function returns `N`.

Example

```

// std__array__array_size.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display size " 4"
    std::cout << " " << c0.size();
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
4

```

array::size_type

The type of an unsigned distance between two element.

```

typedef std::size_t size_type;

```

Remarks

The unsigned integer type describes an object that can represent the length of any controlled sequence. It is a synonym for the type `std::size_t`.

Example

```
// std_array_array_size_type.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display distance last-first " 4"
    Myarray::size_type diff = c0.end() - c0.begin();
    std::cout << " " << diff;
    std::cout << std::endl;

    return (0);
}
```

```
0 1 2 3
4
```

array::swap

Swaps the contents of this array with another array.

```
void swap(array& right);
```

Parameters

right

Array to swap contents with.

Remarks

The member function swaps the controlled sequences between `*this` and *right*. It performs a number of element assignments and constructor calls proportional to `N`.

There is also a non-member [swap](#) function available to swap two **array** instances.

Example

```

// std__array__array_swap.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    Myarray c1 = {4, 5, 6, 7};
    c0.swap(c1);

    // display swapped contents " 4 5 6 7"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    swap(c0, c1);

    // display swapped contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
4 5 6 7
0 1 2 3

```

array::value_type

The type of an element.

```
typedef Ty value_type;
```

Remarks

The type is a synonym for the template parameter `Ty`.

Example

```

// std__array__array_value_type.cpp
// compile with: /EHsc
#include <array>
#include <iostream>

typedef std::array<int, 4> Myarray;
int main()
{
    Myarray c0 = {0, 1, 2, 3};

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
        std::cout << " " << *it;
    std::cout << std::endl;

    // display contents " 0 1 2 3"
    for (Myarray::const_iterator it = c0.begin();
         it != c0.end(); ++it)
    {
        Myarray::value_type val = *it;
        std::cout << " " << val;
    }
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3

```

[<array>](#)

<atomic>

10/31/2018 • 4 minutes to read • [Edit Online](#)

Defines classes and template classes to use to create types that support atomic operations.

Syntax

```
#include <atomic>
```

Remarks

NOTE

In code that's compiled by using **/clr**, this header is blocked.

An atomic operation has two key properties that help you use multiple threads to correctly manipulate an object without using mutex locks.

- Because an atomic operation is indivisible, a second atomic operation on the same object from a different thread can obtain the state of the object only before or after the first atomic operation.
- Based on its [memory_order](#) argument, an atomic operation establishes ordering requirements for the visibility of the effects of other atomic operations in the same thread. Consequently, it inhibits compiler optimizations that violate the ordering requirements.

On some platforms, it might not be possible to efficiently implement atomic operations for some types without using `mutex` locks. An atomic type is *lock-free* if no atomic operations on that type use locks.

C++11: In signal-handlers you can perform atomic operations on an object `obj` if `obj.is_lock_free()` or `atomic_is_lock_free(x)` are true.

The class [atomic_flag](#) provides a minimal atomic type that holds a **bool** flag. Its operations are always lock-free.

The template class `atomic<T>` stores an object of its argument type `T` and provides atomic access to that stored value. You can instantiate it by using any type that can be copied by using [memcpy](#) and tested for equality by using [memcmp](#). In particular, you can use it with user-defined types that meet these requirements and, in many cases, with floating-point types.

The template also has a set of specializations for integral types and a partial specialization for pointers. These specializations provide additional operations that are not available through the primary template.

Pointer Specializations

The `atomic<T*>` partial specializations apply to all pointer types. They provide methods for pointer arithmetic.

Integral Specializations

The `atomic<integral>` specializations apply to all integral types. They provide additional operations that are not available through the primary template.

Each `atomic<integral>` type has a corresponding macro that you can use in an `if directive` to determine at compile time whether operations on that type are lock-free. If the value of the macro is zero, operations on the type are not lock-free. If the value is 1, operations might be lock-free, and a runtime check is required. If the value is 2, operations are lock-free. You can use the function `atomic_is_lock_free` to determine at runtime whether operations on the type are lock-free.

For each of the integral types, there is a corresponding named atomic type that manages an object of that integral type. Each `atomic_integral` type has the same set of member functions as the corresponding instantiation of `atomic<T>` and can be passed to any of the non-member atomic functions.

<code>ATOMIC_INTEGRAL</code> TYPE	INTEGRAL TYPE	<code>ATOMIC_IS_LOCK_FREE</code> MACRO
<code>atomic_char</code>	char	<code>ATOMIC_CHAR_LOCK_FREE</code>

<code>atomic_int_fast64_t</code>	<code>atomic<int_fast64_t></code>
<code>atomic_uint_fast64_t</code>	<code>atomic<uint_fast64_t></code>
<code>atomic_intptr_t</code>	<code>atomic<intptr_t></code>
<code>atomic_uintptr_t</code>	<code>atomic<uintptr_t></code>
<code>atomic_size_t</code>	<code>atomic<size_t></code>

ATOMIC TYPE	TYPEDDEF NAME
<code>atomic_ptrdiff_t</code>	<code>atomic<ptrdiff_t></code>
<code>atomic_intmax_t</code>	<code>atomic<intmax_t></code>
<code>atomic_uintmax_t</code>	<code>atomic<uintmax_t></code>

Structs

NAME	DESCRIPTION
atomic Structure	Describes an object that performs atomic operations on a stored value.
atomic_flag Structure	Describes an object that atomically sets and clears a bool flag.

Enums

NAME	DESCRIPTION
memory_order Enum	Supplies symbolic names for synchronization operations on memory locations. These operations affect how assignments in one thread become visible in another.

Functions

In the following list, the functions that do not end in `_explicit` have the semantics of the corresponding `_explicit`, except that they have the implicit [memory_order](#) arguments of `memory_order_seq_cst`.

NAME	DESCRIPTION
atomic_compare_exchange_strong	Performs an <i>atomic compare and exchange</i> operation.
atomic_compare_exchange_strong_explicit	Performs an <i>atomic compare and exchange</i> operation.
atomic_compare_exchange_weak	Performs a <i>weak atomic compare and exchange</i> operation.
atomic_compare_exchange_weak_explicit	Performs a <i>weak atomic compare and exchange</i> operation.
atomic_exchange	Replaces a stored value.
atomic_exchange_explicit	Replaces a stored value.
atomic_fetch_add	Adds a specified value to an existing stored value.
atomic_fetch_add_explicit	Adds a specified value to an existing stored value.
atomic_fetch_and	Performs a bitwise <code>and</code> on a specified value and an existing stored value.

NAME	DESCRIPTION
atomic_fetch_and_explicit	Performs a bitwise <code>and</code> on a specified value and an existing stored value.
atomic_fetch_or	Performs a bitwise <code>or</code> on a specified value and an existing stored value.
atomic_fetch_or_explicit	Performs a bitwise <code>or</code> on a specified value and an existing stored value.
atomic_fetch_sub	Subtracts a specified value from an existing stored value.
atomic_fetch_sub_explicit	Subtracts a specified value from an existing stored value.
atomic_fetch_xor	Performs a bitwise <code>exclusive or</code> on a specified value and an existing stored value.
atomic_fetch_xor_explicit	Performs a bitwise <code>exclusive or</code> on a specified value and an existing stored value.
atomic_flag_clear	Sets the flag in an <code>atomic_flag</code> object to false .
atomic_flag_clear_explicit	Sets the flag in an <code>atomic_flag</code> object to false .
atomic_flag_test_and_set	Sets the flag in an <code>atomic_flag</code> object to true .
atomic_flag_test_and_set_explicit	Sets the flag in an <code>atomic_flag</code> object to true .
atomic_init	Sets the stored value in an <code>atomic</code> object.
atomic_is_lock_free	Specifies whether atomic operations on a specified object are lock-free.
atomic_load	Atomically retrieves a value.
atomic_load_explicit	Atomically retrieves a value.
atomic_signal_fence	Acts as a <i>fence</i> that establishes memory ordering requirements between fences in a calling thread that has signal handlers executed in the same thread.
atomic_store	Atomically stores a value.
atomic_store_explicit	Atomically stores a value.
atomic_thread_fence	Acts as a <i>fence</i> that establishes memory ordering requirements with respect to other fences.
kill_dependency	Breaks a possible dependency chain.

atomic Structure

10/31/2018 • 11 minutes to read • [Edit Online](#)

Describes an object that performs atomic operations on a stored value of type *Ty*.

Syntax

```
template <class Ty>
struct atomic;
```

Members

MEMBER	DESCRIPTION
Constructor	
atomic	Constructs an atomic object.
Operators	
atomic::operator Ty	Reads and returns the stored value. (atomic::load)
atomic::operator=	Uses a specified value to replace the stored value. (atomic::store)
atomic::operator++	Increments the stored value. Used only by integral and pointer specializations.
atomic::operator+=	Adds a specified value to the stored value. Used only by integral and pointer specializations.
atomic::operator--	Decrements the stored value. Used only by integral and pointer specializations.
atomic::operator-=	Subtracts a specified value from the stored value. Used only by integral and pointer specializations.
atomic::operator&=	Performs a bitwise and on a specified value and the stored value. Used only by integral specializations.
atomic::operator =	Performs a bitwise or on a specified value and the stored value. Used only by integral specializations.
atomic::operator^=	Performs a bitwise exclusive or on a specified value and the stored value. Used only by integral specializations.
Functions	

MEMBER	DESCRIPTION
<code>compare_exchange_strong</code>	Performs an <i>atomic_compare_and_exchange</i> operation on this and returns the result.
<code>compare_exchange_weak</code>	Performs a <i>weak_atomic_compare_and_exchange</i> operation on this and returns the result.
<code>fetch_add</code>	Adds a specified value to the stored value.
<code>fetch_and</code>	Performs a bitwise and on a specified value and the stored value.
<code>fetch_or</code>	Performs a bitwise or on a specified value and the stored value.
<code>fetch_sub</code>	Subtracts a specified value from the stored value.
<code>fetch_xor</code>	Performs a bitwise exclusive or on a specified value and the stored value.
<code>is_lock_free</code>	Specifies whether atomic operations on this are <i>lock free</i> . An atomic type is <i>lock free</i> if no atomic operations on that type use locks.
<code>load</code>	Reads and returns the stored value.
<code>store</code>	Uses a specified value to replace the stored value.

Remarks

The type *Ty* must be *trivially copyable*. That is, using `memcpy` to copy its bytes must produce a valid *Ty* object that compares equal to the original object. The `compare_exchange_weak` and `compare_exchange_strong` member functions use `memcpy` to determine whether two *Ty* values are equal. These functions will not use a *Ty*-defined `operator==`. The member functions of `atomic` use `memcpy` to copy values of type *Ty*.

A partial specialization, **`atomic<Ty*>`**, exists for all pointer types. The specialization enables the addition of an offset to the managed pointer value or the subtraction of an offset from it. The arithmetic operations take an argument of type `ptrdiff_t` and adjust that argument according to the size of *Ty* to be consistent with ordinary address arithmetic.

A specialization exists for every integral type except **`bool`**. Each specialization provides a rich set of methods for atomic arithmetic and logical operations.

<code>atomic<char></code>	<code>atomic<signed char></code>	<code>atomic<unsigned char></code>
<code>atomic<char16_t></code>	<code>atomic<char32_t></code>	<code>atomic<wchar_t></code>
<code>atomic<short></code>	<code>atomic<unsigned short></code>	<code>atomic<int></code>
<code>atomic<unsigned int></code>	<code>atomic<long></code>	<code>atomic<unsigned long></code>

atomic<long long>	atomic<unsigned long long>	

Integral specializations are derived from corresponding `atomic_integral` types. For example, **atomic<unsigned int>** is derived from `atomic_uint`.

Requirements

Header: `<atomic>`

Namespace: `std`

atomic::atomic

Constructs an atomic object.

```
atomic();
atomic( const atomic& );
atomic( Ty Value ) noexcept;
```

Parameters

Value

Initialization value.

Remarks

Atomic objects cannot be copied or moved.

Objects that are instantiations of `atomic<Ty>` can be initialized only by the constructor that takes an argument of type *Ty* and not by using aggregate initialization. However, `atomic_integral` objects can be initialized only by using aggregate initialization.

```
atomic<int> ai0 = ATOMIC_VAR_INIT(0);
atomic<int> ai1(0);
```

atomic::operator Ty

The operator for the type specified to the template, `atomic<Ty>`. Retrieves the stored value in ***this**.

```
atomic<Ty>::operator Ty() const volatile noexcept;
atomic<Ty>::operator Ty() const noexcept;
```

Remarks

This operator applies the `memory_order_seq_cst` [memory_order](#).

atomic::operator=

Stores a specified value.

```
Ty operator=(
    Ty Value
) volatile noexcept;
Ty operator=(
    Ty Value
) noexcept;
```

Parameters

Value

A *Ty* object.

Return Value

Returns *Value*.

atomic::operator++

Increments the stored value. Used only by integral and pointer specializations.

```
Ty atomic<Ty>::operator++(int) volatile noexcept;
Ty atomic<Ty>::operator++(int) noexcept;
Ty atomic<Ty>::operator++() volatile noexcept;
Ty atomic<Ty>::operator++() noexcept;
```

Return Value

The first two operators return the incremented value; the last two operators return the value before the increment.

The operators use the `memory_order_seq_cst` [memory_order](#).

atomic::operator+=

Adds a specified value to the stored value. Used only by integral and pointer specializations.

```
Ty atomic<Ty>::operator+=(
    Ty Value
) volatile noexcept;
Ty atomic<Ty>::operator+=(
    Ty Value
) noexcept;
```

Parameters

Value

An integral or pointer value.

Return Value

A *Ty* object that contains the result of the addition.

Remarks

This operator uses the `memory_order_seq_cst` [memory_order](#).

atomic::operator--

Decrements the stored value. Used only by integral and pointer specializations.

```
Ty atomic<Ty>::operator--(int) volatile noexcept;
Ty atomic<Ty>::operator--(int) noexcept;
Ty atomic<Ty>::operator--() volatile noexcept;
Ty atomic<Ty>::operator--() noexcept;
```

Return Value

The first two operators return the decremented value; the last two operators return the value before the decrement. The operators use the `memory_order_seq_cst` [memory_order](#).

atomic::operator-=

Subtracts a specified value from the stored value. Used only by integral and pointer specializations.

```
Ty atomic<Ty>::operator-=(
    Ty Value
) volatile noexcept;
Ty atomic<Ty>::operator-=(
    Ty Value
) noexcept;
```

Parameters

Value

An integral or pointer value.

Return Value

A *Ty* object that contains the result of the subtraction.

Remarks

This operator uses the `memory_order_seq_cst` [memory_order](#).

atomic::operator&=

Performs a bitwise and on a specified value and the stored value of ***this**. Used only by integral specializations.

```
atomic<Ty>::operator&= (
    Ty Value
) volatile noexcept;
atomic<Ty>::operator&= (
    Ty Value
) noexcept;
```

Parameters

Value

A value of type *Ty*.

Return Value

The result of the bitwise and.

Remarks

This operator performs a read-modify-write operation to replace the stored value of ***this** with a bitwise and of *Value* and the current value that is stored in ***this**, within the constraints of the `memory_order_seq_cst` [memory_order](#).

atomic::operator|=

Performs a bitwise or on a specified value and the stored value of ***this**. Used only by integral specializations.

```
atomic<Ty>::operator|= (
    Ty Value
) volatile noexcept;
atomic<Ty>::operator|= (
    Ty Value
) noexcept;
```

Parameters

Value

A value of type *Ty*.

Return Value

The result of the bitwise or.

Remarks

This operator performs a read-modify-write operation to replace the stored value of ***this** with a bitwise or of *Value* and the current value that is stored in ***this**, within the constraints of the `memory_order_seq_cst` [memory_order](#) constraints.

atomic::operator^=

Performs a bitwise exclusive or on a specified value and the stored value of ***this**. Used only by integral specializations.

```
atomic<Ty>::operator^= (
    Ty Value
) volatile noexcept;
atomic<Ty>::operator^= (
    Ty Value
) noexcept;
```

Parameters

Value

A value of type *Ty*.

Return Value

The result of the bitwise exclusive or.

Remarks

This operator performs a read-modify-write operation to replace the stored value of ***this** with a bitwise exclusive or of *Value* and the current value that is stored in ***this**, within the constraints of the `memory_order_seq_cst` [memory_order](#) constraints.

atomic::compare_exchange_strong

Performs an atomic compare and exchange operation on ***this**.

```

bool compare_exchange_strong(
    Ty& Exp,
    Ty Value,
    memory_order Order1,
    memory_order Order2
) volatile noexcept;
bool compare_exchange_strong(
    Ty& Exp,
    Ty Value,
    memory_order Order1,
    memory_order Order2
) noexcept;
bool compare_exchange_strong(
    Ty& Exp,
    Ty Value,
    memory_order Order1 = memory_order_seq_cst
) volatile noexcept;
bool compare_exchange_strong(
    Ty& Exp,
    Ty Value,
    memory_order Order1 = memory_order_seq_cst
) noexcept;

```

Parameters

Exp

A value of type *Ty*.

Value

A value of type *Ty*.

Order1

First `memory_order` argument.

Order2

Second `memory_order` argument.

Return Value

A **bool** that indicates the result of the value comparison.

Remarks

This atomic compare and exchange operation compares the value that is stored in ***this** with *Exp*. If the values are equal, the operation replaces the value that is stored in ***this** with *Value* by using a read-modify-write operation and applying the memory order constraints that are specified by *Order1*. If the values are not equal, the operation uses the value that is stored in ***this** to replace *Exp* and applies the memory order constraints that are specified by *Order2*.

Overloads that do not have a second `memory_order` use an implicit *Order2* that is based on the value of *Order1*. If *Order1* is `memory_order_acq_rel`, *Order2* is `memory_order_acquire`. If *Order1* is `memory_order_release`, *Order2* is `memory_order_relaxed`. In all other cases, *Order2* is equal to *Order1*.

For overloads that take two `memory_order` parameters, the value of *Order2* must not be `memory_order_release` or `memory_order_acq_rel`, and must not be stronger than the value of *Order1*.

atomic::compare_exchange_weak

Performs a weak atomic compare and exchange operation on ***this**.

```

bool compare_exchange_weak(
    Ty& Exp,
    Ty Value,
    memory_order Order1,
    memory_order Order2
) volatile noexcept;
bool compare_exchange_weak(
    Ty& Exp,
    Ty Value,
    memory_order Order1,
    memory_order Order2
) noexcept;
bool compare_exchange_weak(
    Ty& Exp,
    Ty Value,
    memory_order Order1 = memory_order_seq_cst
) volatile noexcept;
bool compare_exchange_weak(
    Ty& Exp,
    Ty Value,
    memory_order Order1 = memory_order_seq_cst
) noexcept;

```

Parameters

Exp

A value of type *Ty*.

Value

A value of type *Ty*.

Order1

First `memory_order` argument.

Order2

Second `memory_order` argument.

Return Value

A **bool** that indicates the result of the value comparison.

Remarks

This atomic compare and exchange operation compares the value that is stored in ***this** with *Exp*. If the values are equal, the operation replaces the value that is stored in ***this** with *Value* by using a read-modify-write operation and applying the memory order constraints that are specified by *Order1*. If the values are not equal, the operation uses the value that is stored in ***this** to replace *Exp* and applies the memory order constraints that are specified by *Order2*.

A weak atomic compare and exchange operation performs an exchange if the compared values are equal. If the values are not equal, the operation is not guaranteed to perform an exchange.

Overloads that do not have a second `memory_order` use an implicit *Order2* that is based on the value of *Order1*. If *Order1* is `memory_order_acq_rel`, *Order2* is `memory_order_acquire`. If *Order1* is `memory_order_release`, *Order2* is `memory_order_relaxed`. In all other cases, *Order2* is equal to *Order1*.

For overloads that take two `memory_order` parameters, the value of *Order2* must not be `memory_order_release` or `memory_order_acq_rel`, and must not be stronger than the value of *Order1*.

atomic::exchange

Uses a specified value to replace the stored value of ***this**.

```
Ty atomic<Ty>::exchange(  
    Ty Value,  
    memory_order Order = memory_order_seq_cst  
) volatile noexcept;  
Ty atomic<Ty>::exchange(  
    Ty Value,  
    memory_order Order = memory_order_seq_cst  
) noexcept;
```

Parameters

Value

A value of type *Ty*.

Order

A `memory_order`.

Return Value

The stored value of ***this** before the exchange.

Remarks

This operation performs a read-modify-write operation to use *Value* to replace the value that is stored in ***this**, within the memory constraints that are specified by *Order*.

atomic::fetch_add

Fetches the value stored in ***this**, and then adds a specified value to the stored value.

```
Ty atomic<Ty>::fetch_add (  
    Ty Value,  
    memory_order Order = memory_order_seq_cst  
) volatile noexcept;  
Ty atomic<Ty>::fetch_add (  
    Ty Value,  
    memory_order Order = memory_order_seq_cst  
) noexcept;
```

Parameters

Value

A value of type *Ty*.

Order

A `memory_order`.

Return Value

A *Ty* object that contains the value stored in ***this** prior to the addition.

Remarks

The `fetch_add` method performs a read-modify-write operation to atomically add *Value* to the stored value in ***this**, and applies the memory constraints that are specified by *Order*.

atomic::fetch_and

Performs a bitwise and on a value and an existing value that is stored in ***this**.

```

Ty atomic<Ty>::fetch_and (
    Ty Value,
    memory_order Order = memory_order_seq_cst
) volatile noexcept;
Ty atomic<Ty>::fetch_and (
    Ty Value,
    memory_order Order = memory_order_seq_cst
) noexcept;

```

Parameters

Value

A value of type *Ty*.

Order

A `memory_order`.

Return Value

A *Ty* object that contains the result of the bitwise and.

Remarks

The `fetch_and` method performs a read-modify-write operation to replace the stored value of ***this** with a bitwise and of *Value* and the current value that is stored in ***this**, within the memory constraints that are specified by *Order*.

atomic::fetch_or

Performs a bitwise or on a value and an existing value that is stored in ***this**.

```

Ty atomic<Ty>::fetch_or (
    Ty Value,
    memory_order Order = memory_order_seq_cst
) volatile noexcept;
Ty atomic<Ty>::fetch_or (
    Ty Value,
    memory_order Order = memory_order_seq_cst
) noexcept;

```

Parameters

Value

A value of type *Ty*.

Order

A `memory_order`.

Return Value

A *Ty* object that contains the result of the bitwise or.

Remarks

The `fetch_or` method performs a read-modify-write operation to replace the stored value of ***this** with a bitwise or of *Value* and the current value that is stored in ***this**, within the memory constraints that are specified by *Order*.

atomic::fetch_sub

Subtracts a specified value from the stored value.

```

Ty atomic<Ty>::fetch_sub (
    Ty Value,
    memory_order Order = memory_order_seq_cst
) volatile noexcept;
Ty atomic<Ty>::fetch_sub (
    Ty Value,
    memory_order Order = memory_order_seq_cst
) noexcept;

```

Parameters

Value

A value of type *Ty*.

Order

A `memory_order`.

Return Value

A *Ty* object that contains the result of the subtraction.

Remarks

The `fetch_sub` method performs a read-modify-write operation to atomically subtract *Value* from the stored value in ***this**, within the memory constraints that are specified by *Order*.

atomic::fetch_xor

Performs a bitwise exclusive or on a value and an existing value that is stored in ***this**.

```

Ty atomic<Ty>::fetch_xor (
    Ty Value,
    memory_order Order = memory_order_seq_cst
) volatile noexcept;
Ty atomic<Ty>::fetch_xor (
    Ty Value,
    memory_order Order = memory_order_seq_cst
) noexcept;

```

Parameters

Value

A value of type *Ty*.

Order

A `memory_order`.

Return Value

A *Ty* object that contains the result of the bitwise exclusive or.

Remarks

The `fetch_xor` method performs a read-modify-write operation to replace the stored value of ***this** with a bitwise exclusive or of *Value* and the current value that is stored in ***this**, and applies the memory constraints that are specified by *Order*.

atomic::is_lock_free

Specifies whether atomic operations on ***this** are lock free.

```
bool is_lock_free() const volatile noexcept;
```

Return Value

true if atomic operations on ***this** are lock free; otherwise, false.

Remarks

An atomic type is lock free if no atomic operations on that type use locks.

atomic::load

Retrieves the stored value in ***this**, within the specified memory constraints.

```
Ty atomic::load(  
    memory_order Order = memory_order_seq_cst  
) const volatile noexcept;  
Ty atomic::load(  
    memory_order Order = memory_order_seq_cst  
) const noexcept;
```

Parameters

Order

A `memory_order`. *Order* must not be `memory_order_release` or `memory_order_acq_rel`.

Return Value

The retrieved value that is stored in ***this**.

atomic::store

Stores a specified value.

```
void atomic<Ty>::store(  
    Ty Value,  
    memory_order Order = memory_order_seq_cst  
) volatile noexcept;  
void atomic<Ty>::store(  
    Ty Value,  
    memory_order Order = memory_order_seq_cst  
) noexcept;
```

Parameters

Value

A *Ty* object.

Order

A `memory_order` constraint.

Remarks

This member function atomically stores *Value* in `*this`, within the memory constraints that are specified by *Order*.

atomic_flag Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an object that atomically sets and clears a **bool** flag. Operations on atomic flags are always lock-free.

Syntax

```
struct atomic_flag;
```

Members

Public Methods

NAME	DESCRIPTION
clear	Sets the stored flag to false .
test_and_set	Sets the stored flag to true and returns the initial flag value.

Remarks

`atomic_flag` objects can be passed to the non-member functions [atomic_flag_clear](#), [atomic_flag_clear_explicit](#), [atomic_flag_test_and_set](#), and [atomic_flag_test_and_set_explicit](#). They can be initialized by using the value `ATOMIC_FLAG_INIT`.

Requirements

Header: <atomic>

Namespace: std

atomic_flag::clear

Sets the **bool** flag that is stored in `*this` to **false**, within the specified [memory_order](#) constraints.

```
void atomic_flag::clear(memory_order Order = memory_order_seq_cst) volatile noexcept;  
void atomic_flag::clear(memory_order Order = memory_order_seq_cst) noexcept;
```

Parameters

Order

A [memory_order](#).

atomic_flag::test_and_set

Sets the **bool** flag that is stored in `*this` to **true**, within the specified [memory_order](#) constraints.

```
bool atomic_flag::test_and_set(memory_order Order = memory_order_seq_cst) volatile noexcept;  
bool atomic_flag::test_and_set(memory_order Order = memory_order_seq_cst) noexcept;
```

Parameters

Order

A [memory_order](#).

Return Value

The initial value of the flag that is stored in `*this`.

atomic_fetch_and_explicit	atomic_fetch_or	atomic_fetch_or_explicit
atomic_fetch_sub	atomic_fetch_sub_explicit	atomic_fetch_xor
atomic_fetch_xor_explicit	atomic_flag_clear	atomic_flag_clear_explicit
atomic_flag_test_and_set	atomic_flag_test_and_set_explicit	atomic_init
atomic_is_lock_free	atomic_load	atomic_load_explicit
atomic_signal_fence	atomic_store	atomic_store_explicit
atomic_thread_fence	kill_dependency	

atomic_compare_exchange_strong

Performs an atomic compare and exchange operation.

```
template <class Ty>
inline bool atomic_compare_exchange_strong(
    volatile atomic<Ty>* Atom,
    Ty* Exp,
    Value) noexcept;

template <class Ty>
inline bool atomic_compare_exchange_strong(
    atomic<Ty>* Atom,
    Ty* Exp,
    Ty Value) noexcept;
```

Parameters

Atom

A pointer to an *atomic* object that stores a value of type `Ty`.

Exp

A pointer to a value of type `Ty`.

Value

A value of type `Ty`.

Return Value

true if the values are equal, otherwise **false**.

Remarks

This method performs an atomic compare and exchange operation by using implicit `memory_order_seq_cst` `memory_order` arguments. For more information, see [atomic_compare_exchange_strong_explicit](#).

atomic_compare_exchange_strong_explicit

Performs an *atomic compare and exchange* operation.

```
template <class T>
inline bool atomic_compare_exchange_strong_explicit(
    volatile atomic<Ty>* Atom,
    Ty* Exp,
    Ty Value,
    memory_order Order1,
    memory_order Order2) noexcept;

template <class Ty>
inline bool atomic_compare_exchange_strong_explicit(
    atomic<Ty>* Atom,
    Ty* Exp,
    Ty Value,
    memory_order Order1,
    memory_order Order2) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `Ty`.

Exp

A pointer to a value of type `Ty`.

Value

A value of type `Ty`.

Order1

First `memory_order` argument.

Order2

Second `memory_order` argument. The value of *Order2* cannot be `memory_order_release` or `memory_order_acq_rel`, it cannot be stronger than the value of *Order1*.

Return Value

true if the values are equal, otherwise **false**.

Remarks

An *atomic compare and exchange operation* compares the value that is stored in the object that is pointed to by *Atom* against the value that is pointed to by *Exp*. If the values are equal, the value that is stored in the object that is pointed to by *atom* is replaced with *Value* by using a `read-modify-write` operation and applying the memory order constraints that are specified by *Order1*. If the values are not equal, the operation replaces the value that is pointed to by *Exp* with the value that is stored in the object that is pointed to by *Atom* and applies the memory order constraints that are specified by *Order2*.

atomic_compare_exchange_weak

Performs a *weak atomic compare and exchange* operation.

```
template <class Ty>
inline bool atomic_compare_exchange_strong(
    volatile atomic<Ty>* Atom,
    Ty* Exp,
    Ty Value) noexcept;

template <class Ty>
inline bool atomic_compare_exchange_strong(
    atomic<Ty>* Atom,
    Ty* Exp,
    Ty Value) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `Ty`.

Exp

A pointer to a value of type `Ty`.

Value

A value of type `Ty`.

Return Value

true if the values are equal, otherwise **false**.

Remarks

This method performs a *weak atomic compare and exchange operation* that has implicit `memory_order_seq_cst` [memory_order](#) arguments. For more information, see [atomic_compare_exchange_weak_explicit](#).

atomic_compare_exchange_weak_explicit

Performs a *weak atomic compare and exchange* operation.

```
template <class Ty>
inline bool atomic_compare_exchange_weak_explicit(
    volatile atomic<Ty>* Atom,
    Ty* Exp,
    Ty Value,
    memory_order Order1,
    memory_order Order2) noexcept;

template <class Ty>
inline bool atomic_compare_exchange_weak_explicit(
    atomic<Ty>* Atom,
    Ty* Exp,
    Ty Value,
    memory_order Order1,
    memory_order Order2) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `Ty`.

Exp

A pointer to a value of type `Ty`.

Value

A value of type `Ty`.

Order1

First `memory_order` argument.

Order2

Second `memory_order` argument. The value of *Order2* cannot be `memory_order_release` or `memory_order_acq_rel`, nor can it be stronger than the value of *Order1*.

Return Value

true if the values are equal, otherwise **false**.

Remarks

Both the strong and weak flavors of an *atomic compare and exchange operation* guarantee that they do not store the new value if the expected and current values are not equal. The strong flavor guarantees that it will store the new value if the expected and current values are equal. The weak flavor may sometimes return **false** and not store the new value even if the current and expected values are equal. In other words, the function will return **false**, but a later examination of the expected value might reveal that it did not change, and therefore should have compared as equal.

atomic_exchange

Uses *Value* to replace the stored value of *Atom*.

```
template <class T>
inline Ty atomic_exchange(volatile atomic<Ty>* _Atom, Ty Value) noexcept;

template <class Ty>
inline T atomic_exchange(atomic<Ty>* Atom, Ty Value) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `Ty`.

Value

A value of type `Ty`.

Return Value

The stored value of *Atom* before the exchange.

Remarks

The `atomic_exchange` function performs a `read-modify-write` operation to exchange the value that is stored in *Atom* with *Value*, using the `memory_order_seq_cst` `memory_order`.

atomic_exchange_explicit

Replaces the stored value of *Atom* with *Value*.

```
template <class Ty>
inline Ty atomic_exchange_explicit(
    volatile atomic<Ty>* Atom,
    Ty Value,
    memory_order Order) noexcept;

template <class Ty>
inline Ty atomic_exchange_explicit(
    atomic<Ty>* Atom,
    Ty Value,
    memory_order Order) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `Ty`.

Value

A value of type `Ty`.

Order

A [memory_order](#).

Return Value

The stored value of *Atom* before the exchange.

Remarks

The `atomic_exchange_explicit` function performs a `read-modify-write` operation to exchange the value that is stored in *Atom* with *Value*, within the memory constraints that are specified by *Order*.

atomic_fetch_add

Adds a value to an existing value that is stored in an `atomic` object.

```
template <class T>
T* atomic_fetch_add(volatile atomic<T*>* Atom, ptrdiff_t Value) noexcept;
template <class T>
T* atomic_fetch_add(atomic<T*>* Atom, ptrdiff_t Value) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a pointer to type `T`.

Value

A value of type `ptrdiff_t`.

Return Value

The value of the pointer contained by the atomic object immediately before the operation was performed.

Remarks

The `atomic_fetch_add` function performs a `read-modify-write` operation to atomically add *Value* to the stored value in *Atom*, using the `memory_order_seq_cst` [memory_order](#) constraint.

When the atomic type is `atomic_address`, *Value* has type `ptrdiff_t` and the operation treats the stored pointer as a `char *`.

This operation is also overloaded for integral types:

```
integral atomic_fetch_add(volatile atomic-integral* Atom, integral Value) noexcept;
```

```
integral atomic_fetch_add(atomic-integral* Atom, integral Value) noexcept;
```

atomic_fetch_add_explicit

Adds a value to an existing value that is stored in an `atomic` object.

```
template <class T>
T* atomic_fetch_add_explicit(
    volatile atomic<T*>* Atom,
    ptrdiff_t Value,
    memory_order Order) noexcept;
```

```
template <class T>
T* atomic_fetch_add_explicit(
    atomic<T*>* Atom,
    ptrdiff_t Value,
    memory_order Order) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a pointer to type `T`.

Value

A value of type `ptrdiff_t`.

Return Value

The value of the pointer contained by the atomic object immediately before the operation was performed.

Remarks

The `atomic_fetch_add_explicit` function performs a `read-modify-write` operation to atomically add *Value* to the stored value in *Atom*, within the `memory_order` constraints that are specified by `Order`.

When the atomic type is `atomic_address`, *Value* has type `ptrdiff_t` and the operation treats the stored pointer as a `char *`.

This operation is also overloaded for integral types:

```
integral atomic_fetch_add_explicit(
    volatile atomic-integral* Atom,
    integral Value,
    memory_order Order) noexcept;
```

```
integral atomic_fetch_add_explicit(
    atomic-integral* Atom,
    integral Value,
    memory_order Order) noexcept;
```

atomic_fetch_and

Performs a bitwise `and` on a value and an existing value that is stored in an `atomic` object.

```
template <class T>
inline T atomic_fetch_and(volatile atomic<T>* Atom, T Value) noexcept;
template <class T>
inline T atomic_fetch_and(volatile atomic<T>* Atom, T Value) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `T`.

Value

A value of type `T`.

Return Value

The value contained by the atomic object immediately before the operation was performed.

Remarks

The `atomic_fetch_and` function performs a `read-modify-write` operation to replace the stored value of *Atom* with a bitwise `and` of *Value* and the current value that is stored in *Atom*, using the `memory_order_seq_cst` [memory_order](#) constraint.

atomic_fetch_and_explicit

Performs a bitwise `and` of a value and an existing value that is stored in an `atomic` object.

```
template <class T>
inline T atomic_fetch_and_explicit(
    volatile atomic<T>* Atom,
    T Value,
    memory_order Order) noexcept;

template <class T>
inline T atomic_fetch_and_explicit(
    volatile atomic<T>* Atom,
    T Value,
    memory_order Order) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `T`.

Value

A value of type `T`.

Order

A [memory_order](#).

Return Value

The value contained by the atomic object immediately before the operation was performed.

Remarks

The `atomic_fetch_and_explicit` function performs a `read-modify-write` operation to replace the stored value of *Atom* with a bitwise `and` of *Value* and the current value that is stored in *Atom*, within the memory constraints that are specified by *Order*.

atomic_fetch_or

Performs a bitwise `or` on a value and an existing value that is stored in an `atomic` object.

```
template <class T>
inline T atomic_fetch_or (volatile atomic<T>* Atom, T Value) noexcept;
template <class T>
inline T atomic_fetch_or (volatile atomic<T>* Atom, T Value) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `T`.

Value

A value of type `T`.

Return Value

The value contained by the atomic object immediately before the operation was performed.

Remarks

The `atomic_fetch_or` function performs a `read-modify-write` operation to replace the stored value of *Atom* with a bitwise `or` of *Value* and the current value that is stored in *Atom*, using the `memory_order_seq_cst` [memory_order](#).

atomic_fetch_or_explicit

Performs a bitwise `or` on a value and an existing value that is stored in an `atomic` object.

```
template <class T>
inline T atomic_fetch_or_explicit(
    volatile atomic<T>* Atom,
    T Value,
    memory_order Order) noexcept;

template <class T>
inline T atomic_fetch_or_explicit(
    volatile atomic<T>* Atom,
    T Value,
    memory_order Order) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `T`.

Value

A value of type `T`.

Order

A [memory_order](#).

Return Value

The value contained by the atomic object immediately before the operation was performed.

Remarks

The `atomic_fetch_or_explicit` function performs a `read-modify-write` operation to replace the stored value of *Atom* with a bitwise `or` of *Value* and the current value that is stored in *Atom*, within the [memory_order](#) constraints specified by *Order*.

atomic_fetch_sub

Subtracts a value from an existing value that is stored in an `atomic` object.

```
template <class T>
T* atomic_fetch_sub(
    volatile atomic<T*>* Atom,
    ptrdiff_t Value) noexcept;

template <class T>
T* atomic_fetch_sub(
    atomic<T*>* Atom,
    ptrdiff_t Value) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a pointer to type `T`.

Value

A value of type `ptrdiff_t`.

Return Value

The value of the pointer contained by the atomic object immediately before the operation was performed.

Remarks

The `atomic_fetch_sub` function performs a `read-modify-write` operation to atomically subtract *Value* from the stored value in *Atom*, using the `memory_order_seq_cst` [memory_order](#) constraint.

When the atomic type is `atomic_address`, *Value* has type `ptrdiff_t` and the operation treats the stored pointer as a `char *`.

This operation is also overloaded for integral types:

```
integral atomic_fetch_sub(volatile atomic-integral* Atom, integral Value) noexcept;
integral atomic_fetch_sub(atomic-integral* Atom, integral Value) noexcept;
```

atomic_fetch_sub_explicit

Subtracts a value from an existing value that is stored in an `atomic` object.

```
template <class T>
T* atomic_fetch_sub_explicit(
    volatile atomic<T*>* Atom,
    ptrdiff_t Value,
    memory_order Order) noexcept;

template <class T>
T* atomic_fetch_sub_explicit(
    atomic<T*>* Atom,
    ptrdiff_t Value, memory_order Order) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a pointer to type `T`.

Value

A value of type `ptrdiff_t`.

Return Value

The value of the pointer contained by the atomic object immediately before the operation was performed.

Remarks

The `atomic_fetch_sub_explicit` function performs a `read-modify-write` operation to atomically subtract *Value* from the stored value in *Atom*, within the `memory_order` constraints that are specified by `Order`.

When the atomic type is `atomic_address`, *Value* has type `ptrdiff_t` and the operation treats the stored pointer as a `char *`.

This operation is also overloaded for integral types:

```
integral atomic_fetch_sub_explicit(
    volatile atomic-integral* Atom,
    integral Value,
    memory_order Order) noexcept;

integral atomic_fetch_sub_explicit(
    atomic-integral* Atom,
    integral Value,
    memory_order Order) noexcept;
```

atomic_fetch_xor

Performs a bitwise `exclusive or` on a value and an existing value that is stored in an `atomic` object.

```
template <class T>
inline T atomic_fetch_xor(volatile atomic<T>* Atom, T Value) noexcept;

template <class T>
inline T atomic_fetch_xor(volatile atomic<T>* Atom, T Value) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `T`.

Value

A value of type `T`.

Return Value

The value contained by the atomic object immediately before the operation was performed.

Remarks

The `atomic_fetch_xor` function performs a `read-modify-write` operation to replace the stored value of *Atom* with a bitwise `exclusive or` of *Value* and the current value that is stored in *Atom*, using the `memory_order_seq_cst` `memory_order`.

atomic_fetch_xor_explicit

Performs a bitwise `exclusive or` on a value and an existing value that is stored in an `atomic` object.

```

template <class T>
inline T atomic_fetch_xor_explicit(
    volatile atomic<T>* Atom,
    T Value,
    memory_order Order) noexcept;

template <class T>
inline T atomic_fetch_xor_explicit(
    volatile atomic<T>* Atom,
    T Value,
    memory_order Order) noexcept;

```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `T`.

Value

A value of type `T`.

Order

A [memory_order](#).

Return Value

The value contained by the atomic object immediately before the operation was performed.

Remarks

The `atomic_fetch_xor_explicit` function performs a `read-modify-write` operation to replace the stored value of *Atom* with a bitwise `exclusive or` of *Value* and the current value that is stored in *Atom*, within the [memory_order](#) constraints that are specified by *Order*.

atomic_flag_clear

Sets the **bool** flag in an [atomic_flag](#) object to **false**, within the `memory_order_seq_cst` [memory_order](#).

```

inline void atomic_flag_clear(volatile atomic_flag* Flag) noexcept;
inline void atomic_flag_clear(atomic_flag* Flag) noexcept;

```

Parameters

Flag

A pointer to an `atomic_flag` object.

atomic_flag_clear_explicit

Sets the **bool** flag in an [atomic_flag](#) object to **false**, within the specified [memory_order](#) constraints.

```

inline void atomic_flag_clear_explicit(volatile atomic_flag* Flag, memory_order Order) noexcept;
inline void atomic_flag_clear_explicit(atomic_flag* Flag, memory_order Order) noexcept;

```

Parameters

Flag

A pointer to an `atomic_flag` object.

Order

A [memory_order](#).

atomic_flag_test_and_set

Sets the **bool** flag in an [atomic_flag](#) object to **true**, within the constraints of the `memory_order_seq_cst` [memory_order](#).

```
inline bool atomic_flag_test_and_set(volatile atomic_flag* Flag,) noexcept;
inline bool atomic_flag_test_and_set(atomic_flag* Flag,) noexcept;
```

Parameters

Flag

A pointer to an `atomic_flag` object.

Return Value

The initial value of *Flag*.

atomic_flag_test_and_set_explicit

Sets the **bool** flag in an [atomic_flag](#) object to **true**, within the specified [memory_order](#) constraints.

```
inline bool atomic_flag_test_and_set_explicit(volatile atomic_flag* Flag, memory_order Order) noexcept;
inline bool atomic_flag_test_and_set_explicit(atomic_flag* Flag, memory_order Order) noexcept;
```

Parameters

Flag

A pointer to an `atomic_flag` object.

Order

A [memory_order](#).

Return Value

The initial value of *Flag*.

atomic_init

Sets the stored value in an `atomic` object.

```
template <class Ty>
inline void atomic_init(volatile atomic<Ty>* Atom, Ty Value) noexcept;
template <class Ty>
inline void atomic_init(atomic<Ty>* Atom, Ty Value) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `Ty`.

Value

A value of type `Ty`.

Remarks

`atomic_init` is not an atomic operation. It is not thread-safe.

atomic_is_lock_free

Specifies whether atomic operations on an `atomic` object are *lock-free*.

```
template <class T>
inline bool atomic_is_lock_free(const volatile atomic<T>* Atom) noexcept;
template <class T>
inline bool atomic_is_lock_free(const atomic<T>* Atom) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that stores a value of type `T`.

Return Value

true if atomic operations on *Atom* are lock-free; otherwise, **false**.

Remarks

An atomic type is lock-free if no atomic operations on that type use locks. If this function returns true, the type is safe to use in signal-handlers.

atomic_load

Retrieves the stored value in an `atomic` object.

```
template <class Ty>
inline Ty atomic_load(const volatile atomic<Ty>* Atom) noexcept;
template <class Ty>
inline Ty atomic_load(const atomic<Ty>* Atom) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that contains a value of type `Ty`.

Return Value

The retrieved value that is stored in *Atom*.

Remarks

`atomic_load` implicitly uses the `memory_order_seq_cst` [memory_order](#).

atomic_load_explicit

Retrieves the stored value in an `atomic` object, within a specified [memory_order](#).

```
template <class Ty>
inline Ty atomic_load_explicit(const volatile atomic<Ty>* Atom, memory_order Order) noexcept;
template <class Ty>
inline Ty atomic_load_explicit(const atomic<Ty>* Atom, memory_order Order) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that contains a value of type `Ty`.

Order

A [memory_order](#). Do not use `memory_order_release` or `memory_order_acq_rel`.

Return Value

The retrieved value that is stored in *Atom*.

atomic_signal_fence

Acts as a *fence*—which is a memory synchronization primitive that enforces ordering between load/store operations—between other fences in a calling thread that have signal handlers that are executed in the same thread.

```
inline void atomic_signal_fence(memory_order Order) noexcept;
```

Parameters

Order

A memory ordering constraint that determines fence type.

Remarks

The *Order* argument determines fence type.

<code>memory_order_relaxed</code>	The fence has no effect.
<code>memory_order_consume</code>	The fence is an acquire fence.
<code>memory_order_acquire</code>	The fence is an acquire fence.
<code>memory_order_release</code>	The fence is a release fence.
<code>memory_order_acq_rel</code>	The fence is both an acquire fence and a release fence.
<code>memory_order_seq_cst</code>	The fence is both an acquire fence and a release fence, and is sequentially consistent.

atomic_store

Atomically stores a value in an atomic object.

```
template <class Ty>
inline Ty atomic_store_explicit(const volatile atomic<Ty>* Atom, Ty Value) noexcept;
template <class Ty>
inline Ty atomic_store_explicit(const atomic<Ty>* Atom, T Value) noexcept;
```

Parameters

Atom

A pointer to an atomic object that contains a value of type `Ty`.

Value

A value of type `Ty`.

Remarks

`atomic_store` stores *Value* in the object that is pointed to by *Atom*, within the `memory_order_seq_cst` [memory_order](#) constraint.

atomic_store_explicit

Atomically stores a value in an atomic object.

```
template <class Ty>
inline Ty atomic_store_explicit(
    const volatile atomic<Ty>* Atom,
    Ty Value,
    memory_order Order) noexcept;

template <class Ty>
inline Ty atomic_store_explicit(
    const atomic<Ty>* Atom,
    T Value,
    memory_order Order) noexcept;
```

Parameters

Atom

A pointer to an `atomic` object that contains a value of type `Ty`.

Value

A value of type `Ty`.

Order

A [memory_order](#). Do not use `memory_order_consume`, `memory_order_acquire`, or `memory_order_acq_rel`.

Remarks

`atomic_store` stores *Value* in the object that is pointed to by *Atom*, within the `memory_order` that is specified by *Order*.

atomic_thread_fence

Acts as a *fence*—which is a memory synchronization primitive that enforces ordering between load/store operations—without an associated atomic operation.

```
inline void atomic_thread_fence(memory_order Order) noexcept;
```

Parameters

Order

A memory ordering constraint that determines fence type.

Remarks

The *Order* argument determines fence type.

<code>memory_order_relaxed</code>	The fence has no effect.
<code>memory_order_consume</code>	The fence is an acquire fence.
<code>memory_order_acquire</code>	The fence is an acquire fence.
<code>memory_order_release</code>	The fence is a release fence.
<code>memory_order_acq_rel</code>	The fence is both an acquire fence and a release fence.

<div data-bbox="156 143 402 179" data-label="Text"> <pre>memory_order_seq_cst</pre> </div>	<div data-bbox="810 143 1420 208" data-label="Text"> <p>The fence is both an acquire fence and a release fence, and is sequentially consistent.</p> </div>
--	--

kill_dependency

Removes a dependency.

```
template <class Ty>
Ty kill_dependency(Ty Arg) noexcept;
```

Parameters

Arg

A value of type `Ty`.

Return Value

The return value is *Arg*. The evaluation of *Arg* does not carry a dependency to the function call. By breaking a possible dependency chain, the function might permit the compiler to generate more efficient code.

<atomic> enums

10/31/2018 • 2 minutes to read • [Edit Online](#)

memory_order Enum

Supplies symbolic names for synchronization operations on memory locations. These operations affect how assignments in one thread become visible in another.

```
typedef enum memory_order {  
    memory_order_relaxed,  
    memory_order_consume,  
    memory_order_acquire,  
    memory_order_release,  
    memory_order_acq_rel,  
    memory_order_seq_cst,  
} memory_order;
```

Enumeration members

<code>memory_order_relaxed</code>	No ordering required.
<code>memory_order_consume</code>	A load operation acts as a consume operation on the memory location.
<code>memory_order_acquire</code>	A load operation acts as an acquire operation on the memory location.
<code>memory_order_release</code>	A store operation acts as a release operation on the memory location.
<code>memory_order_acq_rel</code>	Combines <code>memory_order_acquire</code> and <code>memory_order_release</code> .
<code>memory_order_seq_cst</code>	Combines <code>memory_order_acquire</code> and <code>memory_order_release</code> . Memory accesses that are marked as <code>memory_order_seq_cst</code> must be sequentially consistent.

[<atomic>](#)

<bitset>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines the template class `bitset` and two supporting template functions for representing and manipulating fixed-size sequences of bits.

Syntax

```
#include <bitset>
```

Operators

OPERATOR	DESCRIPTION
operator&	Performs a bitwise AND between two bitsets.
operator<<	Inserts a text representation of the bit sequence into the standard output stream.
operator>>	Inserts a text representation of the bit sequence into the standard input stream.
operator^	Performs a bitwise EXCLUSIVE-OR between two bitsets.
operator 	Performs a bitwise OR between two bitsets.

Classes

CLASS	DESCRIPTION
bitset Class	The template class describes a type of object that stores a sequence consisting of a fixed number of bits that provide a compact way of keeping flags for a set of items or conditions.

<bitset> operators

11/8/2018 • 5 minutes to read • [Edit Online](#)

<code>operator&</code>	<code>operator>></code>	<code>operator<<</code>
<code>operator^</code>	<code>operator </code>	

operator&

Performs a bitwise `AND` between two bitsets.

```
template <size_t size>
bitset<size>
operator&(
    const bitset<size>& left,
    const bitset<size>& right);
```

Parameters

left

The first of the two bitsets whose respective elements are to be combined with the bitwise `AND`.

right

The second of the two valarrays whose respective elements are to be combined with the bitwise `AND`.

Return Value

A bitset whose elements are the result of performing the `AND` operation on the corresponding elements of *left* and *right*.

Example

```
// bitset_and.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>
#include <string>

using namespace std;

int main()
{
    bitset<4> b1 ( string("0101") );
    bitset<4> b2 ( string("0011") );
    bitset<4> b3 = b1 & b2;
    cout << "bitset 1: " << b1 << endl;
    cout << "bitset 2: " << b2 << endl;
    cout << "bitset 3: " << b3 << endl;
}
```

```
bitset 1: 0101
bitset 2: 0011
bitset 3: 0001
```

operator<<

Inserts a text representation of the bit sequence into the output stream.

```
template <class CharType, class Traits, size_t N>
basic_ostream<CharType, Traits>& operator<<(
    basic_ostream<CharType, Traits>& ostr,
    const bitset<N>& right);
```

Parameters

right

An object of type **bitset<N>** that is to be inserted into the output stream as a string.

Return Value

A text representation of the bit sequence in `ostr`.

Remarks

The template function overloads `operator<<`, allowing a bitset to be written out without first converting it into a string. The template function effectively executes:

```
ostr << _Right.to_string < CharType, Traits, allocator< CharType> > > ( )
```

Example

```
// bitset_op_insert.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 9 );

    // bitset inserted into output stream directly
    cout << "The ordered set of bits in the bitset<5> b1(9)"
        << "\n can be output with the overloaded << as: ( "
        << b1 << " )" << endl;

    // Compare converting bitset to a string before
    // inserting it into the output stream
    string s1;
    s1 = b1.template to_string<char,
        char_traits<char>, allocator<char> >( );
    cout << "The string returned from the bitset b1"
        << "\n by the member function to_string( ) is: "
        << s1 << "." << endl;
}
```

operator>>

Reads a string of bit characters into a bitset.

```
template <class CharType, class Traits, size_t Bits>
basic_istream<CharType, Traits>& operator>> (
    basic_istream<CharType, Traits>&
    _Istr,
    bitset<N>&
    right);
```

Parameters

_Istr

The string that is entered into the input stream to be inserted into the bitset.

right

The bitset that is receiving the bits from the input stream.

Return Value

The template function returns the string *_Istr*.

Remarks

The template function overloads `operator>>` to store in the bitset *_Right* the value `bitset(str)`, where `str` is an object of type `basic_string < CharType, Traits, allocator< CharType> > &` extracted from *_Istr*.

The template function extracts elements from *_Istr* and inserts them into the bitset until:

- All the bit elements have been extracted from the input stream and stored in the bitset.
- The bitset is filled up with bits from the input stream.
- An input element is encountered that is neither 0 nor 1.

Example

```

#include <bitset>
#include <iostream>
#include <string>

using namespace std;
int main()
{

    bitset<5> b1;
    cout << "Enter string of (0 or 1) bits for input into bitset<5>.\n"
         << "Try bit string of length less than or equal to 5,\n"
         << " (for example: 10110): ";
    cin >> b1;

    cout << "The ordered set of bits entered from the "
         << "keyboard\n has been input into bitset<5> b1 as: ( "
         << b1 << " )" << endl;

    // Truncation due to longer string of bits than length of bitset
    bitset<2> b3;
    cout << "Enter string of bits (0 or 1) for input into bitset<2>.\n"
         << " Try bit string of length greater than 2,\n"
         << " (for example: 1011): ";
    cin >> b3;

    cout << "The ordered set of bits entered from the "
         << "keyboard\n has been input into bitset<2> b3 as: ( "
         << b3 << " )" << endl;

    // Flushing the input stream
    char buf[100];
    cin.getline(&buf[0], 99);

    // Truncation with non-bit value
    bitset<5> b2;
    cout << "Enter a string for input into bitset<5>.\n"
         << " that contains a character than is NOT a 0 or a 1,\n "
         << " (for example: 10k01): ";
    cin >> b2;

    cout << "The string entered from the keyboard\n"
         << " has been input into bitset<5> b2 as: ( "
         << b2 << " )" << endl;
}

```

operator[^]

Performs a bitwise **EXCLUSIVE-OR** between two bitsets.

```

template <size_t size>
bitset<size>
operator^(
    const bitset<size>& left,
    const bitset<size>& right);

```

Parameters

left

The first of the two bitsets whose respective elements are to be combined with the bitwise **EXCLUSIVE-OR** .

right

The second of the two valarrays whose respective elements are to be combined with the bitwise **EXCLUSIVE-OR** .

Return Value

A bitset whose elements are the result of performing the `EXCLUSIVE-OR` operation on the corresponding elements of *left* and *right*.

Example

```
// bitset_xor.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>
#include <string>

using namespace std;

int main()
{
    bitset<4> b1 ( string("0101") );
    bitset<4> b2 ( string("0011") );
    bitset<4> b3 = b1 ^ b2;
    cout << "bitset 1: " << b1 << endl;
    cout << "bitset 2: " << b2 << endl;
    cout << "bitset 3: " << b3 << endl;
}
```

```
bitset 1: 0101
bitset 2: 0011
bitset 3: 0110
```

operator|

Performs a bitwise `OR` between two bitsets.

```
template <size_t size>
bitset<size>
operator|(
    const bitset<size>& left,
    const bitset<size>& right);
```

Parameters

left

The first of the two bitsets whose respective elements are to be combined with the bitwise `OR`.

right

The second of the two valarrays whose respective elements are to be combined with the bitwise `OR`.

Return Value

A bitset whose elements are the result of performing the `OR` operation on the corresponding elements of *left* and *right*.

Example

```
// bitset_or.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>
#include <string>

using namespace std;

int main()
{
    bitset<4> b1 ( string("0101") );
    bitset<4> b2 ( string("0011") );
    bitset<4> b3 = b1 | b2;
    cout << "bitset 1: " << b1 << endl;
    cout << "bitset 2: " << b2 << endl;
    cout << "bitset 3: " << b3 << endl;
}
```

```
bitset 1: 0101
bitset 2: 0011
bitset 3: 0111
```

[<bitset>](#)

bitset Class

3/28/2019 • 34 minutes to read • [Edit Online](#)

Describes a type of object that stores a sequence consisting of a fixed number of bits that provide a compact way of keeping flags for a set of items or conditions. The `bitset` class supports operations on objects of type `bitset` that contain a collection of bits and provide constant-time access to each bit.

Syntax

```
template <size_t N>
class bitset
```

Parameters

N

Specifies the number of bits in the `bitset` object with a nonzero integer of type `size_t` that must be known at compile time.

Remarks

Unlike the similar [vector<bool> Class](#), the `bitset` class does not have iterators and is not a C++ Standard Library container. It also differs from `vector<bool>` by being of some specific size that is fixed at compile time in accordance with the size specified by the template parameter *N* when the **`bitset<N>`** is declared.

A bit is set if its value is 1 and reset if its value is 0. To flip or invert a bit is to change its value from 1 to 0 or from 0 to 1. The *N* bits in a `bitset` are indexed by integer values from 0 to *N* - 1, where 0 indexes the first bit position and *N* - 1 the final bit position.

Constructors

CONSTRUCTOR	DESCRIPTION
bitset	Constructs an object of class <code>bitset<N></code> and initializes the bits to zero, to some specified value, or to values obtained from characters in a string.

Typedefs

TYPE NAME	DESCRIPTION
element_type	A type that is a synonym for the data type <code>bool</code> and can be used to reference element bits in a <code>bitset</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
all	Tests all of the bits in this <code>bitset</code> to determine whether they are all set to <code>true</code> .

MEMBER FUNCTION	DESCRIPTION
any	The member function tests whether any bit in the sequence is set to 1.
count	The member function returns the number of bits set in the bit sequence.
flip	Inverts the value of all the bits in a <code>bitset</code> or inverts a single bit at a specified position.
none	Tests if no bit has been set to 1 in a <code>bitset</code> object.
reset	Resets all the bits in a <code>bitset</code> to 0 or resets a bit at a specified position to 0.
set	Sets all the bits in a <code>bitset</code> to 1 or sets a bit at a specified position to 1.
size	Returns the number of bits in a <code>bitset</code> object.
test	Tests whether the bit at a specified position in a <code>bitset</code> is set to 1.
to_string	Converts a <code>bitset</code> object to a string representation.
to_ullong	Returns the sum of the bit values in the <code>bitset</code> as an unsigned long long .
to_ulong	Converts a <code>bitset</code> object to the unsigned long that would generate the sequence of bits contained if used to initialize the <code>bitset</code> .

Member Classes

MEMBER CLASS	DESCRIPTION
reference	A proxy class that provides references to bits contained in a <code>bitset</code> that is used to access and manipulate the individual bits as a helper class for the <code>operator[]</code> of class <code>bitset</code> .

Operators

OPERATOR	DESCRIPTION
operator!=	Tests a target <code>bitset</code> for inequality with a specified <code>bitset</code> .
operator&=	Performs a bitwise combination of bitsets with the logical AND operation.
operator<<	Shifts the bits in a <code>bitset</code> to the left a specified number of positions and returns the result to a new <code>bitset</code> .

OPERATOR	DESCRIPTION
<code>operator<<=</code>	Shifts the bits in a <code>bitset</code> to the left a specified number of positions and returns the result to the targeted <code>bitset</code> .
<code>operator==</code>	Tests a target <code>bitset</code> for equality with a specified <code>bitset</code> .
<code>operator>></code>	Shifts the bits in a <code>bitset</code> to the right a specified number of positions and returns the result to a new <code>bitset</code> .
<code>operator>>=</code>	Shifts the bits in a <code>bitset</code> to the right a specified number of positions and returns the result to the targeted <code>bitset</code> .
<code>operator[]</code>	Returns a reference to a bit at a specified position in a <code>bitset</code> if the <code>bitset</code> is modifiable; otherwise, it returns the value of the bit at that position.
<code>operator^=</code>	Performs a bitwise combination of bitsets with the exclusive <code>OR</code> operation.
<code>operator =</code>	Performs a bitwise combination of bitsets with the inclusive <code>OR</code> operation.
<code>operator~</code>	Inverts all the bits in a target <code>bitset</code> and returns the result.

Requirements

Header: `<bitset>`

Namespace: `std`

`bitset::all`

Tests all of the bits in this `bitset` to determine if they are all set to true.

```
bool all() const;
```

Return Value

Returns true if all bits in this set are true. Returns **false** if one or more bits are false.

`bitset::any`

Tests whether any bit in the sequence is set to 1.

```
bool any() const;
```

Return Value

true if any bit in the `bitset` is set to 1; **false** if all the bits are 0.

Example

```

// bitset_any.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 6 );
    bool b, rb;

    cout << "The original bitset b1( 6 ) is: ( "<< b1 << " )"
         << endl;

    b = b1.any ( );

    if ( b )
        cout << "At least one of the bits in bitset is set to 1."
             << endl;
    else
        cout << "None of the bits in bitset are set to 1."
             << endl;

    bitset<5> rb1;
    rb1 = b1.reset ( );

    cout << "The reset bitset is: ( "<< b1 << " )"
         << endl;

    rb = rb1.any ( );

    if ( rb )
        cout << "At least one of the bits in the reset bitset "
             << "are set to 1." << endl;
    else
        cout << "None of the bits in bitset b1 are set to 1."
             << endl;
}

```

```

The original bitset b1( 6 ) is: ( 00110 )
At least one of the bits in bitset is set to 1.
The reset bitset is: ( 00000 )
None of the bits in bitset b1 are set to 1.

```

bitset::bitset

Constructs an object of class `bitset<N>` and initializes the bits to zero, or to some specified value, or to values obtained from characters in a string.

```

bitset();

bitset(
    unsigned long long val);

explicit bitset(
    const char* _CStr);

template <class CharType,
    class Traits,
    class Allocator>
explicit bitset(
    const basic_string<CharType, Traits, Allocator>& str,
    typename basic_string<CharType, Traits, Allocator>::size_type _Pos = 0);

template <class CharType,
    class Traits,
    class Allocator>
explicit bitset(
    const basic_string<CharType, Traits, Allocator>& str,
    typename basic_string<CharType, Traits, Allocator>::size_type _Pos,
    typename basic_string<CharType, Traits, Allocator>::size_type count,
    CharType _Zero = CharType ('0'),
    CharType _One = CharType ('1'));

```

Parameters

val

The unsigned integer whose base two representation is used to initialize the bits in the bitset being constructed.

str

The string of zeros and ones used to initialize the bitset bit values.

_CStr

A C-style string of zeros and ones used to initialize the bitset bit values.

_Pos

The position of the character in the string, counting from left to right and starting with zero, used to initialize the first bit in the bitset.

count

The number of characters in the string that is used to provide initial values for the bits in the bitset.

_Zero

The character that is used to represent a zero. The default is '0'.

_One

The character that is used to represent a one. The default is '1'.

Remarks

Three constructors can be used to construct objects of class `bitset<N>`:

- The first constructor accepts no parameters, constructs an object of class `bitset<N>` and initializes all N bits to a default value of zero.
- The second constructor constructs an object of class `bitset<N>` and initializes the bits by using the single **unsigned long long** parameter.
- The third constructor constructs an object of class `bitset<N>`, initializing the N bits to values that correspond to the characters provided in a c-style character string of zeros and ones. You call the constructor without casting the string into a string type: `bitset<5> b5("01011");`

There are also two constructor templates provided:

- The first constructor template constructs an object of class `bitset<N>` and initializes bits from the characters provided in a string of zeros and ones. If any characters of the string are other than 0 or 1, the constructor throws an object of class `invalid_argument`. If the position specified (`_Pos`) is beyond the length of the string, then the constructor throws an object of class `out_of_range`. The constructor sets only those bits at position j in the bitset for which the character in the string at position `_Pos + j` is 1. By default, `_Pos` is 0.
- The second constructor template is similar to the first, but includes an additional parameter (`count`) that is used to specify the number of bits to initialize. It also has two optional parameters, `_Zero` and `_One`, which indicate what character in `str` is to be interpreted to mean a 0 bit and a 1 bit, respectively.

Example

```

// bitset_bitset.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    // Using the default constructor
    using namespace std;
    bitset<2> b0;
    cout << "The set of bits in bitset<2> b0 is: ( "
         << b0 << " )." << endl;

    // Using the second member function
    bitset<5> b1 ( 6 );
    cout << "The set of bits in bitset<5> b1( 6 ) is: ( "
         << b1 << " )." << endl;

    // The template parameter N can be an expression
    bitset< 2 * sizeof ( int ) > b2;
    cout << "The set of bits in bitset<2 * sizeof ( int ) > b2 is: ( "
         << b2 << " )." << endl;

    // The base two representation will be truncated
    // if its length exceeds the size of the bitset
    bitset<3> b3 ( 6 );
    cout << "The set of bits in bitset<3> b3( 6 ) is ( "
         << b3 << " )." << endl;

    // Using a c-style string to initialize the bitset
    bitset<7> b3andahalf ( "1001001" );
    cout << "The set of bits in bitset<7> b3andahalf ( \"1001001\" )"
         << " is ( " << b3andahalf << " )." << endl;

    // Using the fifth member function with the first parameter
    string bitval4 ( "10011" );
    bitset<5> b4 ( bitval4 );
    cout << "The set of bits in bitset<5> b4( bitval4 ) is ( "
         << b4 << " )." << endl;

    // Only part of the string may be used for initialization

    // Starting at position 3 for a length of 6 (100110)
    string bitval5 ("11110011011");
    bitset<6> b5 ( bitval5, 3, 6 );
    cout << "The set of bits in bitset<11> b5( bitval, 3, 6 ) is ( "
         << b5 << " )." << endl;

    // The bits not initialized with part of the string
    // will default to zero
    bitset<11> b6 ( bitval5, 3, 5 );
    cout << "The set of bits in bitset<11> b6( bitval5, 3, 5 ) is ( "
         << b6 << " )." << endl;

    // Starting at position 2 and continue to the end of the string
    bitset<9> b7 ( bitval5, 2 );
    cout << "The set of bits in bitset<9> b7( bitval, 2 ) is ( "
         << b7 << " )." << endl;
}

```

```
The set of bits in bitset<2> b0 is: ( 00 ).
The set of bits in bitset<5> b1( 6 ) is: ( 00110 ).
The set of bits in bitset<2 * sizeof ( int ) > b2 is: ( 00000000 ).
The set of bits in bitset<3> b3( 6 ) is ( 110 ).
The set of bits in bitset<5> b4( bitval4 ) is ( 10011 ).
The set of bits in bitset<11> b5( bitval, 3, 6 ) is ( 100110 ).
The set of bits in bitset<11> b6( bitval5, 3, 5 ) is ( 00000010011 ).
The set of bits in bitset<9> b7( bitval, 2 ) is ( 110011011 ).
```

bitset::count

Returns the number of bits set in the bit sequence.

```
size_t count() const;
```

Return Value

The number of bits set in the bit sequence.

Example

The following example demonstrates the use of the `bitset::count` member function.

```
// bitset_count.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<5> b1(4);

    cout << "The collection of bits in the original bitset is: ( "
         << b1 << " )" << endl;

    size_t i;
    i = b1.count();
    cout << "The number of bits in the bitset set to 1 is: "
         << i << "." << endl;

    bitset<5> fb1;
    fb1 = b1.flip();

    cout << "The collection of flipped bits in the modified bitset "
         << "is: ( " << fb1 << " )" << endl;

    size_t ii;
    ii = fb1.count();
    cout << "The number of bits in the bitset set to 1 is: "
         << ii << "." << endl;
}
```

```
The collection of bits in the original bitset is: ( 00100 )
The number of bits in the bitset set to 1 is: 1.
The collection of flipped bits in the modified bitset is: ( 11011 )
The number of bits in the bitset set to 1 is: 4.
```

bitset::element_type

A type that is a synonym for the data type **bool** and can be used to reference element bits in a bitset.

```
typedef bool element_type;
```

Example

```
// bitset_elem_type.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<3> b1 ( 2 );
    cout << "Original bitset b1(6) is: ( "<< b1 << " )"
         << endl;

    //Compare two ways to reference bits in a bitset
    bool b;
    bitset<5>::element_type e;

    b = b1.test ( 2 );
    if ( b )
        cout << "The bit at position 2 of bitset b1"
             << "has a value of 1." << endl;
    else
        cout << "The bit at position 2 of bitset b1"
             << "has a value of 0." << endl;
    b1[2] = 1;
    cout << "Bitset b1 modified by b1[2] = 1 is: ( "<< b1 << " )"
         << endl;

    e = b1.test ( 2 );
    if ( e )
        cout << "The bit at position 2 of bitset b1"
             << "has a value of 1." << endl;
    else
        cout << "The bit at position 2 of bitset b1"
             << "has a value of 0." << endl;
}
```

```
Original bitset b1(6) is: ( 010 )
The bit at position 2 of bitset b1has a value of 0.
Bitset b1 modified by b1[2] = 1 is: ( 110 )
The bit at position 2 of bitset b1has a value of 1.
```

bitset::flip

Inverts the value of all the bits in a bitset or inverts a single bit at a specified position.

```
bitset<N>& flip();
bitset<N>& flip(size_t _Pos);
```

Parameters

_Pos

The position of the bit whose value is to be inverted.

Return Value

A copy of the modified bitset for which the member function was invoked.

Remarks

The second member function throws an [out_of_range](#) exception if the position specified as a parameter is greater than the size N of the **bitset**< N > whose bit was inverted.

Example

```
// bitset_flip.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;
    bitset<5> b1 ( 6 );

    cout << "The collection of bits in the original bitset is: ( "
         << b1 << " )" << endl;

    bitset<5> fb1;
    fb1 = b1.flip ( );

    cout << "After flipping all the bits, the bitset becomes: ( "
         << fb1 << " )" << endl;

    bitset<5> f3b1;
    f3b1 = b1.flip ( 3 );

    cout << "After flipping the fourth bit, the bitset becomes: ( "
         << f3b1 << " )" << endl << endl;

    bitset<5> b2;
    int i;
    for ( i = 0 ; i <= 4 ; i++ )
    {
        b2.flip(i);
        cout << b2 << " The bit flipped is in position "
             << i << ".\n";
    }
}
```

```
The collection of bits in the original bitset is: ( 00110 )
After flipping all the bits, the bitset becomes: ( 11001 )
After flipping the fourth bit, the bitset becomes: ( 10001 )
```

```
00001 The bit flipped is in position 0.
00011 The bit flipped is in position 1.
00111 The bit flipped is in position 2.
01111 The bit flipped is in position 3.
11111 The bit flipped is in position 4.
```

bitset::none

Tests if no bit has been set to 1 in a bitset object.

```
bool none() const;
```

Return Value

true if no bit in the bitset has been set to 1; **false** if at least one bit has been set to 1.

Example

```
// bitset_none.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 6 );
    bool b, rb;

    cout << "Original bitset b1(6) is: ( " << b1 << " )"
         << endl;

    b = b1.none ( );

    if ( b )
        cout << "None of the bits in bitset b1 are set to 1."
              << endl;
    else
        cout << "At least one of the bits in bitset b1 is set to 1."
              << endl;

    bitset<5> rb1;
    rb1 = b1.reset ( );
    rb = rb1.none ( );
    if ( rb )
        cout << "None of the bits in bitset b1 are set to 1."
              << endl;
    else
        cout << "At least one of the bits in bitset b1 is set to 1."
              << endl;
}
```

```
Original bitset b1(6) is: ( 00110 )
At least one of the bits in bitset b1 is set to 1.
None of the bits in bitset b1 are set to 1.
```

bitset::operator!=

Tests a target bitset for inequality with a specified bitset.

```
bool operator!=(const bitset<N>& right) const;
```

Parameters

right

The bitset that is to be compared to the target bitset for inequality.

Return Value

true if the bitsets are different; **false** if they are the same.

Remarks

Bitsets must be of the same size to be tested for inequality by the member operator function.

Example

```
// bitset_op_NE.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 7 );
    bitset<5> b2 ( 7 );
    bitset<5> b3 ( 2 );
    bitset<4> b4 ( 7 );

    if ( b1 != b2 )
        cout << "Bitset b1 is different from bitset b2." << endl;
    else
        cout << "Bitset b1 is the same as bitset b2." << endl;

    if ( b1 != b3 )
        cout << "Bitset b1 is different from bitset b3." << endl;
    else
        cout << "Bitset b1 is the same as bitset b3." << endl;

    // This would cause an error because bitsets must have the
    // same size to be tested
    // if ( b1 != b4 )
    //     cout << "Bitset b1 is different from bitset b4." << endl;
    // else
    //     cout << "Bitset b1 is the same as bitset b4." << endl;
}
```

```
Bitset b1 is the same as bitset b2.
Bitset b1 is different from bitset b3.
```

bitset::operator&=

Performs a bitwise combination of bitsets with the logical **AND** operation.

```
bitset<N>& operator&=(const bitset<N>& right);
```

Parameters

right

The bitset that is to be combined bitwise with the target bitset.

Return Value

The modified target bitset that results from the bitwise **AND** operation with the bitset specified as a parameter.

Remarks

Two bits combined by the **AND** operator return **true** if each bit is true; otherwise, their combination returns **false**.

Bitsets must be of the same size to be combined bitwise with the **AND** operator by the member operator function.

Example

```

// bitset_op_bitwise.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 7 );
    bitset<5> b2 ( 11 );
    bitset<4> b3 ( 7 );

    cout << "The target bitset b1 is:   ( "<< b1 << " )." << endl;
    cout << "The parameter bitset b2 is: ( "<< b2 << " )." << endl;
    cout << endl;

    b1 &= b2;
    cout << "After bitwise AND combination,\n"
        << "the target bitset b1 becomes:  ( "<< b1 << " )."
        << endl;

    // Note that the parameter-specified bitset is unchanged
    cout << "The parameter bitset b2 remains: ( "<< b2 << " )."
        << endl;

    // The following would cause an error because the bisets
    // must be of the same size to be combined
    // b1 &= b3;
}

```

```

The target bitset b1 is:   ( 00111 ).
The parameter bitset b2 is: ( 01011 ).

After bitwise AND combination,
the target bitset b1 becomes:  ( 00011 ).
The parameter bitset b2 remains: ( 01011 ).

```

bitset::operator<<

Shifts the bits in a bitset to the left a specified number of positions and returns the result to a new bitset.

```

bitset<N> operator<<(size_t _Pos) const;

```

Parameters

_Pos

The number of positions to the left that the bits in the bitset are to be shifted.

Return Value

The modified bitset with the bits shifted to the left the required number of positions.

Remarks

The member operator function returns **bitset(*this) <<= pos**, where **<<=** shifts the bits in a bitset to the left a specified number of positions and returns the result to the targeted bitset.

Example

```

// bitset_op_LS.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 7 );

    cout << "The bitset b1 is: ( "<< b1 << " )." << endl;

    bitset<5> b2;
    b2 = b1 << 2;

    cout << "After shifting the bits 2 positions to the left,\n"
        << " the bitset b2 is: ( "<< b2 << " )."
        << endl;

    bitset<5> b3 = b2 >> 1;

    cout << "After shifting the bits 1 position to the right,\n"
        << " the bitset b3 is: ( " << b3 << " )."
        << endl;
}

```

bitset::operator<<=

Shifts the bits in a bitset to the left a specified number of positions and returns the result to the targeted bitset.

```

bitset<N>& operator<<=(size_t _Pos);

```

Parameters

_Pos

The number of positions to the left the bits in the bitset are to be shifted.

Return Value

The targeted bitset modified so that the bits have been shifted to the left the required number of positions.

Remarks

If no element exists to shift into the position, the function clears the bit to a value of 0.

Example

```

// bitset_op_LSE.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;
    bitset<5> b1 ( 7 );
    cout << "The target bitset b1 is: ( "<< b1 << " )." << endl;
    b1 <<= 2;
    cout << "After shifting the bits 2 positions to the left,\n"
        << "the target bitset b1 becomes: ( "<< b1 << " )."
        << endl;
}

```

The target bitset b1 is: (00111).
After shifting the bits 2 positions to the left,
the target bitset b1 becomes: (11100).

bitset::operator==

Tests a target bitset for equality with a specified bitset.

```
bool operator==(const bitset<N>& right) const;
```

Parameters

right

The bitset that is to be compared to the target bitset for equality.

Return Value

true if the bitsets are the same; **false** if they are different.

Remarks

Bitsets must be of the same size to be tested for equality by the member operator function.

Example

```
// bitset_op_EQ.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;
    bitset<5> b1 ( 7 );
    bitset<5> b2 ( 7 );
    bitset<5> b3 ( 2 );
    bitset<4> b4 ( 7 );

    if ( b1 == b2 )
        cout << "Bitset b1 is the same as bitset b2." << endl;
    else
        cout << "Bitset b1 is different from bitset b2." << endl;

    if ( b1 == b3 )
        cout << "Bitset b1 is the same as bitset b3." << endl;
    else
        cout << "Bitset b1 is different from bitset b3." << endl;

    // This would cause an error because bitsets must have the
    // same size to be tested
    // if ( b1 == b4 )
    //     cout << "Bitset b1 is the same as bitset b4." << endl;
    // else
    //     cout << "Bitset b1 is different from bitset b4." << endl;
}
```

```
Bitset b1 is the same as bitset b2.
Bitset b1 is different from bitset b3.
```

bitset::operator>>

Shifts the bits in a bitset to the right a specified number of positions and returns the result to a new bitset.

```
bitset<N> operator>>(size_t _Pos) const;
```

Parameters

_Pos

The number of positions to the right the bits in the bitset are to be shifted.

Return Value

A new bitset where the bits have been shifted to the right the required number of positions relative to the targeted bitset.

Example

```
// bitset_op_RS.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;
    bitset<5> b1 ( 7 );
    cout << "The bitset b1 is: ( "<< b1 << " )." << endl;

    bitset<5> b2;
    b2 = b1 << 2;

    cout << "After shifting the bits 2 positions to the left,\n"
         << "the bitset b2 is: ( "<< b2 << " )."
         << endl;
    bitset<5> b3 = b2 >> 1;

    cout << "After shifting the bits 1 position to the right,\n"
         << "the bitset b3 is: ( " << b3 << " )."
         << endl;
}
```

```
The bitset b1 is: ( 00111 ).
After shifting the bits 2 positions to the left,
the bitset b2 is: ( 11100 ).
After shifting the bits 1 position to the right,
the bitset b3 is: ( 01110 ).
```

bitset::operator>>=

Shifts the bits in a bitset to the right a specified number of positions and returns the result to the targeted bitset.

```
bitset<N>& operator>>=(size_t _Pos);
```

Parameters

_Pos

The number of positions to the right the bits in the bitset are to be shifted.

Return Value

The targeted bitset modified so that the bits have been shifted to the right the required number of positions.

Remarks

If no element exists to shift into the position, the function clears the bit to a value of 0.

Example

```
// bitset_op_RSE.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;
    bitset<5> b1 ( 28 );
    cout << "The target bitset b1 is: ( "<< b1 << " )." << endl;

    b1 >>= 2;
    cout << "After shifting the bits 2 positions to the right,\n"
        << "the target bitset b1 becomes: ( "<< b1 << " )."
        << endl;
}
```

```
The target bitset b1 is: ( 11100 ).
After shifting the bits 2 positions to the right,
the target bitset b1 becomes: ( 00111 ).
```

bitset::operator[]

Returns a reference to a bit at a specified position in a bitset if the bitset is modifiable; otherwise, it returns the value of the bit at that position.

```
bool operator[](size_t _Pos) const;
reference operator[](size_t _Pos);
```

Parameters

_Pos

The position locating the bit within the bitset.

Remarks

When you define `_ITERATOR_DEBUG_LEVEL` as 1 or 2 in your build, a runtime error will occur in your executable if you attempt to access an element outside the bounds of the bitset. For more informations, see [Checked Iterators](#).

Example

```
// bitset_op_REF.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;
    bool b;
    bitset<5> b1 ( 6 );
    cout << "The initialized bitset<5> b1( 2 ) is: ( "<< b1 << " )."
         << endl;

    int i;
    for ( i = 0 ; i <= 4 ; i++ )
    {
        b = b1[ i ];
        cout << " The bit in position "
             << i << " is " << b << ".\n";
    }
}
```

bitset::operator^=

Performs a bitwise combination of bitsets with the exclusive **OR** operation.

```
bitset<N>& operator^=(const bitset<N>& right);
```

Parameters

right

The bitset that is to be combined bitwise with the target bitset.

Return Value

The modified target bitset that results from the bitwise exclusive **OR** operation with the bitset specified as a parameter.

Remarks

Two bits combined by the exclusive **OR** operator return **true** if at least one, but not both, of the bits is **true**; otherwise, their combination returns **false**.

Bitsets must be of the same size to be combined bitwise with the exclusive **OR** operator by the member operator function.

Example

```

// bitset_op_bitwiseOR.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;
    bitset<5> b1 ( 7 );
    bitset<5> b2 ( 11 );
    bitset<4> b3 ( 7 );

    cout << "The target bitset b1 is:   ( "<< b1 << " )." << endl;
    cout << "The parameter bitset b2 is: ( "<< b2 << " )." << endl;
    cout << endl;

    b1 ^= b2;
    cout << "After bitwise exclusive OR combination,\n"
        << "the target bitset b1 becomes:   ( "<< b1 << " )."
        << endl;

    // Note that the parameter-specified bitset is unchanged
    cout << "The parameter bitset b2 remains: ( "<< b2 << " )."
        << endl;

    // The following would cause an error because the bitsets
    // must be of the same size to be combined
    // b1 |= b3;
}

```

```

The target bitset b1 is:   ( 00111 ).
The parameter bitset b2 is: ( 01011 ).

After bitwise exclusive OR combination,
the target bitset b1 becomes:   ( 01100 ).
The parameter bitset b2 remains: ( 01011 ).

```

bitset::operator|=

Performs a bitwise combination of bitsets with the inclusive `OR` operation.

```

bitset<N>& operator|=(const bitset<N>& right);

```

Parameters

right

The bitset that is to be combined bitwise with the target bitset.

Return Value

The modified target bitset that results from the bitwise inclusive `OR` operation with the bitset specified as a parameter.

Remarks

Two bits combined by the inclusive `OR` operator return **true** if at least one of the bits is **true**; if both bits are **false**, their combination returns **false**.

Bitsets must be of the same size to be combined bitwise with the inclusive `OR` operator by the member operator function.

Example

```
// bitset_op_BIO.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 7 );
    bitset<5> b2 ( 11 );
    bitset<4> b3 ( 7 );

    cout << "The target bitset b1 is:    ( "<< b1 << " )." << endl;
    cout << "The parameter bitset b2 is: ( "<< b2 << " )." << endl;
    cout << endl;

    b1 |= b2;
    cout << "After bitwise inclusive OR combination,\n"
        << "the target bitset b1 becomes:  ( "<< b1 << " )."
        << endl;

    // Note that the parameter-specified bitset is unchanged
    cout << "The parameter bitset b2 remains: ( "<< b2 << " )."
        << endl;

    // The following would cause an error because the bisets
    // must be of the same size to be combined
    // b1 |= b3;
}
```

```
The target bitset b1 is:    ( 00111 ).
The parameter bitset b2 is: ( 01011 ).

After bitwise inclusive OR combination,
the target bitset b1 becomes:  ( 01111 ).
The parameter bitset b2 remains: ( 01011 ).
```

bitset::operator~

Inverts all the bits in a target bitset and returns the result.

```
bitset<N> operator~() const;
```

Return Value

The bitset with all its bits inverted with respect to the targeted bitset.

Example

```

// bitset_op_invert.cpp
// compile with: /EHsc
#include <iostream>
#include <string>
#include <bitset>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 7 );
    bitset<5> b2;
    b2 = ~b1;

    cout << "Bitset b1 is: ( "<< b1 << " )." << endl;
    cout << "Bitset b2 = ~b1 is: ( "<< b2 << " )." << endl;

    // These bits could also be flipped using the flip member function
    bitset<5> b3;
    b3 = b1.flip( );
    cout << "Bitset b3 = b1.flip( ) is: ( "<< b3 << " )." << endl;
}

```

```

Bitset b1 is: ( 00111 ).
Bitset b2 = ~b1 is: ( 11000 ).
Bitset b3 = b1.flip( ) is: ( 11000 ).

```

bitset::reference

A proxy class that provides references to bits contained in a `bitset` that is used to access and manipulate the individual bits as a helper class for the `operator[]` of class `bitset`.

```

class reference {
    friend class bitset<N>;
public:
    reference& operator=(bool val);
    reference& operator=(const reference& _Bitref);
    bool operator~() const;
    operator bool() const;
    reference& flip();
};

```

Parameters

val

The value of the object of type **bool** to be assigned to a bit in a `bitset`.

_Bitref

A reference of the form `x[i]` to the bit at position *i* in `bitset` *x*.

Return Value

A reference to the bit in the `bitset` specified by the argument position for the first, second, and fifth member functions of class `reference`, and **true** or **false**, to reflect the value of the modified bit in the `bitset` for the third and fourth member functions of class `reference`.

Remarks

The class `reference` exists only as a helper class for the `bitset` `operator[]`. The member class describes an object that can access an individual bit within a `bitset`. Let *b* be an object of type **bool**, *x* and *y* objects of type `bitset< N >`, and *i* and *j* valid positions within such an object. The notation `x[i]` references the bit at position *i* in `bitset` *x*. The

member functions of class `reference` provide, in order, the following operations:

OPERATION	DEFINITION
$x[i] = b$	Stores bool value b at bit position i in bitset x .
$x[i] = y[j]$	Stores the value of the bit $y[j]$ at bit position i in bitset x .
$b = \sim x[i]$	Stores the flipped value of the bit $x[i]$ in bool b .
$b = x[i]$	Stores the value of the bit $x[i]$ in bool b .
$x[i].\text{flip}()$	Stores the flipped value of the bit $x[i]$ back at bit position i in x .

Example

```

// bitset_reference.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 2 );
    bitset<5> b2 ( 6 );
    cout << "The initialized bitset<5> b1( 2 ) is: ( "<< b1 << " )."
        << endl;
    cout << "The initialized bitset<5> b2( 6 ) is: ( "<< b2 << " )."
        << endl;

    // Example of x [i] = b storing bool b at bit position i
    // in bitset x
    b1[ 0 ] = true;
    cout << "The bitset<5> b1 with the bit at position 0 set to 1"
        << "is: ( "<< b1 << " )" << endl;

    // Example of x [i] = y [j] storing the bool value of the
    // bit at position j in bitset y at bit position i in bitset x
    b2 [4] = b1 [0];      // b1 [0] = true
    cout << "The bitset<5> b2 with the bit at position 4 set to the "
        << "value\nof the bit at position 0 of the bit in "
        << "bitset<5> b1 is: ( "<< b2 << " )" << endl;

    // Example of b = ~x [i] flipping the value of the bit at
    // position i of bitset x and storing the value in an
    // object b of type bool
    bool b = ~b2 [4];      // b2 [4] = false
    if ( b )
        cout << "The value of the object b = ~b2 [4] "
            << "of type bool is true." << endl;
    else
        cout << "The value of the object b = ~b2 [4] "
            << "of type bool is false." << endl;

    // Example of b = x [i] storing the value of the bit at
    // position i of bitset x in the object b of type bool
    b = b2 [4];
    if ( b )
        cout << "The value of the object b = b2 [4] "
            << "of type bool is true." << endl;
    else
        cout << "The value of the object b = b2 [4] "
            << "of type bool is false." << endl;

    // Example of x [i] . flip ( ) toggling the value of the bit at
    // position i of bitset x
    cout << "Before flipping the value of the bit at position 4 in "
        << "bitset b2,\nit is ( "<< b2 << " )." << endl;
    b2 [4].flip( );
    cout << "After flipping the value of the bit at position 4 in "
        << "bitset b2,\nit becomes ( "<< b2 << " )." << endl;
    bool c;
    c = b2 [4].flip( );
    cout << "After a second flip, the value of the position 4 "
        << "bit in b2 is now: " << c << ".";
}

```

The initialized bitset<5> b1(2) is: (00010).
The initialized bitset<5> b2(6) is: (00110).
The bitset<5> b1 with the bit at position 0 set to 1 is: (00011)
The bitset<5> b2 with the bit at position 4 set to the value
of the bit at position 0 of the bit in bitset<5> b1 is: (10110)
The value of the object b = ~b2 [4] of type bool is false.
The value of the object b = b2 [4] of type bool is true.
Before flipping the value of the bit at position 4 in bitset b2,
it is (10110).
After flipping the value of the bit at position 4 in bitset b2,
it becomes (00110).
After a second flip, the value of the position 4 bit in b2 is now: 1.

bitset::reset

Resets all the bits in a bitset to 0 or resets a bit at a specified position to 0.

```
bitset<N>& reset();  
bitset<N>& reset(size_t _Pos);
```

Parameters

_Pos

The position of the bit in the bitset to be reset to 0.

Return Value

A copy of the bitset for which the member function was invoked.

Remarks

The second member function throws an [out_of_range](#) exception if the position specified is greater than the size of the bitset.

Example

```
// bitset_reset.cpp  
// compile with: /EHsc  
#include <bitset>  
#include <iostream>  
  
int main( )  
{  
    using namespace std;  
  
    bitset<5> b1 ( 13 );  
    cout << "The set of bits in bitset<5> b1(13) is: ( "<< b1 << " )"  
        << endl;  
  
    bitset<5> b1r3;  
    b1r3 = b1.reset( 2 );  
    cout << "The collection of bits obtained from resetting the\n"  
        << "third bit of bitset b1 is: ( "<< b1r3 << " )"  
        << endl;  
  
    bitset<5> b1r;  
    b1r = b1.reset( );  
    cout << "The collection of bits obtained from resetting all\n"  
        << "the elements of the bitset b1 is: ( "<< b1r << " )"  
        << endl;  
}
```

```
The set of bits in bitset<5> b1(13) is: ( 01101 )
The collection of bits obtained from resetting the
third bit of bitset b1 is: ( 01001 )
The collection of bits obtained from resetting all
the elements of the bitset b1 is: ( 00000 )
```

bitset::set

Sets all the bits in a bitset to 1 or sets a bit at a specified position to 1.

```
bitset<N>& set();

bitset<N>& set(
    size_t _Pos,
    bool val = true);
```

Parameters

_Pos

The position of the bit in the bitset to be set to assigned a value.

val

The value to be assigned to the bit at the position specified.

Return Value

A copy of the bitset for which the member function was invoked.

Remarks

The second member function throws an [out_of_range](#) exception if the position specified is greater than the size of the bitset.

Example

```
// bitset_set.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 6 );
    cout << "The set of bits in bitset<5> b1(6) is: ( "<< b1 << " )"
         << endl;

    bitset<5> b1s0;
    b1s0 = b1.set( 0 );
    cout << "The collection of bits obtained from setting the\n"
         << "zeroth bit of bitset b1 is: ( "<< b1s0 << " )"
         << endl;

    bitset<5> bs1;
    bs1 = b1.set( );
    cout << "The collection of bits obtained from setting all the\n"
         << "elements of the bitset b1 is: ( "<< bs1 << " )"
         << endl;
}
```

```
The set of bits in bitset<5> b1(6) is: ( 00110 )
The collection of bits obtained from setting the
zeroth bit of bitset b1 is: ( 00111 )
The collection of bits obtained from setting all the
elements of the bitset b1 is: ( 11111 )
```

bitset::size

Returns the number of bits in a bitset object.

```
size_t size() const;
```

Return Value

The number of bits, N , in a bitset< N >.

Example

The following example demonstrates the use of the bitset::size member function.

```
// bitset_size.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main()
{
    using namespace std;

    bitset<5> b1(6);
    size_t i;

    cout << "The set of bits in bitset<5> b1( 6 ) is: ( "<< b1 << " )"
         << endl;

    i = b1.size();

    cout << "The number of bits in bitset b1 is: " << i << "."
         << endl;
}
```

```
The set of bits in bitset<5> b1( 6 ) is: ( 00110 )
The number of bits in bitset b1 is: 5.
```

bitset::test

Tests whether the bit at a specified position in a bitset is set to 1.

```
bool test(size_t _Pos) const;
```

Parameters

_Pos

The position of the bit in the bitset to be tested for its value.

Return Value

true if the bit specified by the argument position is set to 1; otherwise, **false**.

Remarks

The member function throws an [out_of_range](#)

bitset::to_string

Converts a bitset object to a string representation.

```
template <class charT = char, class traits = char_traits<charT>, class Allocator = allocator<charT> >
    basic_string<charT, traits, Allocator> to_string(charT zero = charT{'0'}, charT one = charT{'1'}) const;
```

Return value

A string object of class `basic_string`, where each bit set in the bitset has a corresponding character of 1, and a character of 0 if the bit is unset.

Example

```
// bitset_to_string.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 7 );

    cout << "The ordered set of bits in the bitset<5> b1( 7 )"
         << "\n  that was generated by the number 7 is: ( "
         << b1 << " )" << endl;

    string s1;
    s1 = b1.template to_string<char,
char_traits<char>, allocator<char> >( );
    cout << "The string returned from the bitset b1"
         << "\n  by the member function to_string( ) is: "
         << s1 << "." << endl;
}
```

```
The ordered set of bits in the bitset<5> b1( 7 )
  that was generated by the number 7 is: ( 00111 )
The string returned from the bitset b1
  by the member function to_string( ) is: 00111.
```

bitset::to_ullong

Returns an **unsigned long long** value that contains the same bits set as the contents of the bitset object.

```
unsigned long long to_ullong() const;
```

Return value

Returns the sum of the bit values that are in the bit sequence as an **unsigned long long**. This **unsigned long long** value would re-create the same set bits if it is used to initialize a bitset.

Exceptions

Throws an [overflow_error](#) object if any bit in the bit sequence has a bit value that cannot be represented as a value of type **unsigned long long**.

Remarks

Returns the sum of the bit values that are in the bit sequence as an **unsigned long long**.

bitset::to_ulong

Converts a bitset object to the integer that would generate the sequence of bits contained if used to initialize the bitset.

```
unsigned long to_ulong( ) const;
```

Return value

An integer that would generate the bits in a bitset if used in the initialization of the bitset.

Remarks

Applying the member function would return the integer that has the same sequence of 1 and 0 digits as is found in sequence of bits contained in the bitset.

The member function throws an [overflow_error](#) object if any bit in the bit sequence has a bit value that cannot be represented as a value of type **unsigned long**.

Example

```
// bitset_to_ulong.cpp
// compile with: /EHsc
#include <bitset>
#include <iostream>

int main( )
{
    using namespace std;

    bitset<5> b1 ( 7 );

    cout << "The ordered set of bits in the bitset<5> b1( 7 )"
         << "\n  that was generated by the number 7 is: ( "
         << b1 << " )" << endl;

    unsigned long int i;
    i = b1.to_ulong( );
    cout << "The integer returned from the bitset b1,"
         << "\n  by the member function to_ulong( ), that"
         << "\n  generated the bits as a base two number is: "
         << i << "." << endl;
}
```

```
The ordered set of bits in the bitset<5> b1( 7 )
  that was generated by the number 7 is: ( 00111 )
The integer returned from the bitset b1,
  by the member function to_ulong( ), that
  generated the bits as a base two number is: 7.
```

<chrono>

5/7/2019 • 3 minutes to read • [Edit Online](#)

Include the standard header <chrono> to define classes and functions that represent and manipulate time durations and time instants.

Beginning in Visual Studio 2015, the implementation of `steady_clock` has changed to meet the C++ Standard requirements for steadiness and monotonicity. `steady_clock` is now based on `QueryPerformanceCounter()` and `high_resolution_clock` is now a typedef for `steady_clock`. As a result, in the Microsoft C++ compiler `steady_clock::time_point` is now a typedef for `chrono::time_point<steady_clock>`; however, this is not necessarily the case for other implementations.

Syntax

```
#include <chrono>
```

Classes

NAME	DESCRIPTION
duration Class	Describes a type that holds a time interval.
time_point Class	Describes a type that represents a point in time.

Structs

NAME	DESCRIPTION
common_type Structure	Describes specializations of template class common_type for instantiations of <code>duration</code> and <code>time_point</code> .
duration_values Structure	Provides specific values for the <code>duration</code> template parameter <code>Rep</code> .
steady_clock struct	Represents a <code>steady</code> clock.
system_clock Structure	Represents a <i>clock type</i> that is based on the real-time clock of the system.
treat_as_floating_point Structure	Specifies whether a type can be treated as a floating-point type.

Functions

NAME	DESCRIPTION
duration_cast	Casts a <code>duration</code> object to a specified type.
time_point_cast	Casts a <code>time_point</code> object to a specified type.

Operators

NAME	DESCRIPTION
<code>operator-</code>	Operator for subtraction or negation of <code>duration</code> and <code>time_point</code> objects.
<code>operator!=</code>	Inequality operator that is used with <code>duration</code> or <code>time_point</code> objects.
<code>operator modulo</code>	Operator for modulo operations on <code>duration</code> objects.
<code>operator*</code>	Multiplication operator for <code>duration</code> objects.
<code>operator/</code>	Division operator for <code>duration</code> objects.
<code>operator+</code>	Adds <code>duration</code> and <code>time_point</code> objects.
<code>operator<</code>	Determines whether one <code>duration</code> or <code>time_point</code> object is less than another <code>duration</code> or <code>time_point</code> object.
<code>operator<=</code>	Determines whether one <code>duration</code> or <code>time_point</code> object is less than or equal to another <code>duration</code> or <code>time_point</code> object.
<code>operator==</code>	Determines whether two <code>duration</code> objects represent time intervals that have the same length, or whether two <code>time_point</code> objects represent the same point in time.
<code>operator></code>	Determines whether one <code>duration</code> or <code>time_point</code> object is greater than another <code>duration</code> or <code>time_point</code> object.
<code>operator>=</code>	Determines whether one <code>duration</code> or <code>time_point</code> object is greater than or equal to another <code>duration</code> or <code>time_point</code> object.

Predefined Duration Types

For more information about ratio types that are used in the following typedefs, see [<ratio>](#).

TYPEDEF	DESCRIPTION
<code>typedef duration<long long, nano> nanoseconds;</code>	Synonym for a <code>duration</code> type that has a tick period of one nanosecond.
<code>typedef duration<long long, micro> microseconds;</code>	Synonym for a <code>duration</code> type that has a tick period of one microsecond.
<code>typedef duration<long long, milli> milliseconds;</code>	Synonym for a <code>duration</code> type that has a tick period of one millisecond.
<code>typedef duration<long long> seconds;</code>	Synonym for a <code>duration</code> type that has a tick period of one second.

TYPEDEF	DESCRIPTION
<code>typedef duration<int, ratio<60> > minutes;</code>	Synonym for a <code>duration</code> type that has a tick period of one minute.
<code>typedef duration<int, ratio<3600> > hours;</code>	Synonym for a <code>duration</code> type that has a tick period of one hour.

Literals

(C++11) The `<chrono>` header defines the following [user-defined literals](#) that you can use for greater convenience, type-safety and maintainability of your code. These literals are defined in the `literals::chrono_literals` inline namespace and are in scope when `std::chrono` is in scope.

LITERAL	DESCRIPTION
<code>chrono::hours operator "" h(unsigned long long Val)</code>	Specifies hours as an integral value.
<code>chrono::duration<double, ratio<3600> > operator "" h(long double Val)</code>	Specifies hours as a floating-point value.
<code>chrono::minutes (operator "" min)(unsigned long long Val)</code>	Specifies minutes as an integral value.
<code>chrono::duration<double, ratio<60> > (operator "" min)(long double Val)</code>	Specifies minutes as a floating-point value.
<code>chrono::seconds operator "" s(unsigned long long Val)</code>	Specifies minutes as an integral value.
<code>chrono::duration<double> operator "" s(long double Val)</code>	Specifies seconds as a floating-point value.
<code>chrono::milliseconds operator "" ms(unsigned long long Val)</code>	Specifies milliseconds as an integral value.
<code>chrono::duration<double, milli> operator "" ms(long double Val)</code>	Specifies milliseconds as a floating-point value.
<code>chrono::microseconds operator "" us(unsigned long long Val)</code>	Specifies microseconds as an integral value.
<code>chrono::duration<double, micro> operator "" us(long double Val)</code>	Specifies microseconds as a floating-point value.
<code>chrono::nanoseconds operator "" ns(unsigned long long Val)</code>	Specifies nanoseconds as an integral value.
<code>chrono::duration<double, nano> operator "" ns(long double Val)</code>	Specifies nanoseconds as a floating-point value.

The following examples show how to use the chrono literals.

```
constexpr auto day = 24h;
constexpr auto week = 24h* 7;
constexpr auto my_duration_unit = 108ms;
```

Remarks

[Header Files Reference](#)

<chrono> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

[duration_cast](#)

[time_point_cast](#)

duration_cast

Casts a `duration` object to a specified type.

```
template <class To, class Rep, class Period>
constexpr To duration_cast(const duration<Rep, Period>& Dur);
```

Return Value

A `duration` object of type `To` that represents the time interval `Dur`, which is truncated if it has to fit into the target type.

Remarks

If `To` is an instantiation of `duration`, this function does not participate in overload resolution.

time_point_cast

Casts a `time_point` object to a specified type.

```
template <class To, class Clock, class Duration>
time_point<Clock, To> time_point_cast(const time_point<Clock, Duration>& Tp);
```

Return Value

A `time_point` object that has a duration of type `To`.

Remarks

Unless `To` is an instantiation of `duration`, this function does not participate in overload resolution.

[<chrono>](#)

<chrono> operators

10/31/2018 • 6 minutes to read • [Edit Online](#)

operator modulo	operator!=	operator>
operator>=	operator<	operator<=
operator*	operator+	operator-
operator/	operator==	

operator-

Operator for subtraction or negation of [duration](#) and [time_point](#) objects.

```
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr typename common_type<duration<Rep1, Period1>, duration<Rep2, Period2>>::type
operator-(
    const duration<Rep1, Period1>& Left,
    cconst duration<Rep2, Period2>& Right);

template <class Clock, class Duration1, class Rep2, class Period2>
constexpr time_point<Clock, typename common_type<Duration1, duration<Rep2, Period2>>::type>
operator-(
    const time_point<Clock, Duration1>& Time,
    const duration<Rep2, Period2>& Dur);

template <class Clock, class Duration1, class Duration2>
constexpr typename common_type<Duration1, Duration2>::type
operator-(
    const time_point<Clock, Duration1>& Left,
    const time_point<Clock, Duration2>& Right);
```

Parameters

Left

The left `duration` or `time_point` object.

Right

The right `duration` or `time_point` object.

Time

A `time_point` object.

Dur

A `duration` object.

Return Value

The first function returns a `duration` object whose interval length is the difference between the time intervals of the two arguments.

The second function returns a `time_point` object that represents a point in time that is displaced, by the negation of the time interval that is represented by *Dur*, from the point in time that is specified by *Time*.

The third function returns a `duration` object that represents the time interval between *Left* and *Right*.

operator!=

Inequality operator for `duration` or `time_point` objects.

```
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator!=(
    const duration<Rep1, Period1>& Left,
    const duration<Rep2, Period2>& Right);

template <class Clock, class Duration1, class Duration2>
constexpr bool operator!=(
    const time_point<Clock, Duration1>& Left,
    const time_point<Clock, Duration2>& Right);
```

Parameters

Left

The left `duration` or `time_point` object.

Right

The right `duration` or `time_point` object.

Return Value

Each function returns `!(Left == Right)`.

operator*

Multiplication operator for `duration` objects.

```
template <class Rep1, class Period1, class Rep2>
constexpr duration<typename common_type<Rep1, Rep2>::type, Period1>
operator*(
    const duration<Rep1, Period1>& Dur,
    const Rep2& Mult);

template <class Rep1, class Rep2, class Period2>
constexpr duration<typename common_type<Rep1, Rep2>::type, Period2>
operator*(
    const Rep1& Mult,
    const duration<Rep2,
    Period2>& Dur);
```

Parameters

Dur

A `duration` object.

Mult

An integral value.

Return Value

Each function returns a `duration` object whose interval length is *Mult* multiplied by the length of *Dur*.

Unless `is_convertible<Rep2, common_type<Rep1, Rep2>>` holds true, the first function does not participate in overload resolution. For more information, see [<type_traits>](#).

Unless `is_convertible<Rep1, common_type<Rep1, Rep2>>` holds true, the second function does not participate in

overload resolution. For more information, see [<type_traits>](#).

operator/

Division operator for [duration](#) objects.

```
template <class Rep1, class Period1, class Rep2>
constexpr duration<typename common_type<Rep1, Rep2>::type, Period1>
operator/(
    const duration<Rep1, Period1>& Dur,
    const Rep2& Div);

template <class Rep1, class Period1, class Rep2, class Period2>
constexpr typename common_type<Rep1, Rep2>::type
operator/(
    const duration<Rep1, Period1>& Left,
    const duration<Rep2, Period2>& Right);
```

Parameters

Dur

A `duration` object.

Div

An integral value.

Left

The left `duration` object.

Right

The right `duration` object.

Return Value

The first operator returns a duration object whose interval length is the length of *Dur* divided by the value *Div*.

The second operator returns the ratio of the interval lengths of *Left* and *Right*.

Unless `is_convertible<Rep2, common_type<Rep1, Rep2>>` *holds true*, and `Rep2` is not an instantiation of `duration`, the first operator does not participate in overload resolution. For more information, see [<type_traits>](#).

operator+

Adds [duration](#) and [time_point](#) objects.

```

template <class Rep1, class Period1, class Rep2, class Period2>
constexpr typename common_type<duration<Rep1, Period1>, duration<Rep2, Period2>>::type
operator+(
    const duration<Rep1, Period1>& Left,
    const duration<Rep2, Period2>& Right);

template <class Clock, class Duration1, class Rep2, class Period2>
constexpr time_point<Clock, typename common_type<Duration1, duration<Rep2, Period2>>::type>
operator+(
    const time_point<Clock, Duration1>& Time,
    const duration<Rep2, Period2>& Dur);

template <class Rep1, class Period1, class Clock, class Duration2>
time_point<Clock, constexpr typename common_type<duration<Rep1, Period1>, Duration2>::type>
operator+(
    const duration<Rep1, Period1>& Dur,
    const time_point<Clock, Duration2>& Time);

```

Parameters

Left

The left `duration` or `time_point` object.

Right

The right `duration` or `time_point` object.

Time

A `time_point` object.

Dur

A `duration` object.

Return Value

The first function returns a `duration` object that has a time interval that is equal to the sum of the intervals of *Left* and *Right*.

The second and third functions return a `time_point` object that represents a point in time that is displaced, by the interval *Dur*, from the point in time *Time*.

operator<

Determines whether one `duration` or `time_point` object is less than another `duration` or `time_point` object.

```

template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<(
    const duration<Rep1, Period1>& Left,
    const duration<Rep2, Period2>& Right);

template <class Clock, class Duration1, class Duration2>
constexpr bool operator<(
    const time_point<Clock, Duration1>& Left,
    const time_point<Clock, Duration2>& Right);

```

Parameters

Left

The left `duration` or `time_point` object.

Right

The right `duration` or `time_point` object.

Return Value

The first function returns **true** if the interval length of *Left* is less than the interval length of *Right*. Otherwise, the function returns **false**.

The second function returns **true** if *Left* precedes *Right*. Otherwise, the function returns **false**.

operator<=

Determines whether one `duration` or `time_point` object is less than or equal to another `duration` or `time_point` object.

```
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<=(
    const duration<Rep1, Period1>& Left,
    const duration<Rep2, Period2>& Right);

template <class Clock, class Duration1, class Duration2>
constexpr bool operator<=(
    const time_point<Clock, Duration1>& Left,
    const time_point<Clock, Duration2>& Right);
```

Parameters

Left

The left `duration` or `time_point` object.

Right

The right `duration` or `time_point` object.

Return Value

Each function returns `!(Right < Left)`.

operator==

Determines whether two `duration` objects represent time intervals that have the same length, or whether two `time_point` objects represent the same point in time.

```
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator==(
    const duration<Rep1, Period1>& Left,
    const duration<Rep2, Period2>& Right);

template <class Clock, class Duration1, class Duration2>
constexpr bool operator==(
    const time_point<Clock, Duration1>& Left,
    const time_point<Clock, Duration2>& Right);
```

Parameters

Left

The left `duration` or `time_point` object.

Right

The right `duration` or `time_point` object.

Return Value

The first function returns **true** if *Left* and *Right* represent time intervals that have the same length. Otherwise, the function returns **false**.

The second function returns **true** if *Left* and *Right* represent the same point in time. Otherwise, the function returns **false**.

operator>

Determines whether one [duration](#) or [time_point](#) object is greater than another `duration` or `time_point` object.

```
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>(  
    const duration<Rep1, Period1>& Left,  
    const duration<Rep2, Period2>& Right);  
  
template <class Clock, class Duration1, class Duration2>  
constexpr bool operator>(  
    const time_point<Clock, Duration1>& Left,  
    const time_point<Clock, Duration2>& Right);
```

Parameters

Left

The left `duration` or `time_point` object.

Right

The right `duration` or `time_point` object.

Return Value

Each function returns `Right < Left`.

operator>=

Determines whether one [duration](#) or [time_point](#) object is greater than or equal to another `duration` or `time_point` object.

```
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>=(  
    const duration<Rep1, Period1>& Left,  
    const duration<Rep2, Period2>& Right);  
  
template <class Clock, class Duration1, class Duration2>  
constexpr bool operator>=(  
    const time_point<Clock, Duration1>& Left,  
    const time_point<Clock, Duration2>& Right);
```

Parameters

Left

The left `duration` or `time_point` object.

Right

The right `duration` or `time_point` object.

Return Value

Each function returns `!(Left < Right)`.

operator modulo

Operator for modulo operations on [duration](#) objects.

```

template <class Rep1, class Period1, class Rep2>
constexpr duration<Rep1, Period1, Rep2>::type
operator%(
    const duration<Rep1, Period1>& Dur,
    const Rep2& Div);

template <class Rep1, class Period1, class Rep2, class Period2>
constexpr typename common_type<duration<Rep1, _Period1>, duration<Rep2, Period2>>::type
operator%(
    const duration<Rep1, Period1>& Left,
    const duration<Rep2, Period2>& Right);

```

Parameters

Dur

A `duration` object.

Div

An integral value.

Left

The left `duration` object.

Right

The right `duration` object.

Return Value

The first function returns a `duration` object whose interval length is *Dur* modulo *Div*.

The second function returns a value that represents *Left* modulo *Right*.

[<chrono>](#)

chrono literals

10/31/2018 • 2 minutes to read • [Edit Online](#)

(C++14) The `<chrono>` header defines 12 [user-defined literals](#) to facilitate using literals that represent hours, minutes, seconds, milliseconds, microseconds, and nanoseconds. Each user-defined literal has an integral and a floating-point overload. The literals are defined in the `literals::chrono_literals` inline namespace which is brought into scope automatically when `std::chrono` is in scope.

Syntax

```
inline namespace literals {
    inline namespace chrono_literals {
        // return integral hours
        constexpr chrono::hours operator"" h(unsigned long long Val);

        // return floating-point hours
        constexpr chrono::duration<double, ratio<3600>> operator"" h(long double Val);

        // return integral minutes
        constexpr chrono::minutes(operator"" min)(unsigned long long Val);

        // return floating-point minutes
        constexpr chrono::duration<double, ratio<60>>(operator"" min)(long double Val);

        // return integral seconds
        constexpr chrono::seconds operator"" s(unsigned long long Val);

        // return floating-point seconds
        constexpr chrono::duration<double> operator"" s(long double Val);

        // return integral milliseconds
        constexpr chrono::milliseconds operator"" ms(unsigned long long Val);

        // return floating-point milliseconds
        constexpr chrono::duration<double, milli> operator"" ms(long double Val);

        // return integral microseconds
        constexpr chrono::microseconds operator"" us(unsigned long long Val);

        // return floating-point microseconds
        inline constexpr chrono::duration<double, micro> operator"" us(long double Val);

        // return integral nanoseconds
        inline constexpr chrono::nanoseconds operator"" ns(unsigned long long Val);

        // return floating-point nanoseconds
        constexpr chrono::duration<double, nano> operator"" ns(long double Val);

    } // inline namespace chrono_literals
} // inline namespace literals
```

Return Value

The literals that take a **long long** argument return a value of the corresponding type. The literals that take a floating point argument return a [duration](#).

Example

The following examples show how to use the chrono literals.

```
constexpr auto day = 24h;  
constexpr auto week = 24h* 7;  
constexpr auto my_duration_unit = 108ms;
```

Requirements

Header: <chrono>

Namespace: std::literals::chrono_literals

See also

[<chrono>](#)

common_type Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes specializations of template class [common_type](#) for instantiations of [duration](#) and [time_point](#).

Syntax

```
template <class Rep1, class Period1,
          class Rep2, class Period2>
struct common_type
<chrono::duration<Rep1, Period1>,
 chrono::duration<Rep2, Period2>>;

template <class Clock,
          class Duration1, class Duration2>
struct common_type
<chrono::time_point<Clock, Duration1>,
 chrono::time_point<Clock, Duration2>>;
```

Requirements

Header: <chrono>

Namespace: std

See also

[Header Files Reference](#)

[<chrono>](#)

duration Class

3/28/2019 • 5 minutes to read • [Edit Online](#)

Describes a type that holds a *time interval*, which is an elapsed time between two time points.

Syntax

```
template <class Rep, class Period = ratio<1>>
class duration;
template <class Rep, class Period>
class duration;
template <class Rep, class Period1, class Period2>
class duration <duration<Rep, Period1>, Period2>;
```

Remarks

The template argument `Rep` describes the type that is used to hold the number of clock ticks in the interval. The template argument `Period` is an instantiation of `ratio` that describes the size of the interval that each tick represents.

Members

Public Typedefs

NAME	DESCRIPTION
<code>duration::period</code> Typedef	Represents a synonym for the template parameter <code>Period</code> .
<code>duration::rep</code> Typedef	Represents a synonym for the template parameter <code>Rep</code> .

Public Constructors

NAME	DESCRIPTION
<code>duration</code>	Constructs a <code>duration</code> object.

Public Methods

NAME	DESCRIPTION
<code>count</code>	Returns the number of clock ticks in the time interval.
<code>max</code>	Static. Returns the maximum allowable value of template parameter <code>Rep</code> .
<code>min</code>	Static. Returns the lowest allowable value of template parameter <code>Rep</code> .
<code>zero</code>	Static. In effect, returns <code>Rep(0)</code> .

NAME	DESCRIPTION
------	-------------

Public Operators

NAME	DESCRIPTION
<code>duration::operator-</code>	Returns a copy of the <code>duration</code> object together with a negated tick count.
<code>duration::operator--</code>	Decrements the stored tick count.
<code>duration::operator=</code>	Reduces the stored tick count modulo a specified value.
<code>duration::operator* =</code>	Multiplies the stored tick count by a specified value.
<code>duration::operator/=</code>	Divides the stored tick count by the tick count of a specified <code>duration</code> object.
<code>duration::operator+</code>	Returns <code>*this</code> .
<code>duration::operator++</code>	Increments the stored tick count.
<code>duration::operator+=</code>	Adds the tick count of a specified <code>duration</code> object to the stored tick count.
<code>duration::operator-=</code>	Subtracts the tick count of a specified <code>duration</code> object from the stored tick count.

Requirements

Header: <chrono>

Namespace: std::chrono

duration::count

Retrieves the number of clock ticks in the time interval.

```
constexpr Rep count() const;
```

Return Value

The number of clock ticks in the time interval.

duration::duration Constructor

Constructs a `duration` object.

```
constexpr duration() = default;

template <class Rep2>
constexpr explicit duration(const Rep2& R);

template <class Rep2, class Period2>
constexpr duration(const duration<Rep2, Period2>& Dur);
```

Parameters

Rep2

An arithmetic type to represent the number of ticks.

Period2

A `std::ratio` template specialization to represent the tick period in units of seconds.

R

The number of ticks of default period.

Dur

The number of ticks of period specified by *Period2*.

Remarks

The default constructor constructs an object that is uninitialized. Value initialization by using empty braces initializes an object that represents a time interval of zero clock ticks.

The second, one template argument constructor constructs an object that represents a time interval of *R* clock ticks using a default period of `std::ratio<1>`. To avoid round-off of tick counts, it is an error to construct a duration object from a representation type *Rep2* that can be treated as a floating-point type when `duration::rep` cannot be treated as a floating-point type.

The third, two template argument constructor constructs an object that represents a time interval whose length is the time interval that is specified by *Dur*. To avoid truncation of tick counts, it is an error to construct a duration object from another duration object whose type is *incommensurable* with the target type.

A duration type `D1` is *incommensurable* with another duration type `D2` if `D2` cannot be treated as a floating-point type and `ratio_divide<D1::period, D2::period>::type::den` is not 1.

Unless *Rep2* is implicitly convertible to `rep` and either `treat_as_floating_point<rep>` *holds true* or `treat_as_floating_point<Rep2>` *holds false*, the second constructor does not participate in overload resolution. For more information, see [<type_traits>](#).

Unless no overflow is induced in the conversion and `treat_as_floating_point<rep>` *holds true*, or both `ratio_divide<Period2, period>::den` equals 1 and `treat_as_floating_point<Rep2>` *holds false*, the third constructor does not participate in overload resolution. For more information, see [<type_traits>](#).

duration::max

Static method that returns the upper bound for values of template parameter type `Ref`.

```
static constexpr duration max();
```

Return Value

In effect, returns `duration(duration_values<rep>::max())`.

duration::min

Static method that returns the lower bound for values of template parameter type `Rep`.

```
static constexpr duration min();
```

Return Value

In effect, returns `duration(duration_values<rep>::min())`.

duration::operator-

Returns a copy of the `duration` object together with a negated tick count.

```
constexpr duration operator-() const;
```

duration::operator--

Decrements the stored tick count.

```
duration& operator--();  
  
duration operator--(int);
```

Return Value

The first method returns `*this`.

The second method returns a copy of `*this` that is made before the decrement.

duration::operator=

Reduces the stored tick count modulo a specified value.

```
duration& operator%=(const rep& Div);  
  
duration& operator%=(const duration& Div);
```

Parameters

Div

For the first method, *Div* represents a tick count. For the second method, *Div* is a `duration` object that contains a tick count.

Return Value

The `duration` object after the modulo operation is performed.

duration::operator*=

Multiplies the stored tick count by a specified value.

```
duration& operator*=(const rep& Mult);
```

Parameters

Mult

A value of the type that is specified by `duration::rep`.

Return Value

The `duration` object after the multiplication is performed.

`duration::operator/=`

Divides the stored tick count by a specified value.

```
duration& operator/=(const rep& Div);
```

Parameters

Div

A value of the type that is specified by `duration::rep`.

Return Value

The `duration` object after the division is performed.

`duration::operator+`

Returns `*this`.

```
constexpr duration operator+() const;
```

`duration::operator++`

Increments the stored tick count.

```
duration& operator++();  
  
duration operator++(int);
```

Return Value

The first method returns `*this`.

The second method returns a copy of `*this` that is made before the increment.

`duration::operator+=`

Adds the tick count of a specified `duration` object to the stored tick count.

```
duration& operator+=(const duration& Dur);
```

Parameters

Dur

A `duration` object.

Return Value

The `duration` object after the addition is performed.

`duration::operator-=`

Subtracts the tick count of a specified `duration` object from the stored tick count.

```
duration& operator-=(const duration& Dur);
```

Parameters

Dur

A `duration` object.

Return Value

The `duration` object after the subtraction is performed.

duration::zero

Returns `duration(duration_values<rep>::zero())`.

```
static constexpr duration zero();
```

duration::operator mod=

Reduces the stored tick count modulo `Div` or `Div.count()`.

```
duration& operator%=(const rep& Div);duration& operator%=(const duration& Div);
```

Parameters

Div

The divisor, which is either a duration object or a value that represents tick counts.

Remarks

The first member function reduces the stored tick count modulo `Div` and returns `*this`. The second member function reduces the stored tick count modulo `Div.count()` and returns `*this`.

[duration_values Structure](#)

duration_values Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

Provides specific values for the [duration](#) template parameter `Rep`.

Syntax

```
template <class Rep>
struct duration_values;
```

Members

Public Methods

NAME	DESCRIPTION
max	Static. Specifies the upper limit for a value of type <code>Rep</code> .
min	Static. Specifies the lower limit for a value of type <code>Rep</code> .
zero	Static. Returns <code>Rep(0)</code> .

Requirements

Header: `<chrono>`

Namespace: `std::chrono`

duration_values::max

Static method that returns the upper bound for values of type `Ref`.

```
static constexpr Rep max();
```

Return Value

In effect, returns `numeric_limits<Rep>::max()`.

Remarks

When `Rep` is a user-defined type, the return value must be greater than [duration_values::zero](#).

duration_values::min

Static method that returns the lower bound for values of type `Ref`.

```
static constexpr Rep min();
```

Return Value

In effect, returns `numeric_limits<Rep>::lowest()` .

Remarks

When `Rep` is a user-defined type, the return value must be less than or equal to [duration_values::zero](#).

duration_values::zero

Returns `Rep(0)` .

```
static constexpr Rep zero();
```

Remarks

When `Rep` is a user-defined type, the return value must represent the additive infinity.

[<chrono>](#)

steady_clock struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a *steady* clock.

Syntax

```
struct steady_clock;
```

Remarks

On Windows, `steady_clock` wraps the `QueryPerformanceCounter` function.

A clock is *monotonic* if the value that is returned by a first call to `now` is always less than or equal to the value that is returned by a subsequent call to `now`. A clock is *steady* if it is *monotonic* and if the time between clock ticks is constant.

`high_resolution_clock` is a typedef for `steady_clock`.

Public typedefs

NAME	DESCRIPTION
<code>steady_clock::duration</code>	A synonym for <code>nanoseconds</code> , defined in <code><chrono></code> .
<code>steady_clock::period</code>	A synonym for <code>nano</code> , defined in <code><ratio></code> .
<code>steady_clock::rep</code>	A synonym for long long , the type that is used to represent the number of clock ticks in the contained instantiation of <code>duration</code> .
<code>steady_clock::time_point</code>	A synonym for <code>chrono::time_point<steady_clock></code> .

Public functions

FUNCTION	DESCRIPTION
<code>now</code>	Returns the current time as a <code>time_point</code> value.

Public constants

NAME	DESCRIPTION
<code>steady_clock::is_steady</code>	Holds true . A <code>steady_clock</code> is <i>steady</i> .

Requirements

Header: `<chrono>`

Namespace: `std::chrono`

- [system_clock Structure](#)

system_clock Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a *clock type* that is based on the real-time clock of the system.

Syntax

```
struct system_clock;
```

Remarks

A *clock type* is used to obtain the current time as UTC. The type embodies an instantiation of [duration](#) and the class template [time_point](#), and defines a static member function `now()` that returns the time.

A clock is *monotonic* if the value that is returned by a first call to `now()` is always less than or equal to the value that is returned by a subsequent call to `now()`.

A clock is *steady* if it is *monotonic* and if the time between clock ticks is constant.

Members

Public Typedefs

NAME	DESCRIPTION
<code>system_clock::duration</code>	A synonym for <code>duration<rep, period></code> .
<code>system_clock::period</code>	A synonym for the type that is used to represent the tick period in the contained instantiation of <code>duration</code> .
<code>system_clock::rep</code>	A synonym for the type that is used to represent the number of clock ticks in the contained instantiation of <code>duration</code> .
<code>system_clock::time_point</code>	A synonym for <code>time_point<Clock, duration></code> , where <code>Clock</code> is a synonym for either the clock type itself or another clock type that is based on the same epoch and has the same nested <code>duration</code> type.

Public Methods

NAME	DESCRIPTION
<code>from_time_t</code>	Static. Returns a <code>time_point</code> that most closely approximates a specified time.
<code>now</code>	Static. Returns the current time.
<code>to_time_t</code>	Static. Returns a <code>time_t</code> object that most closely approximates a specified <code>time_point</code> .

Public Constants

NAME	DESCRIPTION
system_clock::is_monotonic Constant	Specifies whether the clock type is monotonic.
system_clock::is_steady Constant	Specifies whether the clock type is steady.

Requirements

Header: <chrono>

Namespace: std::chrono

system_clock::from_time_t

Static method that returns a [time_point](#) that most closely approximates the time that is represented by *Tm*.

```
static time_point from_time_t(time_t Tm) noexcept;
```

Parameters

Tm

A [time_t](#) object.

system_clock::is_monotonic Constant

Static value that specifies whether the clock type is monotonic.

```
static const bool is_monotonic = false;
```

Return Value

In this implementation, `system_clock::is_monotonic` always returns **false**.

Remarks

A clock is *monotonic* if the value that is returned by a first call to `now()` is always less than or equal to the value that is returned by a subsequent call to `now()`.

system_clock::is_steady Constant

Static value that specifies whether the clock type is *steady*.

```
static const bool is_steady = false;
```

Return Value

In this implementation, `system_clock::is_steady` always returns **false**.

Remarks

A clock is *steady* if it is [monotonic](#) and if the time between clock ticks is constant.

system_clock::now

Static method that returns the current time.

```
static time_point now() noexcept;
```

Return Value

A [time_point](#) object that represents the current time.

system_clock::to_time_t

Static method that returns a [time_t](#) that most closely approximates the time that is represented by *Time*.

```
static time_t to_time_t(const time_point& Time) noexcept;
```

Parameters

Time

A [time_point](#) object.

[<chrono>](#)

[steady_clock](#) struct

time_point Class

3/28/2019 • 2 minutes to read • [Edit Online](#)

A `time_point` describes a type that represents a point in time. It holds an object of type `duration` that stores the elapsed time since the epoch that is represented by the template argument `clock`.

Syntax

```
template <class Clock,
          class Duration = typename Clock::duration>
class time_point;
```

Members

Public Typedefs

NAME	DESCRIPTION
<code>time_point::clock</code>	Synonym for the template parameter <code>Clock</code> .
<code>time_point::duration</code>	Synonym for the template parameter <code>Duration</code> .
<code>time_point::period</code>	Synonym for the nested type name <code>duration::period</code> .
<code>time_point::rep</code>	Synonym for the nested type name <code>duration::rep</code> .

Public Constructors

NAME	DESCRIPTION
<code>time_point</code>	Constructs a <code>time_point</code> object.

Public Methods

NAME	DESCRIPTION
<code>max</code>	Specifies the upper limit for <code>time_point::ref</code> .
<code>min</code>	Specifies the lower limit for <code>time_point::ref</code> .
<code>time_since_epoch</code>	Returns the stored <code>duration</code> value.

Public Operators

NAME	DESCRIPTION
<code>time_point::operator+=</code>	Adds a specified value to the stored duration.

NAME	DESCRIPTION
<code>time_point::operator-=</code>	Subtracts a specified value from the stored duration.

Requirements

Header: `<chrono>`

Namespace: `std::chrono`

`time_point::max`

Static method that returns the upper bound for values of type `time_point::ref`.

```
static constexpr time_point max();
```

Return Value

In effect, returns `time_point(duration::max())`.

`time_point::min`

Static method that returns the lower bound for values of type `time_point::ref`.

```
static constexpr time_point min();
```

Return Value

In effect, returns `time_point(duration::min())`.

`time_point::operator+=`

Adds a specified value to the stored [duration](#) value.

```
time_point& operator+=(const duration& Dur);
```

Parameters

Dur

A `duration` object.

Return Value

The `time_point` object after the addition is performed.

`time_point::operator-=`

Subtracts a specified value from the stored [duration](#) value.

```
time_point& operator-=(const duration& Dur);
```

Parameters

Dur

A `duration` object.

Return Value

The `time_point` object after the subtraction is performed.

`time_point::time_point` Constructor

Constructs a `time_point` object.

```
constexpr time_point();

constexpr explicit time_point(const duration& Dur);

template <class Duration2>
constexpr time_point(const time_point<clock, Duration2>& Tp);
```

Parameters

Dur

A [duration](#) object.

Tp

A `time_point` object.

Remarks

The first constructor constructs an object whose stored `duration` value is equal to [duration::zero](#).

The second constructor constructs an object whose stored duration value is equal to *Dur*. Unless `is_convertible<Duration2, duration>` holds true, the second constructor does not participate in overload resolution. For more information, see [<type_traits>](#).

The third constructor initializes its `duration` value by using `Tp.time_since_epoch()`.

`time_point::time_since_epoch`

Retrieves the stored [duration](#) value.

```
constexpr duration time_since_epoch() const;
```

<codecvt>

1/2/2019 • 2 minutes to read • [Edit Online](#)

Defines several template classes that describe objects based on template class `codecvt`. These objects can serve as [locale facets](#) that control conversions between a sequence of values of type `Elem` and a sequence of values of type `char`.

Syntax

```
#include <codecvt>
```

Remarks

The locale facets declared in this header convert between several character encodings. For wide characters (stored within the program in fixed-size integers):

- UCS-4 is Unicode (ISO 10646) encoded within the program as a 32-bit integer.
- UCS-2 is Unicode encoded within the program as a 16-bit integer.
- UTF-16 is Unicode encoded within the program as either one or two 16-bit integers. (Note that this does not meet all the requirements of a valid wide-character encoding for Standard C or Standard C++. Nevertheless it is widely used as such.)

For byte streams (stored in a file, transmitted as a byte sequence, or stored within the program in an array of `char`):

- UTF-8 is Unicode encoded within a byte stream as one or more eight-bit bytes with a deterministic byte order.
- UTF-16LE is Unicode encoded within a byte stream as UTF-16 with each 16-bit integer presented as two eight-bit bytes, less significant byte first.
- UTF-16BE is Unicode encoded within a byte stream as UTF-16 with each 16-bit integer presented as two eight-bit bytes, more significant byte first.

Enumerations

<code>codecvt_mode</code>	Specifies configuration information for locale facets.

Classes

CLASS	DESCRIPTION
<code>codecvt_utf8</code>	Represents a locale facet that converts between wide characters encoded as UCS-2 or UCS-4, and a byte stream encoded as UTF-8.
<code>codecvt_utf8_utf16</code>	Represents a locale facet that converts between wide characters encoded as UTF-16 and a byte stream encoded as UTF-8.

CLASS	DESCRIPTION
codecvt_utf16	Represents a locale facet that converts between wide characters encoded as UCS-2 or UCS-4 and a byte stream encoded as UTF-16LE or UTF-16BE.

Requirements

Header: <codecvt>

Namespace: std

See also

[Header Files Reference](#)

<codecvt> enums

10/31/2018 • 2 minutes to read • [Edit Online](#)

codecvt_mode Enumeration

Specifies configuration information for [locale](#) facets.

```
enum codecvt_mode {  
    consume_header = 4,  
    generate_header = 2,  
    little_endian = 1  
};
```

Remarks

The enumeration defines three constants that supply configuration information to the locale facets declared in [<codecvt>](#). The distinct values are:

- `consume_header`, to consume an initial header sequence when reading a multibyte sequence and determine the endianness of the subsequent multibyte sequence to be read
- `generate_header`, to generate an initial header sequence when writing a multibyte sequence to advertise the endianness of the subsequent multibyte sequence to be written
- `little_endian`, to generate a multibyte sequence in little-endian order, as opposed to the default big-endian order

These constants can be ORed together in arbitrary combinations.

[<codecvt>](#)

codecvt_utf8

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a [locale](#) facet that converts between wide characters encoded as UCS-2 or UCS-4, and a byte stream encoded as UTF-8.

```
template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
class codecvt_utf8 : public std::codecvt<Elem, char, StateType>
```

Parameters

Elem

The wide-character element type.

Maxcode

The maximum number of characters for the locale facet.

Mode

Configuration information for the locale facet.

Remarks

The byte stream can be written to either a binary file or a text file.

Requirements

Header: <codecvt>\

Namespace: std

codecvt_utf8_utf16

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a [locale](#) facet that converts between wide characters encoded as UTF-16 and a byte stream encoded as UTF-8.

```
template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
class codecvt_utf8_utf16 : public _STD codecvt<Elem, char, StateType>
```

Parameters

Elem

The wide-character element type.

Maxcode

The maximum number of characters for the locale facet.

Mode

Configuration information for the locale facet.

Remarks

The byte stream can be written to either a binary file or a text file.

Requirements

Header: <codecvt>

Namespace: std

codecvt_utf16

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a [locale](#) facet that converts between wide characters encoded as UCS-2 or UCS-4 and a byte stream encoded as UTF-16LE or UTF-16BE.

```
template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
class codecvt_utf16 : public std::codecvt<Elem, char, StateType>
```

Parameters

Elem

The wide-character element type.

Maxcode

The maximum number of characters for the locale facet.

Mode

Configuration information for the locale facet.

Remarks

This template class converts between wide characters encoded as UCS-2 or UCS-4 and a byte stream encoded as UTF-16LE, if Mode & little_endian, or UTF-16BE otherwise.

The byte stream should be written to a binary file; it can be corrupted if written to a text file.

Requirements

Header: <codecvt>

Namespace: std

<complex>

10/31/2018 • 5 minutes to read • [Edit Online](#)

Defines the container template class `complex` and its supporting templates.

Syntax

```
#include <complex>
```

Remarks

A complex number is an ordered pair of real numbers. In purely geometrical terms, the complex plane is the real, two-dimensional plane. The special qualities of the complex plane that distinguish it from the real plane are due to its having an additional algebraic structure. This algebraic structure has two fundamental operations:

- Addition defined as $(a, b) + (c, d) = (a + c, b + d)$
- Multiplication defined as $(a, b) * (c, d) = (ac - bd, ad + bc)$

The set of complex numbers with the operations of complex addition and complex multiplication are a field in the standard algebraic sense:

- The operations of addition and multiplication are commutative and associative and multiplication distributes over addition exactly as it does with real addition and multiplication on the field of real numbers.
- The complex number $(0, 0)$ is the additive identity and $(1, 0)$ is the multiplicative identity.
- The additive inverse for a complex number (a, b) is $(-a, -b)$, and the multiplicative inverse for all such complex numbers except $(0, 0)$ is

$$(a/(a^2 + b^2), -b/(a^2 + b^2))$$

By representing a complex number $z = (a, b)$ in the form $z = a + bi$, where $i^2 = -1$, the rules for the algebra of the set of real numbers can be applied to the set of complex numbers and to their components. For example:

$$(1 + 2i) * (2 + 3i) = 1 * (2 + 3i) + 2i * (2 + 3i) = (2 + 3i) + (4i + 6i^2) = (2 - 6) + (3 + 4)i = -4 + 7i$$

The system of complex numbers is a field, but it is not an ordered field. There is no ordering of the complex numbers as there is for the field of real numbers and its subsets, so inequalities cannot be applied to complex numbers as they are to real numbers.

There are three common forms of representing a complex number z :

- Cartesian: $z = a + bi$
- Polar: $z = r (\cos p + i \sin p)$
- Exponential: $z = r * e^{ip}$

The terms used in these standard representations of a complex number are referred to as follows:

- The real Cartesian component or real part a .
- The imaginary Cartesian component or imaginary part b .

- The modulus or absolute value of a complex number r .
- The argument or phase angle p in radians.

Unless otherwise specified, functions that can return multiple values are required to return a principal value for their arguments greater than $-\pi$ and less than or equal to $+\pi$ to keep them single valued. All angles must be expressed in radians, where there are 2π radians (360 degrees) in a circle.

Functions

FUNCTION	DESCRIPTION
<code>abs</code>	Calculates the modulus of a complex number.
<code>arg</code>	Extracts the argument from a complex number.
<code>conj</code>	Returns the complex conjugate of a complex number.
<code>cos</code>	Returns the cosine of a complex number.
<code>cosh</code>	Returns the hyperbolic cosine of a complex number.
<code>exp</code>	Returns the exponential function of a complex number.
<code>imag</code>	Extracts the imaginary component of a complex number.
<code>log</code>	Returns the natural logarithm of a complex number.
<code>log10</code>	Returns the base 10 logarithm of a complex number.
<code>norm</code>	Extracts the norm of a complex number.
<code>polar</code>	Returns the complex number, which corresponds to a specified modulus and argument, in Cartesian form.
<code>pow</code>	Evaluates the complex number obtained by raising a base that is a complex number to the power of another complex number.
<code>real</code>	Extracts the real component of a complex number.
<code>sin</code>	Returns the sine of a complex number.
<code>sinh</code>	Returns the hyperbolic sine of a complex number.
<code>sqrt</code>	Returns the square root of a complex number.
<code>tan</code>	Returns the tangent of a complex number.
<code>tanh</code>	Returns the hyperbolic tangent of a complex number.

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests for inequality between two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.
<code>operator*</code>	Multiplies two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.
<code>operator+</code>	Adds two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.
<code>operator-</code>	Subtracts two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.
<code>operator/</code>	Divides two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.
<code>operator<<</code>	A template function that inserts a complex number into the output stream.
<code>operator==</code>	Tests for equality between two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.
<code>operator>></code>	A template function that extracts a complex value from the input stream.

Classes

CLASS	DESCRIPTION
<code>complex<double></code>	The explicitly specialized template class describes an object that stores an ordered pair of objects, both of type double , where the first represents the real part of a complex number and the second represents the imaginary part.
<code>complex<float></code>	The explicitly specialized template class describes an object that stores an ordered pair of objects, both of type float , where the first represents the real part of a complex number and the second represents the imaginary part.
<code>complex<long double></code>	The explicitly specialized template class describes an object that stores an ordered pair of objects, both of type long double , where the first represents the real part of a complex number and the second represents the imaginary part.
<code>complex</code>	The template class describes an object used to represent the complex number system and perform complex arithmetic operations.

Literals

The `<complex>` header defines the following [user-defined literals](#) which create a complex number with the real

part being zero and the imaginary part being the value of the input parameter.

abs	arg	conj
cos	cosh	exp
imag	log	log10
norm	polar	pow
real	sin	sinh
sqrt	tan	tanh

abs

Calculates the modulus of a complex number.

```
template <class Type>
Type abs(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose modulus is to be determined.

Return Value

The modulus of a complex number.

Remarks

The *modulus* of a complex number is a measure of the length of the vector representing the complex number. The modulus of a complex number $a + bi$ is $\sqrt{a^2 + b^2}$, written $|a + bi|$. The *norm* of a complex number $a + bi$ is $(a^2 + b^2)$, so the modulus of a complex number is the square root of its norm.

Example

```

// complex_abs.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Complex numbers can be entered in polar form with
    // modulus and argument parameter inputs but are
    // stored in Cartesian form as real & imag coordinates
    complex <double> c1 ( polar ( 5.0 ) ); // Default argument = 0
    complex <double> c2 ( polar ( 5.0 , pi / 6 ) );
    complex <double> c3 ( polar ( 5.0 , 13 * pi / 6 ) );
    cout << "c1 = polar ( 5.0 ) = " << c1 << endl;
    cout << "c2 = polar ( 5.0 , pi / 6 ) = " << c2 << endl;
    cout << "c3 = polar ( 5.0 , 13 * pi / 6 ) = " << c3 << endl;

    // The modulus and argument of a complex number can be recovered
    // using abs & arg member functions
    double absc1 = abs ( c1 );
    double argc1 = arg ( c1 );
    cout << "The modulus of c1 is recovered from c1 using: abs ( c1 ) = "
        << absc1 << endl;
    cout << "Argument of c1 is recovered from c1 using:\n arg ( c1 ) = "
        << argc1 << " radians, which is " << argc1 * 180 / pi
        << " degrees." << endl;

    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is recovered from c2 using: abs ( c2 ) = "
        << absc2 << endl;
    cout << "Argument of c2 is recovered from c2 using:\n arg ( c2 ) = "
        << argc2 << " radians, which is " << argc2 * 180 / pi
        << " degrees." << endl;

    // Testing if the principal angles of c2 and c3 are the same
    if ( ( arg ( c2 ) <= ( arg ( c3 ) + .00000001 ) ) ||
        ( arg ( c2 ) >= ( arg ( c3 ) - .00000001 ) ) )
        cout << "The complex numbers c2 & c3 have the "
            << "same principal arguments."<< endl;
    else
        cout << "The complex numbers c2 & c3 don't have the "
            << "same principal arguments." << endl;
}

```

```

c1 = polar ( 5.0 ) = (5,0)
c2 = polar ( 5.0 , pi / 6 ) = (4.33013,2.5)
c3 = polar ( 5.0 , 13 * pi / 6 ) = (4.33013,2.5)
The modulus of c1 is recovered from c1 using: abs ( c1 ) = 5
Argument of c1 is recovered from c1 using:
arg ( c1 ) = 0 radians, which is 0 degrees.
The modulus of c2 is recovered from c2 using: abs ( c2 ) = 5
Argument of c2 is recovered from c2 using:
arg ( c2 ) = 0.523599 radians, which is 30 degrees.
The complex numbers c2 & c3 have the same principal arguments.

```

arg

Extracts the argument from a complex number.

```
template <class Type>
Type arg(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose argument is to be determined.

Return Value

The argument of the complex number.

Remarks

The *argument* is the angle that the complex vector makes with the positive real axis in the complex plane. For a complex number $a + bi$, the argument is equal to $\arctan(b/a)$. The angle has a positive sense when measured in a counterclockwise direction from the positive real axis and a negative sense when measured in a clockwise direction. The principal values are greater than $-\pi$ and less than or equal to $+\pi$.

Example

```

// complex_arg.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Complex numbers can be entered in polar form with
    // modulus and argument parameter inputs but are
    // stored in Cartesian form as real & imag coordinates
    complex <double> c1 ( polar ( 5.0 ) ); // Default argument = 0
    complex <double> c2 ( polar ( 5.0 , pi / 6 ) );
    complex <double> c3 ( polar ( 5.0 , 13 * pi / 6 ) );
    cout << "c1 = polar ( 5.0 ) = " << c1 << endl;
    cout << "c2 = polar ( 5.0 , pi / 6 ) = " << c2 << endl;
    cout << "c3 = polar ( 5.0 , 13 * pi / 6 ) = " << c3 << endl;

    // The modulus and argument of a complex number can be recovered
    // using abs & arg member functions
    double absc1 = abs ( c1 );
    double argc1 = arg ( c1 );
    cout << "The modulus of c1 is recovered from c1 using: abs ( c1 ) = "
        << absc1 << endl;
    cout << "Argument of c1 is recovered from c1 using:\n arg ( c1 ) = "
        << argc1 << " radians, which is " << argc1 * 180 / pi
        << " degrees." << endl;

    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is recovered from c2 using: abs ( c2 ) = "
        << absc2 << endl;
    cout << "Argument of c2 is recovered from c2 using:\n arg ( c2 ) = "
        << argc2 << " radians, which is " << argc2 * 180 / pi
        << " degrees." << endl;

    // Testing if the principal angles of c2 and c3 are the same
    if ( ( arg ( c2 ) <= ( arg ( c3 ) + .00000001 ) ) ||
        ( arg ( c2 ) >= ( arg ( c3 ) - .00000001 ) ) )
        cout << "The complex numbers c2 & c3 have the "
            << "same principal arguments."<< endl;
    else
        cout << "The complex numbers c2 & c3 don't have the "
            << "same principal arguments." << endl;
}

```

```

c1 = polar ( 5.0 ) = (5,0)
c2 = polar ( 5.0 , pi / 6 ) = (4.33013,2.5)
c3 = polar ( 5.0 , 13 * pi / 6 ) = (4.33013,2.5)
The modulus of c1 is recovered from c1 using: abs ( c1 ) = 5
Argument of c1 is recovered from c1 using:
arg ( c1 ) = 0 radians, which is 0 degrees.
The modulus of c2 is recovered from c2 using: abs ( c2 ) = 5
Argument of c2 is recovered from c2 using:
arg ( c2 ) = 0.523599 radians, which is 30 degrees.
The complex numbers c2 & c3 have the same principal arguments.

```

conj

Returns the complex conjugate of a complex number.

```
template <class Type>
complex<Type> conj(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose complex conjugate is being returned.

Return Value

The complex conjugate of the input complex number.

Remarks

The complex conjugate of a complex number $a + bi$ is $a - bi$. The product of a complex number and its conjugate is the norm of the number $a^2 + b^2$.

Example

```
// complex_conj.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;

    complex <double> c1 ( 4.0 , 3.0 );
    cout << "The complex number c1 = " << c1 << endl;

    double dr1 = real ( c1 );
    cout << "The real part of c1 is real ( c1 ) = "
        << dr1 << "." << endl;

    double di1 = imag ( c1 );
    cout << "The imaginary part of c1 is imag ( c1 ) = "
        << di1 << "." << endl;

    complex <double> c2 = conj ( c1 );
    cout << "The complex conjugate of c1 is c2 = conj ( c1 ) = "
        << c2 << endl;

    double dr2 = real ( c2 );
    cout << "The real part of c2 is real ( c2 ) = "
        << dr2 << "." << endl;

    double di2 = imag ( c2 );
    cout << "The imaginary part of c2 is imag ( c2 ) = "
        << di2 << "." << endl;

    // The real part of the product of a complex number
    // and its conjugate is the norm of the number
    complex <double> c3 = c1 * c2;
    cout << "The norm of (c1 * conj (c1) ) is c1 * c2 = "
        << real( c3 ) << endl;
}
```

The complex number $c1 = (4,3)$
The real part of $c1$ is $\text{real} (c1) = 4$.
The imaginary part of $c1$ is $\text{imag} (c1) = 3$.
The complex conjugate of $c1$ is $c2 = \text{conj} (c1) = (4,-3)$
The real part of $c2$ is $\text{real} (c2) = 4$.
The imaginary part of $c2$ is $\text{imag} (c2) = -3$.
The norm of $(c1 * \text{conj} (c1))$ is $c1 * c2 = 25$

COS

Returns the cosine of a complex number.

```
template <class Type>
complex<Type> cos(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose cosine is being determined.

Return Value

The complex number that is the cosine of the input complex number.

Remarks

Identities defining the complex cosines:

$$\cos (z) = (1/2) * (\exp (iz) + \exp (- iz))$$

$$\cos (z) = \cos (a + bi) = \cos (a) \cosh (b) - i \sin (a) \sinh (b)$$

Example

```

// complex_cos.cpp
// compile with: /EHsc
#include <vector>
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    complex <double> c1 ( 3.0 , 4.0 );
    cout << "Complex number c1 = " << c1 << endl;

    // Values of cosine of a complex number c1
    complex <double> c2 = cos ( c1 );
    cout << "Complex number c2 = cos ( c1 ) = " << c2 << endl;
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is: " << absc2 << endl;
    cout << "The argument of c2 is: " << argc2 << " radians, which is "
        << argc2 * 180 / pi << " degrees." << endl << endl;

    // Cosines of the standard angles in the first
    // two quadrants of the complex plane
    vector <complex <double> > v1;
    vector <complex <double> >::iterator Iter1;
    complex <double> vc1 ( polar (1.0, pi / 6) );
    v1.push_back( cos ( vc1 ) );
    complex <double> vc2 ( polar (1.0, pi / 3) );
    v1.push_back( cos ( vc2 ) );
    complex <double> vc3 ( polar (1.0, pi / 2) );
    v1.push_back( cos ( vc3 ) );
    complex <double> vc4 ( polar (1.0, 2 * pi / 3) );
    v1.push_back( cos ( vc4 ) );
    complex <double> vc5 ( polar (1.0, 5 * pi / 6) );
    v1.push_back( cos ( vc5 ) );
    complex <double> vc6 ( polar (1.0, pi) );
    v1.push_back( cos ( vc6 ) );

    cout << "The complex components cos (vci), where abs (vci) = 1"
        << "\n& arg (vci) = i * pi / 6 of the vector v1 are:\n" ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << endl;
}

```

```

Complex number c1 = (3,4)
Complex number c2 = cos ( c1 ) = (-27.0349,-3.85115)
The modulus of c2 is: 27.3079
The argument of c2 is: -3.00009 radians, which is -171.893 degrees.

The complex components cos (vci), where abs (vci) = 1
& arg (vci) = i * pi / 6 of the vector v1 are:
(0.730543,-0.39695)
(1.22777,-0.469075)
(1.54308,1.21529e-013)
(1.22777,0.469075)
(0.730543,0.39695)
(0.540302,-1.74036e-013)

```

cosh

Returns the hyperbolic cosine of a complex number.

```
template <class Type>
complex<Type> cosh(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose hyperbolic cosine is being determined.

Return Value

The complex number that is the hyperbolic cosine of the input complex number.

Remarks

Identities defining the complex hyperbolic cosines:

$$\cos (z) = (1 / 2) * (\exp (z) + \exp (- z))$$

$$\cos (z) = \cosh (a + bi) = \cosh (a) \cos (b) + i \sinh (a) \sin (b)$$

Example

```

// complex_cosh.cpp
// compile with: /EHsc
#include <vector>
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    complex <double> c1 ( 3.0 , 4.0 );
    cout << "Complex number c1 = " << c1 << endl;

    // Values of cosine of a complex number c1
    complex <double> c2 = cosh ( c1 );
    cout << "Complex number c2 = cosh ( c1 ) = " << c2 << endl;
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is: " << absc2 << endl;
    cout << "The argument of c2 is: " << argc2 << " radians, which is "
        << argc2 * 180 / pi << " degrees." << endl << endl;

    // Hyperbolic cosines of the standard angles
    // in the first two quadrants of the complex plane
    vector <complex <double> > v1;
    vector <complex <double> >::iterator Iter1;
    complex <double> vc1 ( polar (1.0, pi / 6) );
    v1.push_back( cosh ( vc1 ) );
    complex <double> vc2 ( polar (1.0, pi / 3) );
    v1.push_back( cosh ( vc2 ) );
    complex <double> vc3 ( polar (1.0, pi / 2) );
    v1.push_back( cosh ( vc3 ) );
    complex <double> vc4 ( polar (1.0, 2 * pi / 3) );
    v1.push_back( cosh ( vc4 ) );
    complex <double> vc5 ( polar (1.0, 5 * pi / 6) );
    v1.push_back( cosh ( vc5 ) );
    complex <double> vc6 ( polar (1.0, pi) );
    v1.push_back( cosh ( vc6 ) );

    cout << "The complex components cosh (vci), where abs (vci) = 1"
        << "\n& arg (vci) = i * pi / 6 of the vector v1 are:\n" ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << endl;
}

```

```

Complex number c1 = (3,4)
Complex number c2 = cosh ( c1 ) = (-6.58066,-7.58155)
The modulus of c2 is: 10.0392
The argument of c2 is: -2.28564 radians, which is -130.957 degrees.

The complex components cosh (vci), where abs (vci) = 1
& arg (vci) = i * pi / 6 of the vector v1 are:
(1.22777,0.469075)
(0.730543,0.39695)
(0.540302,-8.70178e-014)
(0.730543,-0.39695)
(1.22777,-0.469075)
(1.54308,2.43059e-013)

```

exp

Returns the exponential function of a complex number.

```
template <class Type>
complex<Type> exp(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose exponential is being determined.

Return Value

The complex number that is the exponential of the input complex number.

Example

```
// complex_exp.cpp
// compile with: /EHsc
#include <vector>
#include <complex>
#include <iostream>

int main() {
    using namespace std;
    double pi = 3.14159265359;
    complex <double> c1 ( 1 , pi/6 );
    cout << "Complex number c1 = " << c1 << endl;

    // Value of exponential of a complex number c1:
    // note the argument of c2 is determined by the
    // imaginary part of c1 & the modulus by the real part
    complex <double> c2 = exp ( c1 );
    cout << "Complex number c2 = exp ( c1 ) = " << c2 << endl;
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is: " << absc2 << endl;
    cout << "The argument of c2 is: " << argc2 << " radians, which is "
        << argc2 * 180 / pi << " degrees." << endl << endl;

    // Exponentials of the standard angles
    // in the first two quadrants of the complex plane
    vector <complex <double> > v1;
    vector <complex <double> >::iterator Iter1;
    complex <double> vc1 ( 0.0 , -pi );
    v1.push_back( exp ( vc1 ) );
    complex <double> vc2 ( 0.0, -2 * pi / 3 );
    v1.push_back( exp ( vc2 ) );
    complex <double> vc3 ( 0.0, 0.0 );
    v1.push_back( exp ( vc3 ) );
    complex <double> vc4 ( 0.0, pi / 3 );
    v1.push_back( exp ( vc4 ) );
    complex <double> vc5 ( 0.0 , 2 * pi / 3 );
    v1.push_back( exp ( vc5 ) );
    complex <double> vc6 ( 0.0, pi );
    v1.push_back( exp ( vc6 ) );

    cout << "The complex components exp (vci), where abs (vci) = 1"
        << "\n& arg (vci) = i * pi / 3 of the vector v1 are:\n" ;
    for ( Iter1 = v1.begin() ; Iter1 != v1.end() ; Iter1++ )
        cout << ( * Iter1 ) << "\n    with argument = "
            << ( 180/pi ) * arg ( *Iter1 )
            << " degrees\n    modulus = "
            << abs ( * Iter1 ) << endl;
}
```

Extracts the imaginary component of a complex number.

```
template <class Type>
Type imag(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose real part is to be extracted.

Return Value

The imaginary part of the complex number as a global function.

Remarks

This template function cannot be used to modify the real part of the complex number. To change the real part, a new complex number must be assigned the component value.

Example

```
// complexc_imag.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    complex <double> c1 ( 4.0 , 3.0 );
    cout << "The complex number c1 = " << c1 << endl;

    double dr1 = real ( c1 );
    cout << "The real part of c1 is real ( c1 ) = "
         << dr1 << "." << endl;

    double di1 = imag ( c1 );
    cout << "The imaginary part of c1 is imag ( c1 ) = "
         << di1 << "." << endl;
}
```

```
The complex number c1 = (4,3)
The real part of c1 is real ( c1 ) = 4.
The imaginary part of c1 is imag ( c1 ) = 3.
```

log

Returns the natural logarithm of a complex number.

```
template <class Type>
complex<Type> log(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose natural logarithm is being determined.

Return Value

The complex number that is the natural logarithm of the input complex number.

Remarks

The branch cuts are along the negative real axis.

Example

```
// complex_log.cpp
// compile with: /EHsc
#include <vector>
#include <complex>
#include <iostream>

int main() {
    using namespace std;
    double pi = 3.14159265359;
    complex <double> c1 ( 3.0 , 4.0 );
    cout << "Complex number c1 = " << c1 << endl;

    // Values of log of a complex number c1
    complex <double> c2 = log ( c1 );
    cout << "Complex number c2 = log ( c1 ) = " << c2 << endl;
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is: " << absc2 << endl;
    cout << "The argument of c2 is: " << argc2 << " radians, which is "
        << argc2 * 180 / pi << " degrees." << endl << endl;

    // log of the standard angles
    // in the first two quadrants of the complex plane
    vector <complex <double> > v1;
    vector <complex <double> >::iterator Iter1;
    complex <double> vc1 ( polar (1.0, pi / 6) );
    v1.push_back( log ( vc1 ) );
    complex <double> vc2 ( polar (1.0, pi / 3) );
    v1.push_back( log ( vc2 ) );
    complex <double> vc3 ( polar (1.0, pi / 2) );
    v1.push_back( log ( vc3 ) );
    complex <double> vc4 ( polar (1.0, 2 * pi / 3) );
    v1.push_back( log ( vc4 ) );
    complex <double> vc5 ( polar (1.0, 5 * pi / 6) );
    v1.push_back( log ( vc5 ) );
    complex <double> vc6 ( polar (1.0, pi) );
    v1.push_back( log ( vc6 ) );

    cout << "The complex components log (vci), where abs (vci) = 1 "
        << "\n& arg (vci) = i * pi / 6 of the vector v1 are:\n" ;
    for ( Iter1 = v1.begin() ; Iter1 != v1.end() ; Iter1++ )
        cout << *Iter1 << " " << endl;
}
```

log10

Returns the base 10 logarithm of a complex number.

```
template <class Type>
complex<Type> log10(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose base 10 logarithm is being determined.

Return Value

The complex number that is the base 10 logarithm of the input complex number.

Remarks

The branch cuts are along the negative real axis.

Example

```
// complex_log10.cpp
// compile with: /EHsc
#include <vector>
#include <complex>
#include <iostream>

int main() {
    using namespace std;
    double pi = 3.14159265359;
    complex <double> c1 ( 3.0 , 4.0 );
    cout << "Complex number c1 = " << c1 << endl;

    // Values of log10 of a complex number c1
    complex <double> c2 = log10 ( c1 );
    cout << "Complex number c2 = log10 ( c1 ) = " << c2 << endl;
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is: " << absc2 << endl;
    cout << "The argument of c2 is: " << argc2 << " radians, which is "
        << argc2 * 180 / pi << " degrees." << endl << endl;

    // log10 of the standard angles
    // in the first two quadrants of the complex plane
    vector <complex <double> > v1;
    vector <complex <double> >::iterator Iter1;
    complex <double> vc1 ( polar (1.0, pi / 6) );
    v1.push_back( log10 ( vc1 ) );
    complex <double> vc2 ( polar (1.0, pi / 3) );
    v1.push_back( log10 ( vc2 ) );
    complex <double> vc3 ( polar (1.0, pi / 2) );
    v1.push_back( log10 ( vc3 ) );
    complex <double> vc4 ( polar (1.0, 2 * pi / 3) );
    v1.push_back( log10 ( vc4 ) );
    complex <double> vc5 ( polar (1.0, 5 * pi / 6) );
    v1.push_back( log10 ( vc5 ) );
    complex <double> vc6 ( polar (1.0, pi) );
    v1.push_back( log10 ( vc6 ) );

    cout << "The complex components log10 (vci), where abs (vci) = 1"
        << "\n& arg (vci) = i * pi / 6 of the vector v1 are:\n" ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << endl;
}
```

norm

Extracts the norm of a complex number.

```
template <class Type>
Type norm(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose norm is to be determined.

Return Value

The norm of a complex number.

Remarks

The norm of a complex number $a + bi$ is $(a^2 + b^2)$. The norm of a complex number is the square of its modulus. The modulus of a complex number is a measure of the length of the vector representing the complex number. The modulus of a complex number $a + bi$ is $\sqrt{a^2 + b^2}$, written $|a + bi|$.

Example

```
// complex_norm.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Complex numbers can be entered in polar form with
    // modulus and argument parameter inputs but are
    // stored in Cartesian form as real & imag coordinates
    complex <double> c1 ( polar ( 5.0 ) ); // Default argument = 0
    complex <double> c2 ( polar ( 5.0 , pi / 6 ) );
    complex <double> c3 ( polar ( 5.0 , 13 * pi / 6 ) );
    cout << "c1 = polar ( 5.0 ) = " << c1 << endl;
    cout << "c2 = polar ( 5.0 , pi / 6 ) = " << c2 << endl;
    cout << "c3 = polar ( 5.0 , 13 * pi / 6 ) = " << c3 << endl;

    if ( ( arg ( c2 ) <= ( arg ( c3 ) + .00000001 ) ) ||
        ( arg ( c2 ) >= ( arg ( c3 ) - .00000001 ) ) )
        cout << "The complex numbers c2 & c3 have the "
            << "same principal arguments."<< endl;
    else
        cout << "The complex numbers c2 & c3 don't have the "
            << "same principal arguments." << endl;

    // The modulus and argument of a complex number can be recovered
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is recovered from c2 using: abs ( c2 ) = "
        << absc2 << endl;
    cout << "Argument of c2 is recovered from c2 using:\n arg ( c2 ) = "
        << argc2 << " radians, which is " << argc2 * 180 / pi
        << " degrees." << endl;

    // The norm of a complex number is the square of its modulus
    double normc2 = norm ( c2 );
    double sqrtnormc2 = sqrt ( normc2 );
    cout << "The norm of c2 given by: norm ( c2 ) = " << normc2 << endl;
    cout << "The modulus of c2 is the square root of the norm: "
        << "sqrt ( normc2 ) = " << sqrtnormc2 << ".";
}
```

```
c1 = polar ( 5.0 ) = (5,0)
c2 = polar ( 5.0 , pi / 6 ) = (4.33013,2.5)
c3 = polar ( 5.0 , 13 * pi / 6 ) = (4.33013,2.5)
The complex numbers c2 & c3 have the same principal arguments.
The modulus of c2 is recovered from c2 using: abs ( c2 ) = 5
Argument of c2 is recovered from c2 using:
arg ( c2 ) = 0.523599 radians, which is 30 degrees.
The norm of c2 given by: norm ( c2 ) = 25
The modulus of c2 is the square root of the norm: sqrt ( normc2 ) = 5.
```

polar

Returns the complex number, which corresponds to a specified modulus and argument, in Cartesian form.

```
template <class Type>
complex<Type> polar(const Type& _Modulus, const Type& _Argument = 0);
```

Parameters

_Modulus

The modulus of the complex number being input.

_Argument

The argument of the complex number being input.

Return Value

Cartesian form of the complex number specified in polar form.

Remarks

The polar form of a complex number provides the modulus r and the argument p , where these parameters are related to the real and imaginary Cartesian components a and b by the equations $a = r * \cos p$ and $b = r * \sin p$.

Example

```
// complex_polar.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Complex numbers can be entered in polar form with
    // modulus and argument parameter inputs but are
    // stored in Cartesian form as real & imag coordinates
    complex <double> c1 ( polar ( 5.0 ) ); // Default argument = 0
    complex <double> c2 ( polar ( 5.0 , pi / 6 ) );
    complex <double> c3 ( polar ( 5.0 , 13 * pi / 6 ) );
    cout << "c1 = polar ( 5.0 ) = " << c1 << endl;
    cout << "c2 = polar ( 5.0 , pi / 6 ) = " << c2 << endl;
    cout << "c3 = polar ( 5.0 , 13 * pi / 6 ) = " << c3 << endl;

    if ( ( arg ( c2 ) <= ( arg ( c3 ) + .00000001 ) ) ||
        ( arg ( c2 ) >= ( arg ( c3 ) - .00000001 ) ) )
        cout << "The complex numbers c2 & c3 have the "
            << "same principal arguments."<< endl;
    else
        cout << "The complex numbers c2 & c3 don't have the "
            << "same principal arguments." << endl;

    // the modulus and argument of a complex number can be recovered
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is recovered from c2 using: abs ( c2 ) = "
        << absc2 << endl;
    cout << "Argument of c2 is recovered from c2 using:\n arg ( c2 ) = "
        << argc2 << " radians, which is " << argc2 * 180 / pi
        << " degrees." << endl;
}
```

```

c1 = polar ( 5.0 ) = (5,0)
c2 = polar ( 5.0 , pi / 6 ) = (4.33013,2.5)
c3 = polar ( 5.0 , 13 * pi / 6 ) = (4.33013,2.5)
The complex numbers c2 & c3 have the same principal arguments.
The modulus of c2 is recovered from c2 using: abs ( c2 ) = 5
Argument of c2 is recovered from c2 using:
arg ( c2 ) = 0.523599 radians, which is 30 degrees.

```

pow

Evaluates the complex number obtained by raising a base that is a complex number to the power of another complex number.

```

template <class Type>
complex<Type> pow(const complex<Type>& _Base, int _Power);

template <class Type>
complex<Type> pow(const complex<Type>& _Base, const Type& _Power);

template <class Type>
complex<Type> pow(const complex<Type>& _Base, const complex<Type>& _Power);

template <class Type>
complex<Type> pow(const Type& _Base, const complex<Type>& _Power);

```

Parameters

_Base

The complex number or number that is of the parameter type for the complex number that is the base to be raised to a power by the member function.

_Power

The integer or complex number or number that is of the parameter type for the complex number that is the power that the base is to be raised to by the member function.

Return Value

The complex number obtained by raising the specified base to the specified power.

Remarks

The functions each effectively convert both operands to the return type, and then return the converted **left** to the power **right**.

The branch cut is along the negative real axis.

Example

```

// complex_pow.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // First member function
    // type complex<double> base & type integer power
    complex <double> cb1 ( 3 , 4);
    int cp1 = 2;
    complex <double> cp1 = pow ( cb1 , cp1 );
}

```

```

complex <double> ce1 = pow ( cb1 ,cp1 );

cout << "Complex number for base cb1 = " << cb1 << endl;
cout << "Integer for power = " << cp1 << endl;
cout << "Complex number returned from complex base and integer power:"
    << "\n ce1 = cb1 ^ cp1 = " << ce1 << endl;
double absce1 = abs ( ce1 );
double argce1 = arg ( ce1 );
cout << "The modulus of ce1 is: " << absce1 << endl;
cout << "The argument of ce1 is: "<< argce1 << " radians, which is "
    << argce1 * 180 / pi << " degrees." << endl << endl;

// Second member function
// type complex<double> base & type double power
complex <double> cb2 ( 3 , 4 );
double cp2 = pi;
complex <double> ce2 = pow ( cb2 ,cp2 );

cout << "Complex number for base cb2 = " << cb2 << endl;
cout << "Type double for power cp2 = pi = " << cp2 << endl;
cout << "Complex number returned from complex base and double power:"
    << "\n ce2 = cb2 ^ cp2 = " << ce2 << endl;
double absce2 = abs ( ce2 );
double argce2 = arg ( ce2 );
cout << "The modulus of ce2 is: " << absce2 << endl;
cout << "The argument of ce2 is: "<< argce2 << " radians, which is "
    << argce2 * 180 / pi << " degrees." << endl << endl;

// Third member function
// type complex<double> base & type complex<double> power
complex <double> cb3 ( 3 , 4 );
complex <double> cp3 ( -2 , 1 );
complex <double> ce3 = pow ( cb3 ,cp3 );

cout << "Complex number for base cb3 = " << cb3 << endl;
cout << "Complex number for power cp3= " << cp3 << endl;
cout << "Complex number returned from complex base and complex power:"
    << "\n ce3 = cb3 ^ cp3 = " << ce3 << endl;
double absce3 = abs ( ce3 );
double argce3 = arg ( ce3 );
cout << "The modulus of ce3 is: " << absce3 << endl;
cout << "The argument of ce3 is: "<< argce3 << " radians, which is "
    << argce3 * 180 / pi << " degrees." << endl << endl;

// Fourth member function
// type double base & type complex<double> power
double cb4 = pi;
complex <double> cp4 ( 2 , -1 );
complex <double> ce4 = pow ( cb4 ,cp4 );

cout << "Type double for base cb4 = pi = " << cb4 << endl;
cout << "Complex number for power cp4 = " << cp4 << endl;
cout << "Complex number returned from double base and complex power:"
    << "\n ce4 = cb4 ^ cp4 = " << ce4 << endl;
double absce4 = abs ( ce4 );
double argce4 = arg ( ce4 );
cout << "The modulus of ce4 is: " << absce4 << endl;
cout << "The argument of ce4 is: "<< argce4 << " radians, which is "
    << argce4 * 180 / pi << " degrees." << endl << endl;
}

```

```

Complex number for base cb1 = (3,4)
Integer for power = 2
Complex number returned from complex base and integer power:
ce1 = cb1 ^ cp1 = (-7,24)
The modulus of ce1 is: 25
The argument of ce1 is: 1.85459 radians, which is 106.26 degrees.

Complex number for base cb2 = (3,4)
Type double for power cp2 = pi = 3.14159
Complex number returned from complex base and double power:
ce2 = cb2 ^ cp2 = (-152.915,35.5475)
The modulus of ce2 is: 156.993
The argument of ce2 is: 2.91318 radians, which is 166.913 degrees.

Complex number for base cb3 = (3,4)
Complex number for power cp3= (-2,1)
Complex number returned from complex base and complex power:
ce3 = cb3 ^ cp3 = (0.0153517,-0.00384077)
The modulus of ce3 is: 0.0158249
The argument of ce3 is: -0.245153 radians, which is -14.0462 degrees.

Type double for base cb4 = pi = 3.14159
Complex number for power cp4 = (2,-1)
Complex number returned from double base and complex power:
ce4 = cb4 ^ cp4 = (4.07903,-8.98725)
The modulus of ce4 is: 9.8696
The argument of ce4 is: -1.14473 radians, which is -65.5882 degrees.

```

real

Extracts the real component of a complex number.

```

template <class Type>
Type real(const complex<Type>& complexNum);

```

Parameters

complexNum

The complex number whose real part is to be extracted.

Return Value

The real part of the complex number as a global function.

Remarks

This template function cannot be used to modify the real part of the complex number. To change the real part, a new complex number must be assigned the component value.

Example

```
// complex_real.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    complex <double> c1 ( 4.0 , 3.0 );
    cout << "The complex number c1 = " << c1 << endl;

    double dr1 = real ( c1 );
    cout << "The real part of c1 is real ( c1 ) = "
         << dr1 << "." << endl;

    double di1 = imag ( c1 );
    cout << "The imaginary part of c1 is imag ( c1 ) = "
         << di1 << "." << endl;
}
```

```
The complex number c1 = (4,3)
The real part of c1 is real ( c1 ) = 4.
The imaginary part of c1 is imag ( c1 ) = 3.
```

sin

Returns the sine of a complex number.

```
template <class Type>
complex<Type> sin(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose sine is being determined.

Return Value

The complex number that is the sine of the input complex number.

Remarks

Identities defining the complex sines:

$$\sin (z) = (1 / 2 \, i) * (\exp (i z) - \exp (- i z))$$

$$\sin (z) = \sin (a + bi) = \sin (a) \cosh (b) + i \cos (a) \sinh (b)$$

Example

```

// complex_sin.cpp
// compile with: /EHsc
#include <vector>
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    complex <double> c1 ( 3.0 , 4.0 );
    cout << "Complex number c1 = " << c1 << endl;

    // Values of sine of a complex number c1
    complex <double> c2 = sin ( c1 );
    cout << "Complex number c2 = sin ( c1 ) = " << c2 << endl;
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is: " << absc2 << endl;
    cout << "The argument of c2 is: " << argc2 << " radians, which is "
        << argc2 * 180 / pi << " degrees." << endl << endl;

    // sines of the standard angles in the first
    // two quadrants of the complex plane
    vector <complex <double> > v1;
    vector <complex <double> >::iterator Iter1;
    complex <double> vc1 ( polar ( 1.0, pi / 6 ) );
    v1.push_back( sin ( vc1 ) );
    complex <double> vc2 ( polar ( 1.0, pi / 3 ) );
    v1.push_back( sin ( vc2 ) );
    complex <double> vc3 ( polar ( 1.0, pi / 2 ) );
    v1.push_back( sin ( vc3 ) );
    complex <double> vc4 ( polar ( 1.0, 2 * pi / 3 ) );
    v1.push_back( sin ( vc4 ) );
    complex <double> vc5 ( polar ( 1.0, 5 * pi / 6 ) );
    v1.push_back( sin ( vc5 ) );
    complex <double> vc6 ( polar ( 1.0, pi ) );
    v1.push_back( sin ( vc6 ) );

    cout << "The complex components sin (vci), where abs (vci) = 1"
        << "\n& arg (vci) = i * pi / 6 of the vector v1 are:\n" ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << endl;
}

```

```

Complex number c1 = (3,4)
Complex number c2 = sin ( c1 ) = (3.85374,-27.0168)
The modulus of c2 is: 27.2903
The argument of c2 is: -1.42911 radians, which is -81.882 degrees.

```

```

The complex components sin (vci), where abs (vci) = 1
& arg (vci) = i * pi / 6 of the vector v1 are:
(0.85898,0.337596)
(0.670731,0.858637)
(-1.59572e-013,1.1752)
(-0.670731,0.858637)
(-0.85898,0.337596)
(-0.841471,-1.11747e-013)

```

sinh

Returns the hyperbolic sine of a complex number.

```
template <class Type>
complex<Type> sinh(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose hyperbolic sine is being determined.

Return Value

The complex number that is the hyperbolic sine of the input complex number.

Remarks

Identities defining the complex hyperbolic sines:

$$\sinh (z) = (1 / 2) * (\exp (z) - \exp (- z))$$

$$\sinh (z) = \sinh (a + bi) = \sinh (a) \cos (b) + i \cosh (a) \sin (b)$$

Example

```

// complex_sinh.cpp
// compile with: /EHsc
#include <vector>
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    complex <double> c1 ( 3.0 , 4.0 );
    cout << "Complex number c1 = " << c1 << endl;

    // Values of sine of a complex number c1
    complex <double> c2 = sinh ( c1 );
    cout << "Complex number c2 = sinh ( c1 ) = " << c2 << endl;
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is: " << absc2 << endl;
    cout << "The argument of c2 is: " << argc2 << " radians, which is "
        << argc2 * 180 / pi << " degrees." << endl << endl;

    // Hyperbolic sines of the standard angles in
    // the first two quadrants of the complex plane
    vector <complex <double> > v1;
    vector <complex <double> >::iterator Iter1;
    complex <double> vc1 ( polar ( 1.0, pi / 6 ) );
    v1.push_back( sinh ( vc1 ) );
    complex <double> vc2 ( polar ( 1.0, pi / 3 ) );
    v1.push_back( sinh ( vc2 ) );
    complex <double> vc3 ( polar ( 1.0, pi / 2 ) );
    v1.push_back( sinh ( vc3 ) );
    complex <double> vc4 ( polar ( 1.0, 2 * pi / 3 ) );
    v1.push_back( sinh ( vc4 ) );
    complex <double> vc5 ( polar ( 1.0, 5 * pi / 6 ) );
    v1.push_back( sinh ( vc5 ) );
    complex <double> vc6 ( polar ( 1.0, pi ) );
    v1.push_back( sinh ( vc6 ) );

    cout << "The complex components sinh (vci), where abs (vci) = 1"
        << "\n& arg (vci) = i * pi / 6 of the vector v1 are:\n" ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << endl;
}

```

```

Complex number c1 = (3,4)
Complex number c2 = sinh ( c1 ) = (-6.54812,-7.61923)
The modulus of c2 is: 10.0464
The argument of c2 is: -2.28073 radians, which is -130.676 degrees.

The complex components sinh (vci), where abs (vci) = 1
& arg (vci) = i * pi / 6 of the vector v1 are:
(0.858637,0.670731)
(0.337596,0.85898)
(-5.58735e-014,0.841471)
(-0.337596,0.85898)
(-0.858637,0.670731)
(-1.1752,-3.19145e-013)

```

sqrt

Calculates the square root of a complex number.

```
template <class Type>
complex<Type> sqrt(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose square root is to be found.

Return Value

The square root of a complex number.

Remarks

The square root will have a phase angle in the half-open interval $(-\pi/2, \pi/2]$.

The branch cuts in the complex plane are along the negative real axis.

The square root of a complex number will have a modulus that is the square root of the input number and an argument that is one-half that of the input number.

Example

```
// complex_sqrt.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Complex numbers can be entered in polar form with
    // modulus and argument parameter inputs but are
    // stored in Cartesian form as real & imag coordinates
    complex <double> c1 ( polar ( 25.0 , pi / 2 ) );
    complex <double> c2 = sqrt ( c1 );
    cout << "c1 = polar ( 5.0 ) = " << c1 << endl;
    cout << "c2 = sqrt ( c1 ) = " << c2 << endl;

    // The modulus and argument of a complex number can be recovered
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is recovered from c2 using: abs ( c2 ) = "
        << absc2 << endl;
    cout << "Argument of c2 is recovered from c2 using:\n arg ( c2 ) = "
        << argc2 << " radians, which is " << argc2 * 180 / pi
        << " degrees." << endl;

    // The modulus and argument of c2 can be directly calculated
    absc2 = sqrt( abs ( c1 ) );
    argc2 = 0.5 * arg ( c1 );
    cout << "The modulus of c2 = sqrt( abs ( c1 ) ) =" << absc2 << endl;
    cout << "The argument of c2 = ( 1 / 2 ) * arg ( c1 ) ="
        << argc2 << " radians,\n which is " << argc2 * 180 / pi
        << " degrees." << endl;
}
```

```
c1 = polar ( 5.0 ) = (-2.58529e-012,25)
c2 = sqrt ( c1 ) = (3.53553,3.53553)
The modulus of c2 is recovered from c2 using: abs ( c2 ) = 5
Argument of c2 is recovered from c2 using:
arg ( c2 ) = 0.785398 radians, which is 45 degrees.
The modulus of c2 = sqrt( abs ( c1 ) ) =5
The argument of c2 = ( 1 / 2 ) * arg ( c1 ) =0.785398 radians,
which is 45 degrees.
```

tan

Returns the tangent of a complex number.

```
template <class Type>
complex<Type> tan(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose tangent is being determined.

Return Value

The complex number that is the tangent of the input complex number.

Remarks

Identities defining the complex cotangent:

$$\tan (z) = \sin (z) / \cos (z) = (\exp (iz) - \exp (- iz)) / i (\exp (iz) + \exp (- iz))$$

Example

```

// complex_tan.cpp
// compile with: /EHsc
#include <vector>
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    complex <double> c1 ( 3.0 , 4.0 );
    cout << "Complex number c1 = " << c1 << endl;

    // Values of cosine of a complex number c1
    complex <double> c2 = tan ( c1 );
    cout << "Complex number c2 = tan ( c1 ) = " << c2 << endl;
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is: " << absc2 << endl;
    cout << "The argument of c2 is: "<< argc2 << " radians, which is "
        << argc2 * 180 / pi << " degrees." << endl << endl;

    // Hyperbolic tangent of the standard angles
    // in the first two quadrants of the complex plane
    vector <complex <double> > v1;
    vector <complex <double> >::iterator Iter1;
    complex <double> vc1 ( polar ( 1.0, pi / 6 ) );
    v1.push_back( tan ( vc1 ) );
    complex <double> vc2 ( polar ( 1.0, pi / 3 ) );
    v1.push_back( tan ( vc2 ) );
    complex <double> vc3 ( polar ( 1.0, pi / 2 ) );
    v1.push_back( tan ( vc3 ) );
    complex <double> vc4 ( polar ( 1.0, 2 * pi / 3 ) );
    v1.push_back( tan ( vc4 ) );
    complex <double> vc5 ( polar ( 1.0, 5 * pi / 6 ) );
    v1.push_back( tan ( vc5 ) );
    complex <double> vc6 ( polar ( 1.0, pi ) );
    v1.push_back( tan ( vc6 ) );

    cout << "The complex components tan (vci), where abs (vci) = 1"
        << "\n& arg (vci) = i * pi / 6 of the vector v1 are:\n" ;
    for ( Iter1 = v1.begin() ; Iter1 != v1.end() ; Iter1++ )
        cout << *Iter1 << endl;
}

```

```

Complex number c1 = (3,4)
Complex number c2 = tan ( c1 ) = (-0.000187346,0.999356)
The modulus of c2 is: 0.999356
The argument of c2 is: 1.57098 radians, which is 90.0107 degrees.

The complex components tan (vci), where abs (vci) = 1
& arg (vci) = i * pi / 6 of the vector v1 are:
(0.713931,0.85004)
(0.24356,0.792403)
(-4.34302e-014,0.761594)
(-0.24356,0.792403)
(-0.713931,0.85004)
(-1.55741,-7.08476e-013)

```

tanh

Returns the hyperbolic tangent of a complex number.

```
template <class Type>
complex<Type> tanh(const complex<Type>& complexNum);
```

Parameters

complexNum

The complex number whose hyperbolic tangent is being determined.

Return Value

The complex number that is the hyperbolic tangent of the input complex number.

Remarks

Identities defining the complex hyperbolic cotangent:

$$\tanh (z)=\sinh (z) / \cosh (z)=(\exp (z)-\exp (-z)) /(\exp (z)+\exp (-z))$$

Example

```
// complex_tanh.cpp
// compile with: /EHsc
#include <vector>
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    complex <double> c1 ( 3.0 , 4.0 );
    cout << "Complex number c1 = " << c1 << endl;

    // Values of cosine of a complex number c1
    complex <double> c2 = tanh ( c1 );
    cout << "Complex number c2 = tanh ( c1 ) = " << c2 << endl;
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is: " << absc2 << endl;
    cout << "The argument of c2 is: " << argc2 << " radians, which is "
        << argc2 * 180 / pi << " degrees." << endl << endl;

    // Hyperbolic tangents of the standard angles
    // in the first two quadrants of the complex plane
    vector <complex <double> > v1;
    vector <complex <double> >::iterator Iter1;
    complex <double> vc1 ( polar ( 1.0, pi / 6 ) );
    v1.push_back( tanh ( vc1 ) );
    complex <double> vc2 ( polar ( 1.0, pi / 3 ) );
    v1.push_back( tanh ( vc2 ) );
    complex <double> vc3 ( polar ( 1.0, pi / 2 ) );
    v1.push_back( tanh ( vc3 ) );
    complex <double> vc4 ( polar ( 1.0, 2 * pi / 3 ) );
    v1.push_back( tanh ( vc4 ) );
    complex <double> vc5 ( polar ( 1.0, 5 * pi / 6 ) );
    v1.push_back( tanh ( vc5 ) );
    complex <double> vc6 ( polar ( 1.0, pi ) );
    v1.push_back( tanh ( vc6 ) );

    cout << "The complex components tanh (vci), where abs (vci) = 1"
        << "\n& arg (vci) = i * pi / 6 of the vector v1 are:\n" ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << endl;
}
```

```
Complex number c1 = (3,4)
Complex number c2 = tanh ( c1 ) = (1.00071,0.00490826)
The modulus of c2 is: 1.00072
The argument of c2 is: 0.00490474 radians, which is 0.281021 degrees.
```

```
The complex components tanh (vci), where abs (vci) = 1
& arg (vci) = i * pi / 6 of the vector v1 are:
(0.792403,0.24356)
(0.85004,0.713931)
(-3.54238e-013,1.55741)
(-0.85004,0.713931)
(-0.792403,0.24356)

<code>operator!=</code>	<code>operator>></code>	<code>operator<<</code>
<code>operator*</code>	<code>operator+</code>	<code>operator-</code>
<code>operator/</code>	<code>operator==</code>	

operator!=

Tests for inequality between two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.

```
template <class Type>
bool operator!=(
    const complex<Type>& left,
    const complex<Type>& right);

template <class Type>
bool operator!=(
    const complex<Type>& left,
    const Type& right);

template <class Type>
bool operator!=(
    const Type& left,
    const complex<Type>& right);
```

Parameters

left

A complex number or object of its parameter type to be tested for inequality.

right

A complex number or object of its parameter type to be tested for inequality.

Return Value

true if the numbers are not equal; **false** if numbers are equal.

Remarks

Two complex numbers are equal if and only if their real parts are equal and their imaginary parts are equal. Otherwise, they are unequal.

The operation is overloaded so that comparison tests can be executed without the conversion of the data to a particular format.

Example

```
// complex_op_NE.cpp
// compile with: /EHsc
#include <complex>
```

```

#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> compared with type complex<double>
    complex <double> c11 ( polar (3.0, pi / 6 ) );
    complex <double> cr1a ( polar (3.0, pi /6 ) );
    complex <double> cr1b ( polar (2.0, pi / 3 ) );

    cout << "The left-side complex number is c11 = " << c11 << endl;
    cout << "The 1st right-side complex number is cr1a = " << cr1a << endl;
    cout << "The 2nd right-side complex number is cr1b = " << cr1b << endl;
    if ( c11 != cr1a )
        cout << "The complex numbers c11 & cr1a are not equal." << endl;
    else
        cout << "The complex numbers c11 & cr1a are equal." << endl;
    if ( c11 != cr1b )
        cout << "The complex numbers c11 & cr1b are not equal." << endl;
    else
        cout << "The complex numbers c11 & cr1b are equal." << endl;
    cout << endl;

    // Example of the second member function
    // type complex<int> compared with type int
    complex <int> c12a ( 3, 4 );

The complex numbers c12a & cr2a are not equal.
The 2nd left-side complex number is c12b = (5,0)
The 2nd right-side complex number is cr2b = 5
The complex numbers c12b & cr2b are equal.
```

```
The 1st left-side complex number is c13a = 3
The 1st right-side complex number is cr3a = (3,4)
The complex numbers c13a & cr3a are not equal.
The 2nd left-side complex number is c13b = 5
The 2nd right-side complex number is cr3b = (5,0)
The complex numbers c13b & cr3b are equal.
```

operator*

Multiplies two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.

```
template <class Type>
complex<Type> operator*(
    const complex<Type>& left,
    const complex<Type>& right);

template <class Type>
complex<Type> operator*(
    const complex<Type>& left,
    const Type& right);

template <class Type>
complex<Type> operator*(
    const Type& left,
    const complex<Type>& right);
```

Parameters

left

The first of two complex numbers or a number that is of the parameter type for a complex number that is to be multiplied by the * operation.

right

The second of two complex numbers or a number that is of the parameter type for a complex number that is to be multiplied by the * operation.

Return Value

The complex number that results from the multiplication of the two numbers whose value and type are specified by the parameter inputs.

Remarks

The operation is overloaded so that simple arithmetic operations can be executed without the conversion of the data to a particular format.

Example

```
// complex_op_mult.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> times type complex<double>
    complex <double> c11 ( polar (3.0, pi / 6 ) );
    complex <double> cr1 ( polar (2.0, pi / 3 ) );
    complex <double> cs1 = c11 * cr1;

    cout << "The left-side complex number is c11 = " << c11 << endl;
    cout << "The right-side complex number is cr1 = " << cr1 << endl;
    cout << "Product of two complex numbers is: cs1 = " << cs1 << endl;
    double abscs1 = abs ( cs1 );
    double argcs1 = arg ( cs1 );
    cout << "The modulus of cs1 is: " << abscs1 << endl;
    cout << "The argument of cs1 is: "<< argcs1 << " radians, which is "
        << argcs1 * 180 / pi << " degrees." << endl << endl;

    // Example of the second member function
    // type complex<double> times type double
    complex <double> c12 ( polar ( 3.0, pi / 6 ) );
    double cr2 =5;
    complex <double> cs2 = c12 * cr2;

    cout << "The left-side complex number is c12 = " << c12 << endl;
    cout << "The right-side complex number is cr2 = " << cr2 << endl;
    cout << "Product of two complex numbers is: cs2 = " << cs2 << endl;
    double abscs2 = abs ( cs2 );
    double argcs2 = arg ( cs2 );
    cout << "The modulus of cs2 is: " << abscs2 << endl;
    cout << "The argument of cs2 is: "<< argcs2 << " radians, which is "
        << argcs2 * 180 / pi << " degrees." << endl << endl;

    // Example of the third member function
    // type double times type complex<double>
    double c13 = 5;
    complex <double> cr3 ( polar (3.0, pi / 6 ) );
    complex <double> cs3 = c13 * cr3;

    cout << "The left-side complex number is c13 = " << c13 << endl;
    cout << "The right-side complex number is cr3 = " << cr3 << endl;
    cout << "Product of two complex numbers is: cs3 = " << cs3 << endl;
    double abscs3 = abs ( cs3 );
    double argcs3 = arg ( cs3 );
    cout << "The modulus of cs3 is: " << abscs3 << endl;
    cout << "The argument of cs3 is: "<< argcs3 << " radians, which is "
        << argcs3 * 180 / pi << " degrees." << endl << endl;
}
```

operator+

Adds two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.

```

template <class Type>
complex<Type> operator+(
    const complex<Type>& left,
    const complex<Type>& right);

template <class Type>
complex<Type> operator+(
    const complex<Type>& left,
    const Type& right);

template <class Type>
complex<Type> operator+(
    const Type& left,
    const complex<Type>& right);

template <class Type>
complex<Type> operator+(const complex<Type>& left);

```

Parameters

left

The first of two complex numbers or a number that is of the parameter type for a complex number that is to be added by the + operation.

right

The second of two complex numbers or a number that is of the parameter type for a complex number that is to be added by the + operation.

Return Value

The complex number that results from the addition of the two numbers whose value and type are specified by the parameter inputs.

Remarks

The operation is overloaded so that simple arithmetic operations can be executed without the conversion of the data to a particular format. The unary operator returns *left*.

Example

```

// complex_op_add.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> plus type complex<double>
    complex <double> c1 ( 3.0, 4.0 );
    complex <double> cr1 ( 2.0, 5.0 );
    complex <double> cs1 = c1 + cr1;

    cout << "The left-side complex number is c1 = " << c1 << endl;
    cout << "The right-side complex number is cr1 = " << cr1 << endl;
    cout << "The sum of the two complex numbers is: cs1 = " << cs1 << endl;
    double abscs1 = abs ( cs1 );
    double argcs1 = arg ( cs1 );
    cout << "The modulus of cs1 is: " << abscs1 << endl;
    cout << "The argument of cs1 is: " << argcs1 << " radians, which is "
        << argcs1 * 180 / pi << " degrees." << endl << endl;
}

```

```

// Example of the second member function
// type complex<double> plus type double
complex <double> c12 ( 3.0, 4.0 );
double cr2 =5.0;
complex <double> cs2 = c12 + cr2;

cout << "The left-side complex number is c12 = " << c12 << endl;
cout << "The right-side complex number is cr2 = " << cr2 << endl;
cout << "The sum of the two complex numbers is: cs2 = " << cs2 << endl;
double abscs2 = abs ( cs2 );
double argcs2 = arg ( cs2 );
cout << "The modulus of cs2 is: " << abscs2 << endl;
cout << "The argument of cs2 is: "<< argcs2 << " radians, which is "
    << argcs2 * 180 / pi << " degrees." << endl << endl;

// Example of the third member function
// type double plus type complex<double>
double c13 = 5.0;
complex <double> cr3 ( 3.0, 4.0 );
complex <double> cs3 = c13 + cr3;

cout << "The left-side complex number is c13 = " << c13 << endl;
cout << "The right-side complex number is cr3 = " << cr3 << endl;
cout << "The sum of the two complex numbers is: cs3 = " << cs3 << endl;
double abscs3 = abs ( cs3 );
double argcs3 = arg ( cs3 );
cout << "The modulus of cs3 is: " << abscs3 << endl;
cout << "The argument of cs3 is: "<< argcs3 << " radians, which is "
    << argcs3 * 180 / pi << " degrees." << endl << endl;

// Example of the fourth member function
// plus type complex<double>
complex <double> cr4 ( 3.0, 4.0 );
complex <double> cs4 = + cr4;

cout << "The right-side complex number is cr4 = " << cr4 << endl;
cout << "The result of the unary application of + to the right-side"
    << "\n complex number is: cs4 = " << cs4 << endl;
double abscs4 = abs ( cs4 );
double argcs4 = arg ( cs4 );
cout << "The modulus of cs4 is: " << abscs4 << endl;
cout << "The argument of cs4 is: "<< argcs4 << " radians, which is "
    << argcs4 * 180 / pi << " degrees." << endl << endl;
}

```

```

The left-side complex number is c11 = (3,4)
The right-side complex number is cr1 = (2,5)
The sum of the two complex numbers is: cs1 = (5,9)
The modulus of cs1 is: 10.2956
The argument of cs1 is: 1.0637 radians, which is 60.9454 degrees.

The left-side complex number is c12 = (3,4)
The right-side complex number is cr2 = 5
The sum of the two complex numbers is: cs2 = (8,4)
The modulus of cs2 is: 8.94427
The argument of cs2 is: 0.463648 radians, which is 26.5651 degrees.

The left-side complex number is c13 = 5
The right-side complex number is cr3 = (3,4)
The sum of the two complex numbers is: cs3 = (8,4)
The modulus of cs3 is: 8.94427
The argument of cs3 is: 0.463648 radians, which is 26.5651 degrees.

The right-side complex number is cr4 = (3,4)
The result of the unary application of + to the right-side
complex number is: cs4 = (3,4)
The modulus of cs4 is: 5
The argument of cs4 is: 0.927295 radians, which is 53.1301 degrees.

```

operator-

Subtracts two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.

```

template <class Type>
complex<Type> operator-(
    const complex<Type>& left,
    const complex<Type>& right);

template <class Type>
complex<Type> operator-(
    const complex<Type>& left,
    const Type& right);

template <class Type>
complex<Type> operator-(
    const Type& left,
    const complex<Type>& right);

template <class Type>
complex<Type> operator-(const complex<Type>& left);

```

Parameters

left

The first of two complex numbers or a number that is of the parameter type for a complex number that is to be subtracted by the - operation.

right

The second of two complex numbers or a number that is of the parameter type for a complex number that is to be subtracted by the - operation.

Return Value

The complex number that results from the subtraction of *right* from *left*, the two numbers whose values are specified by the parameter inputs.

Remarks

The operation is overloaded so that simple arithmetic operations can be executed without the conversion of the data to a particular format.

The unary operator changes the sign of a complex number and returns a value whose real part is the negative of the real part of the number input and whose imaginary part is the negative of the imaginary part of the number input.

Example

```
// complex_op_sub.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> minus type complex<double>
    complex <double> c1 ( 3.0, 4.0 );
    complex <double> cr1 ( 2.0, 5.0 );
    complex <double> cs1 = c1 - cr1;

    cout << "The left-side complex number is c1 = " << c1 << endl;
    cout << "The right-side complex number is cr1 = " << cr1 << endl;
    cout << "Difference of two complex numbers is: cs1 = " << cs1 << endl;
    double abscs1 = abs ( cs1 );
    double argcs1 = arg ( cs1 );
    cout << "The modulus of cs1 is: " << abscs1 << endl;
    cout << "The argument of cs1 is: "<< argcs1 << " radians, which is "
        << argcs1 * 180 / pi << " degrees." << endl << endl;

    // Example of the second member function
    // type complex<double> minus type double
    complex <double> c2 ( 3.0, 4.0 );
    double cr2 =5.0;
    complex <double> cs2 = c2 - cr2;

    cout << "The left-side complex number is c2 = " << c2 << endl;
    cout << "The right-side complex number is cr2 = " << cr2 << endl;
    cout << "Difference of two complex numbers is: cs2 = " << cs2 << endl;
    double abscs2 = abs ( cs2 );
    double argcs2 = arg ( cs2 );
    cout << "The modulus of cs2 is: " << abscs2 << endl;
    cout << "The argument of cs2 is: "<< argcs2 << " radians, which is "
        << argcs2 * 180 / pi << " degrees." << endl << endl;

    // Example of the third member function
    // type double minus type complex<double>
    double c3 = 5.0;
    complex <double> cr3 ( 3.0, 4.0 );
    complex <double> cs3 = c3 - cr3;

    cout << "The left-side complex number is c3 = " << c3 << endl;
    cout << "The right-side complex number is cr3 = " << cr3 << endl;
    cout << "Difference of two complex numbers is: cs3 = " << cs3 << endl;
    double abscs3 = abs ( cs3 );
    double argcs3 = arg ( cs3 );
    cout << "The modulus of cs3 is: " << abscs3 << endl;
    cout << "The argument of cs3 is: "<< argcs3 << " radians, which is "
        << argcs3 * 180 / pi << " degrees." << endl << endl;

    // Example of the fourth member function
    // minus type complex<double>
```

```
// minus type complex<double>
complex <double> cr4 ( 3.0, 4.0 );
complex <double> cs4 = - cr4;

cout << "The right-side complex number is cr4 = " << cr4 << endl;
cout << "The result of the unary application of - to the right-side"
    << "\n complex number is: cs4 = " << cs4 << endl;
double abscs4 = abs ( cs4 );
double argcs4 = arg ( cs4 );
cout << "The modulus of cs4 is: " << abscs4 << endl;
cout << "The argument of cs4 is: "<< argcs4 << " radians, which is "
    << argcs4 * 180 / pi << " degrees." << endl << endl;
}
```

```
The left-side complex number is cl1 = (3,4)
The right-side complex number is cr1 = (2,5)
Difference of two complex numbers is: cs1 = (1,-1)
The modulus of cs1 is: 1.41421
The argument of cs1 is: -0.785398 radians, which is -45 degrees.

The left-side complex number is cl2 = (3,4)
The right-side complex number is cr2 = 5
Difference of two complex numbers is: cs2 = (-2,4)
The modulus of cs2 is: 4.47214
The argument of cs2 is: 2.03444 radians, which is 116.565 degrees.

The left-side complex number is cl3 = 5
The right-side complex number is cr3 = (3,4)
Difference of two complex numbers is: cs3 = (2,-4)
The modulus of cs3 is: 4.47214
The argument of cs3 is: -1.10715 radians, which is -63.4349 degrees.

The right-side complex number is cr4 = (3,4)
The result of the unary application of - to the right-side
complex number is: cs4 = (-3,-4)
The modulus of cs4 is: 5
The argument of cs4 is: -2.2143 radians, which is -126.87 degrees.
```

operator/

Divides two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.

```
template <class Type>
complex<Type> operator*(
    const complex<Type>& left,
    const complex<Type>& right);

template <class Type>
complex<Type> operator*(
    const complex<Type>& left,
    const Type& right);

template <class Type>
complex<Type> operator*(
    const Type& left,
    const complex<Type>& right);
```

Parameters

left

A complex number or a number that is of the parameter type for a complex number that is the numerator to be divided by the denominator with the / operation.

right

A complex number or a number that is of the parameter type for a complex number that is the denominator to be used to divide the numerator with the / operation.

Return Value

The complex number that results from the division of the numerator by the denominator, the values of which are specified by the parameter inputs.

Remarks

The operation is overloaded so that simple arithmetic operations can be executed without the conversion of the data to a particular format.

Example

```

// complex_op_div.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> divided by type complex<double>
    complex <double> c1 ( polar ( 3.0, pi / 6 ) );
    complex <double> cr1 ( polar ( 2.0, pi / 3 ) );
    complex <double> cs1 = c1 / cr1;

    cout << "The left-side complex number is c1 = " << c1 << endl;
    cout << "The right-side complex number is cr1 = " << cr1 << endl;
    cout << "The quotient of the two complex numbers is: cs1 = c1 / cr1 = "
        << cs1 << endl;
    double abscs1 = abs ( cs1 );
    double argcs1 = arg ( cs1 );
    cout << "The modulus of cs1 is: " << abscs1 << endl;
    cout << "The argument of cs1 is: "<< argcs1 << " radians, which is "
        << argcs1 * 180 / pi << " degrees." << endl << endl;

    // example of the second member function
    // type complex<double> divided by type double
    complex <double> c2 ( polar (3.0, pi / 6 ) );
    double cr2 =5;
    complex <double> cs2 = c2 / cr2;

    cout << "The left-side complex number is c2 = " << c2 << endl;
    cout << "The right-side complex number is cr2 = " << cr2 << endl;
    cout << "The quotient of the two complex numbers is: cs2 = c2 / cr2 = "
        << cs2 << endl;
    double abscs2 = abs ( cs2 );
    double argcs2 = arg ( cs2 );
    cout << "The modulus of cs2 is: " << abscs2 << endl;
    cout << "The argument of cs2 is: "<< argcs2 << " radians, which is "
        << argcs2 * 180 / pi << " degrees." << endl << endl;

    // Example of the third member function
    // type double divided by type complex<double>
    double c3 = 5;
    complex <double> cr3 ( polar ( 3.0, pi / 6 ) );
    complex <double> cs3 = c3 / cr3;

    cout << "The left-side complex number is c3 = " << c3 << endl;
    cout << "The right-side complex number is cr3 = " << cr3 << endl;
    cout << "The quotient of the two complex numbers is: cs3 = c3 / cr2 = "
        << cs3 << endl;
    double abscs3 = abs ( cs3 );
    double argcs3 = arg ( cs3 );
    cout << "The modulus of cs3 is: " << abscs3 << endl;
    cout << "The argument of cs3 is: "<< argcs3 << " radians, which is "
        << argcs3 * 180 / pi << " degrees." << endl << endl;
}

```

The left-side complex number is $cl1 = (2.59808, 1.5)$
The right-side complex number is $cr1 = (1, 1.73205)$
The quotient of the two complex numbers is: $cs1 = cl1 / cr1 = (1.29904, -0.75)$
The modulus of $cs1$ is: 1.5
The argument of $cs1$ is: -0.523599 radians, which is -30 degrees.

The left-side complex number is $cl2 = (2.59808, 1.5)$
The right-side complex number is $cr2 = 5$
The quotient of the two complex numbers is: $cs2 = cl2 / cr2 = (0.519615, 0.3)$
The modulus of $cs2$ is: 0.6
The argument of $cs2$ is: 0.523599 radians, which is 30 degrees.

The left-side complex number is $cl3 = 5$
The right-side complex number is $cr3 = (2.59808, 1.5)$
The quotient of the two complex numbers is: $cs3 = cl3 / cr3 = (1.44338, -0.833333)$
The modulus of $cs3$ is: 1.66667
The argument of $cs3$ is: -0.523599 radians, which is -30 degrees.

operator<<

Inserts a complex number specified into the output stream.

```
template <class Type, class Elem, class Traits>
basic_ostream<Elem, Traits>& operator<<(  
    basic_ostream<Elem, Traits>& Ostr,  
    const complex<Type>& right);
```

Parameters

Ostr

The output stream into which the complex number is being entered.

right

The complex number to be entered into the output stream

Return Value

Writes the value of the specified complex number to the *Ostr* in a Cartesian format: (*real part*, *imaginary part*).

Remarks

The output stream is overloaded so that it will accept any form of a complex number, and its default output format is the Cartesian format.

Example

```
// complex_op_insert.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    complex <double> c1 ( 3.0, 4.0 );
    cout << "Complex number c1 = " << c1 << endl;

    complex <double> c2 ( polar ( 2.0, pi / 6 ) );
    cout << "Complex number c2 = " << c2 << endl;

    // To display in polar form
    double absc2 = abs ( c2 );
    double argc2 = arg ( c2 );
    cout << "The modulus of c2 is: " << absc2 << endl;
    cout << "The argument of c2 is: " << argc2 << " radians, which is "
        << argc2 * 180 / pi << " degrees." << endl << endl;
}
```

```
Complex number c1 = (3,4)
Complex number c2 = (1.73205,1)
The modulus of c2 is: 2
The argument of c2 is: 0.523599 radians, which is 30 degrees.
```

operator==

Tests for equality between two complex numbers, one or both of which may belong to the subset of the type for the real and imaginary parts.

```
template <class Type>
bool operator==(
    const complex<Type>& left,
    const complex<Type>& right);

template <class Type>
bool operator==(
    const complex<Type>& left,
    const Type& right);

template <class Type>
bool operator==(
    const Type& left,
    const complex<Type>& right);
```

Parameters

left

A complex number or object of its parameter type to be tested for inequality.

right

A complex number or object of its parameter type to be tested for inequality.

Return Value

true if the numbers are equal; **false** if numbers are not equal.

Remarks

Two complex numbers are equal if and only if their real parts are equal and their imaginary parts are equal. Otherwise, they are unequal.

The operation is overloaded so that comparison tests can be executed without the conversion of the data to a particular format.

Example

```
// complex_op_EQ.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> compared with type complex<double>
    complex <double> c11 ( polar ( 3.0, pi / 6 ) );
    complex <double> cr1a ( polar ( 3.0, pi / 6 ) );
    complex <double> cr1b ( polar ( 2.0, pi / 3 ) );

    cout << "The left-side complex number is c11 = " << c11 << endl;
    cout << "The 1st right-side complex number is cr1a = " << cr1a << endl;
    cout << "The 2nd right-side complex number is cr1b = " << cr1b << endl;
    if ( c11 == cr1a )
        cout << "The complex numbers c11 & cr1a are equal." << endl;
    else
        cout << "The complex numbers c11 & cr1a are not equal." << endl;
    if ( c11 == cr1b )
        cout << "The complex numbers c11 & cr1b are equal." << endl;
    else
        cout << "The complex numbers c11 & cr1b are not equal." << endl;
    cout << endl;

    // Example of the second member function
    // type complex<int> compared with type int
    complex <int> c12a ( 3, 4 );
    complex <int> c12b ( 5, 0 );
    int cr2a = 3;
    int cr2b = 5;

    cout << "The 1st left-side complex number is c12a = " << c12a << endl;
    cout << "The 1st right-side complex number is cr2a = " << cr2a << endl;
    if ( c12a == cr2a )
        cout << "The complex numbers c12a & cr2a are equal." << endl;
    else
        cout << "The complex numbers c12a & cr2a are not equal." << endl;

    cout << "The 2nd left-side complex number is c12b = " << c12b << endl;
    cout << "The 2nd right-side complex number is cr2b = " << cr2b << endl;
    if ( c12b == cr2b )
        cout << "The complex numbers c12b & cr2b are equal." << endl;
    else
        cout << "The complex numbers c12b & cr2b are not equal." << endl;
    cout << endl;

    // Example of the third member function
    // type double compared with type complex<double>
    double c13a = 3;
    double c13b = 5;
    complex <double> cr3a ( 3, 4 );
    complex <double> cr3b ( 5, 0 );
```

```

cout << "The 1st left-side complex number is c13a = " << c13a << endl;
cout << "The 1st right-side complex number is cr3a = " << cr3a << endl;
if ( c13a == cr3a )
    cout << "The complex numbers c13a & cr3a are equal." << endl;
else
    cout << "The complex numbers c13a & cr3a are not equal." << endl;

cout << "The 2nd left-side complex number is c13b = " << c13b << endl;
cout << "The 2nd right-side complex number is cr3b = " << cr3b << endl;
if ( c13b == cr3b )
    cout << "The complex numbers c13b & cr3b are equal." << endl;
else
    cout << "The complex numbers c13b & cr3b are not equal." << endl;
cout << endl;
}

```

The left-side complex number is c11 = (2.59808,1.5)
 The 1st right-side complex number is cr1a = (2.59808,1.5)
 The 2nd right-side complex number is cr1b = (1,1.73205)
 The complex numbers c11 & cr1a are equal.
 The complex numbers c11 & cr1b are not equal.

The 1st left-side complex number is c12a = (3,4)
 The 1st right-side complex number is cr2a = 3
 The complex numbers c12a & cr2a are not equal.
 The 2nd left-side complex number is c12b = (5,0)
 The 2nd right-side complex number is cr2b = 5
 The complex numbers c12b & cr2b are equal.

The 1st left-side complex number is c13a = 3
 The 1st right-side complex number is cr3a = (3,4)
 The complex numbers c13a & cr3a are not equal.
 The 2nd left-side complex number is c13b = 5
 The 2nd right-side complex number is cr3b = (5,0)
 The complex numbers c13b & cr3b are equal.

operator>>

Extracts a complex value from the input stream.

```

template <class Type, class Elem, class Traits>
basic_istream<Elem, Traits>& operator>>(
    basic_istream<Elem, Traits>& Istr,
    complex<Type>& right);

```

Parameters

Istr

The input stream from which the complex number is being extracted.

right

The complex number that is being extracted from the input stream.

Return Value

Reads the value of the specified complex number from *Istr* and returns it into *right*.

Remarks

The valid input formats are

- *(real part, imaginary part)*

- *(real part)*
- *real part*

Example

```
// complex_op_extract.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    complex <double> c2;

    cout << "Input a complex number ( try: 2.0 ): ";
    cin >> c2;
    cout << c2 << endl;
}
```

```
Input a complex number ( try: 2.0 ): 2.0
2.0
```

complex Class

3/28/2019 • 18 minutes to read • [Edit Online](#)

The template class describes an object that stores two objects of type `Type`, one that represents the real part of a complex number and one that represents the imaginary part.

Syntax

```
template <class Type>
class complex
```

Remarks

An object of class `Type`:

- Has a public default constructor, destructor, copy constructor, and assignment operator with conventional behavior.
- Can be assigned integer or floating-point values, or type cast to such values with conventional behavior.
- Defines the arithmetic operators and math functions, as needed, that are defined for the floating-point types with conventional behavior.

In particular, no subtle differences may exist between copy construction and default construction followed by assignment. None of the operations on objects of class `Type` may throw exceptions.

Explicit specializations of template class `complex` exist for the three floating-point types. In this implementation, a value of any other type `Type` is typecast to **double** for actual calculations, with the **double** result assigned back to the stored object of type `Type`.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>complex</code>	Constructs a complex number with specified real and imaginary parts or as a copy of some other complex number.

Typedefs

TYPE NAME	DESCRIPTION
<code>value_type</code>	A type that represents the data type used to represent the real and imaginary parts of a complex number.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>imag</code>	Extracts the imaginary component of a complex number.
<code>real</code>	Extracts the real component of a complex number.

Operators

OPERATOR	DESCRIPTION
<code>operator* =</code>	Multiplies a target complex number by a factor, which may be complex or be the same type as are the real and imaginary parts of the complex number.
<code>operator+ =</code>	Adds a number to a target complex number, where the number added may be complex or of the same type as are the real and imaginary parts of the complex number to which it is added.
<code>operator- =</code>	Subtracts a number from a target complex number, where the number subtracted may be complex or of the same type as are the real and imaginary parts of the complex number to which it is added.
<code>operator/=</code>	Divides a target complex number by a divisor, which may be complex or be the same type as are the real and imaginary parts of the complex number.
<code>operator=</code>	Assigns a number to a target complex number, where the number assigned may be complex or of the same type as are the real and imaginary parts of the complex number to which it is being assigned.

Requirements

Header: <complex>

Namespace: std

complex::complex

Constructs a complex number with specified real and imaginary parts or as a copy of some other complex number.

```
constexpr complex(  
    const T& _RealVal = 0,  
    const T& _ImagVal = 0);  
  
template <class Other>  
constexpr complex(  
    const complex<Other>& complexNum);
```

Parameters

_RealVal

The value of the real part used to initialize the complex number being constructed.

_ImagVal

The value of the imaginary part used to initialize the complex number being constructed.

complexNum

The complex number whose real and imaginary parts are used to initialize the complex number being constructed.

Remarks

The first constructor initializes the stored real part to *_RealVal* and the stored imaginary part to *_ImagVal*. The second constructor initializes the stored real part to `complexNum.real()` and the stored imaginary part to `complexNum.imag()`.

In this implementation, if a translator does not support member template functions, the template:

```
template <class Other>
complex(const complex<Other>& right);
```

is replaced with:

```
complex(const complex& right);
```

which is the copy constructor.

Example

```
// complex_complex.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // The first constructor specifies real & imaginary parts
    complex<double> c1( 4.0 , 5.0 );
    cout << "Specifying initial real & imaginary parts,"
         << "c1 = " << c1 << endl;

    // The second constructor initializes values of the real &
    // imaginary parts using those of another complex number
    complex<double> c2( c1 );
    cout << "Initializing with the real and imaginary parts of c1,"
         << " c2 = " << c2 << endl;

    // Complex numbers can be initialized in polar form
    // but will be stored in Cartesian form
    complex<double> c3( polar( sqrt( (double)8 ) , pi / 4 ) );
    cout << "c3 = polar( sqrt( 8 ) , pi / 4 ) = " << c3 << endl;

    // The modulus and argument of a complex number can be recovered
    double absc3 = abs( c3 );
    double argc3 = arg( c3 );
    cout << "The modulus of c3 is recovered from c3 using: abs( c3 ) = "
         << absc3 << endl;
    cout << "Argument of c3 is recovered from c3 using:\n arg( c3 ) = "
         << argc3 << " radians, which is " << argc3 * 180 / pi
         << " degrees." << endl;
}
```

complex::imag

Extracts the imaginary component of a complex number.

```
T imag() const;

T imag(const T& right);
```

Parameters

right

A complex number whose imaginary value is to be extracted.

Return Value

The imaginary part of the complex number.

Remarks

For a complex number $a + bi$, the imaginary part or component is $Im(a + bi) = b$.

Example

```
// complex_imag.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;

    complex<double> c1( 4.0 , 3.0 );
    cout << "The complex number c1 = " << c1 << endl;

    double dr1 = c1.real();
    cout << "The real part of c1 is c1.real() = "
        << dr1 << "." << endl;

    double di1 = c1.imag();
    cout << "The imaginary part of c1 is c1.imag() = "
        << di1 << "." << endl;
}
```

```
The complex number c1 = (4,3)
The real part of c1 is c1.real() = 4.
The imaginary part of c1 is c1.imag() = 3.
```

complex::operator*=

Multiplies a target complex number by a factor, which may be complex or be the same type as are the real and imaginary parts of the complex number.

```
template <class Other>
complex& operator*=(const complex<Other>& right);

complex<Type>& operator*=(const Type& right);

complex<Type>& operator*=(const complex<Type>& right);
```

Parameters

right

A complex number or a number that is of the same type as the parameter of the target complex number.

Return Value

A complex number that has been multiplied by the number specified as a parameter.

Remarks

The operation is overloaded so that simple arithmetic operations can be executed without the conversion of the data to a particular format.

Example

```
// complex_op_me.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main()
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> multiplied by type complex<double>
    complex<double> c1( polar ( 3.0 , pi / 6 ) );
    complex<double> cr1( polar ( 2.0 , pi / 3 ) );
    cout << "The left-side complex number is c1 = " << c1 << endl;
    cout << "The right-side complex number is cr1 = " << cr1 << endl;

    complex<double> cs1 = c1 * cr1;
    cout << "Quotient of two complex numbers is: cs1 = c1 * cr1 = "
         << cs1 << endl;

    // This is equivalent to the following operation
    c1 *= cr1;
    cout << "Quotient of two complex numbers is also: c1 *= cr1 = "
         << c1 << endl;

    double abscl1 = abs ( c1 );
    double argcl1 = arg ( c1 );
    cout << "The modulus of c1 is: " << abscl1 << endl;
    cout << "The argument of c1 is: "<< argcl1 << " radians, which is "
         << argcl1 * 180 / pi << " degrees." << endl << endl;

    // Example of the second member function
    // type complex<double> multiplied by type double
    complex<double> c2 ( polar ( 3.0 , pi / 6 ) );
    double cr2 = 5.0;
    cout << "The left-side complex number is c2 = " << c2 << endl;
    cout << "The right-side complex number is cr2 = " << cr2 << endl;

    complex<double> cs2 = c2 * cr2;
    cout << "Quotient of two complex numbers is: cs2 = c2 * cr2 = "
         << cs2 << endl;

    // This is equivalent to the following operation
    c2 *= cr2;
    cout << "Quotient of two complex numbers is also: c2 *= cr2 = "
         << c2 << endl;

    double abscl2 = abs ( c2 );
    double argcl2 = arg ( c2 );
    cout << "The modulus of c2 is: " << abscl2 << endl;
    cout << "The argument of c2 is: "<< argcl2 << " radians, which is "
         << argcl2 * 180 / pi << " degrees." << endl;
}
```

complex::operator+=

Adds a number to a target complex number, where the number added may be complex or of the same type as are the real and imaginary parts of the complex number to which it is added.

```
template <class Other>
complex<Type>& operator+=(const complex<Other>& right);

complex<Type>& operator+=(const Type& right);

complex<Type>& operator+=(const complex<Type>& right);
```

Parameters

right

A complex number or a number that is of the same type as the parameter of the target complex number.

Return Value

A complex number that has had the number specified as a parameter added.

Remarks

The operation is overloaded so that simple arithmetic operations can be executed without the conversion of the data to a particular format.

Example

```

// complex_op_pe.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> added to type complex<double>
    complex<double> cl1( 3.0 , 4.0 );
    complex<double> cr1( 2.0 , -1.0 );
    cout << "The left-side complex number is cl1 = " << cl1 << endl;
    cout << "The right-side complex number is cr1 = " << cr1 << endl;

    complex<double> cs1 = cl1 + cr1;
    cout << "The sum of the two complex numbers is: cs1 = cl1 + cr1 = "
        << cs1 << endl;

    // This is equivalent to the following operation
    cl1 += cr1;
    cout << "The complex number cr1 added to the complex number cl1 is:"
        << "\n cl1 += cr1 = " << cl1 << endl;

    double abscl1 = abs( cl1 );
    double argcl1 = arg( cl1 );
    cout << "The modulus of cl1 is: " << abscl1 << endl;
    cout << "The argument of cl1 is: "<< argcl1 << " radians, which is "
        << argcl1 * 180 / pi << " degrees." << endl << endl;

    // Example of the second member function
    // type double added to type complex<double>
    complex<double> cl2( -2 , 4 );
    double cr2 = 5.0;
    cout << "The left-side complex number is cl2 = " << cl2 << endl;
    cout << "The right-side complex number is cr2 = " << cr2 << endl;

    complex<double> cs2 = cl2 + cr2;
    cout << "The sum of the two complex numbers is: cs2 = cl2 + cr2 = "
        << cs2 << endl;

    // This is equivalent to the following operation
    cl2 += cr2;
    cout << "The complex number cr2 added to the complex number cl2 is:"
        << "\n cl2 += cr2 = " << cl2 << endl;

    double abscl2 = abs( cl2 );
    double argcl2 = arg( cl2 );
    cout << "The modulus of cl2 is: " << abscl2 << endl;
    cout << "The argument of cl2 is: "<< argcl2 << " radians, which is "
        << argcl2 * 180 / pi << " degrees." << endl << endl;
}

```

```
The left-side complex number is c11 = (3,4)
The right-side complex number is cr1 = (2,-1)
The sum of the two complex numbers is: cs1 = c11 + cr1 = (5,3)
The complex number cr1 added to the complex number c11 is:
c11 += cr1 = (5,3)
The modulus of c11 is: 5.83095
The argument of c11 is: 0.54042 radians, which is 30.9638 degrees.

The left-side complex number is c12 = (-2,4)
The right-side complex number is cr2 = 5
The sum of the two complex numbers is: cs2 = c12 + cr2 = (3,4)
The complex number cr2 added to the complex number c12 is:
c12 += cr2 = (3,4)
The modulus of c12 is: 5
The argument of c12 is: 0.927295 radians, which is 53.1301 degrees.
```

complex::operator-=

Subtracts a number from a target complex number, where the number subtracted may be complex or of the same type as are the real and imaginary parts of the complex number to which it is added.

```
template <class Other>
complex<Type>& operator-=(const complex<Other>& complexNum);

complex<Type>& operator-=(const Type& _RealPart);

complex<Type>& operator-=(const complex<Type>& complexNum);
```

Parameters

complexNum

A complex number to be subtracted from the target complex number.

_RealPart

A real number to be subtracted from the target complex number.

Return Value

A complex number that has had the number specified as a parameter subtracted from it.

Remarks

The operation is overloaded so that simple arithmetic operations can be executed without the conversion of the data to a particular format.

Example

```

// complex_op_se.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> subtracted from type complex<double>
    complex<double> cl1( 3.0 , 4.0 );
    complex<double> cr1( 2.0 , -1.0 );
    cout << "The left-side complex number is cl1 = " << cl1 << endl;
    cout << "The right-side complex number is cr1 = " << cr1 << endl;

    complex<double> cs1 = cl1 - cr1;
    cout << "The difference between the two complex numbers is:"
        << "\n cs1 = cl1 - cr1 = " << cs1 << endl;

    // This is equivalent to the following operation
    cl1 -= cr1;
    cout << "Complex number cr1 subtracted from complex number cl1 is:"
        << "\n cl1 -= cr1 = " << cl1 << endl;

    double abscl1 = abs( cl1 );
    double argcl1 = arg( cl1 );
    cout << "The modulus of cl1 is: " << abscl1 << endl;
    cout << "The argument of cl1 is: "<< argcl1 << " radians, which is "
        << argcl1 * 180 / pi << " degrees." << endl << endl;

    // Example of the second member function
    // type double subtracted from type complex<double>
    complex<double> cl2( 2.0 , 4.0 );
    double cr2 = 5.0;
    cout << "The left-side complex number is cl2 = " << cl2 << endl;
    cout << "The right-side complex number is cr2 = " << cr2 << endl;

    complex<double> cs2 = cl2 - cr2;
    cout << "The difference between the two complex numbers is:"
        << "\n cs2 = cl2 - cr2 = " << cs2 << endl;

    // This is equivalent to the following operation
    cl2 -= cr2;
    cout << "Complex number cr2 subtracted from complex number cl2 is:"
        << "\n cl2 -= cr2 = " << cl2 << endl;

    double abscl2 = abs( cl2 );
    double argcl2 = arg( cl2 );
    cout << "The modulus of cl2 is: " << abscl2 << endl;
    cout << "The argument of cl2 is: "<< argcl2 << " radians, which is "
        << argcl2 * 180 / pi << " degrees." << endl << endl;
}

```

```
The left-side complex number is c11 = (3,4)
The right-side complex number is cr1 = (2,-1)
The difference between the two complex numbers is:
cs1 = c11 - cr1 = (1,5)
Complex number cr1 subtracted from complex number c11 is:
c11 -= cr1 = (1,5)
The modulus of c11 is: 5.09902
The argument of c11 is: 1.3734 radians, which is 78.6901 degrees.
```

```
The left-side complex number is c12 = (2,4)
The right-side complex number is cr2 = 5
The difference between the two complex numbers is:
cs2 = c12 - cr2 = (-3,4)
Complex number cr2 subtracted from complex number c12 is:
c12 -= cr2 = (-3,4)
The modulus of c12 is: 5
The argument of c12 is: 2.2143 radians, which is 126.87 degrees.
```

complex::operator/=

Divides a target complex number by a divisor, which may be complex or be the same type as are the real and imaginary parts of the complex number.

```
template <class Other>
complex<Type>& operator/=(const complex<Other>& complexNum);

complex<Type>& operator/=(const Type& _RealPart);

complex<Type>& operator/=(const complex<Type>& complexNum);
```

Parameters

complexNum

A complex number to be subtracted from the target complex number.

_RealPart

A real number to be subtracted from the target complex number.

Return Value

A complex number that has been divided by the number specified as a parameter.

Remarks

The operation is overloaded so that simple arithmetic operations can be executed without the conversion of the data to a particular format.

Example

```

// complex_op_de.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> divided by type complex<double>
    complex<double> c1( polar (3.0 , pi / 6 ) );
    complex<double> cr1( polar (2.0 , pi / 3 ) );
    cout << "The left-side complex number is c1 = " << c1 << endl;
    cout << "The right-side complex number is cr1 = " << cr1 << endl;

    complex<double> cs1 = c1 / cr1;
    cout << "The quotient of the two complex numbers is: cs1 = c1 / cr1 = "
        << cs1 << endl;

    // This is equivalent to the following operation
    c1 /= cr1;
    cout << "Quotient of two complex numbers is also: c1 /= cr1 = "
        << c1 << endl;

    double abscl1 = abs( c1 );
    double argcl1 = arg( c1 );
    cout << "The modulus of c1 is: " << abscl1 << endl;
    cout << "The argument of c1 is: "<< argcl1 << " radians, which is "
        << argcl1 * 180 / pi << " degrees." << endl << endl;

    // Example of the second member function
    // type complex<double> divided by type double
    complex<double> c2( polar(3.0 , pi / 6 ) );
    double cr2 =5;
    cout << "The left-side complex number is c2 = " << c2 << endl;
    cout << "The right-side complex number is cr2 = " << cr2 << endl;

    complex<double> cs2 = c2 / cr2;
    cout << "The quotient of the two complex numbers is: cs2 /= c2 cr2 = "
        << cs2 << endl;

    // This is equivalent to the following operation
    c2 /= cr2;
    cout << "Quotient of two complex numbers is also: c2 = /cr2 = "
        << c2 << endl;

    double abscl2 = abs( c2 );
    double argcl2 = arg( c2 );
    cout << "The modulus of c2 is: " << abscl2 << endl;
    cout << "The argument of c2 is: "<< argcl2 << " radians, which is "
        << argcl2 * 180 / pi << " degrees." << endl << endl;
}

```

```
The left-side complex number is c11 = (2.59808,1.5)
The right-side complex number is cr1 = (1,1.73205)
The quotient of the two complex numbers is: cs1 = c11 /cr1 = (1.29904,-0.75)
Quotient of two complex numbers is also: c11 /= cr1 = (1.29904,-0.75)
The modulus of c11 is: 1.5
The argument of c11 is: -0.523599 radians, which is -30 degrees.

The left-side complex number is c12 = (2.59808,1.5)
The right-side complex number is cr2 = 5
The quotient of the two complex numbers is: cs2 /= c12 cr2 = (0.519615,0.3)
Quotient of two complex numbers is also: c12 = /cr2 = (0.519615,0.3)
The modulus of c12 is: 0.6
The argument of c12 is: 0.523599 radians, which is 30 degrees.
```

complex::operator=

Assigns a number to a target complex number, where the number assigned may be complex or of the same type as are the real and imaginary parts of the complex number to which it is being assigned.

```
template <class Other>
complex<Type>& operator=(const complex<Other>& right);

complex<Type>& operator=(const Type& right);
```

Parameters

right

A complex number or a number that is of the same type as the parameter of the target complex number.

Return Value

A complex number that has been assigned the number specified as a parameter.

Remarks

The operation is overloaded so that simple arithmetic operations can be executed without the conversion of the data to a particular format.

Example

```

// complex_op_as.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // Example of the first member function
    // type complex<double> assigned to type complex<double>
    complex<double> cl1( 3.0 , 4.0 );
    complex<double> cr1( 2.0 , -1.0 );
    cout << "The left-side complex number is cl1 = " << cl1 << endl;
    cout << "The right-side complex number is cr1 = " << cr1 << endl;

    cl1 = cr1;
    cout << "The complex number cr1 assigned to the complex number cl1 is:"
        << "\ncl1 = cr1 = " << cl1 << endl;

    // Example of the second member function
    // type double assigned to type complex<double>
    complex<double> cl2( -2 , 4 );
    double cr2 =5.0;
    cout << "The left-side complex number is cl2 = " << cl2 << endl;
    cout << "The right-side complex number is cr2 = " << cr2 << endl;

    cl2 = cr2;
    cout << "The complex number cr2 assigned to the complex number cl2 is:"
        << "\ncl2 = cr2 = " << cl2 << endl;

    cl2 = complex<double>(3.0, 4.0);
    cout << "The complex number (3, 4) assigned to the complex number cl2 is:"
        << "\ncl2 = " << cl2 << endl;
}

```

```

The left-side complex number is cl1 = (3,4)
The right-side complex number is cr1 = (2,-1)
The complex number cr1 assigned to the complex number cl1 is:
cl1 = cr1 = (2,-1)
The left-side complex number is cl2 = (-2,4)
The right-side complex number is cr2 = 5
The complex number cr2 assigned to the complex number cl2 is:
cl2 = cr2 = (5,0)
The complex number (3, 4) assigned to the complex number cl2 is:
cl2 = (3,4)

```

complex::real

Gets or sets the real component of a complex number.

```

constexpr T real() const;

T real(const T& right);

```

Parameters

right

A complex number whose real value is to be extracted.

Return Value

The real part of the complex number.

Remarks

For a complex number $a + bi$, the real part or component is $Re(a + bi) = a$.

Example

```
// complex_class_real.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;

    complex<double> c1( 4.0 , 3.0 );
    cout << "The complex number c1 = " << c1 << endl;

    double dr1 = c1.real();
    cout << "The real part of c1 is c1.real() = "
        << dr1 << "." << endl;

    double di1 = c1.imag();
    cout << "The imaginary part of c1 is c1.imag() = "
        << di1 << "." << endl;
}
```

```
The complex number c1 = (4,3)
The real part of c1 is c1.real() = 4.
The imaginary part of c1 is c1.imag() = 3.
```

complex::value_type

A type that represents the data type used to represent the real and imaginary parts of a complex number.

```
typedef Type value_type;
```

Remarks

`value_type` is a synonym for the class `complex` `Type` template parameter.

Example

```
// complex_valuetype.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    complex<double>::value_type a = 3, b = 4;

    complex<double> c1 ( a , b );
    cout << "Specifying initial real & imaginary parts"
        << "\nof type value_type: "
        << "c1 = " << c1 << "." << endl;
}
```

```
Specifying initial real & imaginary parts  
of type value_type: c1 = (3,4).
```

[Thread Safety in the C++ Standard Library](#)

complex<double>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an object that stores an ordered pair of objects both of type **double**, the first representing the real part of a complex number and the second representing the imaginary part.

Syntax

```
template <>
class complex<double> {
public:
    constexpr complex(
        double RealVal = 0,
        double ImagVal = 0);

    constexpr complex(const complex<double>& complexNum);

    constexpr explicit complex(const complex<long double>& complexNum);
    // rest same as template class complex
};
```

Parameters

RealVal

The value of type **double** for the real part of the complex number being constructed.

ImagVal

The value of type **double** for the imaginary part of the complex number being constructed.

complexNum

The complex number of type **float** or of type **long double** whose real and imaginary parts are used to initialize a complex number of type **double** being constructed.

Return Value

A complex number of type **double**.

Remarks

The explicit specialization of the template class `complex` to a complex class of type **double** differs from the template class only in the constructors it defines. The conversion from **float** to **double** is allowed to be implicit, but the conversion from **long double** to **double** is required to be **explicit**. The use of **explicit** rules out the initiation with type conversion using assignment syntax.

For more information on the template class `complex`, see [complex Class](#). For a list of members of the template class `complex`, see .

Example

```

// complex_comp_dbl.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // The first constructor specifies real & imaginary parts
    complex <double> c1 ( 4.0 , 5.0 );
    cout << "Specifying initial real & imaginary parts,\n"
         << "as type double gives c1 = " << c1 << endl;

    // The second constructor initializes values of the real &
    // imaginary parts using those of complex number of type float
    complex <float> c2float ( 4.0 , 5.0 );
    complex <double> c2double ( c2float );
    cout << "Implicit conversion from type float to type double,"
         << endl << "gives c2double = " << c2double << endl;

    // The third constructor initializes values of the real &
    // imaginary parts using those of a complex number
    // of type long double
    complex <long double> c3longdouble ( 4.0 , 5.0 );
    complex <double> c3double ( c3longdouble );
    cout << "Explicit conversion from type float to type double,"
         << endl << "gives c3longdouble = " << c3longdouble << endl;

    // The modulus and argument of a complex number can be recovered
    double absc3 = abs ( c3longdouble );
    double argc3 = arg ( c3longdouble );
    cout << "The modulus of c3 is recovered from c3 using: abs ( c3 ) = "
         << absc3 << endl;
    cout << "Argument of c3 is recovered from c3 using:" << endl
         << "arg ( c3 ) = " << argc3 << " radians, which is "
         << argc3 * 180 / pi << " degrees." << endl;
}
/* Output:
Specifying initial real & imaginary parts,
as type double gives c1 = (4,5)
Implicit conversion from type float to type double,
gives c2double = (4,5)
Explicit conversion from type float to type double,
gives c3longdouble = (4,5)
The modulus of c3 is recovered from c3 using: abs ( c3 ) = 6.40312
Argument of c3 is recovered from c3 using:
arg ( c3 ) = 0.896055 radians, which is 51.3402 degrees.
*/

```

Requirements

Header: <complex>

Namespace: std

[complex Class](#)

[Thread Safety in the C++ Standard Library](#)

complex<float>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an object that stores an ordered pair of objects both of type **float**, the first representing the real part of a complex number and the second representing the imaginary part.

Syntax

```
template <>
class complex<float> {
public:
    constexpr complex(
        float _RealVal = 0,
        float _ImagVal = 0);

    constexpr complex(
        const complex<float>& complexNum);

    constexpr complex(
        const complex<double>& complexNum);

    constexpr complex(
        const complex<long double>& complexNum);
    // rest same as template class complex
};
```

Parameters

_RealVal

The value of type **float** for the real part of the complex number being constructed.

_ImagVal

The value of type **float** for the imaginary part of the complex number being constructed.

complexNum

The complex number of type **double** or of type **long double** whose real and imaginary parts are used to initialize a complex number of type **float** being constructed.

Return Value

A complex number of type **float**.

Remarks

The explicit specialization of the template class `complex` to a complex class of type **float** differs from the template class only in the constructors it defines. The conversion from **float** to **double** is allowed to be implicit, but the less safe conversion from **float** to **long double** is required to be **explicit**. The use of **explicit** rules out the initiation with type conversion using assignment syntax.

For more information on the template class `complex`, see [complex Class](#). For a list of members of the template class `complex`, see .

Example

```

// complex_comp_flt.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // The first constructor specifies real & imaginary parts
    complex <float> c1 ( 4.0 , 5.0 );
    cout << "Specifying initial real & imaginary parts,\n"
        << " as type float gives c1 = " << c1 << endl;

    // The second constructor initializes values of the real &
    // imaginary parts using those of complex number of type double
    complex <double> c2double ( 1.0 , 3.0 );
    complex <float> c2float ( c2double );
    cout << "Implicit conversion from type double to type float,"
        << endl << "gives c2float = " << c2float << endl;

    // The third constructor initializes values of the real &
    // imaginary parts using those of a complex number
    // of type long double
    complex <long double> c3longdouble ( 3.0 , 4.0 );
    complex <float> c3float ( c3longdouble );
    cout << "Explicit conversion from type long double to type float,"
        << endl << "gives c3float = " << c3float << endl;

    // The modulus and argument of a complex number can be recovered
    double absc3 = abs ( c3float);
    double argc3 = arg ( c3float);
    cout << "The modulus of c3 is recovered from c3 using: abs ( c3 ) = "
        << absc3 << endl;
    cout << "Argument of c3 is recovered from c3 using:"
        << endl << "arg ( c3 ) = "
        << argc3 << " radians, which is " << argc3 * 180 / pi
        << " degrees." << endl;
}
/* Output:
Specifying initial real & imaginary parts,
as type float gives c1 = (4,5)
Implicit conversion from type double to type float,
gives c2float = (1,3)
Explicit conversion from type long double to type float,
gives c3float = (3,4)
The modulus of c3 is recovered from c3 using: abs ( c3 ) = 5
Argument of c3 is recovered from c3 using:
arg ( c3 ) = 0.927295 radians, which is 53.1301 degrees.

[complex Class](#)

[Thread Safety in the C++ Standard Library](#)

complex<long double>

10/31/2018 • 2 minutes to read • [Edit Online](#)

This explicitly specialized template class describes an object that stores an ordered pair of objects, both of type **long double**, the first representing the real part of a complex number and the second representing the imaginary part.

Syntax

```
template <>
class complex<long double> {
public:
    constexpr complex(
        long double _RealVal = 0,
        long double _ImagVal = 0);

    complex(
        constexpr complex<long double>& complexNum);

    // rest same as template class complex
};
```

Parameters

_RealVal

The value of type **long double** for the real part of the complex number being constructed.

_ImagVal

The value of type **long double** for the imaginary part of the complex number being constructed.

complexNum

The complex number of type **double** or of type **float** whose real and imaginary parts are used to initialize a complex number of type **long double** being constructed.

Return Value

A complex number of type **long double**.

Remarks

The explicit specialization of the template class `complex` to a complex class of type **long double** differs from the template class only in the constructors it defines. The conversion from **long double** to **float** is allowed to be implicit, but the conversion from **double** to **long double** is required to be **explicit**. The use of **explicit** rules out the initiation with type conversion using assignment syntax.

For more information on the template class `complex` and its members, see [complex Class](#).

Microsoft specific: The **long double** and **double** types have the same representation, but are distinct types. For more information, see [Fundamental types](#).

Example

```

// complex_comp_ld.cpp
// compile with: /EHsc
#include <complex>
#include <iostream>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;

    // The first constructor specifies real & imaginary parts
    complex<long double> c1( 4.0 , 5.0 );
    cout << "Specifying initial real & imaginary parts,\n"
        << " as type float gives c1 = " << c1 << endl;

    // The second constructor initializes values of the real &
    // imaginary parts using those of complex number of type float
    complex<float> c2float( 1.0 , 3.0 );
    complex<long double> c2longdouble ( c2float );
    cout << "Implicit conversion from type float to type long double,"
        << "\n gives c2longdouble = " << c2longdouble << endl;

    // The third constructor initializes values of the real &
    // imaginary parts using those of a complex number
    // of type double
    complex<double> c3double( 3.0 , 4.0 );
    complex<long double> c3longdouble( c3double );
    cout << "Implicit conversion from type long double to type float,"
        << "\n gives c3longdouble = " << c3longdouble << endl;

    // The modulus and argument of a complex number can be recovered
    double absc3 = abs( c3longdouble );
    double argc3 = arg( c3longdouble );
    cout << "The modulus of c3 is recovered from c3 using: abs( c3 ) = "
        << absc3 << endl;
    cout << "Argument of c3 is recovered from c3 using:\n arg( c3 ) = "
        << argc3 << " radians, which is " << argc3 * 180 / pi
        << " degrees." << endl;
}

```

```

Specifying initial real & imaginary parts,
as type float gives c1 = (4,5)
Implicit conversion from type float to type long double,
gives c2longdouble = (1,3)
Implicit conversion from type long double to type float,
gives c3longdouble = (3,4)
The modulus of c3 is recovered from c3 using: abs( c3 ) = 5
Argument of c3 is recovered from c3 using:
arg( c3 ) = 0.927295 radians, which is 53.1301 degrees.

```

[complex Class](#)

[Thread Safety in the C++ Standard Library](#)

<condition_variable>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines the classes `condition_variable` and `condition_variable_any` that are used to create objects that wait for a condition to become true.

This header uses Concurrency Runtime (ConcRT) so that you can use it together with other ConcRT mechanisms. For more information about ConcRT, see [Concurrency Runtime](#).

Syntax

```
#include <condition_variable>
```

NOTE

In code that is compiled by using `/clr`, this header is blocked.

Remarks

Code that waits for a condition variable must also use a `mutex`. A calling thread must lock the `mutex` before it calls the functions that wait for the condition variable. The `mutex` is then locked when the called function returns. The `mutex` is not locked while the thread waits for the condition to become true. So that there are no unpredictable results, each thread that waits for a condition variable must use the same `mutex` object.

Objects of type `condition_variable_any` can be used with a mutex of any type. The type of the mutex that is used does not have to provide the `try_lock` method. Objects of type `condition_variable` can only be used with a mutex of type `unique_lock<mutex>`. Objects of this type may be faster than objects of type `condition_variable_any<unique_lock<mutex>>`.

To wait for an event, first lock the mutex, and then call one of the `wait` methods on the condition variable. The `wait` call blocks until another thread signals the condition variable.

Spurious wakeups occur when threads that are waiting for condition variables become unblocked without appropriate notifications. To recognize such spurious wakeups, code that waits for a condition to become true should explicitly check that condition when the code returns from a wait function. This is usually done by using a loop; you can use `wait(unique_lock<mutex>& lock, Predicate pred)` to perform this loop for you.

```
while (condition is false)
    wait for condition variable;
```

The `condition_variable_any` and `condition_variable` classes each have three methods that wait for a condition.

- `wait` waits for an unbounded time period.
- `wait_until` waits until a specified `time`.
- `wait_for` waits for a specified `time interval`.

Each of these methods has two overloaded versions. One just waits and can wake up spuriously. The other takes an additional template argument that defines a predicate. The method does not return until the predicate is **true**.

Each class also has two methods that are used to notify a condition variable that its condition is **true**.

- `notify_one` wakes up one of the threads that is waiting for the condition variable.
- `notify_all` wakes up all of the threads that are waiting for the condition variable.

<condition_variable> enums

10/31/2018 • 2 minutes to read • [Edit Online](#)

[cv_status](#)

cv_status Enumeration

Supplies symbolic names for the return values of the methods of template class [condition_variable](#).

```
class cv_status { no_timeout timeout };
```

See also

[<condition_variable>](#)

condition_variable Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Use the `condition_variable` class to wait for an event when you have a `mutex` of type `unique_lock<mutex>`. Objects of this type may have better performance than objects of type `condition_variable_any<unique_lock<mutex>>`.

Syntax

```
class condition_variable;
```

Members

Public Constructors

NAME	DESCRIPTION
<code>condition_variable</code>	Constructs a <code>condition_variable</code> object.

Public Methods

NAME	DESCRIPTION
<code>native_handle</code>	Returns the implementation-specific type representing the <code>condition_variable</code> handle.
<code>notify_all</code>	Unblocks all threads that are waiting for the <code>condition_variable</code> object.
<code>notify_one</code>	Unblocks one of the threads that are waiting for the <code>condition_variable</code> object.
<code>wait</code>	Blocks a thread.
<code>wait_for</code>	Blocks a thread, and sets a time interval after which the thread unblocks.
<code>wait_until</code>	Blocks a thread, and sets a maximum point in time at which the thread unblocks.

Requirements

Header: `<condition_variable>`

Namespace: `std`

`condition_variable::condition_variable` Constructor

Constructs a `condition_variable` object.

```
condition_variable();
```

Remarks

If not enough memory is available, the constructor throws a [system_error](#) object that has a `not_enough_memory` error code. If the object cannot be constructed because some other resource is not available, the constructor throws a `system_error` object that has a `resource_unavailable_try_again` error code.

condition_variable::native_handle

Returns the implementation-specific type that represents the condition_variable handle.

```
native_handle_type native_handle();
```

Return Value

`native_handle_type` is defined as a pointer to C++ Concurrency Runtime internal data structures.

condition_variable::notify_all

Unblocks all threads that are waiting for the `condition_variable` object.

```
void notify_all() noexcept;
```

condition_variable::notify_one

Unblocks one of the threads that are waiting on the `condition_variable` object.

```
void notify_one() noexcept;
```

condition_variable::wait

Blocks a thread.

```
void wait(unique_lock<mutex>& Lck);

template <class Predicate>
void wait(unique_lock<mutex>& Lck, Predicate Pred);
```

Parameters

Lck

A [unique_lock<mutex>](#) object.

Pred

Any expression that returns **true** or **false**.

Remarks

The first method blocks until the `condition_variable` object is signaled by a call to [notify_one](#) or [notify_all](#). It can also wake up spuriously.

In effect, the second method executes the following code.

```
while(!Pred())
    wait(Lck);
```

condition_variable::wait_for

Blocks a thread, and sets a time interval after which the thread unblocks.

```
template <class Rep, class Period>
cv_status wait_for(
    unique_lock<mutex>& Lck,
    const chrono::duration<Rep, Period>& Rel_time);

template <class Rep, class Period, class Predicate>
bool wait_for(
    unique_lock<mutex>& Lck,
    const chrono::duration<Rep, Period>& Rel_time,
    Predicate Pred);
```

Parameters

Lck

A `unique_lock<mutex>` object.

Rel_time

A `chrono::duration` object that specifies the amount of time before the thread wakes up.

Pred

Any expression that returns **true** or **false**.

Return Value

The first method returns `cv_status::timeout` if the wait terminates when *Rel_time* has elapsed. Otherwise, the method returns `cv_status::no_timeout`.

The second method returns the value of *Pred*.

Remarks

The first method blocks until the `condition_variable` object is signaled by a call to `notify_one` or `notify_all` or until the time interval *Rel_time* has elapsed. It can also wake up spuriously.

In effect, the second method executes the following code.

```
while(!Pred())
    if(wait_for(Lck, Rel_time) == cv_status::timeout)
        return Pred();

return true;
```

condition_variable::wait_until

Blocks a thread, and sets a maximum point in time at which the thread unblocks.

```

template <class Clock, class Duration>
cv_status wait_until(
    unique_lock<mutex>& Lck,
    const chrono::time_point<Clock, Duration>& Abs_time);

template <class Clock, class Duration, class Predicate>
bool wait_until(
    unique_lock<mutex>& Lck,
    const chrono::time_point<Clock, Duration>& Abs_time,
    Predicate Pred);

cv_status wait_until(
    unique_lock<mutex>& Lck,
    const xtime* Abs_time);

template <class Predicate>
bool wait_until(
    unique_lock<mutex>& Lck,
    const xtime* Abs_time,
    Predicate Pred);

```

Parameters

Lck

A [unique_lock<mutex>](#) object.

Abs_time

A [chrono::time_point](#) object.

Pred

Any expression that returns **true** or **false**.

Return Value

Methods that return a `cv_status` type return `cv_status::timeout` if the wait terminates when *Abs_time* elapses. Otherwise, the methods return `cv_status::no_timeout`.

Methods that return a **bool** return the value of *Pred*.

Remarks

The first method blocks until the `condition_variable` object is signaled by a call to [notify_one](#) or [notify_all](#) or until `Abs_time`. It can also wake up spuriously.

In effect, the second method executes the following code

```

while(!Pred())
    if(wait_until(Lck, Abs_time) == cv_status::timeout)
        return Pred();

return true;

```

The third and fourth methods use a pointer to an object of type `xtime` to replace the `chrono::time_point` object. The `xtime` object specifies the maximum amount of time to wait for a signal.

condition_variable_any Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Use the class `condition_variable_any` to wait for an event that has any `mutex` type.

Syntax

```
class condition_variable_any;
```

Members

Public Constructors

NAME	DESCRIPTION
condition_variable_any	Constructs a <code>condition_variable_any</code> object.

Public Methods

NAME	DESCRIPTION
notify_all	Unblocks all threads that are waiting for the <code>condition_variable_any</code> object.
notify_one	Unblocks one of the threads that are waiting for the <code>condition_variable_any</code> object.
wait	Blocks a thread.
wait_for	Blocks a thread, and sets a time interval after which the thread unblocks.
wait_until	Blocks a thread, and sets a maximum point in time at which the thread unblocks.

Requirements

Header: <condition_variable>

Namespace: std

condition_variable_any::condition_variable_any Constructor

Constructs a `condition_variable_any` object.

```
condition_variable_any();
```

Remarks

If not enough memory is available, the constructor throws a `system_error` object that has a `not_enough_memory` error code. If the object cannot be constructed because some other resource is not available, the constructor throws a `system_error` object that has a `resource_unavailable_try_again` error code.

`condition_variable_any::notify_all`

Unblocks all threads that are waiting for the `condition_variable_any` object.

```
void notify_all() noexcept;
```

`condition_variable_any::notify_one`

Unblocks one of the threads that are waiting on the `condition_variable_any` object.

```
void notify_one() noexcept;
```

`condition_variable_any::wait`

Blocks a thread.

```
template <class Lock>
void wait(Lock& Lck);

template <class Lock, class Predicate>
void wait(Lock& Lck, Predicate Pred);
```

Parameters

Lck

A `mutex` object of any type.

Pred

Any expression that returns **true** or **false**.

Remarks

The first method blocks until the `condition_variable_any` object is signaled by a call to `notify_one` or `notify_all`. It can also wake up spuriously.

The second method in effect executes the following code.

```
while (!Pred())
    wait(Lck);
```

`condition_variable_any::wait_for`

Blocks a thread, and sets a time interval after which the thread unblocks.

```
template <class Lock, class Rep, class Period>
bool wait_for(Lock& Lck, const chrono::duration<Rep, Period>& Rel_time);

template <class Lock, class Rep, class Period, class Predicate>
bool wait_for(Lock& Lck, const chrono::duration<Rep, Period>& Rel_time, Predicate Pred);
```

Parameters

Lck

A `mutex` object of any type.

Rel_time

A `chrono::duration` object that specifies the amount of time before the thread wakes up.

Pred

Any expression that returns **true** or **false**.

Return Value

The first method returns `cv_status::timeout` if the wait terminates when *Rel_time* has elapsed. Otherwise, the method returns `cv_status::no_timeout`.

The second method returns the value of *Pred*.

Remarks

The first method blocks until the `condition_variable_any` object is signaled by a call to [notify_one](#) or [notify_all](#), or until the time interval *Rel_time* has elapsed. It can also wake up spuriously.

The second method in effect executes the following code.

```
while(!Pred())
    if(wait_for(Lck, Rel_time) == cv_status::timeout)
        return Pred();

return true;
```

condition_variable_any::wait_until

Blocks a thread, and sets a maximum point in time at which the thread unblocks.

```
template <class Lock, class Clock, class Duration>
void wait_until(Lock& Lck, const chrono::time_point<Clock, Duration>& Abs_time);

template <class Lock, class Clock, class Duration, class Predicate>
void wait_until(
    Lock& Lck,
    const chrono::time_point<Clock, Duration>& Abs_time,
    Predicate Pred);

template <class Lock>
void wait_until(Lock Lck, const xtime* Abs_time);

template <class Lock, class Predicate>
void wait_until(
    Lock Lck,
    const xtime* Abs_time,
    Predicate Pred);
```

Parameters

Lck

A mutex object.

Abs_time

A `chrono::time_point` object.

Pred

Any expression that returns **true** or **false**.

Return Value

Methods that return a `cv_status` type return `cv_status::timeout` if the wait terminates when *Abs_time* elapses. Otherwise, the methods return `cv_status::no_timeout`.

Methods that return a `bool` return the value of *Pred*.

Remarks

The first method blocks until the `condition_variable` object is signaled by a call to [notify_one](#) or [notify_all](#), or until *Abs_time*. It can also wake up spuriously.

The second method in effect executes the following code.

```
while(!Pred())
    if(wait_until(Lck, Abs_time) == cv_status::timeout)
        return Pred();

return true;
```

The third and fourth methods use a pointer to an object of type `xtime` to replace the `chrono::time_point` object. The `xtime` object specifies the maximum amount of time to wait for a signal.

<deque>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template class deque and several supporting templates.

Syntax

```
#include <deque>
```

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests if the deque object on the left side of the operator is not equal to the deque object on the right side.
<code>operator<</code>	Tests if the deque object on the left side of the operator is less than the deque object on the right side.
<code>operator<=</code>	Tests if the deque object on the left side of the operator is less than or equal to the deque object on the right side.
<code>operator==</code>	Tests if the deque object on the left side of the operator is equal to the deque object on the right side.
<code>operator></code>	Tests if the deque object on the left side of the operator is greater than the deque object on the right side.
<code>operator>=</code>	Tests if the deque object on the left side of the operator is greater than or equal to the deque object on the right side.

Functions

FUNCTION	DESCRIPTION
<code>swap</code>	Exchanges the elements of two deques.

Classes

CLASS	DESCRIPTION
<code>deque Class</code>	A template class of sequence containers that arrange elements of a given type in a linear arrangement and, like vectors, allow fast random access to any element and efficient insertion and deletion at the back of the container.

See also

[Header Files Reference](#)

[Thread Safety in the C++ Standard Library](#)

<deque> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

swap

swap

Exchanges the elements of two deques.

```
void swap(  
    deque<Type, Allocator>& left,  
    deque<Type, Allocator>& right,);
```

Parameters

left

An object of type `deque`.

right

An object of type `deque`.

Example

See the example for [deque::swap](#).

See also

[<deque>](#)

<deque> operators

11/9/2018 • 5 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<=</code>	<code>operator==</code>

operator!=

Tests if the deque object on the left side of the operator is not equal to the deque object on the right side.

```
bool operator!=(const deque<Type, Allocator>& left, const deque<Type, Allocator>& right);
```

Parameters

left

An object of type `deque`.

right

An object of type `deque`.

Return Value

true if the deque objects are not equal; **false** if the deque objects are equal.

Remarks

The comparison between deque objects is based on a pairwise comparison of their elements. Two deque objects are equal if they have the same number of elements and their respective elements have the same values.

Otherwise, they are unequal.

Example

```
// deque_op_ne.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1, c2;

    c1.push_back( 1 );
    c2.push_back( 2 );

    if ( c1 != c2 )
        cout << "The deques are not equal." << endl;
    else
        cout << "The deques are equal." << endl;
}
/* Output:
The deques are not equal.
*/
```

operator<

Tests if the deque object on the left side of the operator is less than the deque object on the right side.

```
bool operator<(const deque<Type, Allocator>& left, const deque<Type, Allocator>& right);
```

Parameters

left

An object of type `deque`.

right

An object of type `deque`.

Return Value

true if the deque on the left side of the operator is less than and not equal to the deque on the right side of the operator; otherwise **false**.

Remarks

The comparison between deque objects is based on a pairwise comparison of their elements. The less-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```
// deque_op_lt.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1, c2;

    c1.push_back( 1 );
    c1.push_back( 2 );
    c1.push_back( 4 );

    c2.push_back( 1 );
    c2.push_back( 3 );

    if ( c1 < c2 )
        cout << "Deque c1 is less than deque c2." << endl;
    else
        cout << "Deque c1 is not less than deque c2." << endl;
}
/* Output:
Deque c1 is less than deque c2.
*/
```

operator<=

Tests if the deque object on the left side of the operator is less than or equal to the deque object on the right side.

```
bool operator<=(const deque<Type, Allocator>& left, const deque<Type, Allocator>& right);
```

Parameters

left

An object of type `deque` .

right

An object of type `deque` .

Return Value

true if the deque on the left side of the operator is less than or equal to the deque on the right side of the operator; otherwise **false**.

Remarks

The comparison between deque objects is based on a pairwise comparison of their elements. The less than or equal to relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```
// deque_op_le.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1, c2;

    c1.push_back( 1 );
    c1.push_back( 2 );
    c1.push_back( 4 );

    c2.push_back( 1 );
    c2.push_back( 3 );

    if ( c1 <= c2 )
        cout << "Deque c1 is less than or equal to deque c2." << endl;
    else
        cout << "Deque c1 is greater than deque c2." << endl;
}
/* Output:
Deque c1 is less than or equal to deque c2.
*/
```

operator==

Tests if the deque object on the left side of the operator is equal to the deque object on the right side.

```
bool operator==(const deque<Type, Allocator>& left, const deque<Type, Allocator>& right);
```

Parameters

left

An object of type `deque` .

right

An object of type `deque` .

Return Value

true if the deque on the left side of the operator is equal to the deque on the right side of the operator; otherwise **false**.

Remarks

The comparison between deque objects is based on a pairwise comparison of their elements. Two deques are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// deque_op_eq.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1, c2;

    c1.push_back( 1 );
    c2.push_back( 1 );

    if ( c1 == c2 )
        cout << "The deques are equal." << endl;
    else
        cout << "The deques are not equal." << endl;

    c1.push_back( 1 );
    if ( c1 == c2 )
        cout << "The deques are equal." << endl;
    else
        cout << "The deques are not equal." << endl;
}
/* Output:
The deques are equal.
The deques are not equal.
*/
```

operator>

Tests if the deque object on the left side of the operator is greater than the deque object on the right side.

```
bool operator>(const deque<Type, Allocator>& left, const deque<Type, Allocator>& right);
```

Parameters

left

An object of type `deque`.

right

An object of type `deque`.

Return Value

true if the deque on the left side of the operator is greater than the deque on the right side of the operator; otherwise **false**.

Remarks

The comparison between deque objects is based on a pairwise comparison of their elements. The greater-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// deque_op_gt.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1, c2;

    c1.push_back( 1 );
    c1.push_back( 3 );
    c1.push_back( 1 );

    c2.push_back( 1 );
    c2.push_back( 2 );
    c2.push_back( 2 );

    if ( c1 > c2 )
        cout << "Deque c1 is greater than deque c2." << endl;
    else
        cout << "Deque c1 is not greater than deque c2." << endl;
}
/* Output:
Deque c1 is greater than deque c2.
*/

```

operator>=

Tests if the deque object on the left side of the operator is greater than or equal to the deque object on the right side.

```
bool operator>=(const deque<Type, Allocator>& left, const deque<Type, Allocator>& right);
```

Parameters

left

An object of type `deque`.

right

An object of type `deque`.

Return Value

true if the deque on the left side of the operator is greater than or equal to the deque on the right side of the operator; otherwise **false**.

Remarks

The comparison between deque objects is based on a pairwise comparison of their elements. The greater than or equal to relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// deque_op_ge.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1, c2;

    c1.push_back( 1 );
    c1.push_back( 3 );
    c1.push_back( 1 );

    c2.push_back( 1 );
    c2.push_back( 2 );
    c2.push_back( 2 );

    if ( c1 >= c2 )
        cout << "Deque c1 is greater than or equal to deque c2." << endl;
    else
        cout << "Deque c1 is less than deque c2." << endl;
}
/* Output:
Deque c1 is greater than or equal to deque c2.
*/

```

[<deque>](#)

deque Class

11/9/2018 • 40 minutes to read • [Edit Online](#)

Arranges elements of a given type in a linear arrangement and, like a vector, enables fast random access to any element, and efficient insertion and deletion at the back of the container. However, unlike a vector, the `deque` class also supports efficient insertion and deletion at the front of the container.

Syntax

```
template <class Type, class Allocator =allocator<Type>>
class deque
```

Parameters

Type

The element data type to be stored in the deque.

Allocator

The type that represents the stored allocator object that encapsulates details about the deque's allocation and deallocation of memory. This argument is optional, and the default value is **`allocator<Type>`**.

Remarks

The choice of container type should be based in general on the type of searching and inserting required by the application. [Vectors](#) should be the preferred container for managing a sequence when random access to any element is at a premium and insertions or deletions of elements are only required at the end of a sequence. The performance of the list container is superior when efficient insertions and deletions (in constant time) at any location within the sequence is at a premium. Such operations in the middle of the sequence require element copies and assignments proportional to the number of elements in the sequence (linear time).

Deque reallocation occurs when a member function must insert or erase elements of the sequence:

- If an element is inserted into an empty sequence, or if an element is erased to leave an empty sequence, then iterators earlier returned by [begin](#) and [end](#) become invalid.
- If an element is inserted at the first position of the deque, then all iterators, but no references, that designate existing elements become invalid.
- If an element is inserted at the end of the deque, then [end](#) and all iterators, but no references, that designate existing elements become invalid.
- If an element is erased at the front of the deque, only that iterator and references to the erased element become invalid.
- If the last element is erased from the end of the deque, only that iterator to the final element and references to the erased element become invalid.

Otherwise, inserting or erasing an element invalidates all iterators and references.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>deque</code>	Constructs a <code>deque</code> . Several constructors are provided to set up the contents of the new <code>deque</code> in different ways: empty; loaded with a specified number of empty elements; contents moved or copied from another <code>deque</code> ; contents copied or moved by using an iterator; and one element copied into the <code>deque</code> <code>count</code> times. Some of the constructors enable using a custom <code>allocator</code> to create elements.

Typedefs

TYPE NAME	DESCRIPTION
<code>allocator_type</code>	A type that represents the <code>allocator</code> class for the <code>deque</code> object.
<code>const_iterator</code>	A type that provides a random-access iterator that can access and read elements in the <code>deque</code> as <code>const</code> .
<code>const_pointer</code>	A type that provides a pointer to an element in a <code>deque</code> as a <code>const</code> .
<code>const_reference</code>	A type that provides a reference to an element in a <code>deque</code> for reading and other operations as a <code>const</code> .
<code>const_reverse_iterator</code>	A type that provides a random-access iterator that can access and read elements in the <code>deque</code> as const . The deque is viewed in reverse. For more information, see reverse_iterator Class
<code>difference_type</code>	A type that provides the difference between two random-access iterators that refer to elements in the same <code>deque</code> .
<code>iterator</code>	A type that provides a random-access iterator that can read or modify any element in a <code>deque</code> .
<code>pointer</code>	A type that provides a pointer to an element in a <code>deque</code> .
<code>reference</code>	A type that provides a reference to an element stored in a <code>deque</code> .
<code>reverse_iterator</code>	A type that provides a random-access iterator that can read or modify an element in a <code>deque</code> . The deque is viewed in reverse order.
<code>size_type</code>	A type that counts the number of elements in a <code>deque</code> .
<code>value_type</code>	A type that represents the data type stored in a <code>deque</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>assign</code>	Erases elements from a <code>deque</code> and copies a new sequence of elements to the target <code>deque</code> .
<code>at</code>	Returns a reference to the element at a specified location in the <code>deque</code> .
<code>back</code>	Returns a reference to the last element of the <code>deque</code> .
<code>begin</code>	Returns a random-access iterator addressing the first element in the <code>deque</code> .
<code>cbegin</code>	Returns a const iterator to the first element in the <code>deque</code> .
<code>cend</code>	Returns a random-access const iterator that points just beyond the end of the <code>deque</code> .
<code>clear</code>	Erases all the elements of a <code>deque</code> .
<code>crbegin</code>	Returns a random-access const iterator to the first element in a <code>deque</code> viewed in reverse order.
<code>crend</code>	Returns a random-access const iterator to the first element in a <code>deque</code> viewed in reverse order.
<code>emplace</code>	Inserts an element constructed in place into the <code>deque</code> at a specified position.
<code>emplace_back</code>	Adds an element constructed in place to the end of the <code>deque</code> .
<code>emplace_front</code>	Adds an element constructed in place to the start of the <code>deque</code> .
<code>empty</code>	Returns true if the <code>deque</code> contains zero elements, and false if it contains one or more elements.
<code>end</code>	Returns a random-access iterator that points just beyond the end of the <code>deque</code> .
<code>erase</code>	Removes an element or a range of elements in a <code>deque</code> from specified positions.
<code>front</code>	Returns a reference to the first element in a <code>deque</code> .
<code>get_allocator</code>	Returns a copy of the <code>allocator</code> object that is used to construct the <code>deque</code> .
<code>insert</code>	Inserts an element, several elements, or a range of elements into the <code>deque</code> at a specified position.
<code>max_size</code>	Returns the maximum possible length of the <code>deque</code> .

MEMBER FUNCTION	DESCRIPTION
pop_back	Erases the element at the end of the <code>deque</code> .
pop_front	Erases the element at the start of the <code>deque</code> .
push_back	Adds an element to the end of the <code>deque</code> .
push_front	Adds an element to the start of the <code>deque</code> .
rbegin	Returns a random-access iterator to the first element in a reversed <code>deque</code> .
rend	Returns a random-access iterator that points just beyond the last element in a reversed <code>deque</code> .
resize	Specifies a new size for a <code>deque</code> .
shrink_to_fit	Discards excess capacity.
size	Returns the number of elements in the <code>deque</code> .
swap	Exchanges the elements of two <code>deque</code> s.

Operators

OPERATOR	DESCRIPTION
operator[]	Returns a reference to the <code>deque</code> element at a specified position.
operator=	Replaces the elements of the <code>deque</code> with a copy of another <code>deque</code> .

Requirements

Header: `<deque>`

`deque::allocator_type`

A type that represents the allocator class for the deque object.

```
typedef Allocator allocator_type;
```

Remarks

`allocator_type` is a synonym for the template parameter `Allocator`.

Example

See the example for [get_allocator](#).

`deque::assign`

Erases elements from a deque and copies a new set of elements to the target deque.

```
template <class InputIterator>
void assign(
    InputIterator First,
    InputIterator Last);

void assign(
    size_type Count,
    const Type& Val);

void assign(initializer_list<Type> IList);
```

Parameters

First

Position of the first element in the range of elements to be copied from the argument deque.

Last

Position of the first element beyond the range of elements to be copied from the argument deque.

Count

The number of copies of an element being inserted into the deque.

Val

The value of the element being inserted into the deque.

IList

The initializer_list being inserted into the deque.

Remarks

After any existing elements in the target deque are erased, `assign` either inserts a specified range of elements from the original deque or from some other deque into the target deque, or inserts copies of a new element of a specified value into the target deque.

Example

```

// deque_assign.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>
#include <initializer_list>

int main()
{
    using namespace std;
    deque<int> c1, c2;
    deque<int>::const_iterator cIter;

    c1.push_back(10);
    c1.push_back(20);
    c1.push_back(30);
    c2.push_back(40);
    c2.push_back(50);
    c2.push_back(60);

    deque<int> d1{ 1, 2, 3, 4 };
    initializer_list<int> ilist{ 5, 6, 7, 8 };
    d1.assign(ilist);

    cout << "d1 = ";
    for (int i : d1)
        cout << i;
    cout << endl;

    cout << "c1 =";
    for (int i : c1)
        cout << i;
    cout << endl;

    c1.assign(++c2.begin(), c2.end());
    cout << "c1 =";
    for (int i : c1)
        cout << i;
    cout << endl;

    c1.assign(7, 4);
    cout << "c1 =";
    for (int i : c1)
        cout << i;
    cout << endl;
}

```

```
d1 = 5678c1 =102030c1 =5060c1 =4444444
```

deque::at

Returns a reference to the element at a specified location in the deque.

```

reference at(size_type pos);

const_reference at(size_type pos) const;

```

Parameters

pos

The subscript (or position number) of the element to reference in the deque.

Return Value

If *pos* is greater than the size of the deque, `at` throws an exception.

Return Value

If the return value of `at` is assigned to a `const_reference`, the deque object cannot be modified. If the return value of `at` is assigned to a `reference`, the deque object can be modified.

Example

```
// deque_at.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1;

    c1.push_back( 10 );
    c1.push_back( 20 );

    const int& i = c1.at( 0 );
    int& j = c1.at( 1 );
    cout << "The first element is " << i << endl;
    cout << "The second element is " << j << endl;
}
```

```
The first element is 10
The second element is 20
```

deque::back

Returns a reference to the last element of the deque.

```
reference back();
const_reference back() const;
```

Return Value

The last element of the deque. If the deque is empty, the return value is undefined.

Remarks

If the return value of `back` is assigned to a `const_reference`, the deque object cannot be modified. If the return value of `back` is assigned to a `reference`, the deque object can be modified.

When compiled by using `_ITERATOR_DEBUG_LEVEL` defined as 1 or 2, a runtime error will occur if you attempt to access an element in an empty deque. See [Checked Iterators](#) for more information.

Example

```

// deque_back.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1;

    c1.push_back( 10 );
    c1.push_back( 11 );

    int& i = c1.back( );
    const int& ii = c1.front( );

    cout << "The last integer of c1 is " << i << endl;
    i--;
    cout << "The next-to-last integer of c1 is " << ii << endl;
}

```

```

The last integer of c1 is 11
The next-to-last integer of c1 is 10

```

deque::begin

Returns an iterator addressing the first element in the deque.

```

const_iterator begin() const;
iterator begin();

```

Return Value

A random-access iterator addressing the first element in the deque or to the location succeeding an empty deque.

Remarks

If the return value of `begin` is assigned to a `const_iterator`, the deque object cannot be modified. If the return value of `begin` is assigned to an `iterator`, the deque object can be modified.

Example

```
// deque_begin.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1;
    deque<int>::iterator c1_Iter;
    deque<int>::const_iterator c1_cIter;

    c1.push_back( 1 );
    c1.push_back( 2 );

    c1_Iter = c1.begin( );
    cout << "The first element of c1 is " << *c1_Iter << endl;

    *c1_Iter = 20;
    c1_Iter = c1.begin( );
    cout << "The first element of c1 is now " << *c1_Iter << endl;

    // The following line would be an error because iterator is const
    // *c1_cIter = 200;
}
```

```
The first element of c1 is 1
The first element of c1 is now 20
```

deque::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** random-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin` , the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator` . Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- `const`) container of any kind that supports `begin()` and `cbegin()` .

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

deque::cend

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A random-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non-**const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

deque::clear

Erases all the elements of a deque.

```
void clear();
```

Example

```
// deque_clear.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );

    cout << "The size of the deque is initially " << c1.size( ) << endl;
    c1.clear( );
    cout << "The size of the deque after clearing is " << c1.size( ) << endl;
}
```

```
The size of the deque is initially 3
The size of the deque after clearing is 0
```

deque::const_iterator

A type that provides a random-access iterator that can access and read a **const** element in the deque.

```
typedef implementation-defined const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

Example

See the example for [back](#).

deque::const_pointer

Provides a pointer to a **const** element in a deque.

```
typedef typename Allocator::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element. An [iterator](#) is more commonly used to access a deque element.

deque::const_reference

A type that provides a reference to a **const** element stored in a deque for reading and performing **const** operations.

```
typedef typename Allocator::const_reference const_reference;
```

Remarks

A type `const_reference` cannot be used to modify the value of an element.

Example

```
// deque_const_ref.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1;

    c1.push_back( 10 );
    c1.push_back( 20 );

    const deque<int> c2 = c1;
    const int &i = c2.front( );
    const int &j = c2.back( );
    cout << "The first element is " << i << endl;
    cout << "The second element is " << j << endl;

    // The following line would cause an error as c2 is const
    // c2.push_back( 30 );
}
```

```
The first element is 10
The second element is 20
```

deque::const_reverse_iterator

A type that provides a random-access iterator that can read any **const** element in the deque.

```
typedef std::reverse_iterator<const_iterator> const_reverse_iterator;
```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is used to iterate through the deque in reverse.

Example

See the example for [rbegin](#) for an example of how to declare and use an iterator.

deque::crbegin

Returns a const iterator to the first element in a reversed deque.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse random-access iterator addressing the first element in a reversed [deque](#) or addressing what had been the last element in the unreversed `deque`.

Remarks

With the return value of `crbegin`, the `deque` object cannot be modified.

Example

```
// deque_crbegin.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> v1;
    deque<int>::iterator v1_Iter;
    deque<int>::const_reverse_iterator v1_rIter;

    v1.push_back( 1 );
    v1.push_back( 2 );

    v1_Iter = v1.begin( );
    cout << "The first element of deque is "
         << *v1_Iter << "." << endl;

    v1_rIter = v1.crbegin( );
    cout << "The first element of the reversed deque is "
         << *v1_rIter << "." << endl;
}
```

The first element of deque is 1.
The first element of the reversed deque is 2.

deque::crend

Returns a const iterator that addresses the location succeeding the last element in a reversed deque.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse random-access iterator that addresses the location succeeding the last element in a reversed [deque](#) (the location that had preceded the first element in the unreversed deque).

Remarks

`crend` is used with a reversed `deque` just as [array::cend](#) is used with a `deque`.

With the return value of `crend` (suitably decremented), the `deque` object cannot be modified.

`crend` can be used to test to whether a reverse iterator has reached the end of its deque.

The value returned by `crend` should not be dereferenced.

Example

```
// deque_crend.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> v1;
    deque <int>::const_reverse_iterator v1_rIter;

    v1.push_back( 1 );
    v1.push_back( 2 );

    for ( v1_rIter = v1.rbegin( ) ; v1_rIter != v1.rend( ) ; v1_rIter++ )
        cout << *v1_rIter << endl;
}
```

```
2
1
```

deque::deque

Constructs a deque of a specific size, or with elements of a specific value, or with a specific allocator, or as a copy of all or part of some other deque.

```

deque();

explicit deque(const Allocator& Al);
explicit deque(size_type Count);
deque(size_type Count, const Type& Val);

deque(
    size_type Count,
    const Type& Val,
    const Allocator& Al);

deque(const deque& Right);

template <class InputIterator>
deque(InputIterator First, InputIterator Last);

template <class InputIterator>
deque(
    InputIterator First,
    InputIterator Last,
    const Allocator& Al);

deque(initializer_list<value_type> Ilist, const Allocator& Al);

```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The allocator class to use with this object.
<i>Count</i>	The number of elements in the constructed deque.
<i>Val</i>	The value of the elements in the constructed deque.
<i>Right</i>	The deque of which the constructed deque is to be a copy.
<i>First</i>	Position of the first element in the range of elements to be copied.
<i>Last</i>	Position of the first element beyond the range of elements to be copied.
<i>*Ilist`</i>	The initializer_list to be copied.

Remarks

All constructors store an allocator object (*Al*) and initialize the deque.

The first two constructors specify an empty initial deque; the second one also specifies the allocator type (`_Al`) to be used.

The third constructor specifies a repetition of a specified number (`count`) of elements of the default value for class `Type` .

The fourth and fifth constructors specify a repetition of (*Count*) elements of value `val` .

The sixth constructor specifies a copy of the deque *Right*.

The seventh and eighth constructors copy the range `[First, Last)` of a deque.

The seventh constructor moves the deque *Right*.

The eighth constructor copies the contents of an `initializer_list`.

None of the constructors perform any interim reallocations.

Example

```
/ compile with: /EHsc
#include <deque>
#include <iostream>
#include <forward_list>

int main()
{
    using namespace std;

    forward_list<int> f1{ 1, 2, 3, 4 };

    f1.insert_after(f1.begin(), { 5, 6, 7, 8 });

    deque<int>::iterator c1_Iter, c2_Iter, c3_Iter, c4_Iter, c5_Iter, c6_Iter;

    // Create an empty deque c0
    deque<int> c0;

    // Create a deque c1 with 3 elements of default value 0
    deque<int> c1(3);

    // Create a deque c2 with 5 elements of value 2
    deque<int> c2(5, 2);

    // Create a deque c3 with 3 elements of value 1 and with the
    // allocator of deque c2
    deque<int> c3(3, 1, c2.get_allocator());

    // Create a copy, deque c4, of deque c2
    deque<int> c4(c2);

    // Create a deque c5 by copying the range c4[ first, last)
    c4_Iter = c4.begin();
    c4_Iter++;
    c4_Iter++;
    deque<int> c5(c4.begin(), c4_Iter);

    // Create a deque c6 by copying the range c4[ first, last) and
    // c2 with the allocator of deque
    c4_Iter = c4.begin();
    c4_Iter++;
    c4_Iter++;
    c4_Iter++;
    deque<int> c6(c4.begin(), c4_Iter, c2.get_allocator());

    // Create a deque c8 by copying the contents of an initializer_list
    // using brace initialization
    deque<int> c8({ 1, 2, 3, 4 });

    initializer_list<int> iList{ 5, 6, 7, 8 };
    deque<int> c9( iList);

    cout << "c1 = ";
    for (int i : c1)
        cout << i << " ";
    cout << endl;

    cout << "c2 = ";
    for (int i : c2)
        cout << i << " ";
    cout << endl;
```

```

    cout << "c3 = ";
    for (int i : c3)
        cout << i << " ";
    cout << endl;

    cout << "c4 = ";
    for (int i : c4)
        cout << i << " ";
    cout << endl;

    cout << "c5 = ";
    for (int i : c5)
        cout << i << " ";
    cout << endl;

    cout << "c6 = ";
    for (int i : c6)
        cout << i << " ";
    cout << endl;

    // Move deque c6 to deque c7
    deque<int> c7(move(c6));
    deque<int>::iterator c7_Iter;

    cout << "c7 =";
    for (int i : c7)
        cout << i << " ";
    cout << endl;

    cout << "c8 = ";
    for (int i : c8)
        cout << i << " ";
    cout << endl;

    cout << "c9 = ";
    for (int i : c9)
        cout << i << " ";
    cout << endl;

    int x = 3;
}
// deque_deque.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int>::iterator c1_Iter, c2_Iter, c3_Iter, c4_Iter, c5_Iter, c6_Iter;

    // Create an empty deque c0

    cout << i << " ";
cout << endl;

cout << "c9 = ";
or (int i : c9)
    cout << i << " ";
cout << endl;
}

```

deque::difference_type

A type that provides the difference between two iterators that refer to elements within the same deque.

```
typedef typename Allocator::difference_type difference_type;
```

Remarks

A `difference_type` can also be described as the number of elements between two pointers.

Example

```
// deque_diff_type.cpp
// compile with: /EHsc
#include <iostream>
#include <deque>
#include <algorithm>

int main( )
{
    using namespace std;

    deque<int> c1;
    deque<int>::iterator c1_Iter, c2_Iter;

    c1.push_back( 30 );
    c1.push_back( 20 );
    c1.push_back( 30 );
    c1.push_back( 10 );
    c1.push_back( 30 );
    c1.push_back( 20 );

    c1_Iter = c1.begin( );
    c2_Iter = c1.end( );

    deque<int>::difference_type df_typ1, df_typ2, df_typ3;

    df_typ1 = count( c1_Iter, c2_Iter, 10 );
    df_typ2 = count( c1_Iter, c2_Iter, 20 );
    df_typ3 = count( c1_Iter, c2_Iter, 30 );
    cout << "The number '10' is in c1 collection " << df_typ1 << " times.\n";
    cout << "The number '20' is in c1 collection " << df_typ2 << " times.\n";
    cout << "The number '30' is in c1 collection " << df_typ3 << " times.\n";
}
```

```
The number '10' is in c1 collection 1 times.
The number '20' is in c1 collection 2 times.
The number '30' is in c1 collection 3 times.
```

deque::emplace

Inserts an element constructed in place into the deque at a specified position.

```
iterator emplace(
    const_iterator _Where,
    Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Where</code>	The position in the <code>deque</code> where the first element is inserted.
<code>val</code>	The value of the element being inserted into the <code>deque</code> .

Return Value

The function returns an iterator that points to the position where the new element was inserted into the deque.

Remarks

Any insertion operation can be expensive, see `deque` for a discussion of `deque` performance.

Example

```
// deque_emplace.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> v1;
    deque<int>::iterator Iter;

    v1.push_back( 10 );
    v1.push_back( 20 );
    v1.push_back( 30 );

    cout << "v1 =" ;
    for ( Iter = v1.begin( ) ; Iter != v1.end( ) ; Iter++ )
        cout << " " << *Iter;
    cout << endl;

    // initialize a deque of deques by moving v1
    deque< deque<int> > vv1;

    vv1.emplace( vv1.begin(), move( v1 ) );
    if ( vv1.size( ) != 0 && vv1[0].size( ) != 0 )
    {
        cout << "vv1[0] =";
        for (Iter = vv1[0].begin( ); Iter != vv1[0].end( ); Iter++ )
            cout << " " << *Iter;
        cout << endl;
    }
}
```

```
v1 = 10 20 30
vv1[0] = 10 20 30
```

deque::emplace_back

Adds an element constructed in place to the end of the deque.

```
void emplace_back(Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The element added to the end of the deque .

Example

```
// deque_emplace_back.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> v1;

    v1.push_back( 1 );
    if ( v1.size( ) != 0 )
        cout << "Last element: " << v1.back( ) << endl;

    v1.push_back( 2 );
    if ( v1.size( ) != 0 )
        cout << "New last element: " << v1.back( ) << endl;

    // initialize a deque of deques by moving v1
    deque< deque<int> > vv1;

    vv1.emplace_back( move( v1 ) );
    if ( vv1.size( ) != 0 && vv1[0].size( ) != 0 )
        cout << "Moved last element: " << vv1[0].back( ) << endl;
}
```

```
Last element: 1
New last element: 2
Moved last element: 2
```

deque::emplace_front

Adds an element constructed in place to the end of the deque.

```
void emplace_front(Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The element added to the beginning of the deque .

Example

```

// deque_emplace_front.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> v1;

    v1.push_back( 1 );
    if ( v1.size( ) != 0 )
        cout << "Last element: " << v1.back( ) << endl;

    v1.push_back( 2 );
    if ( v1.size( ) != 0 )
        cout << "New last element: " << v1.back( ) << endl;

    // initialize a deque of deques by moving v1
    deque< deque<int> > vv1;

    vv1.emplace_front( move( v1 ) );
    if ( vv1.size( ) != 0 && vv1[0].size( ) != 0 )
        cout << "Moved last element: " << vv1[0].back( ) << endl;
}

```

```

Last element: 1
New last element: 2
Moved last element: 2

```

deque::empty

Tests if a deque is empty.

```
bool empty() const;
```

Return Value

true if the deque is empty; **false** if the deque is not empty.

Example

```

// deque_empty.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1;

    c1.push_back( 10 );
    if ( c1.empty( ) )
        cout << "The deque is empty." << endl;
    else
        cout << "The deque is not empty." << endl;
}

```

The deque is not empty.

deque::end

Returns an iterator that addresses the location succeeding the last element in a deque.

```
const_iterator end() const;

iterator end();
```

Return Value

A random-access iterator that addresses the location succeeding the last element in a deque. If the deque is empty, then `deque::end == deque::begin`.

Remarks

`end` is used to test whether an iterator has reached the end of its deque.

Example

```
// deque_end.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1;
    deque<int>::iterator c1_Iter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );

    c1_Iter = c1.end( );
    c1_Iter--;
    cout << "The last integer of c1 is " << *c1_Iter << endl;

    c1_Iter--;
    *c1_Iter = 400;
    cout << "The new next-to-last integer of c1 is " << *c1_Iter << endl;

    // If a const iterator had been declared instead with the line:
    // deque<int>::const_iterator c1_Iter;
    // an error would have resulted when inserting the 400

    cout << "The deque is now:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
}
```

```
The last integer of c1 is 30
The new next-to-last integer of c1 is 400
The deque is now: 10 400 30
```

deque::erase

Removes an element or a range of elements in a deque from specified positions.

```
iterator erase(iterator _Where);

iterator erase(iterator first, iterator last);
```

Parameters

_Where

Position of the element to be removed from the deque.

first

Position of the first element removed from the deque.

last

Position just beyond the last element removed from the deque.

Return Value

A random-access iterator that designates the first element remaining beyond any elements removed, or a pointer to the end of the deque if no such element exists.

Remarks

`erase` never throws an exception.

Example

```
// deque_erase.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1;
    deque <int>::iterator Iter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );
    c1.push_back( 40 );
    c1.push_back( 50 );
    cout << "The initial deque is: ";
    for ( Iter = c1.begin( ); Iter != c1.end( ); Iter++ )
        cout << *Iter << " ";
    cout << endl;
    c1.erase( c1.begin( ) );
    cout << "After erasing the first element, the deque becomes: ";
    for ( Iter = c1.begin( ); Iter != c1.end( ); Iter++ )
        cout << *Iter << " ";
    cout << endl;
    Iter = c1.begin( );
    Iter++;
    c1.erase( Iter, c1.end( ) );
    cout << "After erasing all elements but the first, deque becomes: ";
    for ( Iter = c1.begin( ); Iter != c1.end( ); Iter++ )
        cout << *Iter << " ";
    cout << endl;
}
```

```
The initial deque is: 10 20 30 40 50
After erasing the first element, the deque becomes: 20 30 40 50
After erasing all elements but the first, deque becomes: 20
```

deque::front

Returns a reference to the first element in a deque.

```
reference front();

const_reference front() const;
```

Return Value

If the deque is empty, the return is undefined.

Remarks

If the return value of `front` is assigned to a `const_reference`, the deque object cannot be modified. If the return value of `front` is assigned to a `reference`, the deque object can be modified.

When compiled by using `_ITERATOR_DEBUG_LEVEL` defined as 1 or 2, a runtime error will occur if you attempt to access an element in an empty deque. See [Checked Iterators](#) for more information.

Example

```
// deque_front.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1;

    c1.push_back( 10 );
    c1.push_back( 11 );

    int& i = c1.front( );
    const int& ii = c1.front( );

    cout << "The first integer of c1 is " << i << endl;
    i++;
    cout << "The second integer of c1 is " << ii << endl;
}
```

```
The first integer of c1 is 10
The second integer of c1 is 11
```

deque::get_allocator

Returns a copy of the allocator object used to construct the deque.

```
Allocator get_allocator() const;
```

Return Value

The allocator used by the deque.

Remarks

Allocators for the deque class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```
// deque_get_allocator.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    // The following lines declare objects that use the default allocator.
    deque<int> c1;
    deque<int, allocator<int> > c2 = deque<int, allocator<int> >( allocator<int>( ) );

    // c3 will use the same allocator class as c1
    deque<int> c3( c1.get_allocator( ) );

    deque<int>::allocator_type xlst = c1.get_allocator( );
    // You can now call functions on the allocator class used by c1
}
```

deque::insert

Inserts an element or a number of elements or a range of elements into the deque at a specified position.

```
iterator insert(
    const_iterator Where,
    const Type& Val);

iterator insert(
    const_iterator Where,
    Type&& Val);

void insert(
    iterator Where,
    size_type Count,
    const Type& Val);

template <class InputIterator>
void insert(
    iterator Where,
    InputIterator First,
    InputIterator Last);

iterator insert(
    iterator Where,initializer_list<Type>
    Ilist);
```

Parameters

PARAMETER	DESCRIPTION
Where	The position in the target deque where the first element is inserted.

PARAMETER	DESCRIPTION
<i>Val</i>	The value of the element being inserted into the deque.
<i>Count</i>	The number of elements being inserted into the deque.
<i>First</i>	The position of the first element in the range of elements in the argument deque to be copied.
<i>Last</i>	The position of the first element beyond the range of elements in the argument deque to be copied.
<i>IList</i>	The initializer_list of elements to insert.

Return Value

The first two insert functions return an iterator that points to the position where the new element was inserted into the deque.

Remarks

Any insertion operation can be expensive.

deque::iterator

A type that provides a random-access iterator that can read or modify any element in a deque.

```
typedef implementation-defined iterator;
```

Remarks

A type `iterator` can be used to modify the value of an element.

Example

See the example for [begin](#).

deque::max_size

Returns the maximum length of the deque.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the deque.

Example

```
// deque_max_size.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1;
    deque <int>::size_type i;

    i = c1.max_size( );
    cout << "The maximum possible length of the deque is " << i << "." << endl;
}
```

deque::operator[]

Returns a reference to the deque element at a specified position.

```
reference operator[](size_type pos);

const_reference operator[](size_type pos) const;
```

Parameters

pos

The position of the deque element to be referenced.

Return Value

A reference to the element whose position is specified in the argument. If the position specified is greater than the size of the deque, the result is undefined.

Remarks

If the return value of `operator[]` is assigned to a `const_reference`, the deque object cannot be modified. If the return value of `operator[]` is assigned to a `reference`, the deque object can be modified.

When compiled by using `_ITERATOR_DEBUG_LEVEL` defined as 1 or 2, a runtime error will occur if you attempt to access an element outside the bounds of the deque. See [Checked Iterators](#) for more information.

Example

```
// deque_op_ref.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1;

    c1.push_back( 10 );
    c1.push_back( 20 );
    cout << "The first integer of c1 is " << c1[0] << endl;
    int& i = c1[1];
    cout << "The second integer of c1 is " << i << endl;
}
```

```
The first integer of c1 is 10
The second integer of c1 is 20
```

deque::operator=

Replaces the elements of this deque using the elements from another deque.

```
deque& operator=(const deque& right);

deque& operator=(deque&& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The deque that provides the new content.

Remarks

The first override copies elements to this deque from *right*, the source of the assignment. The second override moves elements to this deque from *right*.

Elements that are contained in this deque before the operator executes are removed.

Example

```

// deque_operator_as.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>
using namespace std;

typedef deque<int> MyDeque;

template<typename MyDeque> struct S;

template<typename MyDeque> struct S<MyDeque&> {
    static void show( MyDeque& d ) {
        MyDeque::const_iterator iter;
        for (iter = d.cbegin(); iter != d.cend(); iter++)
            cout << *iter << " ";
        cout << endl;
    }
};

template<typename MyDeque> struct S<MyDeque&&> {
    static void show( MyDeque&& d ) {
        MyDeque::const_iterator iter;
        for (iter = d.cbegin(); iter != d.cend(); iter++)
            cout << *iter << " ";
        cout << " via unnamed rvalue reference " << endl;
    }
};

int main( )
{
    MyDeque d1, d2;

    d1.push_back(10);
    d1.push_back(20);
    d1.push_back(30);
    d1.push_back(40);
    d1.push_back(50);

    cout << "d1 = " ;
    S<MyDeque&>::show( d1 );

    d2 = d1;
    cout << "d2 = ";
    S<MyDeque&>::show( d2 );

    cout << "      ";
    S<MyDeque&&>::show ( move< MyDeque& > (d1) );
}

```

deque::pointer

Provides a pointer to an element in a [deque](#).

```
typedef typename Allocator::pointer pointer;
```

Remarks

A type `pointer` can be used to modify the value of an element. An [iterator](#) is more commonly used to access a deque element.

deque::pop_back

Deletes the element at the end of the deque.

```
void pop_back();
```

Remarks

The last element must not be empty. `pop_back` never throws an exception.

Example

```
// deque_pop_back.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1;

    c1.push_back( 1 );
    c1.push_back( 2 );
    cout << "The first element is: " << c1.front( ) << endl;
    cout << "The last element is: " << c1.back( ) << endl;

    c1.pop_back( );
    cout << "After deleting the element at the end of the deque, the "
         << "last element is: " << c1.back( ) << endl;
}
```

```
The first element is: 1
The last element is: 2
After deleting the element at the end of the deque, the last element is: 1
```

deque::pop_front

Deletes the element at the beginning of the deque.

```
void pop_front();
```

Remarks

The first element must not be empty. `pop_front` never throws an exception.

Example

```
// deque_pop_front.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1;

    c1.push_back( 1 );
    c1.push_back( 2 );
    cout << "The first element is: " << c1.front( ) << endl;
    cout << "The second element is: " << c1.back( ) << endl;

    c1.pop_front( );
    cout << "After deleting the element at the beginning of the "
        "deque, the first element is: " << c1.front( ) << endl;
}
```

```
The first element is: 1
The second element is: 2
After deleting the element at the beginning of the deque, the first element is: 2
```

deque::push_back

Adds an element to the end of the deque.

```
void push_back(const Type& val);

void push_back(Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The element added to the end of the deque.

Remarks

If an exception is thrown, the deque is left unaltered and the exception is rethrown.

deque::push_front

Adds an element to the beginning of the deque.

```
void push_front(const Type& val);
void push_front(Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The element added to the beginning of the deque.

Remarks

If an exception is thrown, the deque is left unaltered and the exception is rethrown.

Example

```
// deque_push_front.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    deque <int> c1;

    c1.push_front( 1 );
    if ( c1.size( ) != 0 )
        cout << "First element: " << c1.front( ) << endl;

    c1.push_front( 2 );
    if ( c1.size( ) != 0 )
        cout << "New first element: " << c1.front( ) << endl;

    // move initialize a deque of strings
    deque <string> c2;
    string str("a");

    c2.push_front( move( str ) );
    cout << "Moved first element: " << c2.front( ) << endl;
}
```

```
First element: 1
New first element: 2
Moved first element: a
```

deque::rbegin

Returns an iterator to the first element in a reversed deque.

```
const_reverse_iterator rbegin() const;

reverse_iterator rbegin();
```

Return Value

A reverse random-access iterator addressing the first element in a reversed deque or addressing what had been the last element in the unreversed deque.

Remarks

`rbegin` is used with a reversed deque just as `begin` is used with a deque.

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, the deque object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, the deque object can be modified.

`rbegin` can be used to iterate through a deque backwards.

Example

```

// deque_rbegin.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1;
    deque<int>::iterator c1_Iter;
    deque<int>::reverse_iterator c1_rIter;

    // If the following line had replaced the line above, an error
    // would have resulted in the line modifying an element
    // (commented below) because the iterator would have been const
    // deque<int>::const_reverse_iterator c1_rIter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );

    c1_rIter = c1.rbegin( );
    cout << "Last element in the deque is " << *c1_rIter << "." << endl;

    cout << "The deque contains the elements: ";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << *c1_Iter << " ";
    cout << "in that order.";
    cout << endl;

    // rbegin can be used to iterate through a deque in reverse order
    cout << "The reversed deque is: ";
    for ( c1_rIter = c1.rbegin( ); c1_rIter != c1.rend( ); c1_rIter++ )
        cout << *c1_rIter << " ";
    cout << endl;

    c1_rIter = c1.rbegin( );
    *c1_rIter = 40; // This would have caused an error if a
                   // const_reverse iterator had been declared as
                   // noted above
    cout << "Last element in deque is now " << *c1_rIter << "." << endl;
}

```

```

Last element in the deque is 30.
The deque contains the elements: 10 20 30 in that order.
The reversed deque is: 30 20 10
Last element in deque is now 40.

```

deque::reference

A type that provides a reference to an element stored in a deque.

```

typedef typename Allocator::reference reference;

```

Example

```
// deque_reference.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque <int> c1;

    c1.push_back( 10 );
    c1.push_back( 20 );

    const int &i = c1.front( );
    int &j = c1.back( );
    cout << "The first element is " << i << endl;
    cout << "The second element is " << j << endl;
}
```

```
The first element is 10
The second element is 20
```

deque::rend

Returns an iterator that addresses the location succeeding the last element in a reversed deque.

```
const_reverse_iterator rend() const;

reverse_iterator rend();
```

Return Value

A reverse random-access iterator that addresses the location succeeding the last element in a reversed deque (the location that had preceded the first element in the unreversed deque).

Remarks

`rend` is used with a reversed deque just as `end` is used with a deque.

If the return value of `rend` is assigned to a `const_reverse_iterator`, the deque object cannot be modified. If the return value of `rend` is assigned to a `reverse_iterator`, the deque object can be modified.

`rend` can be used to test whether a reverse iterator has reached the end of its deque.

The value returned by `rend` should not be dereferenced.

Example

```

// deque_rend.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;

    deque<int> c1;
    deque<int>::iterator c1_Iter;
    deque<int>::reverse_iterator c1_rIter;
    // If the following line had replaced the line above, an error
    // would have resulted in the line modifying an element
    // (commented below) because the iterator would have been const
    // deque<int>::const_reverse_iterator c1_rIter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );

    c1_rIter = c1.rend( );
    c1_rIter --; // Decrementing a reverse iterator moves it forward
                 // in the deque (to point to the first element here)
    cout << "The first element in the deque is: " << *c1_rIter << endl;

    cout << "The deque is: ";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << *c1_Iter << " ";
    cout << endl;

    // rend can be used to test if an iteration is through all of
    // the elements of a reversed deque
    cout << "The reversed deque is: ";
    for ( c1_rIter = c1.rbegin( ); c1_rIter != c1.rend( ); c1_rIter++ )
        cout << *c1_rIter << " ";
    cout << endl;

    c1_rIter = c1.rend( );
    c1_rIter--; // Decrementing the reverse iterator moves it backward
                // in the reversed deque (to the last element here)
    *c1_rIter = 40; // This modification of the last element would
                    // have caused an error if a const_reverse
                    // iterator had been declared (as noted above)
    cout << "The modified reversed deque is: ";
    for ( c1_rIter = c1.rbegin( ); c1_rIter != c1.rend( ); c1_rIter++ )
        cout << *c1_rIter << " ";
    cout << endl;
}

```

```

The first element in the deque is: 10
The deque is: 10 20 30
The reversed deque is: 30 20 10
The modified reversed deque is: 30 20 40

```

deque::resize

Specifies a new size for a deque.

```

void resize(size_type _Newsize);

void resize(size_type _Newsize, Type val);

```

Parameters

_Newsize

The new size of the deque.

val

The value of the new elements to be added to the deque if the new size is larger than the original size. If the value is omitted, the new elements are assigned the default value for the class.

Remarks

If the deque's size is less than the requested size, *_Newsize*, elements are added to the deque until it reaches the requested size.

If the deque's size is larger than the requested size, the elements closest to the end of the deque are deleted until the deque reaches the size *_Newsize*.

If the present size of the deque is the same as the requested size, no action is taken.

[size](#) reflects the current size of the deque.

Example

```
// deque_resize.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );

    c1.resize( 4,40 );
    cout << "The size of c1 is: " << c1.size( ) << endl;
    cout << "The value of the last element is " << c1.back( ) << endl;

    c1.resize( 5 );
    cout << "The size of c1 is now: " << c1.size( ) << endl;
    cout << "The value of the last element is now " << c1.back( ) << endl;

    c1.resize( 2 );
    cout << "The reduced size of c1 is: " << c1.size( ) << endl;
    cout << "The value of the last element is now " << c1.back( ) << endl;
}
```

```
The size of c1 is: 4
The value of the last element is 40
The size of c1 is now: 5
The value of the last element is now 0
The reduced size of c1 is: 2
The value of the last element is now 20
```

deque::reverse_iterator

A type that provides a random-access iterator that can read or modify an element in a reversed deque.

```
typedef std::reverse_iterator<iterator> reverse_iterator;
```

Remarks

A type `reverse_iterator` is use to iterate through the deque.

Example

See the example for `rbegin`.

deque::shrink_to_fit

Discards excess capacity.

```
void shrink_to_fit();
```

Remarks

There is no portable way to determine if `shrink_to_fit` reduces the storage used by a [deque](#).

Example

```
// deque_shrink_to_fit.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> v1;
    //deque<int>::iterator Iter;

    v1.push_back( 1 );
    v1.push_back( 2 );
    cout << "Current size of v1 = "
         << v1.size( ) << endl;
    v1.shrink_to_fit();
    cout << "Current size of v1 = "
         << v1.size( ) << endl;
}
```

```
Current size of v1 = 1
Current size of v1 = 1
```

deque::size

Returns the number of elements in the deque.

```
size_type size() const;
```

Return Value

The current length of the deque.

Example

```
// deque_size.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1;
    deque<int>::size_type i;

    c1.push_back( 1 );
    i = c1.size( );
    cout << "The deque length is " << i << "." << endl;

    c1.push_back( 2 );
    i = c1.size( );
    cout << "The deque length is now " << i << "." << endl;
}
```

```
The deque length is 1.
The deque length is now 2.
```

deque::size_type

A type that counts the number of elements in a deque.

```
typedef typename Allocator::size_type size_type;
```

Example

See the example for [size](#).

deque::swap

Exchanges the elements of two deques.

```
void swap(deque<Type, Allocator>& right);

friend void swap(deque<Type, Allocator>& left, deque<Type, Allocator>& right) template <class Type, class
Allocator>
void swap(deque<Type, Allocator>& left, deque<Type, Allocator>& right);
```

Parameters

right

The deque providing the elements to be swapped, or the deque whose elements are to be exchanged with those of the deque `left`.

left

A deque whose elements are to be exchanged with those of the deque *right*.

Example

```

// deque_swap.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>

int main( )
{
    using namespace std;
    deque<int> c1, c2, c3;
    deque<int>::iterator c1_Iter;

    c1.push_back( 1 );
    c1.push_back( 2 );
    c1.push_back( 3 );
    c2.push_back( 10 );
    c2.push_back( 20 );
    c3.push_back( 100 );

    cout << "The original deque c1 is:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    c1.swap( c2 );

    cout << "After swapping with c2, deque c1 is:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    swap( c1,c3 );

    cout << "After swapping with c3, deque c1 is:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    swap<>(c1, c2);
    cout << "After swapping with c2, deque c1 is:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;
}

```

```

The original deque c1 is: 1 2 3
After swapping with c2, deque c1 is: 10 20
After swapping with c3, deque c1 is: 100
After swapping with c2, deque c1 is: 1 2 3

```

deque::value_type

A type that represents the data type stored in a deque.

```
typedef typename Allocator::value_type value_type;
```

Remarks

`value_type` is a synonym for the template parameter `Type`.

Example

```
// deque_value_type.cpp
// compile with: /EHsc
#include <deque>
#include <iostream>
int main( )
{
    using namespace std;
    deque<int>::value_type AnInt;
    AnInt = 44;
    cout << AnInt << endl;
}
```

44

<exception>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines several types and functions related to the handling of exceptions. Exception handling is used in situations in which the system can recover from an error. It provides a means for control to be returned from a function to the program. The objective of incorporating exception handling is to increase the program's robustness while providing a way to recover from an error in an orderly fashion.

Syntax

```
#include <exception>
```

Typedefs

TYPE NAME	DESCRIPTION
exception_ptr	A type that describes a pointer to an exception.
terminate_handler	A type that describes a pointer to a function suitable for use as a <code>terminate_handler</code> .
unexpected_handler	A type that describes a pointer to a function suitable for use as an <code>unexpected_handler</code> .

Functions

FUNCTION	DESCRIPTION
current_exception	Obtains a pointer to the current exception.
get_terminate	Obtains the current <code>terminate_handler</code> function.
get_unexpected	Obtains the current <code>unexpected_handler</code> function.
make_exception_ptr	Creates an <code>exception_ptr</code> object that holds a copy of an exception.
rethrow_exception	Throws an exception passed as a parameter.
set_terminate	Establishes a new <code>terminate_handler</code> to be called at the termination of the program.
set_unexpected	Establishes a new <code>unexpected_handler</code> to be when an unexpected exception is encountered.
terminate	Calls a terminate handler.
uncaught_exception	Returns true only if a thrown exception is being currently processed.

FUNCTION	DESCRIPTION
unexpected	Calls an unexpected handler.

Classes

CLASS	DESCRIPTION
bad_exception Class	The class describes an exception that can be thrown from an <code>unexpected_handler</code> .
exception Class	The class serves as the base class for all exceptions thrown by certain expressions and by the C++ Standard Library.

<exception> functions

11/9/2018 • 5 minutes to read • [Edit Online](#)

current_exception	get_terminate	get_unexpected
make_exception_ptr	rethrow_exception	set_terminate
set_unexpected	terminate	uncaught_exception
unexpected		

current_exception

Obtains a smart pointer to the current exception.

```
exception_ptr current_exception();
```

Return Value

An [exception_ptr](#) object pointing to the current exception.

Remarks

Call the `current_exception` function in a catch block. If an exception is in flight and the catch block can catch the exception, the `current_exception` function returns an `exception_ptr` object that references the exception. Otherwise, the function returns a null `exception_ptr` object.

The `current_exception` function captures the exception that is in flight regardless of whether the **catch** statement specifies an [exception-declaration](#) statement.

The destructor for the current exception is called at the end of the **catch** block if you do not rethrow the exception. However, even if you call the `current_exception` function in the destructor, the function returns an `exception_ptr` object that references the current exception.

Successive calls to the `current_exception` function return `exception_ptr` objects that refer to different copies of the current exception. Consequently, the objects compare as unequal because they refer to different copies, even though the copies have the same binary value.

make_exception_ptr

Creates an [exception_ptr](#) object that holds a copy of an exception.

```
template <class E>  
exception_ptr make_exception_ptr(E Except);
```

Parameters

Except

The class with the exception to copy. Usually, you specify an [exception class](#) object as the argument to the `make_exception_ptr` function, although any class object can be the argument.

Return Value

An [exception_ptr](#) object pointing to a copy of the current exception for *Except*.

Remarks

Calling the `make_exception_ptr` function is equivalent to throwing a C++ exception, catching it in a catch block, and then calling the [current_exception](#) function to return an `exception_ptr` object that references the exception. The Microsoft implementation of the `make_exception_ptr` function is more efficient than throwing and then catching an exception.

An application typically does not require the `make_exception_ptr` function, and we discourage its use.

rethrow_exception

Throws an exception passed as a parameter.

```
void rethrow_exception(exception_ptr P);
```

Parameters

P

The caught exception to re-throw. If *P* is a null [exception_ptr](#), the function throws [std::bad_exception](#).

Remarks

After you store a caught exception in an `exception_ptr` object, the primary thread can process the object. In your primary thread, call the `rethrow_exception` function together with the `exception_ptr` object as its argument. The `rethrow_exception` function extracts the exception from the `exception_ptr` object and then throws the exception in the context of the primary thread.

get_terminate

Obtains the current `terminate_handler` function.

```
terminate_handler get_terminate();
```

set_terminate

Establishes a new `terminate_handler` to be called at the termination of the program.

```
terminate_handler set_terminate(terminate_handler fnew) throw();
```

Parameters

fnew

The function to be called at termination.

Return Value

The address of the previous function that used to be called at termination.

Remarks

The function establishes a new [terminate_handler](#) as the function * *fnew*. Thus, *fnew* must not be a null pointer. The function returns the address of the previous terminate handler.

Example

```

// exception_set_terminate.cpp
// compile with: /EHsc
#include <exception>
#include <iostream>

using namespace std;

void termfunction()
{
    cout << "My terminate function called." << endl;
    abort();
}

int main()
{
    terminate_handler oldHandler = set_terminate(termfunction);

    // Throwing an unhandled exception would also terminate the program
    // or we could explicitly call terminate();

    //throw bad_alloc();
    terminate();
}

```

get_unexpected

Obtains the current `unexpected_handler` function.

```
unexpected_handler get_unexpected();
```

set_unexpected

Establishes a new `unexpected_handler` to be when an unexpected exception is encountered.

```
unexpected_handler set_unexpected(unexpected_handler fnew) throw();
```

Parameters

fnew

The function to be called when an unexpected exception is encountered.

Return Value

The address of the previous `unexpected_handler`.

Remarks

fnew must not be a null pointer.

The C++ Standard requires that `unexpected` is called when a function throws an exception that is not on its throw list. The current implementation does not support this. The following example calls `unexpected` directly, which then calls the `unexpected_handler`.

Example

```
// exception_set_unexpected.cpp
// compile with: /EHsc
#include <exception>
#include <iostream>

using namespace std;

void uefunction()
{
    cout << "My unhandled exception function called." << endl;
    terminate(); // this is what unexpected() calls by default
}

int main()
{
    unexpected_handler oldHandler = set_unexpected(uefunction);

    unexpected(); // library function to force calling the
                // current unexpected handler
}
```

terminate

Calls a terminate handler.

```
void terminate();
```

Remarks

The function calls a terminate handler, a function of type **void**. If `terminate` is called directly by the program, the terminate handler is the one most recently set by a call to [set_terminate](#). If `terminate` is called for any of several other reasons during evaluation of a throw expression, the terminate handler is the one in effect immediately after evaluating the throw expression.

A terminate handler may not return to its caller. At program startup, the terminate handler is a function that calls `abort`.

Example

See [set_unexpected](#) for an example of the use of `terminate`.

uncaught_exception

Returns **true** only if a thrown exception is being currently processed.

```
bool uncaught_exception();
```

Return Value

Returns **true** after completing evaluation of a throw expression and before completing initialization of the exception declaration in the matching handler or calling [unexpected](#) as a result of the throw expression. In particular, `uncaught_exception` will return **true** when called from a destructor that is being invoked during an exception unwind. On devices, `uncaught_exception` is only supported on Windows CE 5.00 and higher versions, including Windows Mobile 2005 platforms.

Example

```

// exception_uncaught_exception.cpp
// compile with: /EHsc
#include <exception>
#include <iostream>
#include <string>

class Test
{
public:
    Test( std::string msg ) : m_msg( msg )
    {
        std::cout << "In Test::Test(\"" << m_msg << "\"" << std::endl;
    }
    ~Test( )
    {
        std::cout << "In Test::~Test(\"" << m_msg << "\"" << std::endl
        << "        std::uncaught_exception( ) = "
        << std::uncaught_exception( )
        << std::endl;
    }
private:
    std::string m_msg;
};

// uncaught_exception will be true in the destructor
// for the object created inside the try block because
// the destructor is being called as part of the unwind.

int main( void )
{
    Test t1( "outside try block" );
    try
    {
        Test t2( "inside try block" );
        throw 1;
    }
    catch (...) {
    }
}

```

```

In Test::Test("outside try block")
In Test::Test("inside try block")
In Test::~Test("inside try block")
    std::uncaught_exception( ) = 1
In Test::~Test("outside try block")
    std::uncaught_exception( ) = 0

```

unexpected

Calls the unexpected handler.

```
void unexpected();
```

Remarks

The C++ Standard requires that `unexpected` is called when a function throws an exception that is not on its throw list. The current implementation does not support this. The example calls `unexpected` directly, which calls the unexpected handler.

The function calls an unexpected handler, a function of type **void**. If `unexpected` is called directly by the program, the unexpected handler is the one most recently set by a call to [set_unexpected](#).

An unexpected handler may not return to its caller. It may terminate execution by:

- Throwing an object of a type listed in the exception specification or an object of any type if the unexpected handler is called directly by the program.
- Throwing an object of type [bad_exception](#).
- Calling [terminate](#), `abort` or `exit(int)`.

At program startup, the unexpected handler is a function that calls [terminate](#).

Example

See [set_unexpected](#) for an example of the use of `unexpected`.

[<exception>](#)

<exception> typedefs

10/31/2018 • 2 minutes to read • [Edit Online](#)

exception_ptr	terminate_handler	unexpected_handler

exception_ptr

A type that describes a pointer to an exception.

```
typedef unspecified exception_ptr;
```

Remarks

An unspecified internal class that is used to implement the `exception_ptr` type.

Use an `exception_ptr` object to reference the current exception or an instance of a user-specified exception. In the Microsoft implementation, an exception is represented by an `EXCEPTION_RECORD` structure. Each `exception_ptr` object includes an exception reference field that points to a copy of the `EXCEPTION_RECORD` structure that represents the exception.

When you declare an `exception_ptr` variable, the variable is not associated with any exception. That is, its exception reference field is NULL. Such an `exception_ptr` object is called a *null exception_ptr*.

Use the `current_exception` or `make_exception_ptr` function to assign an exception to an `exception_ptr` object. When you assign an exception to an `exception_ptr` variable, the variable's exception reference field points to a copy of the exception. If there is insufficient memory to copy the exception, the exception reference field points to a copy of a `std::bad_alloc` exception. If the `current_exception` or `make_exception_ptr` function cannot copy the exception for any other reason, the function calls the `terminate` CRT function to exit the current process.

Despite its name, an `exception_ptr` object is not itself a pointer. It does not obey pointer semantics and cannot be used with the pointer member access (`->`) or indirection (`*`) operators. The `exception_ptr` object has no public data members or member functions.

Comparisons:

You can use the equal (`==`) and not-equal (`!=`) operators to compare two `exception_ptr` objects. The operators do not compare the binary value (bit pattern) of the `EXCEPTION_RECORD` structures that represent the exceptions. Instead, the operators compare the addresses in the exception reference field of the `exception_ptr` objects. Consequently, a null `exception_ptr` and the NULL value compare as equal.

terminate_handler

The type describes a pointer to a function suitable for use as a `terminate_handler` .

```
typedef void (*terminate_handler)();
```

Remarks

The type describes a pointer to a function suitable for use as a terminate handler.

Example

See [set_terminate](#) for an example of the use of `terminate_handler`.

unexpected_handler

The type describes a pointer to a function suitable for use as an `unexpected_handler`.

```
typedef void (*unexpected_handler)();
```

Example

See [set_unexpected](#) for an example of the use of `unexpected_handler`.

See also

[<exception>](#)

bad_exception Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The class describes an exception that can be thrown from an unexpected handler.

Syntax

```
class bad_exception : public exception {};
```

Remarks

[unexpected](#) will throw a `bad_exception` instead of terminating or instead of calling another function specified with [set_unexpected](#) if `bad_exception` is included in the throw list of a function.

The value returned by `what` is an implementation-defined C string. None of the member functions throw any exceptions.

For a list of members inherited by the `bad_exception` class, see [exception Class](#).

Example

See [set_unexpected](#) for an example of the use of [unexpected](#) throwing a `bad_exception`.

Requirements

Header: <exception>

Namespace: std

See also

[exception Class](#)

[Thread Safety in the C++ Standard Library](#)

exception Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The class serves as the base class for all exceptions thrown by certain expressions and by the C++ Standard Library.

Syntax

```
class exception {
public:
    exception();
    exception(const char* const &message);
    exception(const char* const &message, int);
    exception(const exception &right);
    exception& operator=(const exception &right);
    virtual ~exception();
    virtual const char *what() const;
};
```

Remarks

Specifically, this base class is the root of the standard exception classes defined in [<stdexcept>](#). The C string value returned by `what` is left unspecified by the default constructor, but may be defined by the constructors for certain derived classes as an implementation-defined C string. None of the member functions throw any exceptions.

The **int** parameter allows you to specify that no memory should be allocated. The value of the **int** is ignored.

NOTE

The constructors `exception(const char* const &message)` and `exception(const char* const &message, int)` are Microsoft extensions to the C++ Standard Library.

Example

For examples of the use of the standard exception classes that inherit from the `exception` class, see any of the classes defined in [<stdexcept>](#).

Requirements

Header: `<exception>`

Namespace: `std`

[Thread Safety in the C++ Standard Library](#)

<filesystem>

5/7/2019 • 3 minutes to read • [Edit Online](#)

Include the header <filesystem> for access to classes and functions that manipulate and retrieve information about paths, files and directories.

Syntax

```
#include <experimental/filesystem> // C++-standard header file name
#include <filesystem> // Microsoft-specific implementation header file name
using namespace std::experimental::filesystem::v1;
```

IMPORTANT

As of the release of Visual Studio 2017, the <filesystem> header was not yet a C++ standard. C++ in Visual Studio 2017 (MSVC v141) implements the final draft standard, found in [ISO/IEC JTC 1/SC 22/WG 21 N4100](#).

This header supports filesystems for one of two broad classes of host operating systems: Microsoft Windows and Posix.

While most functionality is common to both operating systems, this document identifies where differences occur. For example:

- Windows supports multiple root names, such as c: or \\network_name. A filesystem consists of a forest of trees, each with its own root directory, such as c:\ or \\network_name\, and each with its own current directory, for completing a relative pathname (one that is not an absolute pathname).
- Posix supports a single tree, with no root name, the single root directory /, and a single current directory.

Another significant difference is the native representation of pathnames:

- Windows uses a null-terminated sequence of wchar_t, encoded as UTF-16 (one or two elements for each character).
- Posix uses a null-terminated sequence of char, encoded as UTF-8 (one or more elements for each character).
- An object of class path stores the pathname in native form, but supports easy conversion between this stored form and several external forms:
 - A null-terminated sequence of char, encoded as favored by the operating system.
 - A null-terminated sequence of char, encoded as UTF-8.
 - A null-terminated sequence of wchar_t, encoded as favored by the operating system.
 - A null-terminated sequence of char16_t, encoded as UTF-16.
 - A null-terminated sequence of char32_t, encoded as UTF-32.

Interconversions between these representations are mediated, as needed, by the use of one or more `codecvt` facets. If a specific locale object is not designated, these facets are obtained from the global locale.

Another difference is the detail with which each operating system lets you specify file or directory access

permissions:

1. Windows records whether a file is read only or writable, an attribute that has no meaning for directories.
2. Posix records whether a file can be read, written, or executed (scanned if a directory), by the owner, by the owner's group, or by everybody, plus a few other permissions.

Common to both systems is the structure imposed on a pathname once you get past the root name. For the pathname `c:/abc/xyz/def.ext`:

- The root name is `c:`.
- The root directory is `/`.
- The root path is `c:/`.
- The relative path is `abc/xyz/def.ext`.
- The parent path is `c:/abc/xyz`.
- The filename is `def.ext`.
- The stem is `def`.
- The extension is `.ext`.

A minor difference is the **preferred separator**, between the sequence of directories in a pathname. Both operating systems let you write a forward slash `/`, but in some contexts Windows prefers a backslash `\`.

Finally, an important feature of path objects is that you can use them wherever a filename argument is required in the classes defined in the header `<fstream>`.

For more information and code examples, see [File System Navigation \(C++\)](#).

Classes

NAME	DESCRIPTION
directory_entry Class	Describes an object that is returned by a <code>directory_iterator</code> or a <code>recursive_directory_iterator</code> and contains a path.
directory_iterator Class	Describes an input iterator that sequences through the file names in a file-system directory.
filesystem_error Class	A base class for exceptions that are thrown to report a low-level system overflow.
path Class	Defines a class that stores an object of template type <code>String</code> that is suitable for use as a file name.
recursive_directory_iterator Class	Describes an input iterator that sequences through the file names in a file-system directory. The iterator can also descend into subdirectories.
file_status Class	Wraps a <code>file_type</code> .

Structs

NAME	DESCRIPTION
space_info Structure	Holds information about a volume.

Functions

[<filesystem> functions](#)

Operators

[<filesystem> operators](#)

Enumerations

NAME	DESCRIPTION
copy_options	An enumeration that is used with copy_file and determines behavior if a destination file already exists.
copy_options	An enumeration that is used with copy_file and determines behavior if a destination file already exists.
directory_options	An enumeration that specifies options for directory iterators.
file_type	An enumeration for file types.
perms	A bitmask type used to convey permissions and options to permissions

[Header Files Reference](#)

<filesystem> operators

10/31/2018 • 2 minutes to read • [Edit Online](#)

The operators perform a lexical comparison of two paths as strings. Use the `equivalent` function to determine whether two paths (for example a relative path and an absolute path) refer to the same file or directory on disk.

For more information, see [File System Navigation \(C++\)](#).

operator==

```
bool operator==(const path& left, const path& right) noexcept;
```

The function returns `left.native() == right.native()`.

operator!=

```
bool operator!=(const path& left, const path& right) noexcept;
```

The function returns `!(left == right)`.

operator<

```
bool operator<(const path& left, const path& right) noexcept;
```

The function returns `left.native() < right.native()`.

operator<=

```
bool operator<=(const path& left, const path& right) noexcept;
```

The function returns `!(right < left)`.

operator>

```
bool operator>(const path& left, const path& right) noexcept;
```

The function returns `right < left`.

operator>=

```
bool operator>=(const path& left, const path& right) noexcept;
```

The function returns `!(left < right)`.

operator/

```
path operator/(const path& left, const path& right);
```

The function executes:

```
basic_string<Elem, Traits> str;  
path ans = left;  
return (ans /= right);
```

operator<<

```
template <class Elem, class Traits>  
basic_ostream<Elem, Traits>& operator<<(basic_ostream<Elem, Traits>& os, const path& pval);
```

The function returns `os << pval.string<Elem, Traits>()`.

operator>>

```
template <class Elem, class Traits>  
basic_istream<Elem, Traits>& operator>>(basic_istream<Elem, Traits>& is, const path& pval);
```

The function executes:

```
basic_string<Elem, Traits> str;  
is>> str;  
pval = str;  
return (is);
```

[File System Navigation \(C++\)](#)

[<filesystem>](#)

<filesystem> functions

3/28/2019 • 9 minutes to read • [Edit Online](#)

These free functions in the [<filesystem>](#) header perform modifying and query operations on paths, files, symlinks, directories and volumes. For more information and code examples, see [File System Navigation \(C++\)](#).

absolute	begin	canonical
copy	copy_file	copy_symlink
create_directories	create_directory	create_directory_symlink
create_hard_link	create_symlink	current_path
end	equivalent	exists
file_size	hard_link_count	hash_value
is_block_file	is_character_file	is_directory
is_empty	is_fifo	is_other
is_regular_file	is_socket	is_symlink
last_write_time	permissions	read_symlink
remove	remove_all	rename
resize_file	space	status
status_known	swap	symlink_status
system_complete	temp_directory_path	u8path

absolute

```
path absolute(const path& pval, const path& base = current_path());
```

The function returns the absolute pathname corresponding to *pval* relative to the pathname `base`:

1. If `pval.has_root_name() && pval.has_root_directory()` the function returns *pval*.
2. If `pval.has_root_name() && !pval.has_root_directory()` the function returns `pval.root_name() / absolute(base).root_directory() / absolute(base).relative_path() / pval.relative_path()`.
3. If `!pval.has_root_name() && pval.has_root_directory()` the function returns `absolute(base).root_name() / pval`.

4. If `!pval.has_root_name() && !pval.has_root_directory()` the function returns `absolute(base) / pval`.

begin

```
const directory_iterator& begin(const directory_iterator& iter) noexcept;
const recursive_directory_iterator&
    begin(const recursive_directory_iterator& iter) noexcept;
```

Both functions return *iter*.

canonical

```
path canonical(const path& pval, const path& base = current_path());
path canonical(const path& pval, error_code& ec);
path canonical(const path& pval, const path& base, error_code& ec);
```

The functions all form an absolute pathname `pabs = absolute(pval, base)` (or `pabs = absolute(pval)` for the overload with no base parameter), then reduce it to a canonical form in the following sequence of steps:

1. Every path component `x` for which `is_symlink(X)` is **true** is replaced by `read_symlink(X)`.
2. Every path component `.` (dot is the current directory established by previous path components) is removed.
3. Every pair of path components `x / ..` (dot-dot is the parent directory established by previous path components) is removed.

The function then returns `pabs`.

copy

```
void copy(const path& from, const path& to);
void copy(const path& from, const path& to, error_code& ec) noexcept;
void copy(const path& from, const path& to, copy_options opts);
void copy(const path& from, const path& to, copy_options opts, error_code& ec) noexcept;
```

The functions all possibly copy or link one or more files at *from* to *to* under control of *opts*, which is taken as `copy_options::none` for the overloads with no *opts* parameter. *opts* shall contain at most one of:

- `skip_existing`, `overwrite_existing`, OR `update_existing`
- `copy_symlinks` OR `skip_symlinks`
- `directories_only`, `create_symlinks`, OR `create_hard_links`

The functions first determine the file_status values `f` for *from* and `t` for *to*:

- if `opts & (copy_options::create_symlinks | copy_options::skip_symlinks)`, by calling `symlink_status`
- otherwise, by calling `status`
- Otherwise report an error.

If `!exists(f) || equivalent(f, t) || is_other(f) || is_other(t) || is_directory(f) && is_regular_file(t)`, they then report an error (and do nothing else).

Otherwise, if `is_symlink(f)` then:

- If `options & copy_options::skip_symlinks` then do nothing.
- Otherwise, if `!exists(t) && options & copy_options::copy_symlinks` then `copy_symlink(from, to, opts)`.
- Otherwise report an error.

Otherwise, if `is_regular_file(f)` then:

- If `opts & copy_options::directories_only` then do nothing.
- Otherwise, if `opts & copy_options::create_symlinks` then `create_symlink(to, from)`.
- Otherwise, if `opts & copy_options::create_hard_links` then `create_hard_link(to, from)`.
- Otherwise, if `is_directory(f)` then `copy_file(from, to / from.filename(), opts)`.
- Otherwise, `copy_file(from, to, opts)`.

Otherwise, if `is_directory(f) && (opts & copy_options::recursive || !opts)` then:

```
if (!exists(t))
{ // copy directory contents recursively
    create_directory(to, from, ec);

    for (directory_iterator next(from), end; ec == error_code() && next != end; ++next)
    {
        copy(next->path(), to / next->path().filename(), opts, ec);
    }
}
```

Otherwise, do nothing.

copy_file

```
bool copy_file(const path& from, const path& to);
bool copy_file(const path& from, const path& to, error_code& ec) noexcept;
bool copy_file(const path& from, const path& to, copy_options opts);
bool copy_file(const path& from, const path& to, copy_options opts, error_code& ec) noexcept;
```

The functions all possibly copy the file at *from* to *to* under control of *opts*, which is taken as `copy_options::none` for the overloads with no *opts* parameter. *opts* shall contain at most one of `skip_existing`, `overwrite_existing`, or `update_existing`.

If

```
exists(to) && !(opts & (copy_options::skip_existing | copy_options::overwrite_existing |
copy_options::update_existing))
```

then report as an error that the file already exists.

Otherwise, if

```
!exists(to) || opts & copy_options::overwrite_existing || opts & copy_options::update_existing &&
last_write_time(to) < last_write_time(from) || !(opts & (copy_options::skip_existing |
copy_options::overwrite_existing | copy_options::update_existing))
```

then attempt to copy the contents and attributes of the file *from* to the file *to*. Report as an error if the copy attempt fails.

The functions return **true** if the copy is attempted and succeeds, otherwise **false**.

copy_symlink

```
void copy_symlink(const path& from, const path& to);  
void copy_symlink(const path& from, const path& to, error_code& ec) noexcept;
```

If `is_directory(from)` the function calls `create_directory_symlink(from, to)`. Otherwise, it calls `create_symlink(from, to)`.

create_directories

```
bool create_directories(const path& pval);  
bool create_directories(const path& pval, error_code& ec) noexcept;
```

For a pathname such as `a/b/c` the function creates directories `a` and `a/b` as needed so that it can create the directory `a/b/c` as needed. It returns **true** only if it actually creates the directory `pval`.

create_directory

```
bool create_directory(const path& pval);  
  
bool create_directory(const path& pval, error_code& ec) noexcept;  
bool create_directory(const path& pval, const path& attr);  
bool create_directory(const path& pval, const path& attr, error_code& ec) noexcept;
```

The function creates the directory `pval` as needed. It returns true only if it actually creates the directory `pval`, in which case it copies permissions from the existing file `attr`, or uses `perms::all` for the overloads with no `attr` parameter.

create_directory_symlink

```
void create_directory_symlink(const path& to, const path& link);  
void create_directory_symlink(const path& to, const path& link, error_code& ec) noexcept;
```

The function creates `link` as a symlink to the directory `to`.

create_hard_link

```
void create_hard_link(const path& to, const path& link);  
void create_hard_link(const path& to, const path& link, error_code& ec) noexcept;
```

The function creates `link` as a hard link to the directory or file `to`.

create_symlink

```
void create_symlink(const path& to, const path& link);  
  
void create_symlink(const path& to, const path& link, error_code& ec) noexcept;
```

The function creates `link` as a symlink to the file `to`.

current_path

```
path current_path();
path current_path(error_code& ec);
void current_path(const path& pval);
void current_path(const path& pval, error_code& ec) noexcept;
```

The functions with no parameter *pval* return the pathname for the current directory. The remaining functions set the current directory to *pval*.

end

```
directory_iterator& end(const directory_iterator& iter) noexcept;
recursive_directory_iterator& end(const recursive_directory_iterator& iter) noexcept;
```

The first function returns `directory_iterator()` and the second function returns `recursive_directory_iterator()`

equivalent

```
bool equivalent(const path& left, const path& right);
bool equivalent(const path& left, const path& right, error_code& ec) noexcept;
```

The functions return **true** only if *left* and *right* designate the same filesystem entity.

exists

```
bool exists(file_status stat) noexcept;
bool exists(const path& pval);
bool exists(const path& pval, error_code& ec) noexcept;
```

The first function returns `status_known && stat.type() != file_not_found`. The second and third functions return `exists(status(pval))`.

file_size

```
uintmax_t file_size(const path& pval);
uintmax_t file_size(const path& pval, error_code& ec) noexcept;
```

The functions return the size in bytes of the file designated by *pval*, if `exists(pval) && is_regular_file(pval)` and the file size can be determined. Otherwise they report an error and return `uintmax_t(-1)`.

hard_link_count

```
uintmax_t hard_link_count(const path& pval);
uintmax_t hard_link_count(const path& pval, error_code& ec) noexcept;
```

The function returns the number of hard links for *pval*, or -1 if an error occurs.

hash_value

```
size_t hash_value(const path& pval) noexcept;
```

The function returns a hash value for `pval.native()` .

is_block_file

```
bool is_block_file(file_status stat) noexcept;  
bool is_block_file(const path& pval);  
bool is_block_file(const path& pval, error_code& ec) noexcept;
```

The first function returns `stat.type() == file_type::block` . The remaining functions return `is_block_file(status(pval))` .

is_character_file

```
bool is_character_file(file_status stat) noexcept;  
bool is_character_file(const path& pval);  
bool is_character_file(const path& pval, error_code& ec) noexcept;
```

The first function returns `stat.type() == file_type::character` . The remaining functions return `is_character_file(status(pval))` .

is_directory

```
bool is_directory(file_status stat) noexcept;  
bool is_directory(const path& pval);  
bool is_directory(const path& pval, error_code& ec) noexcept;
```

The first function returns `stat.type() == file_type::directory` . The remaining functions return `is_directory_file(status(pval))` .

is_empty

```
bool is_empty(file_status stat) noexcept;  
bool is_empty(const path& pval);  
bool is_empty(const path& pval, error_code& ec) noexcept;
```

If `is_directory(pval)` then the function returns `directory_iterator(pval) == directory_iterator()` ; otherwise it returns `file_size(pval) == 0` .

is_fifo

```
bool is_fifo(file_status stat) noexcept;  
bool is_fifo(const path& pval);  
bool is_fifo(const path& pval, error_code& ec) noexcept;
```

The first function returns `stat.type() == file_type::fifo` . The remaining functions return `is_fifo(status(pval))` .

is_other

```
bool is_other(file_status stat) noexcept;
bool is_other(const path& pval);
bool is_other(const path& pval, error_code& ec) noexcept;
```

The first function returns `stat.type() == file_type::other`. The remaining functions return `is_other(status(pval))`.

is_regular_file

```
bool is_regular_file(file_status stat) noexcept;
bool is_regular_file(const path& pval);
bool is_regular_file(const path& pval, error_code& ec) noexcept;
```

The first function returns `stat.type() == file_type::regular`. The remaining functions return `is_regular_file(status(pval))`.

is_socket

```
bool is_socket(file_status stat) noexcept;
bool is_socket(const path& pval);
bool is_socket(const path& pval, error_code& ec) noexcept;
```

The first function returns `stat.type() == file_type::socket`. The remaining functions return `is_socket(status(pval))`.

is_symlink

```
bool is_symlink(file_status stat) noexcept;
bool is_symlink(const path& pval);
bool is_symlink(const path& pval, error_code& ec) noexcept;
```

The first function returns `stat.type() == file_type::symlink`. The remaining functions return `is_symlink(status(pval))`.

last_write_time

```
file_time_type last_write_time(const path& pval);
file_time_type last_write_time(const path& pval, error_code& ec) noexcept;
void last_write_time(const path& pval, file_time_type new_time);
void last_write_time(const path& pval, file_time_type new_time, error_code& ec) noexcept;
```

The first two functions return the time of last data modification for *pval*, or `file_time_type(-1)` if an error occurs. The last two functions set the time of last data modification for *pval* to *new_time*.

permissions

```
void permissions(const path& pval, perms mask);
void permissions(const path& pval, perms mask, error_code& ec) noexcept;
```

The functions set the permissions for the pathname designated by *pval* to `mask & perms::mask` under control of

`perms & (perms::add_perms | perms::remove_perms)` . *mask* shall contain at most one of `perms::add_perms` and `perms::remove_perms` .

If `mask & perms::add_perms` the functions set the permissions to `status(pval).permissions() | mask & perms::mask` . Otherwise, if `mask & perms::remove_perms` the functions set the permissions to `status(pval).permissions() & ~(mask & perms::mask)` . Otherwise, the functions set the permissions to `mask & perms::mask` .

read_symlink

```
path read_symlink(const path& pval);  
path read_symlink(const path& pval, error_code& ec);
```

The functions report an error and return `path()` if `!is_symlink(pval)` . Otherwise, the functions return an object of type `path` containing the symbolic link.

remove

```
bool remove(const path& pval);  
bool remove(const path& pval, error_code& ec) noexcept;
```

The functions return **true** only if `exists(symlink_status(pval))` and the file is successfully removed. A symlink is itself removed, not the file it designates.

remove_all

```
uintmax_t remove_all(const path& pval);  
uintmax_t remove_all(const path& pval, error_code& ec) noexcept;
```

If *pval* is a directory, the functions recursively remove all directory entries, then the entry itself. Otherwise, the functions call `remove` . They return a count of all elements successfully removed.

rename

```
void rename(const path& from, const path& to);  
void rename(const path& from, const path& to, error_code& ec) noexcept;
```

The functions rename *from* to *to* . A symlink is itself renamed, not the file it designates.

resize_file

```
void resize(const path& pval, uintmax_t size);  
void resize(const path& pval, uintmax_t size, error_code& ec) noexcept;
```

The functions alter the size of a file such that `file_size(pval) == size`

space

```
space_info space(const path& pval);
space_info space(const path& pval, error_code& ec) noexcept;
```

The function returns information about the volume designated by *pval*, in a structure of type `space_info`. The structure contains `uintmax_t(-1)` for any value that cannot be determined.

status

```
file_status status(const path& pval);
file_status status(const path& pval, error_code& ec) noexcept;
```

The functions return the pathname status, the file type and permissions, associated with *pval*. A symlink is itself not tested, but the file it designates.

status_known

```
bool status_known(file_status stat) noexcept;
```

The function returns `stat.type() != file_type::none`

swap

```
void swap(path& left, path& right) noexcept;
```

The function exchanges the contents of *left* and *right*.

symlink_status

```
file_status symlink_status(const path& pval);
file_status symlink_status(const path& pval, error_code& ec) noexcept;
```

The functions return the pathname symlink status, the file type and permissions, associated with *pval*. The functions behave the same as `status(pval)` except that a symlink is itself tested, not the file it designates.

system_complete

```
path system_complete(const path& pval);
path system_complete(const path& pval, error_code& ec);
```

The functions return an absolute pathname that takes into account, as necessary, the current directory associated with its root name. (For Posix, the functions return `absolute(pval)`.)

temp_directory_path

```
path temp_directory_path();
path temp_directory_path(error_code& ec);
```

The functions return a pathname for a directory suitable for containing temporary files.

u8path

```
template <class Source>
path u8path(const Source& source);

template <class InIt>
path u8path(InIt first, InIt last);
```

The first function behaves the same as `path(source)` and the second function behaves the same as `path(first, last)` except that the designated source in each case is taken as a sequence of char elements encoded as UTF-8, regardless of the filesystem.

<filesystem> enumerations

10/31/2018 • 2 minutes to read • [Edit Online](#)

This topic documents the enums in the filesystem header.

Requirements

Header: <experimental/filesystem>

Namespace: std::experimental::filesystem

copy_options

An enumeration of bitmask values that is used with [copy](#) and [copy_file](#) functions to specify behavior.

Syntax

```
enum class copy_options {
    none = 0,
    skip_existing = 1,
    overwrite_existing = 2,
    update_existing = 4,
    recursive = 8,
    copy_symlinks = 16,
    skip_symlinks = 32,
    directories_only = 64,
    create_symlinks = 128,
    create_hard_links = 256
};
```

Values

NAME	DESCRIPTION
<code>none</code>	Perform the default behavior for the operation.
<code>skip_existing</code>	Do not copy if the file already exists, do not report an error.
<code>overwrite_existing</code>	Overwrite the file if it already exists.
<code>update_existing</code>	Overwrite the file if it already exists and is older than the replacement.
<code>recursive</code>	Recursively copy subdirectories and their contents.
<code>copy_symlinks</code>	Copy symbolic links as symbolic links, instead of copying the files they point to.
<code>skip_symlinks</code>	Ignore symbolic links.
<code>directories_only</code>	Only iterate over directories, ignore files.

NAME	DESCRIPTION
<code>create_symlinks</code>	Make symbolic links instead of copying files. An absolute path must be used as the source path unless the destination is the current directory.
<code>create_hard_links</code>	Make hard links instead of copying files.

directory_options

Specifies whether to follow symbolic links to directories or to ignore them.

Syntax

```
enum class directory_options {
    none = 0,
    follow_directory_symlink
};
```

Values

NAME	DESCRIPTION
<code>none</code>	Default behavior: ignore symbolic links to directories. Permission denied is an error.
<code>follow_directory_symlink</code>	Treat symbolic links to directories as actual directories.

file_type

An enumeration for file types. The supported values are regular, directory, not_found, and unknown.

Syntax

```
enum class file_type {
    not_found = -1,
    none,
    regular,
    directory,
    symlink,
    block,
    character,
    fifo,
    socket,
    unknown
};
```

Values

NAME	VALUE	DESCRIPTION
<code>not_found</code>	-1	Represents a file that does not exist.
<code>none</code>	0	Represents a file that has no type attribute. (Not supported.)

NAME	VALUE	DESCRIPTION
<code>regular</code>	1	Represents a conventional disk file.
<code>directory</code>	2	Represents a directory.
<code>symlink</code>	3	Represents a symbolic link. (Not supported.)
<code>block</code>	4	Represents a block-special file on UNIX-based systems. (Not supported.)
<code>character</code>	5	Represents a character-special file on UNIX-based systems. (Not supported.)
<code>fifo</code>	6	Represents a FIFO file on UNIX-based systems. (Not supported.)
<code>socket</code>	7	Represents a socket on UNIX based systems. (Not supported.)
<code>unknown</code>	8	Represents a file whose status cannot be determined.

perms

Flags for file permissions. The supported values are essentially “readonly” and all. For a readonly file, none of the *_write bits are set. Otherwise the `all` bit (0x0777) is set.

Syntax

```
enum class perms { // names for permissions
    none = 0,
    owner_read = 0400, // S_IRUSR
    owner_write = 0200, // S_IWUSR
    owner_exec = 0100, // S_IXUSR
    owner_all = 0700, // S_IRWXU
    group_read = 040, // S_IRGRP
    group_write = 020, // S_IWGRP
    group_exec = 010, // S_IXGRP
    group_all = 070, // S_IRWXG
    others_read = 04, // S_IROTH
    others_write = 02, // S_IWOTH
    others_exec = 01, // S_IXOTH
    others_all = 07, // S_IRWXO
    all = 0777,
    set_uid = 04000, // S_ISUID
    set_gid = 02000, // S_ISGID
    sticky_bit = 01000, // S_ISVTX
    mask = 07777,
    unknown = 0xFFFF,
    add_perms = 0x10000,
    remove_perms = 0x20000,
    resolve_symlinks = 0x40000
};
```

directory_entry Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Describes an object that is returned by `*x`, where *X* is a [directory_iterator](#) or a [recursive_directory_iterator](#).

Syntax

```
class directory_entry;
```

Remarks

The class stores an object of type [path](#). The stored `path` can be an instance of the [path Class](#) or of a type that is derived from `path`. It also stores two [file_type](#) values; one that represents what is known about the status of the stored file name, and another that represents what is known about the symbolic link status of the file name.

For more information and code examples, see [File System Navigation \(C++\)](#).

Constructors

CONSTRUCTOR	DESCRIPTION
directory_entry	The defaulted constructors behave as expected. The fourth constructor initializes <code>mypath</code> to <i>pval</i> , <code>mystat</code> to <i>stat_arg</i> , and <code>mysymstat</code> to <i>symstat_arg</i> .

Member functions

MEMBER FUNCTION	DESCRIPTION
assign	The member function assigns <i>pval</i> to <code>mypath</code> , <i>stat</i> to <code>mystat</code> , and <i>symstat</i> to <code>mysymstat</code> .
path	The member function returns <code>mypath</code> .
replace_filename	The member function replaces <code>mypath</code> with <code>mypath.parent_path() / pval</code> , <code>mystat</code> with <i>stat_arg</i> , and <code>mysymstat</code> with <i>symstat_arg</i> .
status	Both member functions return <code>mystat</code> possibly first altered.
symlink_status	Both member functions return <code>mysymstat</code> possibly first altered.

Operators

OPERATOR	DESCRIPTION
operator!=	Replaces the elements of the list with a copy of another list.

OPERATOR	DESCRIPTION
<code>operator=</code>	The defaulted member assignment operators behave as expected.
<code>operator==</code>	Returns <code>mypath == right.mypath</code> .
<code>operator<</code>	Returns <code>mypath < right.mypath</code> .
<code>operator<=</code>	Returns <code>!(right < *this)</code> .
<code>operator></code>	Returns <code>right < *this</code> .
<code>operator>=</code>	Returns <code>!(*this < right)</code> .
<code>operator const path_type&</code>	Returns <code>mypath</code> .

Requirements

Header: `<experimental/filesystem>`

Namespace: `std::experimental::filesystem`

assign

The member function assigns *pval* to `mypath` , *stat_arg* to `mystat` , and *symstat_arg* to `mysymstat` .

```
void assign(const std::experimental::filesystem::path& pval,
            file_status stat_arg = file_status(),
            file_status symstat_arg = file_status());
```

Parameters

pval

The stored file name path.

stat_arg

The status of the stored file name.

symstat_arg

The symbolic link status of the stored file name.

directory_entry

The defaulted constructors behave as expected. The fourth constructor initializes `mypath` to *pval*, `mystat` to *stat_arg*, and `mysymstat` to *symstat_arg*.

```
directory_entry() = default;
directory_entry(const directory_entry&) = default;
directory_entry(directory_entry&&) noexcept = default;
explicit directory_entry(const std::experimental::filesystem::path& pval,
                        file_status stat_arg = file_status(),
                        file_status symstat_arg = file_status());
```

Parameters

pval

The stored file name path.

stat_arg

The status of the stored file name.

symstat_arg

The symbolic link status of the stored file name.

operator!=

The member function returns `!(*this == right)`.

```
bool operator!=(const directory_entry& right) const noexcept;
```

Parameters

right

The [directory_entry](#) being compared to the `directory_entry`.

operator=

The defaulted member assignment operators behave as expected.

```
directory_entry& operator=(const directory_entry&) = default;  
directory_entry& operator=(directory_entry&&) noexcept = default;
```

Parameters

right

The [directory_entry](#) being copied into the `directory_entry`.

operator==

The member function returns `mypath == right.mypath`.

```
bool operator==(const directory_entry& right) const noexcept;
```

Parameters

right

The [directory_entry](#) being compared to the `directory_entry`.

operator<

The member function returns `mypath < right.mypath`.

```
bool operator<(const directory_entry& right) const noexcept;
```

Parameters

right

The [directory_entry](#) being compared to the `directory_entry`.

operator<=

The member function returns `!(right < *this)` .

```
bool operator<=(const directory_entry& right) const noexcept;
```

Parameters

right

The `directory_entry` being compared to the `directory_entry` .

operator>

The member function returns `right < *this` .

```
bool operator>(const directory_entry& right) const noexcept;
```

Parameters

right

The `directory_entry` being compared to the `directory_entry` .

operator>=

The member function returns `!(*this < right)` .

```
bool operator>=(const directory_entry& right) const noexcept;
```

Parameters

right

The `directory_entry` being compared to the `directory_entry` .

operator const path_type&

The member operator returns `mypath` .

```
operator const std::experimental::filesystem::path&() const;
```

path

The member function returns `mypath` .

```
const std::experimental::filesystem::path& path() const noexcept;
```

replace_filename

The member function replaces `mypath` with `mypath.parent_path() / pval`, `mystat` with `stat_arg`, and `mysymstat` with `symstat_arg`

```
void replace_filename(  
    const std::experimental::filesystem::path& pval,  
    file_status stat_arg = file_status(),  
    file_status symstat_arg = file_status());
```

Parameters

pval

The stored file name path.

stat_arg

The status of the stored file name.

symstat_arg

The symbolic link status of the stored file name.

status

Both member functions return `mystat` possibly first altered as follows:

1. If `status_known(mystat)` then do nothing.
2. Otherwise, if `!status_known(mysymstat) && !is_symlink(mysymstat)` then `mystat = mysymstat`.

```
file_status status() const;  
file_status status(error_code& ec) const noexcept;
```

Parameters

ec

The status error code.

symlink_status

Both member functions return `mysymstat` possibly first altered as follows: If `status_known(mysymstat)` then do nothing. Otherwise, `mysymstat = symlink_status(mypval)`.

```
file_status symlink_status() const;  
file_status symlink_status(error_code& ec) const noexcept;
```

Parameters

ec

The status error code.

[Header Files Reference](#)

[<filesystem>](#)

directory_iterator Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an input iterator that sequences through the filenames in a directory. For an iterator `x`, the expression `*x` evaluates to an object of class `directory_entry` that wraps the filename and anything known about its status.

The class stores an object of type `path`, called `mydir` here for the purposes of exposition, which represents the name of the directory to be sequenced, and an object of type `directory_entry` called `myentry` here, which represents the current filename in the directory sequence. A default constructed object of type `directory_iterator` has an empty `mydir` pathname and represents the end-of-sequence iterator.

For example, given the directory `abc` with entries `def` and `ghi`, the code:

```
for (directory_iterator next(path("abc")), end; next != end; ++next) visit(next->path());
```

will call `visit` with the arguments `path("abc/def")` and `path("abc/ghi")`.

For more information and code examples, see [File System Navigation \(C++\)](#).

Syntax

```
class directory_iterator;
```

Constructors

CONSTRUCTOR	DESCRIPTION
<code>directory_iterator</code>	Constructs an input iterator that sequences through the filenames in a directory.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>increment</code>	Attempts to advance to the next filename in the directory.

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Returns <code>!(*this == right)</code> .
<code>operator=</code>	The defaulted member assignment operators behave as expected.
<code>operator==</code>	Returns true only if both <code>*this</code> and <code>right</code> are end-of-sequence iterators or both are not end-of-sequence-iterators.
<code>operator*</code>	Returns <code>myentry</code> .
<code>operator-></code>	Returns <code>&*this</code> .

OPERATOR	DESCRIPTION
<code>operator++</code>	Calls <code>increment()</code> , then returns <code>*this</code> , or makes a copy of the object, calls <code>increment()</code> , then returns the copy.

Requirements

Header: `<experimental/filesystem>`

Namespace: `std::experimental::filesystem`

`directory_iterator::directory_iterator`

The first constructor produces an end-of-sequence iterator. The second and third constructors store *pval* in `mydir`, then attempt to open and read `mydir` as a directory. If successful, they store the first filename in the directory in `myentry`; otherwise they produce an end-of-sequence iterator.

The defaulted constructors behave as expected.

```
directory_iterator() noexcept;
explicit directory_iterator(const path& pval);

directory_iterator(const path& pval, error_code& ec) noexcept;
directory_iterator(const directory_iterator&) = default;
directory_iterator(directory_iterator&&) noexcept = default;
```

Parameters

pval

The stored file name path.

ec

The status error code.

directory_iterator

The stored object.

`directory_iterator::increment`

The function attempts to advance to the next filename in the directory. If successful, it stores that filename in `myentry`; otherwise it produces an end-of-sequence iterator.

```
directory_iterator& increment(error_code& ec) noexcept;
```

`directory_iterator::operator!=`

The member operator returns `!(*this == right)`.

```
bool operator!=(const directory_iterator& right) const;
```

Parameters

right

The `directory_iterator` being compared to the `directory_iterator`.

`directory_iterator::operator=`

The defaulted member assignment operators behave as expected.

```
directory_iterator& operator=(const directory_iterator&) = default;  
directory_iterator& operator=(directory_iterator&&) noexcept = default;
```

Parameters

right

The `directory_iterator` being copied into the `directory_iterator`.

`directory_iterator::operator==`

The member operator returns **true** only if both `*this` and *right* are end-of-sequence iterators or both are not end-of-sequence-iterators.

```
bool operator==(const directory_iterator& right) const;
```

Parameters

right

The `directory_iterator` being compared to the `directory_iterator`.

`directory_iterator::operator*`

The member operator returns `myentry`.

```
const directory_entry& operator*() const;
```

`directory_iterator::operator->`

The member function returns `&*this`.

```
const directory_entry * operator->() const;
```

`directory_iterator::operator++`

The first member function calls `increment()`, then returns `*this`. The second member function makes a copy of the object, calls `increment()`, then returns the copy.

```
directory_iterator& operator++();  
directory_iterator& operator++(int);
```

Parameters

int

The number of increments.

[Header Files Reference](#)

[<filesystem>](#)

[File System Navigation \(C++\)](#)

file_status Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Wraps a [file_type](#) and file [perms](#).

Syntax

```
class file_status;
```

Constructors

CONSTRUCTOR	DESCRIPTION
file_status	Constructs a wrapper for file_type and file perms .

Member functions

MEMBER FUNCTION	DESCRIPTION
type	Gets or sets the <code>file_type</code> .
permissions	Gets or sets the file permissions.

Operators

OPERATOR	DESCRIPTION
operator=	The defaulted member assignment operators behave as expected.

Requirements

Header: <filesystem>

Namespace: std::experimental::filesystem, std::experimental::filesystem

file_status::file_status

Constructs a wrapper for [file_type](#) and file [perms](#).

```
explicit file_status(
    file_type ftype = file_type::none,
    perms mask = perms::unknown) noexcept;

file_status(const file_status&) noexcept = default;

file_status(file_status&&) noexcept = default;

~file_status() noexcept = default;
```

Parameters

ftype

Specified `file_type`, defaults to `file_type::none`.

mask

Specified file `perms`, defaults to `perms::unknown`.

file_status

The stored object.

file_status::operator=

The defaulted member assignment operators behave as expected.

```
file_status& operator=(const file_status&) noexcept = default;
file_status& operator=(file_status&&) noexcept = default;
```

Parameters

file_status

The [file_status](#) being copied into the `file_status`.

type

Gets or sets the `file_type`.

```
file_type type() const noexcept
void type(file_type ftype) noexcept
```

Parameters

ftype

Specified `file_type`.

permissions

Gets or sets the file permissions.

Use the setter to make a file `readonly` or remove the `readonly` attribute.

```
perms permissions() const noexcept
void permissions(perms mask) noexcept
```

Parameters

mask

Specified `perms`.

[path Class](#)

[<filesystem>](#)

filesystem_error Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

A base class for all exceptions that are thrown to report a low-level system overflow.

Syntax

```
class filesystem_error : public system_error;
```

Remarks

The class serves as the base class for all exceptions thrown to report an error in <filesystem> functions. It stores an object of type `string`, called `mymesg` here for the purposes of exposition. It also stores two objects of type `path`, called `mypva11` and `mypva12`.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>filesystem_error</code>	Constructs a <code>filesystem_error</code> message.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>path1</code>	Returns <code>mypva11</code>
<code>path2</code>	Returns <code>mypva12</code>
<code>what</code>	Returns a pointer to an <code>NTBS</code> .

Requirements

Header: <filesystem>

Namespace: `std::experimental::filesystem`

filesystem_error::filesystem_error

The first constructor constructs its message from *what_arg* and *ec*. The second constructor also constructs its message from *pva11*, which it stores in `mypva11`. The third constructor also constructs its message from *pva11*, which it stores in `mypva11`, and from *pva12*, which it stores in `mypva12`.

```

filesystem_error(const string& what_arg,
                error_code ec);

filesystem_error(const string& what_arg,
                const path& pval1,
                error_code ec);

filesystem_error(const string& what_arg,
                const path& pval1,
                const path& pval2,
                error_code ec);

```

Parameters

what_arg

Specified message.

ec

Specified error code.

mypval1

Further specified message parameter.

mypval2

Further specified message parameter.

filesystem_error::path1

The member function returns `mypval1`

```
const path& path1() const noexcept;
```

filesystem_error::path2

The member function returns `mypval2`

```
const path& path2() const noexcept;
```

filesystem_error::what

The member function returns a pointer to an `NTBS`, preferably composed from `runtime_error::what()`, `system_error::what()`, `mymesg`, `mypval1.native_string()`, and `mypval2.native_string()`.

```
const char *what() const noexcept;
```

[Header Files Reference](#)

[system_error Class](#)

[<filesystem>](#)

[<exception>](#)

path Class

10/31/2018 • 10 minutes to read • [Edit Online](#)

The **path** class stores an object of type `string_type`, called `myname` here for the purposes of exposition, suitable for use as a pathname. `string_type` is a synonym for `basic_string<value_type>`, where `value_type` is a synonym for **wchar_t** on Windows or **char** on POSIX.

For more information, and code examples, see [File System Navigation \(C++\)](#).

Syntax

```
class path;
```

Constructors

CONSTRUCTOR	DESCRIPTION
path	Constructs a <code>path</code> .

Typedefs

TYPE NAME	DESCRIPTION
const_iterator	A synonym for <code>iterator</code> .
iterator	A bidirectional constant iterator that designates the <code>path</code> components of <code>myname</code> .
string_type	The type is a synonym for <code>basic_string<value_type></code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
append	Appends the specified sequence to <code>mypath</code> , converted and inserting a preferred_separator as needed.
assign	Replaces <code>mypath</code> with the specified sequence, converted as needed.
begin	Returns a <code>path::iterator</code> designating the first path element in the pathname, if present.
c_str	Returns a pointer to the first character in <code>mypath</code> .
clear	Executes <code>mypath.clear()</code> .
compare	Returns comparison values.

MEMBER FUNCTION	DESCRIPTION
<code>concat</code>	Appends the specified sequence to <code>mypath</code> , converted (but not inserting a separator) as needed.
<code>empty</code>	Returns <code>mypath.empty()</code> .
<code>end</code>	Returns an end-of-sequence iterator of type <code>iterator</code> .
<code>extension</code>	Returns the suffix of <code>filename()</code> .
<code>filename</code>	Returns the root directory component of myname, specifically <code>empty() path() : *--end()</code> . The component may be empty.
<code>generic_string</code>	Returns <code>this->string<Elem, Traits, Alloc>(al)</code> with (under Windows) any backslash converted to a forward slash.
<code>generic_u16string</code>	Returns <code>u16string()</code> with (under Windows) any backslash converted to a forward slash.
<code>generic_u32string</code>	Returns <code>u32string()</code> with (under Windows) any backslash converted to a forward slash.
<code>generic_u8string</code>	Returns <code>u8string()</code> with (under Windows) any backslash converted to a forward slash.
<code>generic_wstring</code>	Returns <code>wstring()</code> with (under Windows) any backslash converted to a forward slash.
<code>has_extension</code>	Returns <code>!extension().empty()</code> .
<code>has_filename</code>	Returns <code>!filename().empty()</code> .
<code>has_parent_path</code>	Returns <code>!parent_path().empty()</code> .
<code>has_relative_path</code>	Returns <code>!relative_path().empty()</code> .
<code>has_root_directory</code>	Returns <code>!root_directory().empty()</code> .
<code>has_root_name</code>	Returns <code>!root_name().empty()</code> .
<code>has_root_path</code>	Returns <code>!root_path().empty()</code> .
<code>has_stem</code>	Returns <code>!stem().empty()</code> .
<code>is_absolute</code>	For Windows, the function returns <code>has_root_name() && has_root_directory()</code> . For Posix, the function returns <code>has_root_directory()</code> .
<code>is_relative</code>	Returns <code>!is_absolute()</code> .

MEMBER FUNCTION	DESCRIPTION
<code>make_preferred</code>	Converts each separator to a preferred_separator as needed.
<code>native</code>	Returns <code>myname</code> .
<code>parent_path</code>	Returns the parent path component of <code>myname</code> .
<code>preferred_separator</code>	The constant object gives the preferred character for separating path components, depending on the host operating system.
<code>relative_path</code>	Returns the relative path component of <code>myname</code> .
<code>remove_filename</code>	Removes the filename.
<code>replace_extension</code>	Replaces the extension of <code>myname</code> .
<code>replace_filename</code>	Replaces the filename.
<code>root_directory</code>	Returns the root directory component of <code>myname</code> .
<code>root_name</code>	Returns the root name component of <code>myname</code> .
<code>root_path</code>	Returns the root path component of <code>myname</code> .
<code>stem</code>	Returns the <code>stem</code> component of <code>myname</code> .
<code>string</code>	Converts the sequence stored in <code>mypath</code> .
<code>swap</code>	Executes <code>swap(mypath, right.mypath)</code> .
<code>u16string</code>	Converts the sequence stored in <code>mypath</code> to UTF-16 and returns it stored in an object of type <code>u16string</code> .
<code>u32string</code>	Converts the sequence stored in <code>mypath</code> to UTF-32 and returns it stored in an object of type <code>u32string</code> .
<code>u8string</code>	Converts the sequence stored in <code>mypath</code> to UTF-8 and returns it stored in an object of type <code>u8string</code> .
<code>value_type</code>	The type describes the path elements favored by the host operating system.
<code>wstring</code>	Converts the sequence stored in <code>mypath</code> to the encoding favored by the host system for a <code>wchar_t</code> sequence and returns it stored in an object of type <code>wstring</code> .

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Replaces the elements of the path with a copy of another path.
<code>operator+=</code>	Various <code>concat</code> expressions.
<code>operator/=</code>	Various <code>append</code> expressions.
<code>operator string_type</code>	Returns <code>myname</code> .

Requirements

Header: `<filesystem>`

Namespace: `std::experimental::filesystem`

`path::append`

Appends the specified sequence to `mypath` , converted and inserting a `preferred_separator` as needed.

```
template <class Source>
path& append(const Source& source);

template <class InIt>
path& append(InIt first, InIt last);
```

Parameters

source

Specified sequence.

first

Start of specified sequence.

last

End of specified sequence.

`path::assign`

Replaces `mypath` with the specified sequence, converted as needed.

```
template <class Source>
path& assign(const Source& source);

template <class InIt>
path& assign(InIt first, InIt last);
```

Parameters

source

Specified sequence.

first

Start of specified sequence.

last

End of specified sequence.

path::begin

Returns a `path::iterator` designating the first path element in the pathname, if present.

```
iterator begin() const;
```

path::c_str

Returns a pointer to the first character in `mypath`.

```
const value_type& *c_str() const noexcept;
```

path::clear

Executes `mypath.clear()`.

```
void clear() noexcept;
```

path::compare

The first function returns `mypath.compare(pval.native())`. The second function returns `mypath.compare(str)`. The third function returns `mypath.compare(ptr)`.

```
int compare(const path& pval) const noexcept;  
int compare(const string_type& str) const;  
int compare(const value_type *ptr) const;
```

Parameters

pval

Path to compare.

str

String to compare.

ptr

Pointer to compare.

path::concat

Appends the specified sequence to `mypath`, converted (but not inserting a separator) as needed.

```
template <class Source>  
path& concat(const Source& source);  
  
template <class InIt>  
path& concat(InIt first, InIt last);
```

Parameters

source

Specified sequence.

first

Start of specified sequence.

last

End of specified sequence.

path::const_iterator

A synonym for `iterator`.

```
typedef iterator const_iterator;
```

path::empty

Returns `mypath.empty()`.

```
bool empty() const noexcept;
```

path::end

Returns an end-of-sequence iterator of type `iterator`.

```
iterator end() const;
```

path::extension

Returns the suffix of `filename()`.

```
path extension() const;
```

Remarks

Returns the suffix of `filename() x` such that:

If `x == path(".")` || `x == path("..")` or if `x` contains no dot, the suffix is empty.

Otherwise, the suffix begins with (and includes) the rightmost dot.

path::filename

Returns the root directory component of myname, specifically `empty() path() : *--end()`. The component may be empty.

```
path filename() const;
```

path::generic_string

Returns `this->string<Elem, Traits, Alloc>(al)` with (under Windows) any backslash converted to a forward slash.

```
template <class Elem,
        class Traits = char_traits<Elem>,
        class Alloc = allocator<Elem>>
basic_string<Elem, Traits, Alloc>
    generic_string(const Alloc& al = Alloc()) const;

string generic_string() const;
```

path::generic_u16string

Returns `u16string()` with (under Windows) any backslash converted to a forward slash.

```
u16string generic_u16string() const;
```

path::generic_u32string

Returns `u32string()` with (under Windows) any backslash converted to a forward slash.

```
u32string generic_u32string() const;
```

path::generic_u8string

Returns `u8string()` with (under Windows) any backslash converted to a forward slash.

```
string generic_u8string() const;
```

path::generic_wstring

Returns `wstring()` with (under Windows) any backslash converted to a forward slash.

```
wstring generic_wstring() const;
```

path::has_extension

Returns `!extension().empty()` .

```
bool has_extension() const;
```

path::has_filename

Returns `!filename().empty()` .

```
bool has_filename() const;
```

path::has_parent_path

Returns `!parent_path().empty()` .

```
bool has_parent_path() const;
```

path::has_relative_path

Returns `!relative_path().empty()` .

```
bool has_relative_path() const;
```

path::has_root_directory

Returns `!root_directory().empty()` .

```
bool has_root_directory() const;
```

path::has_root_name

Returns `!root_name().empty()` .

```
bool has_root_name() const;
```

path::has_root_path

Returns `!root_path().empty()` .

```
bool has_root_path() const;
```

path::has_stem

Returns `!stem().empty()` .

```
bool has_stem() const;
```

path::is_absolute

For Windows, the function returns `has_root_name() && has_root_directory()` . For Posix, the function returns `has_root_directory()` .

```
bool is_absolute() const;
```

path::is_relative

Returns `!is_absolute()` .

```
bool is_relative() const;
```

path::iterator

A bidirectional constant iterator that designates the path components of `myname`.

```
class iterator
{
    // bidirectional iterator for path
    typedef bidirectional_iterator_tag iterator_category;
    typedef path_type value_type;
    typedef ptrdiff_t difference_type;
    typedef const value_type *pointer;
    typedef const value_type& reference;
    // ...
};
```

Remarks

The class describes a bidirectional constant iterator that designates the `path` components of `myname` in the sequence:

1. the root name, if present
2. the root directory, if present
3. the remaining directory elements of the parent `path`, if present, ending with the filename, if present

For `pval` an object of type `path`:

1. `path::iterator X = pval.begin()` designates the first `path` element in the pathname, if present.
2. `X == pval.end()` is true when `X` points just past the end of the sequence of components.
3. `*X` returns a string that matches the current component
4. `++X` designates the next component in the sequence, if present.
5. `--X` designates the preceding component in the sequence, if present.
6. Altering `myname` invalidates all iterators designating elements in `myname`.

path::make_preferred

Converts each separator to a `preferred_separator` as needed.

```
path& make_preferred();
```

path::native

Returns `myname`.

```
const string_type& native() const noexcept;
```

path::operator=

Replaces the elements of the path with a copy of another path.

```

path& operator=(const path& right);
path& operator=(path&& right) noexcept;

template <class Source>
path& operator=(const Source& source);

```

Parameters

right

The [path](#) being copied into the `path`.

source

The source path.

Remarks

The first member operator copies `right.myname` to `myname`. The second member operator moves `right.myname` to `myname`. The third member operator behaves the same as `*this = path(source)`.

path::operator+=

Various `concat` expressions.

```

path& operator+=(const path& right);
path& operator+=(const string_type& str);
path& operator+=(const value_type *ptr);
path& operator+=(value_type elem);

template <class Source>
path& operator+=(const Source& source);

template <class Elem>
path& operator+=(Elem elem);

```

Parameters

right

The added path.

str

The added string.

ptr

The added pointer.

elem

The added `value_type` or `Elem`.

source

The added source.

Remarks

The member functions behave the same as the following corresponding expressions:

1. `concat(right);`
2. `concat(path(str));`
3. `concat(ptr);`

4. `concat(string_type(1, elem));`
5. `concat(source);`
6. `concat(path(basic_string<Elem>(1, elem)));`

path::operator/=

Various `append` expressions.

```
path& operator/=(const path& right);

template <class Source>
path& operator/=(const Source& source);
```

Parameters

right

The added path.

source

The added source.

Remarks

The member functions behave the same as the following corresponding expressions:

1. `append(right);`
2. `append(source);`

path::operator string_type

Returns `myname` .

```
operator string_type() const;
```

path::parent_path

Returns the parent path component of `myname` .

```
path parent_path() const;
```

Remarks

Returns the parent path component of `myname` , specifically the prefix of `myname` after removing `filename().native()` and any immediately preceding directory separators. (Equally, if `begin() != end()` , it is the combining of all elements in the range `[begin(), --end())` by successively applying `operator/=` .) The component may be empty.

path::path

Constructs a `path` in various ways.

```

path();

path(const path& right);
path(path&& right) noexcept;

template <class Source>
path(const Source& source);

template <class Source>
path(const Source& source, const locale& loc);

template <class InIt>
path(InIt first, InIt last);

template <class InIt>
path(InIt first, InIt last, const locale& loc);

```

Parameters

right

The path of which the constructed path is to be a copy.

source

The source of which the constructed path is to be a copy.

loc

The specified locale.

first

The position of the first element to be copied.

last

The position of the last element to be copied.

Remarks

The constructors all construct `myname` in various ways:

For `path()` it is `myname()`.

For `path(const path& right)` it is `myname(right.myname)`.

For `path(path&& right)` it is `myname(right.myname)`.

For `template<class Source> path(const Source& source)` it is `myname(source)`.

For `template<class Source> path(const Source& source, const locale& loc)` it is `myname(source)`, obtaining any needed codecvt facets from `loc`.

For `template<class InIt> path(InIt first, InIt last)` it is `myname(first, last)`.

For `template<class InIt> path(InIt first, InIt last, const locale& loc)` it is `myname(first, last)`, obtaining any needed codecvt facets from `loc`.

path::preferred_separator

The constant object gives the preferred character for separating path components, depending on the host operating system.

```
#if _WIN32_C_LIB
static constexpr value_type preferred_separator == L'\\';
#else // assume Posix
static constexpr value_type preferred_separator == '/';
#endif // filesystem model now defined
```

Remarks

Note that it is equally permissible in most contexts under Windows to use L'/' in its place.

path::relative_path

Returns the relative path component of `myname`.

```
path relative_path() const;
```

Remarks

Returns the relative path component of `myname`, specifically the suffix of `myname` after removing `root_path().native()` and any immediately subsequent redundant directory separators. The component may be empty.

path::remove_filename

Removes the filename.

```
path& remove_filename();
```

path::replace_extension

Replaces the extension of `myname`.

```
path& replace_extension(const path& newext = path());
```

Parameters

newext

The new extension.

Remarks

First removes the suffix `extension().native()` from `myname`. Then if `!newext.empty() && newext[0] != dot` (where `dot` is `*path(".").c_str()`), then `dot` is appended to `myname`. Then *newext* is appended to `myname`.

path::replace_filename

Replaces the filename.

```
path& replace_filename(const path& pval);
```

Parameters

pval

The path of the filename.

Remarks

The member function executes:

```
remove_filename();

*this /= pval;
return (*this);
```

path::root_directory

Returns the root directory component of `myname` .

```
path root_directory() const;
```

Remarks

The component may be empty.

path::root_name

Returns the root name component of `myname` .

```
path root_name() const;
```

Remarks

The component may be empty.

path::root_path

Returns the root path component of `myname` .

```
path root_path() const;
```

Remarks

Returns the root path component of `myname` , specifically `root_name()` / `root_directory` . The component may be empty.

path::stem

Returns the `stem` component of `myname` .

```
path stem() const;
```

Remarks

Returns the `stem` component of `myname` , specifically `filename().native()` with any trailing `extension().native()` removed. The component may be empty.

path::string

Converts the sequence stored in `mypath` .

```
template \<class Elem, class Traits = char_traits\<Elem>, class Alloc = allocator\<Elem>>
basic_string\<Elem, Traits, Alloc> string(const Alloc& al = Alloc()) const;
string string() const;
```

Remarks

The first (template) member function converts the sequence stored in `mypath` the same way as:

1. `string()` for `string<char, Traits, Alloc>()`
2. `wstring()` for `string<wchar_t, Traits, Alloc>()`
3. `u16string()` for `string<char16_t, Traits, Alloc>()`
4. `u32string()` for `string<char32_t, Traits, Alloc>()`

The second member function converts the sequence stored in `mypath` to the encoding favored by the host system for a **char** sequence and returns it stored in an object of type `string`.

path::string_type

The type is a synonym for `basic_string<value_type>`.

```
typedef basic_string<value_type> string_type;
```

path::swap

Executes `swap(mypath, right.mypath)`.

```
void swap(path& right) noexcept;
```

path::u16string

Converts the sequence stored in `mypath` to UTF-16 and returns it stored in an object of type `u16string`.

```
u16string u16string() const;
```

path::u32string

Converts the sequence stored in `mypath` to UTF-32 and returns it stored in an object of type `u32string`.

```
u32string u32string() const;
```

path::u8string

Converts the sequence stored in `mypath` to UTF-8 and returns it stored in an object of type `u8string`.

```
string u8string() const;
```

path::value_type

The type describes the `path` elements favored by the host operating system.

```
#if _WIN32_C_LIB
typedef wchar_t value_type;
#else // assume Posix
typedef char value_type;
#endif // filesystem model now defined
```

path::wstring

Converts the sequence stored in `mypath` to the encoding favored by the host system for a **wchar_t** sequence and returns it stored in an object of type `wstring`.

```
wstring wstring() const;
```

[Header Files Reference](#)

recursive_directory_iterator Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Describes an input iterator that sequences through the filenames in a directory, possibly descending into subdirectories recursively. For an iterator `x`, the expression `*x` evaluates to an object of class `directory_entry` that wraps the filename and anything known about its status.

For more information and code examples, see [File System Navigation \(C++\)](#).

Syntax

```
class recursive_directory_iterator;
```

Remarks

The template class stores:

1. an object of type `stack<pair<directory_iterator, path>>`, called `mystack` here for the purposes of exposition, which represents the nest of directories to be sequenced
2. an object of type `directory_entry` called `myentry` here, which represents the current filename in the directory sequence
3. an object of type **bool**, called `no_push` here, which records whether recursive descent into subdirectories is disabled
4. an object of type `directory_options`, called `myoptions` here, which records the options established at construction

A default constructed object of type `recursive_directory_iterator` has an end-of-sequence iterator at `mystack.top().first` and represents the end-of-sequence iterator. For example, given the directory `abc` with entries `def` (a directory), `def/ghi`, and `jkl`, the code:

```
for (recursive_directory_iterator next(path("abc")), end; next != end; ++next)
    visit(next->path());
```

will call `visit` with the arguments `path("abc/def/ghi")` and `path("abc/jkl")`. You can qualify sequencing through a directory subtree in two ways:

1. A directory symlink will be scanned only if you construct a `recursive_directory_iterator` with a `directory_options` argument whose value is `directory_options::follow_directory_symlink`.
2. If you call `disable_recursion_pending` then a subsequent directory encountered during an increment will not be recursively scanned.

Constructors

CONSTRUCTOR	DESCRIPTION
recursive_directory_iterator	Constructs a <code>recursive_directory_iterator</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
depth	Returns <code>mystack.size() - 1</code> , so <code>pval</code> is at depth zero.
disable_recursion_pending	Stores true in <code>no_push</code> .
increment	Advances to the next filename in sequence.
options	Returns <code>myoptions</code> .
pop	Returns the next object.
recursion_pending	Returns <code>!no_push</code> .

Operators

OPERATOR	DESCRIPTION
operator!=	Returns <code>!(*this == right)</code> .
operator=	The defaulted member assignment operators behave as expected.
operator==	Returns true only if both <code>*this</code> and <i>right</i> are end-of-sequence iterators or both are not end-of-sequence-iterators.
operator*	Returns <code>myentry</code> .
operator->	Returns <code>&*this</code> .
operator++	Increments the <code>recursive_directory_iterator</code> .

Requirements

Header: `<filesystem>`

Namespace: `std::tr2::sys`

`recursive_directory_iterator::depth`

Returns `mystack.size() - 1`, so `pval` is at depth zero.

```
int depth() const;
```

`recursive_directory_iterator::disable_recursion_pending`

Stores **true** in `no_push`.

```
void disable_recursion_pending();
```

recursive_directory_iterator::increment

Advances to the next filename in sequence.

```
recursive_directory_iterator& increment(error_code& ec) noexcept;
```

Parameters

ec

Specified error code.

Remarks

The function attempts to advance to the next filename in the nested sequence. If successful, it stores that filename in `myentry`; otherwise it produces an end-of-sequence iterator.

recursive_directory_iterator::operator!=

Returns `!(*this == right)`.

```
bool operator!=(const recursive_directory_iterator& right) const;
```

Parameters

right

The [recursive_directory_iterator](#) for comparison.

recursive_directory_iterator::operator=

The defaulted member assignment operators behave as expected.

```
recursive_directory_iterator& operator=(const recursive_directory_iterator&) = default;  
recursive_directory_iterator& operator=(recursive_directory_iterator&&) noexcept = default;
```

Parameters

recursive_directory_iterator

The [recursive_directory_iterator](#) being copied into the `recursive_directory_iterator`.

recursive_directory_iterator::operator==

Returns **true** only if both `*this` and *right* are end-of-sequence iterators or both are not end-of-sequence iterators.

```
bool operator==(const recursive_directory_iterator& right) const;
```

Parameters

right

The [recursive_directory_iterator](#) for comparison.

recursive_directory_iterator::operator*

Returns `myentry`.

```
const directory_entry& operator*() const;
```

recursive_directory_iterator::operator->

Returns `&*this` .

```
const directory_entry * operator->() const;
```

recursive_directory_iterator::operator++

Increments the `recursive_directory_iterator` .

```
recursive_directory_iterator& operator++();  
recursive_directory_iterator& operator++(int);
```

Parameters

int

The specified increment.

Remarks

The first member function calls `increment()` , then returns `*this` . The second member function makes a copy of the object, calls `increment()` , then returns the copy.

recursive_directory_iterator::options

Returns `myoptions` .

```
directory_options options() const;
```

recursive_directory_iterator::pop

Returns the next object.

```
void pop();
```

Remarks

If `depth() == 0` the object becomes an end-of-sequence iterator. Otherwise, the member function terminates scanning of the current (deepest) directory and resumes at the next lower depth.

recursive_directory_iterator::recursion_pending

Returns `!no_push` .

```
bool recursion_pending() const;
```

recursive_directory_iterator::recursive_directory_iterator

Constructs a `recursive_directory_iterator`.

```
recursive_directory_iterator() noexcept;
explicit recursive_directory_iterator(const path& pval);

recursive_directory_iterator(const path& pval,
    error_code& ec) noexcept;
recursive_directory_iterator(const path& pval,
    directory_options opts);

recursive_directory_iterator(const path& pval,
    directory_options opts,
    error_code& ec) noexcept;
recursive_directory_iterator(const recursive_directory_iterator&) = default;
recursive_directory_iterator(recursive_directory_iterator&&) noexcept = default;
```

Parameters

pval

The specified path.

error_code

The specified error code.

opts

The specified directory options.

recursive_directory_iterator

The `recursive_directory_iterator` of which the constructed `recursive_directory_iterator` is to be a copy.

Remarks

The first constructor produces an end-of-sequence iterator. The second and third constructors store **false** in `no_push` and `directory_options::none` in `myoptions`, then attempt to open and read *pval* as a directory. If successful, they initialize `mystack` and `myentry` to designate the first non-directory filename in the nested sequence; otherwise they produce an end-of-sequence iterator.

The fourth and fifth constructors behave the same as the second and third, except that they first store *opts* in `myoptions`. The defaulted constructors behave as expected.

[<filesystem>](#)

[File System Navigation \(C++\)](#)

space_info Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

Holds information about a volume.

Syntax

```
struct space_info
{
    uintmax_t capacity;
    uintmax_t free;
    uintmax_t available;
};
```

Members

Public Data Members

NAME	DESCRIPTION
<code>unsigned long long capacity</code>	Represents the total number of bytes that the volume can represent.
<code>unsigned long long free</code>	Represents the number of bytes that are not used to represent data on the volume.
<code>unsigned long long available</code>	Represents the number of bytes that are available to represent data on the volume.

Requirements

Header: <filesystem>

Namespace: std::experimental::filesystem

<forward_list>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template class `forward_list` and several supporting templates.

Syntax

```
#include <forward_list>
```

Operators

OPERATOR	DESCRIPTION
<code>operator==</code>	Tests if the forward list object on the left side of the operator is equal to the forward list object on the right side.
<code>operator!=</code>	Tests if the forward list object on the left side of the operator is not equal to the forward list object on the right side.
<code>operator<</code>	Tests if the forward list object on the left side of the operator is less than the forward list object on the right side.
<code>operator<=</code>	Tests if the forward list object on the left side of the operator is less than or equal to the forward list object on the right side.
<code>operator></code>	Tests if the forward list object on the left side of the operator is greater than the forward list object on the right side.
<code>operator>=</code>	Tests if the forward list object on the left side of the operator is greater than or equal to the forward list object on the right side.

Functions

FUNCTION	DESCRIPTION
<code>swap</code>	Exchanges the elements of two forward lists.

Classes

CLASS	DESCRIPTION
<code>forward_list</code>	Describes an object that controls a varying-length sequence of elements. The sequence is stored as a singly-linked list of elements, each containing a member of type <code>Type</code> .

See also

[Header Files Reference](#)

<forward_list> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

swap

swap

Exchanges the elements of two forward lists.

```
void swap(  
    forward_list <Type, Allocator>& left,  
    forward_list <Type, Allocator>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	An object of type <code>forward_list</code> .
<i>right</i>	An object of type <code>forward_list</code> .

Remarks

This template function executes `left.swap(right)` .

See also

[<forward_list>](#)

<forward_list> operators

10/31/2018 • 2 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<=</code>	<code>operator==</code>

operator==

Tests if the forward list object on the left side of the operator is equal to the forward list object on the right side.

```
bool operator==(
    const forward_list<Type, Allocator>& left,
    const forward_list<Type, Allocator>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	An object of type <code>forward_list</code> .
<i>right</i>	An object of type <code>forward_list</code> .

Remarks

This template function overloads `operator==` to compare two objects of template class `forward_list`. The function returns

```
distance(left.begin(), end()) == distance(right.begin(),right.end()) && equal(left.begin(),left.end(),right.begin())
```

operator!=

Tests if the forward list object on the left side of the operator is not equal to the forward list object on the right side.

```
bool operator!=(
    const forward_list<Type, Allocator>& left,
    const forward_list<Type, Allocator>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	An object of type <code>forward_list</code> .
<i>right</i>	An object of type <code>forward_list</code> .

Return Value

true if the lists are not equal; **false** if the lists are equal.

Remarks

This template function returns `!(left == right)`.

operator<

Tests if the forward list object on the left side of the operator is less than the forward list object on the right side.

```
bool operator<(
    const forward_list<Type, Allocator>& left,
    const forward_list<Type, Allocator>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	An object of type <code>forward_list</code> .
<i>right</i>	An object of type <code>forward_list</code> .

Return Value

true if the list on the left side of the operator is less than but not equal to the list on the right side of the operator; otherwise **false**.

Remarks

This template function overloads `operator<` to compare two objects of template class `forward_list`. The function returns `lexicographical_compare(lhs.begin(), lhs.end(), rhs.begin(), rhs.end())`.

operator<=

Tests if the forward list object on the left side of the operator is less than or equal to the forward list object on the right side.

```
bool operator<=(
    const forward_list<Type, Allocator>& left,
    const forward_list<Type, Allocator>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	An object of type <code>forward_list</code> .
<i>right</i>	An object of type <code>forward_list</code> .

Return Value

true if the list on the left side of the operator is less than or equal to the list on the right side of the operator; otherwise **false**.

Remarks

This template function returns `!(right < left)`.

operator>

Tests if the forward list object on the left side of the operator is greater than the forward list object on the right side.

```
bool operator>(  
    const forward_list<Type, Allocator>& left,  
    const forward_list<Type, Allocator>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	An object of type <code>forward_list</code> .
<i>right</i>	An object of type <code>forward_list</code> .

Return Value

true if the list on the left side of the operator is greater than the list on the right side of the operator; otherwise **false**.

Remarks

This template function returns `right < left` .

operator>=

Tests if the forward list object on the left side of the operator is greater than or equal to the forward list object on the right side.

```
bool operator>=(  
    const forward_list<Type, Allocator>& left,  
    const forward_list<Type, Allocator>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	An object of type <code>forward_list</code> .
<i>right</i>	An object of type <code>forward_list</code> .

Return Value

true if the forward list on the left side of the operator is greater than or equal to the forward list on the right side of the operator; otherwise **false**.

Remarks

The template function returns `!(left < right)` .

See also

[<forward_list>](#)

forward_list Class

4/29/2019 • 21 minutes to read • [Edit Online](#)

Describes an object that controls a varying-length sequence of elements. The sequence is stored as a singly-linked list of nodes, each containing a member of type `Type`.

Syntax

```
template <class Type,  
         class Allocator = allocator<Type>>  
class forward_list
```

Parameters

PARAMETER	DESCRIPTION
<i>Type</i>	The element data type to be stored in the <code>forward_list</code> .
<i>Allocator</i>	The stored allocator object that encapsulates details about the <code>forward_list</code> allocation and deallocation of memory. This parameter is optional. The default value is <code>allocator<Type></code> .

Remarks

A `forward_list` object allocates and frees storage for the sequence it controls through a stored object of class *Allocator* that is based on [allocator Class](#) (commonly known as `std::allocator`). For more information, see [Allocators](#). An allocator object must have the same external interface as an object of template class `allocator`.

NOTE

The stored allocator object is not copied when the container object is assigned.

Iterators, pointers and references might become invalid when elements of their controlled sequence are erased through `forward_list`. Insertions and splices performed on the controlled sequence through `forward_list` do not invalidate iterators.

Additions to the controlled sequence might occur by calls to `forward_list::insert_after`, which is the only member function that calls the constructor `Type(const T&)`. `forward_list` might also call move constructors. If such an expression throws an exception, the container object inserts no new elements and rethrows the exception. Thus, an object of template class `forward_list` is left in a known state when such exceptions occur.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>forward_list</code>	Constructs an object of type <code>forward_list</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>allocator_type</code>	A type that represents the allocator class for a forward list object.
<code>const_iterator</code>	A type that provides a constant iterator for the forward list.
<code>const_pointer</code>	A type that provides a pointer to a const element in a forward list.
<code>const_reference</code>	A type that provides a constant reference to an element in the forward list.
<code>difference_type</code>	A signed integer type that can be used to represent the number of elements of a forward list in a range between elements pointed to by iterators.
<code>iterator</code>	A type that provides an iterator for the forward list.
<code>pointer</code>	A type that provides a pointer to an element in the forward list.
<code>reference</code>	A type that provides a reference to an element in the forward list.
<code>size_type</code>	A type that represents the unsigned distance between two elements.
<code>value_type</code>	A type that represents the type of element stored in a forward list.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>assign</code>	Erases elements from a forward list and copies a new set of elements to a target forward list.
<code>before_begin</code>	Returns an iterator addressing the position before the first element in a forward list.
<code>begin</code>	Returns an iterator addressing the first element in a forward list.
<code>cbegin</code>	Returns a const iterator addressing the first element in a forward list.
<code>cend</code>	Returns a const iterator that addresses the location succeeding the last element in a forward list.
<code>clear</code>	Erases all the elements of a forward list.

MEMBER FUNCTION	DESCRIPTION
<code>emplace_after</code>	Move constructs a new element after a specified position.
<code>emplace_front</code>	Adds an element constructed in place to the beginning of the list.
<code>empty</code>	Tests whether a forward list is empty.
<code>end</code>	Returns an iterator that addresses the location succeeding the last element in a forward list.
<code>erase_after</code>	Removes elements from the forward list after a specified position.
<code>front</code>	Returns a reference to the first element in a forward list.
<code>get_allocator</code>	Returns a copy of the allocator object used to construct a forward list.
<code>insert_after</code>	Adds elements to the forward list after a specified position.
<code>max_size</code>	Returns the maximum length of a forward list.
<code>merge</code>	Removes the elements from the argument list, inserts them into the target forward list, and orders the new, combined set of elements in ascending order or in some other specified order.
<code>pop_front</code>	Deletes the element at the beginning of a forward list.
<code>push_front</code>	Adds an element to the beginning of a forward list.
<code>remove</code>	Erases elements in a forward list that matches a specified value.
<code>remove_if</code>	Erases elements from a forward list for which a specified predicate is satisfied.
<code>resize</code>	Specifies a new size for a forward list.
<code>reverse</code>	Reverses the order in which the elements occur in a forward list.
<code>sort</code>	Arranges the elements in ascending order or with an order specified by a predicate.
<code>splice_after</code>	Restitches links between nodes.
<code>swap</code>	Exchanges the elements of two forward lists.
<code>unique</code>	Removes adjacent elements that pass a specified test.

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Replaces the elements of the forward list with a copy of another forward list.

Requirements

Header: `<forward_list>`

Namespace: `std`

`forward_list::allocator_type`

A type that represents the allocator class for a forward list object.

```
typedef Allocator allocator_type;
```

Remarks

`allocator_type` is a synonym for the template parameter `Allocator`.

`forward_list::assign`

Erases elements from a forward list and copies a new set of elements to a target forward list.

```
void assign(
    size_type Count,
    const Type& Val);

void assign(
    initializer_list<Type> IList);

template <class InputIterator>
void assign(InputIterator First, InputIterator Last);
```

Parameters

PARAMETER	DESCRIPTION
<i>first</i>	The beginning of the replacement range.
<i>last</i>	The end of the replacement range.
<i>count</i>	The number of elements to assign.
<i>val</i>	The value to assign each element.
<i>Type</i>	The type of the value.
<i>IList</i>	The <code>initializer_list</code> to copy.

Remarks

If the `forward_list` is an integer type, the first member function behaves the same as

`assign((size_type)First, (Type)Last)`. Otherwise, the first member function replaces the sequence controlled by

`*this` with the sequence [`First`, `Last`), which must not overlap the initial controlled sequence.

The second member function replaces the sequence controlled by `*this` with a repetition of `Count` elements of value `Val`.

The third member function copies the elements of the `initializer_list` into the `forward_list`.

`forward_list::before_begin`

Returns an iterator addressing the position before the first element in a forward list.

```
const_iterator before_begin() const;
iterator before_begin();
```

Return Value

A forward iterator that points just before the first element of the sequence (or just before the end of an empty sequence).

Remarks

`forward_list::begin`

Returns an iterator addressing the first element in a forward list.

```
const_iterator begin() const;
iterator begin();
```

Return Value

A forward iterator that points at the first element of the sequence (or just beyond the end of an empty sequence).

Remarks

`forward_list::cbefore_begin`

Returns a const iterator addressing the position before the first element in a forward list.

```
const_iterator cbefore_begin() const;
```

Return Value

A forward iterator that points just before the first element of the sequence (or just before the end of an empty sequence).

Remarks

`forward_list::cbegin`

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** forward-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin`, the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();
// i2 is Container<T>::const_iterator
```

forward_list::cend

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A forward-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

forward_list::clear

Erases all the elements of a forward list.

```
void clear();
```

Remarks

This member function calls `erase_after(before_begin(), end())`.

forward_list::const_iterator

A type that provides a constant iterator for the forward list.

```
typedef implementation-defined const_iterator;
```

Remarks

`const_iterator` describes an object that can serve as a constant forward iterator for the controlled sequence. It is described here as a synonym for an implementation-defined type.

forward_list::const_pointer

A type that provides a pointer to a **const** element in a forward list.

```
typedef typename Allocator::const_pointer  
const_pointer;
```

Remarks

forward_list::const_reference

A type that provides a constant reference to an element in the forward list.

```
typedef typename Allocator::const_reference const_reference;
```

Remarks

forward_list::difference_type

A signed integer type that can be used to represent the number of elements of a forward list in a range between elements pointed to by iterators.

```
typedef typename Allocator::difference_type difference_type;
```

Remarks

`difference_type` describes an object that can represent the difference between the addresses of any two elements in the controlled sequence.

forward_list::emplace_after

Move constructs a new element after a specified position.

```
template <class T>  
iterator emplace_after(const_iterator Where, Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>Where</i>	The position in the target forward list where the new element is constructed.
<i>val</i>	The constructor argument.

Return Value

An iterator that designates the newly inserted element.

Remarks

This member function inserts an element with the constructor arguments *val* just after the element pointed to by *Where* in the controlled sequence. Its behavior is otherwise the same as [forward_list::insert_after](#).

forward_list::emplace_front

Adds an element constructed in place to the beginning of the list.

```
template <class Type>
void emplace_front(Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The element added to the beginning of the forward list.

Remarks

This member function inserts an element with the constructor arguments `_ val` at the end of the controlled sequence.

If an exception is thrown, the container is left unaltered and the exception is rethrown.

forward_list::empty

Tests whether a forward list is empty.

```
bool empty() const;
```

Return Value

true if the forward list is empty; otherwise, **false**.

forward_list::end

Returns an iterator that addresses the location succeeding the last element in a forward list.

```
const_iterator end() const;
iterator end();
```

Return Value

A forward iterator that points just beyond the end of the sequence.

forward_list::erase_after

Removes elements from the forward list after a specified position.

```
iterator erase_after(const_iterator Where);
iterator erase_after(const_iterator first, const_iterator last);
```

Parameters

PARAMETER	DESCRIPTION
<i>Where</i>	The position in the target forward list where the element is erased.
<i>first</i>	The beginning of the range to erase.
<i>last</i>	The end of the range to erase.

Return Value

An iterator that designates the first element remaining beyond any elements removed, or `forward_list::end` if no such element exists.

Remarks

The first member function removes the element of the controlled sequence just after *Where*.

The second member function removes the elements of the controlled sequence in the range `(first, last)` (neither end point is included).

Erasing `N` elements causes `N` destructor calls. [Reallocation](#) occurs, so iterators and references become invalid for the erased elements.

The member functions never throw an exception.

forward_list::forward_list

Constructs an object of type `forward_list`.

```
forward_list();
explicit forward_list(const Allocator& Al);
explicit forward_list(size_type Count);
forward_list(size_type Count, const Type& Val);
forward_list(size_type Count, const Type& Val, const Allocator& Al);
forward_list(const forward_list& Right);
forward_list(const forward_list& Right, const Allocator& Al);
forward_list(forward_list&& Right);
forward_list(forward_list&& Right, const Allocator& Al);
forward_list(initializer_list<Type> IList, const Alloc& Al);
template <class InputIterator>
forward_list(InputIterator First, InputIterator Last);
template <class InputIterator>
forward_list(InputIterator First, InputIterator Last, const Allocator& Al);
```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The allocator class to use with this object.
<i>Count</i>	The number of elements in the list constructed.
<i>Val</i>	The value of the elements in the list constructed.
<i>Right</i>	The list of which the constructed list is to be a copy.

PARAMETER	DESCRIPTION
<i>First</i>	The position of the first element in the range of elements to be copied.
<i>Last</i>	The position of the first element beyond the range of elements to be copied.
<i>lList</i>	The initializer_list to copy.

Remarks

All constructors store an [allocator](#) and initialize the controlled sequence. The allocator object is the argument *Al*, if present. For the copy constructor, it is `right.get_allocator()`. Otherwise, it is `Allocator()`.

The first two constructors specify an empty initial controlled sequence.

The third constructor specifies a repetition of *Count* elements of value `Type()`.

The fourth and fifth constructors specify a repetition of *Count* elements of value *Val*.

The sixth constructor specifies a copy of the sequence controlled by *Right*. If `InputIterator` is an integer type, the next two constructors specify a repetition of `(size_type)First` elements of value `(Type)Last`. Otherwise, the next two constructors specify the sequence `[First, Last)`.

The ninth and tenth constructors are the same as the sixth, but with an [rvalue](#) reference.

The last constructor specifies the initial controlled sequence with an object of class `initializer_list<Type>`.

forward_list::front

Returns a reference to the first element in a forward list.

```
reference front();
const_reference front() const;
```

Return Value

A reference to the first element of the controlled sequence, which must be non-empty.

forward_list::get_allocator

Returns a copy of the allocator object used to construct a forward list.

```
allocator_type get_allocator() const;
```

Return Value

The stored [allocator](#) object.

forward_list::insert_after

Adds elements to the forward list after a specified position.

```

iterator insert_after(const_iterator Where, const Type& Val);
void insert_after(const_iterator Where, size_type Count, const Type& Val);
void insert_after(const_iterator Where, initializer_list<Type> Ilist);
iterator insert_after(const_iterator Where, Type&& Val);
template <class InputIterator>
void insert_after(const_iterator Where, InputIterator First, InputIterator Last);

```

Parameters

PARAMETER	DESCRIPTION
<i>Where</i>	The position in the target forward list where the first element is inserted.
<i>Count</i>	The number of elements to insert.
<i>First</i>	The beginning of the insertion range.
<i>Last</i>	The end of the insertion range.
<i>Val</i>	The element added to the forward list.
<i>Ilist</i>	The <code>initializer_list</code> to insert.

Return Value

An iterator that designates the newly inserted element (first and last member functions only).

Remarks

Each of the member functions inserts—just after the element pointed to by *Where* in the controlled sequence—a sequence that's specified by the remaining operands.

The first member function inserts an element that has value *Val* and returns an iterator that designates the newly inserted element.

The second member function inserts a repetition of *Count* elements of value *Val*.

If `InputIterator` is an integer type, the third member function behaves the same as `insert(it, (size_type)First, (Type)Last)`. Otherwise, it inserts the sequence `[First, Last)`, which must not overlap the initial controlled sequence.

The fourth member function inserts the sequence that's specified by an object of class `initializer_list<Type>`.

The last member function is the same as the first, but with an [rvalue](#) reference.

Inserting `N` elements causes `N` constructor calls. [Reallocation](#) occurs, but no iterators or references become invalid.

If an exception is thrown during the insertion of one or more elements, the container is left unaltered and the exception is rethrown.

forward_list::iterator

A type that provides an iterator for the forward list.

```
typedef implementation-defined iterator;
```

Remarks

`iterator` describes an object that can serve as a forward iterator for the controlled sequence. It is described here as a synonym for an implementation-defined type.

forward_list::max_size

Returns the maximum length of a forward list.

```
size_type max_size() const;
```

Return Value

The length of the longest sequence that the object can control.

Remarks

forward_list::merge

Combines two sorted sequences into a single sorted sequence in linear time. Removes the elements from the argument list, and inserts them into this `forward_list`. The two lists should be sorted by the same compare function object before the call to `merge`. The combined list will be sorted by that compare function object.

```
void merge(forward_list& right);  
template <class Predicate>  
void merge(forward_list& right, Predicate comp);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The forward list to merge from.
<i>comp</i>	The compare function object that is used to sort elements.

Remarks

`forward_list::merge` removes the elements from the `forward_list` `right`, and inserts them into this `forward_list`. Both sequences must be ordered by the same predicate, described below. The combined sequence is also ordered by that compare function object.

For the iterators `Pi` and `Pj` designating elements at positions `i` and `j`, the first member function imposes the order `!(*Pj < *Pi)` whenever `i < j`. (The elements are sorted in `ascending` order.) The second member function imposes the order `! comp(*Pj, *Pi)` whenever `i < j`.

No pairs of elements in the original controlled sequence are reversed in the resulting controlled sequence. If a pair of elements in the resulting controlled sequence compares equal (`!(*Pi < *Pj) && !(*Pj < *Pi)`), an element from the original controlled sequence appears before an element from the sequence controlled by `right`.

An exception occurs only if `comp` throws an exception. In that case, the controlled sequence is left in unspecified order and the exception is rethrown.

forward_list::operator=

Replaces the elements of the forward list with a copy of another forward list.

```
forward_list& operator=(const forward_list& right);
forward_list& operator=(initializer_list<Type> IList);
forward_list& operator=(forward_list&& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The forward list being copied into the forward list.
<i>IList</i>	A brace-enclosed initializer list, which behaves just like a sequence of elements of type <code>Type</code> .

Remarks

The first member operator replaces the controlled sequence with a copy of the sequence controlled by *right*.

The second member operator replaces the controlled sequence from an object of class `initializer_list<Type>` .

The third member operator is the same as the first, but with an [rvalue](#) reference.

forward_list::pointer

A type that provides a pointer to an element in the forward list.

```
typedef typename Allocator::pointer pointer;
```

Remarks

forward_list::pop_front

Deletes the element at the beginning of a forward list.

```
void pop_front();
```

Remarks

The first element of the forward list must be non-empty.

The member function never throws an exception.

forward_list::push_front

Adds an element to the beginning of a forward list.

```
void push_front(const Type& val);
void push_front(Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The element added to the beginning of the forward list.

Remarks

If an exception is thrown, the container is left unaltered and the exception is rethrown.

forward_list::reference

A type that provides a reference to an element in the forward list.

```
typedef typename Allocator::reference reference;
```

Remarks

forward_list::remove

Erases elements in a forward list that matches a specified value.

```
void remove(const Type& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value which, if held by an element, will result in that element's removal from the list.

Remarks

The member function removes from the controlled sequence all elements, designated by the iterator `P`, for which `*P == val`.

The member function never throws an exception.

forward_list::remove_if

Erases elements from a forward list for which a specified predicate is satisfied.

```
template <class Predicate>
void remove_if(Predicate pred);
```

Parameters

PARAMETER	DESCRIPTION
<i>pred</i>	The unary predicate which, if satisfied by an element, results in the deletion of that element from the list.

Remarks

The member function removes from the controlled sequence all elements, designated by the iterator `P`, for which `pred(*P)` is true.

An exception occurs only if *pred* throws an exception. In that case, the controlled sequence is left in an unspecified state and the exception is rethrown.

forward_list::resize

Specifies a new size for a forward list.

```
void resize(size_type _Newsize);
void resize(size_type _Newsize, const Type& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>_Newsize</i>	The number of elements in the resized forward list.
<i>val</i>	The value to use for padding.

Remarks

The member functions both ensure that the number of elements in the list henceforth is *_Newsize*. If it must make the controlled sequence longer, the first member function appends elements with value `Type()`, while the second member function appends elements with value *val*. To make the controlled sequence shorter, both member functions effectively call `erase_after(begin() + _Newsize - 1, end())`.

forward_list::reverse

Reverses the order in which the elements occur in a forward list.

```
void reverse();
```

Remarks

forward_list::size_type

A type that represents the unsigned distance between two elements.

```
typedef typename Allocator::size_type size_type;
```

Remarks

The unsigned integer type describes an object that can represent the length of any controlled sequence.

forward_list::sort

Arranges the elements in ascending order or with an order specified by a predicate.

```
void sort();
template <class Predicate>
void sort(Predicate pred);
```

Parameters

PARAMETER	DESCRIPTION
<i>pred</i>	The ordering predicate.

Remarks

Both member functions order the elements in the controlled sequence by a predicate, described below.

For the iterators `Pi` and `Pj` designating elements at positions `i` and `j`, the first member function imposes the order `!(*Pj < *Pi)` whenever `i < j`. (The elements are sorted in `ascending` order.) The member template function imposes the order `! pred(*Pj, *Pi)` whenever `i < j`. No ordered pairs of elements in the original controlled sequence are reversed in the resulting controlled sequence. (The sort is stable.)

An exception occurs only if *pred* throws an exception. In that case, the controlled sequence is left in unspecified order and the exception is rethrown.

forward_list::splice_after

Removes elements from a source `forward_list` and inserts them into a destination `forward_list`.

```
// insert the entire source forward_list
void splice_after(const_iterator Where, forward_list& Source);
void splice_after(const_iterator Where, forward_list&& Source);

// insert one element of the source forward_list
void splice_after(const_iterator Where, forward_list& Source, const_iterator Iter);
void splice_after(const_iterator Where, forward_list&& Source, const_iterator Iter);

// insert a range of elements from the source forward_list
void splice_after(
    const_iterator Where,
    forward_list& Source,
    const_iterator First,
    const_iterator Last);

void splice_after(
    const_iterator Where,
    forward_list&& Source,
    const_iterator First,
    const_iterator Last);
```

Parameters

Where

The position in the destination `forward_list` after which to insert.

Source

The source `forward_list` that is to be inserted into the destination `forward_list`.

Iter

The element to be inserted from the source `forward_list`.

First

The first element in the range to be inserted from source `forward_list`.

Last

The first position beyond the range to be inserted from the source `forward_list`.

Remarks

The first pair of member functions inserts the sequence controlled by *Source* just after the element in the controlled sequence pointed to by *Where*. It also removes all elements from *Source*. (`&Source` must not equal **this**.)

The second pair of member functions removes the element just after *Iter* in the sequence controlled by *Source* and inserts it just after the element in the controlled sequence pointed to by *Where*. (If

```
Where == Iter || Where == ++Iter
```

, no change occurs.)

The third pair of member functions (ranged splice) inserts the subrange designated by `(First, Last)` from the

sequence controlled by *Source* just after the element in the controlled sequence pointed to by *Where*. It also removes the original subrange from the sequence controlled by *Source*. (If `&Source == this`, the range `(First, Last)` must not include the element pointed to by *Where*.)

If the ranged splice inserts `N` elements, and `&Source != this`, an object of class `iterator` is incremented `N` times.

No iterators, pointers, or references that designate spliced elements become invalid.

Example

```

// forward_list_splice_after.cpp
// compile with: /EHsc /W4
#include <forward_list>
#include <iostream>

using namespace std;

template <typename S> void print(const S& s) {
    for (const auto& p : s) {
        cout << "(" << p << ") ";
    }

    cout << endl;
}

int main()
{
    forward_list<int> c1{ 10, 11 };
    forward_list<int> c2{ 20, 21, 22 };
    forward_list<int> c3{ 30, 31 };
    forward_list<int> c4{ 40, 41, 42, 43 };

    forward_list<int>::iterator where_iter;
    forward_list<int>::iterator first_iter;
    forward_list<int>::iterator last_iter;

    cout << "Beginning state of lists:" << endl;
    cout << "c1 = ";
    print(c1);
    cout << "c2 = ";
    print(c2);
    cout << "c3 = ";
    print(c3);
    cout << "c4 = ";
    print(c4);

    where_iter = c2.begin();
    ++where_iter; // start at second element
    c2.splice_after(where_iter, c1);
    cout << "After splicing c1 into c2:" << endl;
    cout << "c1 = ";
    print(c1);
    cout << "c2 = ";
    print(c2);

    first_iter = c3.begin();
    c2.splice_after(where_iter, c3, first_iter);
    cout << "After splicing the first element of c3 into c2:" << endl;
    cout << "c3 = ";
    print(c3);
    cout << "c2 = ";
    print(c2);

    first_iter = c4.begin();
    last_iter = c4.end();
    // set up to get the middle elements
    ++first_iter;
    c2.splice_after(where_iter, c4, first_iter, last_iter);
    cout << "After splicing a range of c4 into c2:" << endl;
    cout << "c4 = ";
    print(c4);
    cout << "c2 = ";
    print(c2);
}

```

```
Beginning state of lists:c1 = (10) (11)c2 = (20) (21) (22)c3 = (30) (31)c4 = (40) (41) (42) (43)After splicing
c1 into c2:c1 =c2 = (20) (21) (10) (11) (22)After splicing the first element of c3 into c2:c3 = (30)c2 = (20)
(21) (31) (10) (11) (22)After splicing a range of c4 into c2:c4 = (40) (41)c2 = (20) (21) (42) (43) (31) (10)
(11) (22)
```

forward_list::swap

Exchanges the elements of two forward lists.

```
void swap(forward_list& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The forward list providing the elements to be exchanged.

Remarks

The member function swaps the controlled sequences between `*this` and *right*. If `get_allocator() == right.get_allocator()`, it does so in constant time, it throws no exceptions, and it invalidates no references, pointers, or iterators that designate elements in the two controlled sequences. Otherwise, it performs a number of element assignments and constructor calls proportional to the number of elements in the two controlled sequences.

forward_list::unique

Eliminates all but the first element from every consecutive group of equal elements.

```
void unique();
template <class BinaryPredicate>
void unique(BinaryPredicate comp);
```

Parameters

PARAMETER	DESCRIPTION
<i>comp</i>	The binary predicate used to compare successive elements.

Remarks

Keeps the first of each unique element, and removes the rest. The elements must be sorted so that elements of equal value are adjacent in the list.

The first member function removes from the controlled sequence every element that compares equal to its preceding element. For the iterators `Pi` and `Pj` designating elements at positions `i` and `j`, the second member function removes every element for which `i + 1 == j && comp(*Pi, *Pj)`.

For a controlled sequence of length `N` (> 0), the predicate `comp(*Pi, *Pj)` is evaluated `N - 1` times.

An exception occurs only if `comp` throws an exception. In that case, the controlled sequence is left in an unspecified state and the exception is rethrown.

forward_list::value_type

A type that represents the type of element stored in a forward list.

```
typedef typename Allocator::value_type value_type;
```

Remarks

The type is a synonym for the template parameter `Ty`.

[<forward_list>](#)

<fstream>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines several classes that support iostreams operations on sequences stored in external files.

Syntax

```
#include <fstream>
```

Typedefs

TYPE NAME	DESCRIPTION
filebuf	A type <code>basic_filebuf</code> specialized on char template parameters.
fstream	A type <code>basic_fstream</code> specialized on char template parameters.
ifstream	A type <code>basic_ifstream</code> specialized on char template parameters.
ofstream	A type <code>basic_ofstream</code> specialized on char template parameters.
wfstream	A type <code>basic_fstream</code> specialized on wchar_t template parameters.
wifstream	A type <code>basic_ifstream</code> specialized on wchar_t template parameters.
wofstream	A type <code>basic_ofstream</code> specialized on wchar_t template parameters.
wfilebuf	A type <code>basic_filebuf</code> specialized on wchar_t template parameters.

Classes

CLASS	DESCRIPTION
basic_filebuf	The template class describes a stream buffer that controls the transmission of elements of type <code>Elem</code> , whose character traits are determined by the class <code>Tr</code> , to and from a sequence of elements stored in an external file.

CLASS	DESCRIPTION
basic_fstream	The template class describes an object that controls insertion and extraction of elements and encoded objects using a stream buffer of class basic_filebuf < Elem , Tr >, with elements of type <code>Elem</code> , whose character traits are determined by the class <code>Tr</code> .
basic_ifstream	The template class describes an object that controls extraction of elements and encoded objects from a stream buffer of class basic_filebuf < Elem , Tr >, with elements of type <code>Elem</code> , whose character traits are determined by the class <code>Tr</code> .
basic_ofstream	The template class describes an object that controls insertion of elements and encoded objects into a stream buffer of class basic_filebuf < Elem , Tr >, with elements of type <code>Elem</code> , whose character traits are determined by the class <code>Tr</code> .

<fstream> typedefs

10/31/2018 • 2 minutes to read • [Edit Online](#)

filebuf	fstream	ifstream
ofstream	wfilebuf	wfstream
wifstream	wofstream	

filebuf

A type `basic_filebuf` specialized on **char** template parameters.

```
typedef basic_filebuf<char, char_traits<char>> filebuf;
```

Remarks

The type is a synonym for template class [basic_filebuf](#), specialized for elements of type **char** with default character traits.

fstream

A type `basic_fstream` specialized on **char** template parameters.

```
typedef basic_fstream<char, char_traits<char>> fstream;
```

Remarks

The type is a synonym for template class [basic_fstream](#), specialized for elements of type **char** with default character traits.

ifstream

Defines a stream to be used to read single-byte character data serially from a file. `ifstream` is a typedef that specializes the template class `basic_ifstream` for **char**.

There is also `wifstream`, a typedef that specializes `basic_ifstream` to read **wchar_t** double-wide characters. For more information, see [wifstream](#).

```
typedef basic_ifstream<char, char_traits<char>> ifstream;
```

Remarks

The type is a synonym for template class [basic_ifstream](#), specialized for elements of type char with default character traits. An example is

```
using namespace std;

ifstream infile("existingtextfile.txt");

if (!infile.bad())
{
    // Dump the contents of the file to cout.
    cout << infile.rdbuf();infile.close();
}
```

ofstream

A type `basic_ofstream` specialized on **char** template parameters.

```
typedef basic_ofstream<char, char_traits<char>> ofstream;
```

Remarks

The type is a synonym for template class [basic_ofstream](#), specialized for elements of type **char** with default character traits.

wfstream

A type `basic_fstream` specialized on **wchar_t** template parameters.

```
typedef basic_fstream<wchar_t, char_traits<wchar_t>> wfstream;
```

Remarks

The type is a synonym for template class [basic_fstream](#), specialized for elements of type **wchar_t** with default character traits.

wifstream

A type `basic_ifstream` specialized on **wchar_t** template parameters.

```
typedef basic_ifstream<wchar_t, char_traits<wchar_t>> wifstream;
```

Remarks

The type is a synonym for template class [basic_ifstream](#), specialized for elements of type **wchar_t** with default character traits.

wofstream

A type `basic_ofstream` specialized on **wchar_t** template parameters.

```
typedef basic_ofstream<wchar_t, char_traits<wchar_t>> wofstream;
```

Remarks

The type is a synonym for template class [basic_ofstream](#), specialized for elements of type **wchar_t** with default character traits.

wfilebuf

A type `basic_filebuf` specialized on **wchar_t** template parameters.

```
typedef basic_filebuf<wchar_t, char_traits<wchar_t>> wfilebuf;
```

Remarks

The type is a synonym for template class [basic_filebuf](#), specialized for elements of type **wchar_t** with default character traits.

basic_filebuf Class

11/8/2018 • 15 minutes to read • [Edit Online](#)

Describes a stream buffer that controls the transmission of elements of type *Elem*, whose character traits are determined by the class *Tr*, to and from a sequence of elements stored in an external file.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>>
class basic_filebuf : public basic_streambuf<Elem, Tr>
```

Parameters

Elem

The basic element of the file buffer.

Tr

The traits of the basic element of the file buffer (usually `char_traits < Elem >`).

Remarks

The template class describes a stream buffer that controls the transmission of elements of type *Elem*, whose character traits are determined by the class *Tr*, to and from a sequence of elements stored in an external file.

NOTE

Objects of type `basic_filebuf` are created with an internal buffer of type `char *` regardless of the `char_type` specified by the type parameter *Elem*. This means that a Unicode string (containing `wchar_t` characters) will be converted to an ANSI string (containing `char` characters) before it is written to the internal buffer. To store Unicode strings in the buffer, create a new buffer of type `wchar_t` and set it using the `basic_streambuf::pubsetbuf()` method. To see an example that demonstrates this behavior, see below.

An object of class `basic_filebuf < Elem, Tr >` stores a file pointer, which designates the `FILE` object that controls the stream associated with an open file. It also stores pointers to two file conversion facets for use by the protected member functions `overflow` and `underflow`. For more information, see `basic_filebuf::open`.

Example

The following example demonstrates how to force an object of type `basic_filebuf<wchar_t>` to store Unicode characters in its internal buffer by calling the `pubsetbuf()` method.

```
// unicode_basic_filebuf.cpp
// compile with: /EHsc

#include <iostream>
#include <string>
#include <fstream>
#include <iomanip>
#include <memory.h>
#include <string.h>

#define IBUFSIZE 16
```

```

using namespace std;

void hexdump(const string& filename);

int main()
{
    wchar_t* wszHello = L"Hello World";
    wchar_t wBuffer[128];

    basic_filebuf<wchar_t> wOutFile;

    // Open a file, wcHello.txt, then write to it, then dump the
    // file's contents in hex
    wOutFile.open("wcHello.txt",
        ios_base::out | ios_base::trunc | ios_base::binary);
    if(!wOutFile.is_open())
    {
        cout << "Error Opening wcHello.txt\n";
        return -1;
    }
    wOutFile.sputn(wszHello, (streamsize)wcslen(wszHello));
    wOutFile.close();
    cout << "Hex Dump of wcHello.txt - note that output is ANSI chars:\n";
    hexdump(string("wcHello.txt"));

    // Open a file, wwHello.txt, then set the internal buffer of
    // the basic_filebuf object to be of type wchar_t, then write
    // to the file and dump the file's contents in hex
    wOutFile.open("wwHello.txt",
        ios_base::out | ios_base::trunc | ios_base::binary);
    if(!wOutFile.is_open())
    {
        cout << "Error Opening wwHello.txt\n";
        return -1;
    }
    wOutFile.pubsetbuf(wBuffer, (streamsize)128);
    wOutFile.sputn(wszHello, (streamsize)wcslen(wszHello));
    wOutFile.close();
    cout << "\nHex Dump of wwHello.txt - note that output is wchar_t chars:\n";
    hexdump(string("wwHello.txt"));

    return 0;
}

// dump contents of filename to stdout in hex
void hexdump(const string& filename)
{
    ifstream ifile(filename.c_str(),
        ios_base::in | ios_base::binary);
    char *ibuff = new char[IBUFSIZE];
    char *obuff = new char[(IBUFSIZE*2)+1];
    int i;

    if(!ifile.is_open())
    {
        cout << "Cannot Open " << filename.c_str()
            << " for reading\n";
        return;
    }
    if(!ibuff || !obuff)
    {
        cout << "Cannot Allocate buffers\n";
        ifile.close();
        return;
    }

    while(!ifile.eof())
    {

```

```

memset(obuff,0,(IBUFSIZE*2)+1);
memset(ibuff,0,IBUFSIZE);
ifile.read(ibuff,IBUFSIZE);

// corner case where file is exactly a multiple of
// 16 bytes in length
if(ibuff[0] == 0 && ifile.eof())
    break;

for(i = 0; i < IBUFSIZE; i++)
{
    if(ibuff[i] >= ' ')
        obuff[i] = ibuff[i];
    else
        obuff[i] = '.';

    cout << setfill('0') << setw(2) << hex
        << (int)ibuff[i] << ' ';
}
cout << " " << obuff << endl;
}
ifile.close();
}

```

Hex Dump of wcHello.txt - note that output is ANSI chars:

```
48 65 6c 6c 6f 20 57 6f 72 6c 64 00 00 00 00 00 Hello World.....
```

Hex Dump of wwHello.txt - note that output is wchar_t chars:

```
48 00 65 00 6c 00 6c 00 6f 00 20 00 57 00 6f 00 H.e.l.l.o. .W.o.
72 00 6c 00 64 00 00 00 00 00 00 00 00 00 00 00 r.l.d.....
```

Constructors

CONSTRUCTOR	DESCRIPTION
basic_filebuf	Constructs an object of type <code>basic_filebuf</code> .

Typedefs

TYPE NAME	DESCRIPTION
char_type	Associates a type name with the <code>Elem</code> template parameter.
int_type	Makes this type within <code>basic_filebuf</code> 's scope equivalent to the type of the same name in the <code>Tr</code> scope.
off_type	Makes this type within <code>basic_filebuf</code> 's scope equivalent to the type of the same name in the <code>Tr</code> scope.
pos_type	Makes this type within <code>basic_filebuf</code> 's scope equivalent to the type of the same name in the <code>Tr</code> scope.
traits_type	Associates a type name with the <code>Tr</code> template parameter.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>close</code>	Closes a file.
<code>is_open</code>	Indicates whether a file is open.
<code>open</code>	Opens a file.
<code>overflow</code>	A protected virtual function that can be called when a new character is inserted into a full buffer.
<code>pbackfail</code>	The protected virtual member function tries to put back an element into the input stream, then make it the current element (pointed to by the next pointer).
<code>seekoff</code>	The protected virtual member function tries to alter the current positions for the controlled streams.
<code>seekpos</code>	The protected virtual member function tries to alter the current positions for the controlled streams.
<code>setbuf</code>	The protected virtual member function performs an operation particular to each derived stream buffer.
<code>Swap</code>	Exchanges the content of this <code>basic_filebuf</code> for the content of the provided <code>basic_filebuf</code> parameter.
<code>sync</code>	Protected, virtual function tries to synchronize the controlled streams with any associated external streams.
<code>uflow</code>	Protected, virtual function to extract the current element from the input stream.
<code>underflow</code>	Protected, virtual function to extract the current element from the input stream.

Requirements

Header: `<fstream>`

Namespace: `std`

`basic_filebuf::basic_filebuf`

Constructs an object of type `basic_filebuf`.

```
basic_filebuf();

basic_filebuf(basic_filebuf&& right);
```

Remarks

The first constructor stores a null pointer in all the pointers controlling the input buffer and the output buffer. It also stores a null pointer in the file pointer.

The second constructor initializes the object with the contents of `right`, treated as an rvalue reference.

basic_filebuf::char_type

Associates a type name with the `Elem` template parameter.

```
typedef Elem char_type;
```

basic_filebuf::close

Closes a file.

```
basic_filebuf<Elem, Tr> *close();
```

Return Value

The member function returns a null pointer if the file pointer is a null pointer.

Remarks

`close` calls `fclose` (**fp**). If that function returns a nonzero value, the function returns a null pointer. Otherwise, it returns **this** to indicate that the file was successfully closed.

For a wide stream, if any insertions have occurred since the stream was opened, or since the last call to `streampos`, the function calls `overflow`. It also inserts any sequence needed to restore the initial conversion state, by using the file conversion facet `fac` to call `fac.unshift` as needed. Each element `byte` of type **char** thus produced is written to the associated stream designated by the file pointer `fp` as if by successive calls of the form `fputc` (**byte, fp**). If the call to `fac.unshift` or any write fails, the function does not succeed.

Example

The following sample assumes two files in the current directory: `basic_filebuf_close.txt` (contents is "testing") and `iotest.txt` (contents is "ssss").

```
// basic_filebuf_close.cpp
// compile with: /EHsc
#include <fstream>
#include <iostream>

int main() {
    using namespace std;
    ifstream file;
    basic_ifstream <wchar_t> wfile;
    char c;
    // Open and close with a basic_filebuf
    file.rdbuf()->open( "basic_filebuf_close.txt", ios::in );
    file >> c;
    cout << c << endl;
    file.rdbuf( )->close( );

    // Open/close directly
    file.open( "iotest.txt" );
    file >> c;
    cout << c << endl;
    file.close( );

    // open a file with a wide character name
    wfile.open( L"iotest.txt" );

    // Open and close a nonexistent with a basic_filebuf
    file.rdbuf()->open( "ziotest.txt", ios::in );
    cout << file.fail() << endl;
    file.rdbuf( )->close( );

    // Open/close directly
    file.open( "ziotest.txt" );
    cout << file.fail() << endl;
    file.close( );
}
```

```
t
s
0
1
```

basic_filebuf::int_type

Makes this type within basic_filebuf's scope equivalent to the type of the same name in the `Tr` scope.

```
typedef typename traits_type::int_type int_type;
```

basic_filebuf::is_open

Indicates whether a file is open.

```
bool is_open() const;
```

Return Value

true if the file pointer is not a null pointer.

Example

```
// basic_filebuf_is_open.cpp
// compile with: /EHsc
#include <fstream>
#include <iostream>

int main( )
{
    using namespace std;
    ifstream file;
    cout << boolalpha << file.rdbuf( )->is_open( ) << endl;

    file.open( "basic_filebuf_is_open.cpp" );
    cout << file.rdbuf( )->is_open( ) << endl;
}
```

```
false
true
```

basic_filebuf::off_type

Makes this type within `basic_filebuf`'s scope equivalent to the type of the same name in the `Tr` scope.

```
typedef typename traits_type::off_type off_type;
```

basic_filebuf::open

Opens a file.

```
basic_filebuf<Elem, Tr> *open(
    const char* _Filename,
    ios_base::openmode _Mode,
    int _Prot = (int)ios_base::_Openprot);

basic_filebuf<Elem, Tr> *open(
    const char* _Filename,
    ios_base::openmode _Mode);

basic_filebuf<Elem, Tr> *open(
    const wchar_t* _Filename,
    ios_base::openmode _Mode,
    int _Prot = (int)ios_base::_Openprot);

basic_filebuf<Elem, Tr> *open(
    const wchar_t* _Filename,
    ios_base::openmode _Mode);
```

Parameters

_Filename

The name of the file to open.

_Mode

One of the enumerations in [ios_base::openmode](#).

_Prot

The default file opening protection, equivalent to the *shflag* parameter in [_fsopen](#), [_wfsopen](#).

Return Value

If the file pointer is a null pointer, the function returns a null pointer. Otherwise, it returns **this**.

Remarks

The member function opens the file with filename *filename*, by calling `fopen(filename, strmode)`. `strmode` is determined from **mode** & ~(`ate` & | `binary`):

- `ios_base::in` becomes "r" (open existing file for reading).
- `ios_base::out` or `ios_base::out | ios_base::trunc` becomes "w" (truncate existing file or create for writing).
- `ios_base::out | app` becomes "a" (open existing file for appending all writes).
- `ios_base::in | ios_base::out` becomes "r+" (open existing file for reading and writing).
- `ios_base::in | ios_base::out | ios_base::trunc` becomes "w+" (truncate existing file or create for reading and writing).
- `ios_base::in | ios_base::out | ios_base::app` becomes "a+" (open existing file for reading and for appending all writes).

If **mode** & `ios_base::binary` is nonzero, the function appends `b` to `strmode` to open a binary stream instead of a text stream. It then stores the value returned by `fopen` in the file pointer `fp`. If **mode** & `ios_base::ate` is nonzero and the file pointer is not a null pointer, the function calls `fseek(fp, 0, SEEK_END)` to position the stream at end of file. If that positioning operation fails, the function calls `close(fp)` and stores a null pointer in the file pointer.

If the file pointer is not a null pointer, the function determines the file conversion facet: `use_facet < codecvt < Elem, char, traits_type::state_type> >(getloc)`, for use by `underflow` and `overflow`.

If the file pointer is a null pointer, the function returns a null pointer. Otherwise, it returns **this**.

Example

See `basic_filebuf::close` for an example that uses `open`.

basic_filebuf::operator=

Assign the content of this stream buffer object. This is a move assignment involving an rvalue that does not leave a copy behind.

```
basic_filebuf& operator=(basic_filebuf&& right);
```

Parameters

right

An rvalue reference to a `basic_filebuf` object.

Return Value

Returns `*this`.

Remarks

The member operator replaces the contents of the object by using the contents of *right*, treated as an rvalue reference. For more information, see [Rvalue Reference Declarator: &&](#).

basic_filebuf::overflow

Called when a new character is inserted into a full buffer.

```
virtual int_type overflow(int_type _Meta = traits_type::eof);
```

Parameters

_Meta

The character to insert into the buffer or `traits_type::eof`.

Return Value

If the function cannot succeed, it returns `traits_type::eof`. Otherwise, it returns **`traits_type::not_eof`**(*_Meta*).

Remarks

If *_Meta* != **`traits_type::eof`**, the protected virtual member function endeavors to insert the element **`ch = traits_type::to_char_type`**(*_Meta*) into the output buffer. It can do so in various ways:

- If a write position is available, it can store the element into the write position and increment the next pointer for the output buffer.
- It can make a write position available by allocating new or additional storage for the output buffer.
- It can convert any pending output in the output buffer, followed by `ch`, by using the file conversion facet `fac` to call `fac.out` as needed. Each element `ch` of type *char* thus produced is written to the associated stream designated by the file pointer `fp` as if by successive calls of the form `fputc(ch, fp)`. If any conversion or write fails, the function does not succeed.

basic_filebuf::pbackfail

Tries to put back an element into the input stream, then make it the current element (pointed to by the next pointer).

```
virtual int_type pbackfail(int_type _Meta = traits_type::eof);
```

Parameters

_Meta

The character to insert into the buffer, or `traits_type::eof`.

Return Value

If the function cannot succeed, it returns `traits_type::eof`. Otherwise, it returns **`traits_type::not_eof`**(*_Meta*).

Remarks

The protected virtual member function puts back an element into the input buffer and then makes it the current element (pointed to by the next pointer). If *_Meta* == **`traits_type::eof`**, the element to push back is effectively the one already in the stream before the current element. Otherwise, that element is replaced by **`ch = traits_type::to_char_type`**(*_Meta*). The function can put back an element in various ways:

- If a putback position is available, and the element stored there compares equal to `ch`, it can decrement the next pointer for the input buffer.
- If the function can make a `putback` position available, it can do so, set the next pointer to point at that position, and store `ch` in that position.
- If the function can push back an element onto the input stream, it can do so, such as by calling `ungetc` for an element of type **`char`**.

basic_filebuf::pos_type

Makes this type within `basic_filebuf`'s scope equivalent to the type of the same name in the `Tr` scope.

```
typedef typename traits_type::pos_type pos_type;
```

`basic_filebuf::seekoff`

Tries to alter the current positions for the controlled streams.

```
virtual pos_type seekoff(off_type _Off,  
    ios_base::seekdir _Way,  
    ios_base::openmode _Which = ios_base::in | ios_base::out);
```

Parameters

_Off

The position to seek for relative to *_Way*.

_Way

The starting point for offset operations. See [seekdir](#) for possible values.

_Which

Specifies the mode for the pointer position. The default is to allow you to modify the read and write positions.

Return Value

Returns the new position or an invalid stream position.

Remarks

The protected virtual member function endeavors to alter the current positions for the controlled streams. For an object of class `basic_filebuf`< `Elem`, `Tr` >, a stream position can be represented by an object of type `fpos_t`, which stores an offset and any state information needed to parse a wide stream. Offset zero designates the first element of the stream. (An object of type `pos_type` stores at least an `fpos_t` object.)

For a file opened for both reading and writing, both the input and output streams are positioned in tandem. To switch between inserting and extracting, you must call either `pubseekoff` or `pubseekpos`. Calls to `pubseekoff` (and hence to `seekoff`) have various limitations for [text streams](#), [binary streams](#), and [wide streams](#).

If the file pointer `fp` is a null pointer, the function fails. Otherwise, it endeavors to alter the stream position by calling `fseek (fp, _Off, _Way)`. If that function succeeds and the resulting position `fposn` can be determined by calling `fgetpos (fp, &fposn)`, the function succeeds. If the function succeeds, it returns a value of type `pos_type` containing `fposn`. Otherwise, it returns an invalid stream position.

`basic_filebuf::seekpos`

Tries to alter the current positions for the controlled streams.

```
virtual pos_type seekpos(pos_type _Sp, ios_base::openmode _Which = ios_base::in | ios_base::out);
```

Parameters

_Sp

The position to seek for.

_Which

Specifies the mode for the pointer position. The default is to allow you to modify the read and write positions.

Return Value

If the file pointer `fp` is a null pointer, the function fails. Otherwise, it endeavors to alter the stream position by calling `fsetpos (fp, &fposn)`, where `fposn` is the `fpos_t` object stored in `pos`. If that function succeeds, the function returns `pos`. Otherwise, it returns an invalid stream position. To determine if the stream position is invalid, compare the return value with `pos_type(off_type(-1))`.

Remarks

The protected virtual member function endeavors to alter the current positions for the controlled streams. For an object of class `basic_filebuf< Elem, Tr>`, a stream position can be represented by an object of type `fpos_t`, which stores an offset and any state information needed to parse a wide stream. Offset zero designates the first element of the stream. (An object of type `pos_type` stores at least an `fpos_t` object.)

For a file opened for both reading and writing, both the input and output streams are positioned in tandem. To switch between inserting and extracting, you must call either `pubseekoff` or `pubseekpos`. Calls to `pubseekoff` (and hence to `seekoff`) have various limitations for text streams, binary streams, and wide streams.

For a wide stream, if any insertions have occurred since the stream was opened, or since the last call to `streampos`, the function calls `overflow`. It also inserts any sequence needed to restore the initial conversion state, by using the file conversion facet `fac` to call `fac.unshift` as needed. Each element `byte` of type `char` thus produced is written to the associated stream designated by the file pointer `fp` as if by successive calls of the form `fputc (byte, fp)`. If the call to `fac.unshift` or any write fails, the function does not succeed.

basic_filebuf::setbuf

Performs an operation particular to each derived stream buffer.

```
virtual basic_streambuf<Elem, Tr> *setbuf(
    char_type* _Buffer,
    streamsize count);
```

Parameters

_Buffer

Pointer to a buffer.

count

Size of the buffer.

Return Value

The protected member function returns zero if the file pointer `fp` is a null pointer.

Remarks

`setbuf` calls `setvbuf (fp, (char *) _Buffer, _IOFBF, count * sizeof (Elem))` to offer the array of `count` elements beginning at *_Buffer* as a buffer for the stream. If that function returns a nonzero value, the function returns a null pointer. Otherwise, it returns **this** to signal success.

basic_filebuf::swap

Exchanges the contents of this `basic_filebuf` for the contents of the provided `basic_filebuf`.

```
void swap(basic_filebuf& right);
```

Parameters

right

An `lvalue` reference to another `basic_filebuf`.

`basic_filebuf::sync`

Tries to synchronize the controlled streams with any associated external streams.

```
virtual int sync();
```

Return Value

Returns zero if the file pointer `fp` is a null pointer. Otherwise, it returns zero only if calls to both [overflow](#) and `fflush`(`fp`) succeed in flushing any pending output to the stream.

`basic_filebuf::traits_type`

Associates a type name with the `Tr` template parameter.

```
typedef Tr traits_type;
```

`basic_filebuf::underflow`

Extracts the current element from the input stream.

```
virtual int_type underflow();
```

Return Value

If the function cannot succeed, it returns **`traits_type::eof`**. Otherwise, it returns `ch`, converted as described in the Remarks section.

Remarks

The protected virtual member function endeavors to extract the current element `ch` from the input stream, and return the element as **`traits_type::to_int_type`**(`ch`). It can do so in various ways:

- If a read position is available, it takes `ch` as the element stored in the read position and advances the next pointer for the input buffer.
- It can read one or more elements of type **`char`**, as if by successive calls of the form `fgetc`(`fp`), and convert them to an element **`ch`** of type `Elem` by using the file conversion facet `fac` to call `fac.in` as needed. If any read or conversion fails, the function does not succeed.

basic_fstream Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Describes an object that controls insertion and extraction of elements and encoded objects using a stream buffer of class `basic_filebuf` < `Elem` , `Tr` >, with elements of type `Elem` , whose character traits are determined by the class `Tr` .

Syntax

```
template <class Elem, class Tr = char_traits<Elem>>
class basic_fstream : public basic_iostream<Elem, Tr>
```

Parameters

Elem

The basic element of the file buffer.

Tr

The traits of the basic element of the file buffer (usually `char_traits` < `Elem` >).

Remarks

The object stores an object of class `basic_filebuf` < `Elem` , `Tr` >.

NOTE

The get pointer and put pointer of an fstream object are **NOT** independent of each other. If the get pointer moves, so does the put pointer.

Example

The following example demonstrates how to create a `basic_fstream` object that can be read from and written to.

```
// basic_fstream_class.cpp
// compile with: /EHsc

#include <fstream>
#include <iostream>

using namespace std;

int main(int argc, char **argv)
{
    fstream fs("fstream.txt", ios::in | ios::out | ios::trunc);
    if (!fs.bad())
    {
        // Write to the file.
        fs << "Writing to a basic_fstream object..." << endl;
        fs.close();

        // Dump the contents of the file to cout.
        fs.open("fstream.txt", ios::in);
        cout << fs.rdbuf();
        fs.close();
    }
}
```

```
Writing to a basic_fstream object...
```

Constructors

CONSTRUCTOR	DESCRIPTION
basic_fstream	Constructs an object of type <code>basic_fstream</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
close	Closes a file.
is_open	Determines if a file is open.
open	Opens a file.
rdbuf	Returns the address of the stored stream buffer, of type pointer to basic_filebuf < <code>Elem</code> , <code>Tr</code> >.
swap	Exchanges the content of this object with the content of another <code>basic_fstream</code> object.

Requirements

Header: `<fstream>`

Namespace: `std`

`basic_fstream::basic_fstream`

Constructs an object of type `basic_fstream`.

```

basic_fstream();

explicit basic_fstream(
    const char* _Filename,
    ios_base::openmode _Mode = ios_base::in | ios_base::out,
    int _Prot = (int)ios_base::_Openprot);

explicit basic_fstream(
    const wchar_t* _Filename,
    ios_base::openmode _Mode = ios_base::in | ios_base::out,
    int _Prot = (int)ios_base::_Openprot);

basic_fstream(basic_fstream&& right);

```

Parameters

_Filename

The name of the file to open.

_Mode

One of the enumerations in [ios_base::openmode](#).

_Prot

The default file opening protection, equivalent to the *shflag* parameter in [_fsopen](#), [_wfsopen](#).

Remarks

The first constructor initializes the base class by calling [basic_iostream](#)(`sb`), where `sb` is the stored object of class [basic_filebuf](#)< **Elem**, **Tr**>. It also initializes `sb` by calling [basic_filebuf](#)< **Elem**, **Tr**>.

The second and third constructors initialize the base class by calling [basic_iostream](#)(`sb`). It also initializes `sb` by calling [basic_filebuf](#)< **Elem**, **Tr**>, and then `sb.open(_Filename, _Mode)`. If the latter function returns a null pointer, the constructor calls [setstate](#)(`failbit`).

The fourth constructor initializes the object with the contents of `right`, treated as an rvalue reference.

Example

See [streampos](#) for an example that uses `basic_fstream`.

basic_fstream::close

Closes a file.

```

void close();

```

Remarks

The member function calls `rdbuf->close`.

Example

See [basic_filebuf::close](#) for an example of how to use `close`.

basic_fstream::is_open

Determines if a file is open.

```

bool is_open() const;

```

Return Value

true if the file is open, **false** otherwise.

Remarks

The member function returns `rdbuf->is_open`.

Example

See `basic_filebuf::is_open` for an example of how to use `is_open`.

basic_fstream::open

Opens a file.

```
void open(
    const char* _Filename,
    ios_base::openmode _Mode = ios_base::in | ios_base::out,
    int _Prot = (int)ios_base::_Openprot);

void open(
    const char* _Filename,
    ios_base::openmode _Mode);

void open(
    const wchar_t* _Filename,
    ios_base::openmode _Mode = ios_base::in | ios_base::out,
    int _Prot = (int)ios_base::_Openprot);

void open(
    const wchar_t* _Filename,
    ios_base::openmode _Mode);
```

Parameters

_Filename

The name of the file to open.

_Mode

One of the enumerations in `ios_base::openmode`.

_Prot

The default file opening protection, equivalent to the *shflag* parameter in `_fsopen`, `_wfsopen`.

Remarks

The member function calls `rdbuf -> open(_Filename, _Mode)`. If that function returns a null pointer, the function calls `setstate(failbit)`.

Example

See `basic_filebuf::open` for an example of how to use `open`.

basic_fstream::operator=

Assigns to this object the content from a specified stream object. This is a move assignment that involves an rvalue that does not leave a copy behind.

```
basic_fstream& operator=(basic_fstream&& right);
```

Parameters

right

An lvalue reference to a `basic_fstream` object.

Return Value

Returns `*this`.

Remarks

The member operator replaces the contents of the object by using the contents of *right*, treated as an rvalue reference.

`basic_fstream::rdbuf`

Returns the address of the stored stream buffer, of type pointer to `basic_filebuf<Elem, Tr>`.

```
basic_filebuf<Elem, Tr> *rdbuf() const
```

Return Value

The address of the stored stream buffer.

Example

See [basic_filebuf::close](#) for an example of how to use `rdbuf`.

`basic_fstream::swap`

Exchanges the contents of two `basic_fstream` objects.

```
void swap(basic_fstream& right);
```

Parameters

right

An lvalue reference to a `basic_fstream` object.

Remarks

The member function exchanges the contents of this object and the contents of *right*.

basic_ifstream Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Describes an object that controls extraction of elements and encoded objects from a stream buffer of class `basic_filebuf` < `Elem`, `Tr` >, with elements of type `Elem`, whose character traits are determined by the class `Tr`.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>>
class basic_ifstream : public basic_istream<Elem, Tr>
```

Parameters

Elem

The basic element of the file buffer.

Tr

The traits of the basic element of the file buffer (usually `char_traits` < `Elem` >).

Remarks

The object stores an object of class `basic_filebuf` < `Elem`, `Tr` >.

Example

The following example shows how to read in text from a file.

```
// basic_ifstream_class.cpp
// compile with: /EHsc

#include <fstream>
#include <iostream>

using namespace std;

int main(int argc, char **argv)
{
    ifstream ifs("basic_ifstream_class.txt");
    if (!ifs.bad())
    {
        // Dump the contents of the file to cout.
        cout << ifs.rdbuf();
        ifs.close();
    }
}
```

Input: basic_ifstream_class.txt

This is the contents of basic_ifstream_class.txt.

Output

This is the contents of `basic_ifstream_class.txt`.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>basic_ifstream</code>	Initializes a new instance of a <code>basic_ifstream</code> object.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>close</code>	Closes a file.
<code>is_open</code>	Determines if a file is open.
<code>open</code>	Opens a file.
<code>rdbuf</code>	Returns the address of the stored stream buffer.
<code>swap</code>	Exchanges the content of this <code>basic_ifstream</code> for the content of the provided <code>basic_ifstream</code> .

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Assigns the content of this stream object. This is a move assignment involving an <code>rvalue</code> that does not leave a copy behind.

Requirements

Header: `<fstream>`

Namespace: `std`

`basic_ifstream::basic_ifstream`

Constructs an object of type `basic_ifstream`.

```
basic_ifstream();

explicit basic_ifstream(
    const char* _Filename,
    ios_base::openmode _Mode = ios_base::in,
    int _Prot = (int)ios_base::_Openprot);

explicit basic_ifstream(
    const wchar_t* _Filename,
    ios_base::openmode _Mode = ios_base::in,
    int _Prot = (int)ios_base::_Openprot);

basic_ifstream(basic_ifstream&& right);
```

Parameters

_Filename

The name of the file to open.

_Mode

One of the enumerations in [ios_base::openmode](#).

_Prot

The default file opening protection, equivalent to the `shflag` parameter in [_fsopen](#), [_wfsopen](#).

Remarks

The first constructor initializes the base class by calling [basic_istream](#)(`sb`), where `sb` is the stored object of class [basic_filebuf](#)< `Elem`, `Tr` >. It also initializes `sb` by calling [basic_filebuf](#)< `Elem`, `Tr` >.

The second and third constructors initialize the base class by calling [basic_istream](#)(`sb`). It also initializes `sb` by calling [basic_filebuf](#)< `Elem`, `Tr` >, then `sb.open(_Filename, _Mode | ios_base::in)`. If the latter function returns a null pointer, the constructor calls **setstate**(`failbit`).

The fourth constructor initializes the object with the contents of `right`, treated as an rvalue reference.

Example

The following example shows how to read in text from a file. To create the file, see the example for [basic_ofstream::basic_ofstream](#).

```
// basic_ifstream_ctor.cpp
// compile with: /EHsc

#include <fstream>
#include <iostream>

using namespace std;

int main(int argc, char **argv)
{
    ifstream ifs("basic_ifstream_ctor.txt");
    if (!ifs.bad())
    {
        // Dump the contents of the file to cout.
        cout << ifs.rdbuf();
        ifs.close();
    }
}
```

basic_ifstream::close

Closes a file.

```
void close();
```

Remarks

The member function calls [rdbuf](#) -> [close](#).

Example

See [basic_filebuf::close](#) for an example that uses `close`.

basic_ifstream::is_open

Determines if a file is open.

```
bool is_open() const;
```

Return Value

true if the file is open, **false** otherwise.

Remarks

The member function returns [rdbuf](#) -> [is_open](#).

Example

See [basic_filebuf::is_open](#) for an example that uses `is_open`.

basic_ifstream::open

Opens a file.

```
void open(
    const char* _Filename,
    ios_base::openmode _Mode = ios_base::in,
    int _Prot = (int)ios_base::_Openprot);

void open(
    const char* _Filename,
    ios_base::openmode _Mode);

void open(
    const wchar_t* _Filename,
    ios_base::openmode _Mode = ios_base::in,
    int _Prot = (int)ios_base::_Openprot);

void open(
    const wchar_t* _Filename,
    ios_base::openmode _Mode);
```

Parameters

_Filename

The name of the file to open.

_Mode

One of the enumerations in [ios_base::openmode](#).

_Prot

The default file opening protection, equivalent to the `shflag` parameter in [_fsopen](#), [_wfsopen](#).

Remarks

The member function calls [rdbuf](#) -> [open](#)(*_Filename*, `_Mode` | **ios_base::in**). If open fails, the function calls [setstate](#)(`failbit`), which may throw an `ios_base::failure` exception.

Example

See [basic_filebuf::open](#) for an example that uses `open`.

basic_ifstream::operator=

Assigns the content of this stream object. This is a move assignment involving an rvalue that does not leave a copy behind.

```
basic_ifstream& operator=(basic_ifstream&& right);
```

Parameters

right

An rvalue reference to a `basic_ifstream` object.

Return Value

Returns `*this`.

Remarks

The member operator replaces the contents of the object by using the contents of *right*, treated as an rvalue reference. For more information, see [Lvalues and Rvalues](#).

basic_ifstream::rdbuf

Returns the address of the stored stream buffer.

```
basic_filebuf<Elem, Tr> *rdbuf() const
```

Return Value

A pointer to a [basic_filebuf](#) object representing the stored stream buffer.

Example

See [basic_filebuf::close](#) for an example that uses `rdbuf`.

basic_ifstream::swap

Exchanges the contents of two `basic_ifstream` objects.

```
void swap(basic_ifstream& right);
```

Parameters

right

A reference to another stream buffer.

Remarks

The member function exchanges the contents of this object for the contents of *right*.

[iostreams Conventions](#)

basic_ofstream Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

Describes an object that controls insertion of elements and encoded objects into a stream buffer of class `basic_filebuf` < `Elem`, `Tr` >, with elements of type `Elem`, whose character traits are determined by the class `Tr`.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>>
class basic_ofstream : public basic_ostream<Elem, Tr>
```

Parameters

Elem

The basic element of the file buffer.

Tr

The traits of the basic element of the file buffer (usually `char_traits` < `Elem` >).

Remarks

When the **wchar_t** specialization of `basic_ofstream` writes to the file, if the file is opened in text mode it will write a MBCS sequence. The internal representation will use a buffer of `wchar_t` characters.

The object stores an object of class `basic_filebuf` < `Elem`, `Tr` >.

Example

The following example shows how to create a `basic_ofstream` object and write text to it.

```
// basic_ofstream_class.cpp
// compile with: /EHsc
#include <fstream>

using namespace std;

int main(int argc, char **argv)
{
    ofstream ofs("ofstream.txt");
    if (!ofs.bad())
    {
        ofs << "Writing to a basic_ofstream object..." << endl;
        ofs.close();
    }
}
```

Constructors

CONSTRUCTOR	DESCRIPTION
<code>basic_ofstream</code>	Creates an object of type <code>basic_ofstream</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
close	Closes a file.
is_open	Determines if a file is open.
open	Opens a file.
rdbuf	Returns the address of the stored stream buffer.
swap	Exchange the contents of this <code>basic_ofstream</code> for the contents of the provided <code>basic_ofstream</code> .

Operators

OPERATOR	DESCRIPTION
operator=	Assigns the content of this stream object. This is a move assignment involving an <code>rvalue reference</code> that does not leave a copy behind.

Requirements

Header: `<fstream>`

Namespace: `std`

`basic_ofstream::basic_ofstream`

Creates an object of type `basic_ofstream`.

```
basic_ofstream();

explicit basic_ofstream(
    const char* _Filename,
    ios_base::openmode _Mode = ios_base::out,
    int _Prot = (int)ios_base::_Openprot);

explicit basic_ofstream(
    const wchar_t* _Filename,
    ios_base::openmode _Mode = ios_base::out,
    int _Prot = (int)ios_base::_Openprot);

basic_ofstream(
    basic_ofstream&& right);
```

Parameters

_Filename

The name of the file to open.

_Mode

One of the enumerations in [ios_base::openmode](#).

_Prot

The default file opening protection, equivalent to the `shf1ag` parameter in [_fsopen](#), [_wfsopen](#).

right

The rvalue reference to the `basic_ofstream` object being used to initialize this `basic_ofstream` object.

Remarks

The first constructor initializes the base class by calling `basic_ostream(sb)`, where `sb` is the stored object of class `basic_filebuf< Elem, Tr >`. It also initializes `sb` by calling `basic_filebuf< Elem, Tr >`.

The second and third constructors initialize the base class by calling `basic_ostream(sb)`. It also initializes `sb` by calling `basic_filebuf< Elem, Tr >` and then `sb.open(_Filename, _Mode | ios_base::out)`. If the latter function returns a null pointer, the constructor calls `setstate(failbit)`.

The fourth constructor is a copy function. It initializes the object with the contents of *right*, treated as an rvalue reference.

Example

The following example shows how to create a `basic_ofstream` object and write text to it.

```
// basic_ofstream_ctor.cpp
// compile with: /EHsc
#include <fstream>

using namespace std;

int main(int argc, char **argv)
{
    ofstream ofs("C:\\\\ofstream.txt");
    if (!ofs.bad())
    {
        ofs << "Writing to a basic_ofstream object..." << endl;
        ofs.close();
    }
}
```

basic_ofstream::close

Closes a file.

```
void close();
```

Remarks

The member function calls `rdbuf->close`.

Example

See `basic_filebuf::close` for an example that uses `close`.

basic_ofstream::is_open

Indicates whether a file is open.

```
bool is_open() const;
```

Return Value

true if the file is open, **false** otherwise.

Remarks

The member function returns `rdbuf -> is_open`.

Example

```
// basic_ofstream_is_open.cpp
// compile with: /EHsc
#include <fstream>
#include <iostream>

int main( )
{
    using namespace std;
    ifstream file;
    // Open and close with a basic_filebuf
    file.rdbuf( )->open( "basic_ofstream_is_open.txt", ios::in );
    file.close( );
    if (file.is_open())
        cout << "it's open" << endl;
    else
        cout << "it's closed" << endl;
}
```

basic_ofstream::open

Opens a file.

```
void open(
    const char* _Filename,
    ios_base::openmode _Mode = ios_base::out,
    int _Prot = (int)ios_base::_Openprot);

void open(
    const char* _Filename,
    ios_base::openmode _Mode);

void open(
    const wchar_t* _Filename,
    ios_base::openmode _Mode = ios_base::out,
    int _Prot = (int)ios_base::_Openprot);

void open(
    const wchar_t* _Filename,
    ios_base::openmode _Mode);
```

Parameters

_Filename

The name of the file to open.

_Mode

One of the enumerations in [ios_base::openmode](#).

_Prot

The default file opening protection, equivalent to the `shflag` parameter in [_fsopen](#), [_wfsopen](#).

Remarks

The member function calls `rdbuf -> open(_Filename, _Mode | ios_base::out)`. If that function returns a null pointer, the function calls `setstate(failbit)`.

Example

See [basic_filebuf::open](#) for an example that uses `open`.

basic_ofstream::operator=

Assigns the content of this stream object. This is a move assignment involving an `rvalue reference` that does not leave a copy behind.

```
basic_ofstream& operator=(basic_ofstream&& right);
```

Parameters

right

An rvalue reference to a `basic_ofstream` object.

Return Value

Returns `*this`.

Remarks

The member operator replaces the contents of the object by using the contents of *right*, treated as an rvalue reference.

basic_ofstream::rdbuf

Returns the address of the stored stream buffer.

```
basic_filebuf<Elem, Tr> *rdbuf() const
```

Return Value

Returns the address of the stored stream buffer.

Example

See [basic_filebuf::close](#) for an example that uses `rdbuf`.

basic_ofstream::swap

Exchanges the contents of two `basic_ofstream` objects.

```
void swap(basic_ofstream& right);
```

Parameters

right

An `lvalue` reference to another `basic_ofstream` object.

Remarks

The member function exchanges the contents of this object for the contents of *right*.

[basic_ostream Class](#)

[Thread Safety in the C++ Standard Library](#)

[iostream Programming](#)

[iostreams Conventions](#)

<functional>

2/28/2019 • 10 minutes to read • [Edit Online](#)

Defines C++ Standard Library functions that help construct *function objects*, also known as *functors*, and their binders. A function object is an object of a type that defines `operator()`. A function object can be a function pointer, but more typically, the object is used to store additional information that can be accessed during a function call.

Syntax

```
#include <functional>
```

Remarks

Algorithms require two types of function objects: *unary* and *binary*. Unary function objects require one argument, and binary function objects require two arguments. A function object and function pointers can be passed as a predicate to an algorithm, but function objects are also adaptable and increase the scope, flexibility, and efficiency of the C++ Standard Library. If, for example, a value needed to be bound to a function before being passed to an algorithm, then a function pointer could not be used. Function adaptors convert function pointers into adaptable function objects that can be bound to a value. The header `<functional>` also contains member function adaptors that allow member functions to be called as adaptable function objects. Functions are adaptable if they have nested type declarations specifying their argument and return types. Function objects and their adaptors allow the C++ Standard Library to upgrade existing applications and help integrate the library into the C++ programming environment.

The implementation of the function objects in `<functional>` includes *transparent operator functors*, which are specializations of standard function objects and take no template parameters, and perform perfect forwarding of the function arguments and perfect return of the result. These template specializations do not require that you specify argument types when you invoke arithmetic, comparison, logical, and bitwise operator functors. You can overload arithmetic, comparison, logical, or bitwise operators for your own types, or for heterogeneous combinations of types, and then use the transparent operator functors as function arguments. For example, if your type *MyType* implements `operator<`, you can call

```
sort(my_collection.begin(), my_collection.end(), less<>()) instead of explicitly specifying the type  
sort(my_collection.begin(), my_collection.end(), less<MyType>()).
```

The following features are added in C++11, C++14 and C++17:

- A *call signature* is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.
- A *callable type* is a pointer to function, a pointer to member function, a pointer to member data, or a class type whose objects can appear immediately to the left of a function call operator.
- A *callable object* is an object of a callable type.
- A *call wrapper type* is a type that holds a callable object and supports a call operation that forwards to that object.
- A *call wrapper* is an object of a call wrapper type.
- A *target object* is the callable object held by a call wrapper object.

The pseudo-function `INVOKE(f, t1, t2, ..., tN)` means one of the following things:

- `(t1.*f)(t2, ..., tN)` when `f` is a pointer to member function of class `T` and `t1` is an object of type `T` or a reference to an object of type `T` or a reference to an object of a type derived from `T`.
- `((*t1).*f)(t2, ..., tN)` when `f` is a pointer to member function of class `T` and `t1` is not one of the types described in the previous item.
- `t1.*f` when `N == 1` and `f` is a pointer to member data of a class `T` and `t1` is an object of type `T` or a reference to an object of type `T` or a reference to an object of a type derived from `T`.
- `(*t1).*f` when `N == 1` and `f` is a pointer to member data of a class `T` and `t1` is not one of the types described in the previous item.
- `f(t1, t2, ..., tN)` in all other cases.

The pseudo-function `INVOKE(f, t1, t2, ..., tN, R)` means `INVOKE(f, t1, t2, ..., tN)` implicitly converted to `R`.

If a call wrapper has a *weak result type*, the type of its member type `result_type` is based on the type `T` of the target object of the wrapper, as follows:

- If `T` is a pointer to function, `result_type` is a synonym for the return type of `T`.
- If `T` is a pointer to member function, `result_type` is a synonym for the return type of `T`.
- If `T` is a class type that has a member type `result_type`, then `result_type` is a synonym for `T::result_type`.
- Otherwise, there is no member `result_type`.

Every call wrapper has a move constructor and a copy constructor. A *simple call wrapper* is a call wrapper that has an assignment operator and whose copy constructor, move constructor, and assignment operator do not throw exceptions. A *forwarding call wrapper* is a call wrapper that can be called by using an arbitrary argument list and that delivers the arguments to the wrapped callable object as references. All rvalue arguments are delivered as rvalue references, and lvalue arguments are delivered as lvalue references.

Classes

CLASS	DESCRIPTION
bad_function_call	A class that describes an exception thrown to indicate that a call to <code>operator()</code> on a function object failed because the object was empty.
binary_negate	A template class providing a member function that negates the return value of a specified binary function. (Deprecated in C++17.)
binder1st	A template class providing a constructor that converts a binary function object into a unary function object by binding the first argument of the binary function to a specified value. (Deprecated in C++11, removed in C++17.)

CLASS	DESCRIPTION
binder2nd	A template class providing a constructor that converts a binary function object into a unary function object by binding the second argument of the binary function to a specified value. (Deprecated in C++11, removed in C++17.)
const_mem_fun_ref_t	An adapter class that allows a const member function that takes no arguments to be called as a unary function object when initialized with a reference argument. (Deprecated in C++11, removed in C++17.)
const_mem_fun_t	An adapter class that allows a const member function that takes no arguments to be called as a unary function object when initialized with a pointer argument. (Deprecated in C++11, removed in C++17.)
const_mem_fun1_ref_t	An adapter class that allows a const member function that takes a single argument to be called as a binary function object when initialized with a reference argument. (Deprecated in C++11, removed in C++17.)
const_mem_fun1_t	An adapter class that allows a const member function that takes a single argument to be called as a binary function object when initialized with a pointer argument. (Deprecated in C++11, removed in C++17.)
function	A class that wraps a callable object.
hash	A class that computes a hash code for a value.
is_bind_expression	A class that tests if a particular type is generated by calling <code>bind</code> .
is_placeholder	A class that tests if a particular type is a placeholder.
mem_fun_ref_t	An adapter class that allows a <code>non_const</code> member function that takes no arguments to be called as a unary function object when initialized with a reference argument. (Deprecated in C++11, removed in C++17.)
mem_fun_t	An adapter class that allows a <code>non_const</code> member function that takes no arguments to be called as a unary function object when initialized with a pointer argument. (Deprecated in C++11, removed in C++17.)
mem_fun1_ref_t	An adapter class that allows a <code>non_const</code> member function that takes a single argument to be called as a binary function object when initialized with a reference argument. (Deprecated in C++11, removed in C++17.)
mem_fun1_t	An adapter class that allows a <code>non_const</code> member function that takes a single argument to be called as a binary function object when initialized with a pointer argument. (Deprecated in C++11, removed in C++17.)

CLASS	DESCRIPTION
pointer_to_binary_function	Converts a binary function pointer into an adaptable binary function. (Deprecated in C++11, removed in C++17.)
pointer_to_unary_function	Converts a unary function pointer into an adaptable unary function. (Deprecated in C++11, removed in C++17.)
reference_wrapper	A class that wraps a reference.
unary_negate	A template class providing a member function that negates the return value of a specified unary function. (Deprecated in C++17.)

Functions

FUNCTION	DESCRIPTION
bind	Binds arguments to a callable object.
bind1st	A helper template function that creates an adaptor to convert a binary function object into a unary function object by binding the first argument of the binary function to a specified value. (Deprecated in C++11, removed in C++17.)
bind2nd	A helper template function that creates an adaptor to convert a binary function object into a unary function object by binding the second argument of the binary function to a specified value. (Deprecated in C++11, removed in C++17.)
bit_and	Returns the bitwise logical AND (binary operator&) of the two parameters.
bit_not	Returns the bitwise logical complement (operator~) of the parameter. (Added in C++14.)
bit_or	Returns the bitwise logical OR (operator) of the two parameters.
bit_xor	Returns the bitwise logical XOR (operator^) of the two parameters.
cref	Constructs a const <code>reference_wrapper</code> from an argument.
mem_fn	Generates a simple call wrapper.
mem_fun	Helper template functions used to construct function object adaptors for member functions when initialized with pointer arguments. (Deprecated in C++11, removed in C++17.)

FUNCTION	DESCRIPTION
mem_fun_ref	A helper template function used to construct function object adaptors for member functions when initialized with reference arguments.
not1	Returns the complement of a unary predicate. (Deprecated in C++17.)
not2	Returns the complement of a binary predicate. (Deprecated in C++17.)
not_fn	Returns the complement of the result of its function object. (Added in C++17.)
ptr_fun	A helper template function used to convert unary and binary function pointers, respectively, into unary and binary adaptable functions. (Deprecated in C++11, removed in C++17.)
ref	Constructs a <code>reference_wrapper</code> from an argument.
swap	Swaps two <code>function</code> objects.

Structs

STRUCT	DESCRIPTION
binary_function	An empty base class that defines types that may be inherited by derived class that provides a binary function object. (Deprecated in C++11, removed in C++17.)
divides	The class provides a predefined function object that performs the arithmetic operation of division on elements of a specified value type.
equal_to	A binary predicate that tests whether a value of a specified type is equal to another value of that type.
greater	A binary predicate that tests whether a value of a specified type is greater than another value of that type.
greater_equal	A binary predicate that tests whether a value of a specified type is greater than or equal to another value of that type.
less	A binary predicate that tests whether a value of a specified type is less than another value of that type.
less_equal	A binary predicate that tests whether a value of a specified type is less than or equal to another value of that type.
logical_and	The class provides a predefined function object that performs the logical operation of conjunction on elements of a specified value type and tests for the truth or falsity of the result.

STRUCT	DESCRIPTION
logical_not	The class provides a predefined function object that performs the logical operation of negation on elements of a specified value type and tests for the truth or falsity of the result.
logical_or	The class provides a predefined function object that performs the logical operation of disjunction on elements of a specified value type and tests for the truth or falsity of the result.
minus	The class provides a predefined function object that performs the arithmetic operation of subtraction on elements of a specified value type.
modulus	The class provides a predefined function object that performs the arithmetic operation of modulus on elements of a specified value type.
multiplies	The class provides a predefined function object that performs the arithmetic operation of multiplication on elements of a specified value type.
negate	The class provides a predefined function object that returns the negative of an element value.
not_equal_to	A binary predicate that tests whether a value of a specified type is not equal to another value of that type.
plus	The class provides a predefined function object that performs the arithmetic operation of addition on elements of a specified value type.
unary_function	An empty base class that defines types that may be inherited by derived class that provides a unary function object. (Deprecated in C++11, removed in C++17.)

Objects

OBJECT	DESCRIPTION
_1.._M	Placeholders for replaceable arguments.

Operators

OPERATOR	DESCRIPTION
operator==	Disallows equality comparison of callable objects.
operator!=	Disallows inequality comparison of callable objects.

<functional> functions

3/4/2019 • 27 minutes to read • [Edit Online](#)

bind	bit_and	bit_not
bit_or	bit_xor	cref
invoke	mem_fn	not_fn
ref	swap	

These functions are deprecated in C++11 and removed in C++17:

bind1st	bind2nd	mem_fun
mem_fun_ref	ptr_fun	

These functions are deprecated in C++17:

not1	not2

bind

Binds arguments to a callable object.

```
template <class FT, class T1, class T2, ..., class TN>
unspecified bind(FT fn, T1 t1, T2 t2, ..., TN tN);

template <class RTy, class FT, class T1, class T2, ..., class TN>
unspecified bind(FT fn, T1 t1, T2 t2, ..., TN tN);
```

Parameters

Fy

The type of the object to call.

TN

The type of the Nth call argument.

fn

The object to call.

tN

The Nth call argument.

Remarks

The types `FT, T1, T2, ..., TN` must be copy-constructible, and `INVOKE(fn, t1, ..., tN)` must be a valid

expression for some values `w1, w2, ..., wN`.

The first template function returns a forwarding call wrapper `g` with a weak result type. The effect of `g(u1, u2, ..., uM)` is `INVOKE(f, v1, v2, ..., vN, invoke_result<FT cv (V1, V2, ..., VN)>::type)`, where `cv` is the cv-qualifiers of `g` and the values and types of the bound arguments `v1, v2, ..., vN` are determined as specified below. You use it to bind arguments to a callable object to make a callable object with a tailored argument list.

The second template function returns a forwarding call wrapper `g` with a nested type `result_type` that is a synonym for `RTy`. The effect of `g(u1, u2, ..., uM)` is `INVOKE(f, v1, v2, ..., vN, RTy)`, where `cv` is the cv-qualifiers of `g` and the values and types of the bound arguments `v1, v2, ..., vN` are determined as specified below. You use it to bind arguments to a callable object to make a callable object with a tailored argument list and with a specified return type.

The values of the bound arguments `v1, v2, ..., vN` and their corresponding types `V1, V2, ..., VN` depend on the type of the corresponding argument `ti` of type `Ti` in the call to `bind` and the cv-qualifiers `cv` of the call wrapper `g` as follows:

if `ti` is of type `reference_wrapper<T>` the argument `vi` is `ti.get()` and its type `Vi` is `T&`;

if the value of `std::is_bind_expression<Ti>::value` is **true** the argument `vi` is `ti(u1, u2, ..., uM)` and its type `Vi` is `result_of<Ti cv (U1&, U2&, ..., UN&)>::type`;

if the value `j` of `std::is_placeholder<Ti>::value` isn't zero the argument `vi` is `uj` and its type `Vi` is `Uj&`;

otherwise the argument `vi` is `ti` and its type `Vi` is `Ti cv &`.

For example, given a function `f(int, int)` the expression `bind(f, _1, 0)` returns a forwarding call wrapper `cw` such that `cw(x)` calls `f(x, 0)`. The expression `bind(f, 0, _1)` returns a forwarding call wrapper `cw` such that `cw(x)` calls `f(0, x)`.

The number of arguments in a call to `bind` and the argument `fn` must be equal to the number of arguments that can be passed to the callable object `fn`. For example, `bind(cos, 1.0)` is correct, and both `bind(cos)` and `bind(cos, _1, 0.0)` are incorrect.

The number of arguments in the function call to the call wrapper returned by `bind` must be at least as large as the highest numbered value of `is_placeholder<PH>::value` for all of the placeholder arguments in the call to `bind`. For example, `bind(cos, _2)(0.0, 1.0)` is correct (and returns `cos(1.0)`), and `bind(cos, _2)(0.0)` is incorrect.

Example

```

// std_functional_bind.cpp
// compile with: /EHsc
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std::placeholders;

void square(double x)
{
    std::cout << x << "^2 == " << x * x << std::endl;
}

void product(double x, double y)
{
    std::cout << x << "*" << y << " == " << x * y << std::endl;
}

int main()
{
    double arg[] = { 1, 2, 3 };

    std::for_each(&arg[0], arg + 3, square);
    std::cout << std::endl;

    std::for_each(&arg[0], arg + 3, std::bind(product, _1, 2));
    std::cout << std::endl;

    std::for_each(&arg[0], arg + 3, std::bind(square, _1));

    return (0);
}

```

```

1^2 == 1
2^2 == 4
3^2 == 9

1*2 == 2
2*2 == 4
3*2 == 6

1^2 == 1
2^2 == 4
3^2 == 9

```

bind1st

A helper template function that creates an adaptor to convert a binary function object into a unary function object. It binds the first argument of the binary function to a specified value. Deprecated in C++11, removed in C++17.

```

template <class Operation, class Type>
binder1st <Operation> bind1st (const Operation& func, const Type& left);

```

Parameters

func

The binary function object to be converted to a unary function object.

left

The value to which the first argument of the binary function object is to be bound.

Return Value

The unary function object that results from binding the first argument of the binary function object to the value *left*.

Remarks

Function binders are a kind of function adaptor. Because they return function objects, they can be used in certain types of function composition to construct more complicated and powerful expressions.

If *func* is an object of type `Operation` and `c` is a constant, then `bind1st(func, c)` is the same as the [binder1st](#) class constructor `binder1st<Operation>(func, c)`, and is more convenient to use.

Example

```

// functional_bind1st.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

// Creation of a user-defined function object
// that inherits from the unary_function base class
class greaterthan5: unary_function<int, bool>
{
public:
    result_type operator()(argument_type i)
    {
        return (result_type)(i > 5);
    }
};

int main()
{
    vector<int> v1;
    vector<int>::iterator Iter;

    int i;
    for (i = 0; i <= 5; i++)
    {
        v1.push_back(5 * i);
    }

    cout << "The vector v1 = ( " ;
    for (Iter = v1.begin(); Iter != v1.end(); Iter++)
        cout << *Iter << " ";
    cout << ")" << endl;

    // Count the number of integers > 10 in the vector
    vector<int>::iterator::difference_type result1a;
    result1a = count_if(v1.begin(), v1.end(), bind1st(less<int>(), 10));
    cout << "The number of elements in v1 greater than 10 is: "
        << result1a << "." << endl;

    // Compare: counting the number of integers > 5 in the vector
    // with a user defined function object
    vector<int>::iterator::difference_type result1b;
    result1b = count_if(v1.begin(), v1.end(), greaterthan5());
    cout << "The number of elements in v1 greater than 5 is: "
        << result1b << "." << endl;

    // Count the number of integers < 10 in the vector
    vector<int>::iterator::difference_type result2;
    result2 = count_if(v1.begin(), v1.end(), bind2nd(less<int>(), 10));
    cout << "The number of elements in v1 less than 10 is: "
        << result2 << "." << endl;
}

```

```

The vector v1 = ( 0 5 10 15 20 25 )
The number of elements in v1 greater than 10 is: 3.
The number of elements in v1 greater than 5 is: 4.
The number of elements in v1 less than 10 is: 2.

```

bind2nd

A helper template function that creates an adaptor to convert a binary function object into a unary function object.

It binds the second argument of the binary function to a specified value. Deprecated in C++11, removed in C++17.

```
template <class Operation, class Type>
binder2nd <Operation> bind2nd(const Operation& func, const Type& right);
```

Parameters

func

The binary function object to be converted to a unary function object.

right

The value to which the second argument of the binary function object is to be bound.

Return Value

The unary function object result of binding the second argument of the binary function object to *right*.

Remarks

Function binders are a kind of function adaptor. Because they return function objects, they can be used in certain types of function composition to construct more complicated and powerful expressions.

If *func* is an object of type `Operation` and `c` is a constant, then `bind2nd(func, c)` is the same as the [binder2nd](#) class constructor `binder2nd<Operation>(func, c)`, and more convenient to use.

Example

```

// functional_bind2nd.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

// Creation of a user-defined function object
// that inherits from the unary_function base class
class greaterthan15: unary_function<int, bool>
{
public:
    result_type operator()(argument_type i)
    {
        return (result_type)(i > 15);
    }
};

int main()
{
    vector<int> v1;
    vector<int>::iterator Iter;

    int i;
    for (i = 0; i <= 5; i++)
    {
        v1.push_back(5 * i);
    }

    cout << "The vector v1 = ( ";
    for (Iter = v1.begin(); Iter != v1.end(); Iter++)
        cout << *Iter << " ";
    cout << ")" << endl;

    // Count the number of integers > 10 in the vector
    vector<int>::iterator::difference_type result1a;
    result1a = count_if(v1.begin(), v1.end(), bind2nd(greater<int>(), 10));
    cout << "The number of elements in v1 greater than 10 is: "
        << result1a << "." << endl;

    // Compare counting the number of integers > 15 in the vector
    // with a user-defined function object
    vector<int>::iterator::difference_type result1b;
    result1b = count_if(v1.begin(), v1.end(), greaterthan15());
    cout << "The number of elements in v1 greater than 15 is: "
        << result1b << "." << endl;

    // Count the number of integers < 10 in the vector
    vector<int>::iterator::difference_type result2;
    result2 = count_if(v1.begin(), v1.end(), bind1st(greater<int>(), 10));
    cout << "The number of elements in v1 less than 10 is: "
        << result2 << "." << endl;
}

```

```

The vector v1 = ( 0 5 10 15 20 25 )
The number of elements in v1 greater than 10 is: 3.
The number of elements in v1 greater than 15 is: 2.
The number of elements in v1 less than 10 is: 2.

```

A predefined function object that does a bitwise AND operation (binary `operator&`) on its arguments.

```
template <class Type = void>
struct bit_and : public binary_function<Type, Type, Type> {
    Type operator()(
        const Type& Left,
        const Type& Right) const;
};

// specialized transparent functor for operator&
template <>
struct bit_and<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const ->
        decltype(std::forward<T>(Left) & std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator&` that takes operands of the specified or inferred types.

Left

The left operand of the bitwise AND operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the bitwise AND operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left & Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator&`.

Remarks

The `bit_and` functor is restricted to integral types for the basic data types, or to user-defined types that implement binary `operator&`.

bit_not

A predefined function object that does a bitwise complement (NOT) operation (unary `operator~`) on its argument. Added in C++14.

```
template <class Type = void>
struct bit_not : public unary_function<Type, Type>
{
    Type operator()(const Type& Right) const;
};

// specialized transparent functor for operator~
template <>
struct bit_not<void>
{
    template <class Type>
    auto operator()(Type&& Right) const -> decltype(~std::forward<Type>(Right));
};
```

Parameters

Type

A type that supports a unary `operator~`.

Right

The operand of the bitwise complement operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of an lvalue or rvalue reference argument of inferred type *Type*.

Return Value

The result of `~ Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator~`.

Remarks

The `bit_not` functor is restricted to integral types for the basic data types, or to user-defined types that implement binary `operator~`.

bit_or

A predefined function object that does a bitwise OR operation (`operator|`) on its arguments.

```
template <class Type = void>
struct bit_or : public binary_function<Type, Type, Type> {
    Type operator()(
        const Type& Left,
        const Type& Right) const;
};

// specialized transparent functor for operator|
template <>
struct bit_or<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const
        -> decltype(std::forward<T>(Left) | std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator|` that takes operands of the specified or inferred types.

Left

The left operand of the bitwise OR operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the bitwise OR operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left | Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator|`.

Remarks

The `bit_or` functor is restricted to integral types for the basic data types, or to user-defined types that implement

operator| .

bit_xor

A predefined function object that does a bitwise XOR operation (binary `operator^`) on its arguments.

```
template <class Type = void>
struct bit_xor : public binary_function<Type, Type, Type> {
    Type operator()(
        const Type& Left,
        const Type& Right) const;
};

// specialized transparent functor for operator^
template <>
struct bit_xor<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const
        -> decltype(std::forward<T>(Left) ^ std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator^` that takes operands of the specified or inferred types.

Left

The left operand of the bitwise XOR operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the bitwise XOR operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left ^ Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator^`.

Remarks

The `bit_xor` functor is restricted to integral types for the basic data types, or to user-defined types that implement binary `operator^`.

cref

Constructs a const `reference_wrapper` from an argument.

```
template <class Ty>
reference_wrapper<const Ty> cref(const Ty& arg);

template <class Ty>
reference_wrapper<const Ty> cref(const reference_wrapper<Ty>& arg);
```

Parameters

Ty

The type of the argument to wrap.

arg

The argument to wrap.

Remarks

The first function returns `reference_wrapper<const Ty>(arg.get())`. You use it to wrap a const reference. The second function returns `reference_wrapper<const Ty>(arg)`. You use it to rewrap a wrapped reference as a const reference.

Example

```
// std__functional__cref.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    int i = 1;

    std::cout << "i = " << i << std::endl;
    std::cout << "cref(i) = " << std::cref(i) << std::endl;
    std::cout << "cref(neg)(i) = "
        << std::cref(neg)(i) << std::endl;

    return (0);
}
```

```
i = 1
cref(i) = 1
cref(neg)(i) = -1
```

invoke

Invokes any callable object with the given arguments. Added in C++17.

```
template <class Callable, class... Args>
invoke_result_t<Callable, Args...>
    invoke(Callable&& fn, Args&&... args) noexcept(/* specification */);
```

Parameters

Callable

The type of the object to call.

Args

The types of the call arguments.

fn

The object to call.

args

The call arguments.

specification

The **noexcept** specification `std::is_nothrow_invocable_v<Callable, Args>`.

Remarks

Invokes the callable object *fn* using the parameters *args*. Effectively,

`INVOKE(std::forward<Callable>(fn), std::forward<Args>(args)...) ,` where the pseudo-function

`INVOKE(f, t1, t2, ..., tN)` means one of the following things:

- `(t1.*f)(t2, ..., tN)` when `f` is a pointer to member function of class `T` and `t1` is an object of type `T` or a reference to an object of type `T` or a reference to an object of a type derived from `T`. That is, when `std::is_base_of<T, std::decay_t<decltype(t1)>>::value` is true.
- `(t1.get().*f)(t2, ..., tN)` when `f` is a pointer to member function of class `T` and `std::decay_t<decltype(t1)>` is a specialization of `std::reference_wrapper`.
- `((*t1).*f)(t2, ..., tN)` when `f` is a pointer to member function of class `T` and `t1` isn't one of the previous types.
- `t1.*f` when `N == 1` and `f` is a pointer to member data of a class `T` and `t1` is an object of type `T` or a reference to an object of type `T` or a reference to an object of a type derived from `T`. That is, when `std::is_base_of<T, std::decay_t<decltype(t1)>>::value` is true.
- `t1.get().*f` when `N == 1` and `f` is a pointer to member data of a class `T` and `std::decay_t<decltype(t1)>` is a specialization of `std::reference_wrapper`.
- `(*t1).*f` when `N == 1` and `f` is a pointer to member data of a class `T` and `t1` isn't one of the previous types.
- `f(t1, t2, ..., tN)` in all other cases.

For information on the result type of a callable object, see [invoke_result](#). For predicates on callable types, see [is_invocable](#), [is_invocable_r](#), [is_nothrow_invocable](#), [is_nothrow_invocable_r](#) classes.

Example

```

// functional_invoke.cpp
// compile using: cl /EHsc /std:c++17 functional_invoke.cpp
#include <functional>
#include <iostream>

struct Demo
{
    int n_;

    Demo(int const n) : n_{n} {}

    void operator()( int const i, int const j ) const
    {
        std::cout << "Demo operator( " << i << ", "
                    << j << " ) is " << i * j << "\n";
    }

    void difference( int const i ) const
    {
        std::cout << "Demo.difference( " << i << " ) is "
                    << n_ - i << "\n";
    }
};

void divisible_by_3(int const i)
{
    std::cout << i << ( i % 3 == 0 ? " is" : " isn't" )
                << " divisible by 3.\n";
}

int main()
{
    Demo d{ 42 };
    Demo * pd{ &d };
    auto pmf = &Demo::difference;
    auto pmd = &Demo::n_;

    // Invoke a function object, like calling d( 3, -7 )
    std::invoke( d, 3, -7 );

    // Invoke a member function, like calling
    // d.difference( 29 ) or (d.*pmf)( 29 )
    std::invoke( &Demo::difference, d, 29 );
    std::invoke( pmf, pd, 13 );

    // Invoke a data member, like access to d.n_ or d.*pmd
    std::cout << "d.n_: " << std::invoke( &Demo::n_, d ) << "\n";
    std::cout << "pd->n_: " << std::invoke( pmd, pd ) << "\n";

    // Invoke a stand-alone (free) function
    std::invoke( divisible_by_3, 42 );

    // Invoke a lambda
    auto divisible_by_7 = [] ( int const i ) {
        std::cout << i << ( i % 7 == 0 ? " is" : " isn't" )
                    << " divisible by 7.\n";
    };
    std::invoke( divisible_by_7, 42 );
}

```

```
Demo operator( 3, -7 ) is -21
Demo.difference( 29 ) is 13
Demo.difference( 13 ) is 29
d.n_: 42
pd->n_: 42
42 is divisible by 3.
42 is divisible by 7.
```

mem_fn

Generates a simple call wrapper.

```
template <class RTy, class Ty>
unspecified mem_fn(RTy Ty::*pm);
```

Parameters

RTy

The return type of the wrapped function.

Ty

The type of the member function pointer.

Remarks

The template function returns a simple call wrapper `cw`, with a weak result type, such that the expression `cw(t, a2, ..., aN)` is the same as `INVOKE(pm, t, a2, ..., aN)`. It doesn't throw any exceptions.

The returned call wrapper is derived from `std::unary_function<cv Ty*, RTy>` (and defining the nested type `result_type` as a synonym for `RTy` and the nested type `argument_type` as a synonym for `cv Ty*`) only if the type `Ty` is a pointer to member function with cv-qualifier `cv` that takes no arguments.

The returned call wrapper is derived from `std::binary_function<cv Ty*, T2, RTy>` (and defining the nested type `result_type` as a synonym for `RTy`, the nested type `first argument_type` as a synonym for `cv Ty*`, and the nested type `second argument_type` as a synonym for `T2`) only if the type `Ty` is a pointer to member function with cv-qualifier `cv` that takes one argument, of type `T2`.

Example

```

// std_functional_mem_fn.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

class Funs
{
public:
    void square(double x)
    {
        std::cout << x << "^2 == " << x * x << std::endl;
    }

    void product(double x, double y)
    {
        std::cout << x << "*" << y << " == " << x * y << std::endl;
    }
};

int main()
{
    Funs funs;

    std::mem_fn(&Funs::square)(funs, 3.0);
    std::mem_fn(&Funs::product)(funs, 3.0, 2.0);

    return (0);
}

```

```

3^2 == 9
3*2 == 6

```

mem_fun

Helper template functions used to construct function object adaptors for member functions when initialized with pointer arguments. Deprecated in C++11 for [mem_fn](#) and [bind](#), and removed in C++17.

```

template <class Result, class Type>
mem_fun_t<Result, Type> mem_fun (Result(Type::* pMem)());

template <class Result, class Type, class Arg>
mem_fun1_t<Result, Type, Arg> mem_fun(Result (Type::* pMem)(Arg));

template <class Result, class Type>
const_mem_fun_t<Result, Type> mem_fun(Result (Type::* pMem)() const);

template <class Result, class Type, class Arg>
const_mem_fun1_t<Result, Type, Arg> mem_fun(Result (Type::* pMem)(Arg) const);

```

Parameters

pMem

A pointer to the member function of class `Type` to be converted to a function object.

Return Value

A **const** or **non_const** function object of type `mem_fun_t` or `mem_fun1_t`.

Example

```

// functional_mem_fun.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

class StoreVals
{
    int val;
public:
    StoreVals() { val = 0; }
    StoreVals(int j) { val = j; }

    bool display() { cout << val << " "; return true; }
    int squareval() { val *= val; return val; }
    int lessconst(int k) {val -= k; return val; }
};

int main( )
{
    vector<StoreVals *> v1;

    StoreVals sv1(5);
    v1.push_back(&sv1);
    StoreVals sv2(10);
    v1.push_back(&sv2);
    StoreVals sv3(15);
    v1.push_back(&sv3);
    StoreVals sv4(20);
    v1.push_back(&sv4);
    StoreVals sv5(25);
    v1.push_back(&sv5);

    cout << "The original values stored are: " ;
    for_each(v1.begin(), v1.end(), mem_fun<bool, StoreVals>(&StoreVals::display));
    cout << endl;

    // Use of mem_fun calling member function through a pointer
    // square each value in the vector using squareval ()
    for_each(v1.begin(), v1.end(), mem_fun<int, StoreVals>(&StoreVals::squareval));
    cout << "The squared values are: " ;
    for_each(v1.begin(), v1.end(), mem_fun<bool, StoreVals>(&StoreVals::display));
    cout << endl;

    // Use of mem_fun1 calling member function through a pointer
    // subtract 5 from each value in the vector using lessconst ()
    for_each(v1.begin(), v1.end(),
        bind2nd (mem_fun1<int, StoreVals,int>(&StoreVals::lessconst), 5));
    cout << "The squared values less 5 are: " ;
    for_each(v1.begin(), v1.end(), mem_fun<bool, StoreVals>(&StoreVals::display));
    cout << endl;
}

```

mem_fun_ref

Helper template functions used to construct function object adaptors for member functions when initialized by using reference arguments. Deprecated in C++11, removed in C++17.

```

template <class Result, class Type>
mem_fun_ref_t<Result, Type> mem_fun_ref(Result (Type::* pMem)());

template <class Result, class Type, class Arg>
mem_fun1_ref_t<Result, Type, Arg> mem_fun_ref(Result (Type::* pMem)(Arg));

template <class Result, class Type>
const_mem_fun_ref_t<Result, Type> mem_fun_ref(Result Type::* pMem]() const);

template <class Result, class Type, class Arg>
const_mem_fun1_ref_t<Result, Type, Arg> mem_fun_ref(Result (T::* pMem)(Arg) const);

```

Parameters

pMem

A pointer to the member function of class `Type` to be converted to a function object.

Return Value

A **const** or `non_const` function object of type `mem_fun_ref_t` or `mem_fun1_ref_t`.

Example

```

// functional_mem_fun_ref.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

class NumVals
{
    int val;
public:
    NumVals ( ) { val = 0; }
    NumVals ( int j ) { val = j; }

    bool display ( ) { cout << val << " "; return true; }
    bool isEven ( ) { return ( bool ) !( val %2 ); }
    bool isPrime( )
    {
        if (val < 2) { return true; }
        for (int i = 2; i <= val / i; ++i)
        {
            if (val % i == 0) { return false; }
        }
        return true;
    }
};

int main( )
{
    vector <NumVals> v1 ( 13 ), v2 ( 13 );
    vector <NumVals>::iterator v1_Iter, v2_Iter;
    int i, k;

    for ( i = 0; i < 13; i++ ) v1 [ i ] = NumVals ( i+1 );
    for ( k = 0; k < 13; k++ ) v2 [ k ] = NumVals ( k+1 );

    cout << "The original values stored in v1 are: " ;
    for_each( v1.begin( ), v1.end( ),
        mem_fun_ref ( &NumVals::display ) );
    cout << endl;

    // Use of mem_fun_ref calling member function through a reference
    // remove the primes in the vector using isPrime ( )
    v1_Iter = remove_if ( v1.begin( ), v1.end( ),
        mem_fun_ref ( &NumVals::isPrime ) );
    cout << "With the primes removed, the remaining values in v1 are: " ;
    for_each( v1.begin( ), v1_Iter,
        mem_fun_ref ( &NumVals::display ) );
    cout << endl;

    cout << "The original values stored in v2 are: " ;
    for_each( v2.begin( ), v2.end( ),
        mem_fun_ref ( &NumVals::display ) );
    cout << endl;

    // Use of mem_fun_ref calling member function through a reference
    // remove the even numbers in the vector v2 using isEven ( )
    v2_Iter = remove_if ( v2.begin( ), v2.end( ),
        mem_fun_ref ( &NumVals::isEven ) );
    cout << "With the even numbers removed, the remaining values are: " ;
    for_each( v2.begin( ), v2_Iter,
        mem_fun_ref ( &NumVals::display ) );
    cout << endl;
}

```

```
The original values stored in v1 are: 1 2 3 4 5 6 7 8 9 10 11 12 13
With the primes removed, the remaining values in v1 are: 4 6 8 9 10 12
The original values stored in v2 are: 1 2 3 4 5 6 7 8 9 10 11 12 13
With the even numbers removed, the remaining values are: 1 3 5 7 9 11 13
```

not1

Returns the complement of a unary predicate. Deprecated for [not_fn](#) in C++17.

```
template <class UnaryPredicate>
unary_negate<UnaryPredicate> not1(const UnaryPredicate& predicate);
```

Parameters

predicate

The unary predicate to be negated.

Return Value

A unary predicate that is the negation of the unary predicate modified.

Remarks

If a `unary_negate` is constructed from a unary predicate `predicate(x)`, then it returns `!predicate(x)`.

Example

```

// functional_not1.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main()
{
    vector<int> v1;
    vector<int>::iterator Iter;

    int i;
    for (i = 0; i <= 7; i++)
    {
        v1.push_back(5 * i);
    }

    cout << "The vector v1 = ( ";
    for (Iter = v1.begin(); Iter != v1.end(); Iter++)
        cout << *Iter << " ";
    cout << ")" << endl;

    vector<int>::iterator::difference_type result1;
    // Count the elements greater than 10
    result1 = count_if(v1.begin(), v1.end(), bind2nd(greater<int>(), 10));
    cout << "The number of elements in v1 greater than 10 is: "
        << result1 << "." << endl;

    vector<int>::iterator::difference_type result2;
    // Use the negator to count the elements less than or equal to 10
    result2 = count_if(v1.begin(), v1.end(),
        not1(bind2nd(greater<int>(), 10)));

    cout << "The number of elements in v1 not greater than 10 is: "
        << result2 << "." << endl;
}

```

```

The vector v1 = ( 0 5 10 15 20 25 30 35 )
The number of elements in v1 greater than 10 is: 5.
The number of elements in v1 not greater than 10 is: 3.

```

not2

Returns the complement of a binary predicate. Deprecated for [not_fn](#) in C++17.

```

template <class BinaryPredicate>
binary_negate<BinaryPredicate> not2(const BinaryPredicate& func);

```

Parameters

func

The binary predicate to be negated.

Return Value

A binary predicate that is the negation of the binary predicate modified.

Remarks

If a `binary_negate` is constructed from a binary predicate `binary_predicate(x, y)`, then it returns `!binary_predicate(x, y)`.

Example

```
// functional_not2.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <cstdlib>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1;

    int i;
    v1.push_back( 6262 );
    v1.push_back( 6262 );
    for ( i = 0 ; i < 5 ; i++ )
    {
        v1.push_back( rand( ) );
    }

    cout << "Original vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in ascending order,
    // use default binary predicate less<int>( )
    sort( v1.begin( ), v1.end( ) );
    cout << "Sorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in descending order,
    // use the binary_negate helper function not2
    sort( v1.begin( ), v1.end( ), not2(less<int>( ) ) );
    cout << "Resorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
}
```

```
Original vector v1 = ( 6262 6262 41 18467 6334 26500 19169 )
Sorted vector v1 = ( 41 6262 6262 6334 18467 19169 26500 )
Resorted vector v1 = ( 26500 19169 18467 6334 6262 6262 41 )
```

not_fn

The `not_fn` function template takes a callable object and returns a callable object. When the returned callable object is later invoked with some arguments, it passes them to the original callable object, and logically negates the result. It preserves the const qualification and value category behavior of the wrapped callable object. `not_fn` is new in C++17, and replaces the deprecated `std::not1`, `std::not2`, `std::unary_negate`, and `std::binary_negate`.

```
template <class Callable>
/* unspecified */ not_fn(Callable&& func);
```

Parameters

func

A callable object used to construct the forwarding call wrapper.

Remarks

The template function returns a call wrapper like `return call_wrapper(std::forward<Callable>(func))`, based on this exposition-only class:

```
class call_wrapper
{
    using FD = decay_t<Callable>;
    explicit call_wrapper(Callable&& func);

public:
    call_wrapper(call_wrapper&&) = default;
    call_wrapper(call_wrapper const&) = default;

    template<class... Args>
        auto operator()(Args&&...) & -> decltype(!declval<invoke_result_t<FD&(Args...)>>());

    template<class... Args>
        auto operator()(Args&&...) const& -> decltype(!declval<invoke_result_t<FD const&(Args...)>>());

    template<class... Args>
        auto operator()(Args&&...) && -> decltype(!declval<invoke_result_t<FD(Args...)>>());

    template<class... Args>
        auto operator()(Args&&...) const&& -> decltype(!declval<invoke_result_t<FD const(Args...)>>());

private:
    FD fd;
};
```

The explicit constructor on the callable object *func* requires type `std::decay_t<Callable>` to satisfy the requirements of `MoveConstructible`, and `is_constructible_v<FD, Callable>` must be true. It initializes the wrapped callable object `fd` from `std::forward<Callable>(func)`, and throws any exception thrown by construction of `fd`.

The wrapper exposes call operators distinguished by lvalue or rvalue reference category and const qualification as shown here:

```
template<class... Args> auto operator()(Args&&... args) & -> decltype(!declval<invoke_result_t<FD&(Args...)>>());
template<class... Args> auto operator()(Args&&... args) const& -> decltype(!declval<invoke_result_t<FD const&(Args...)>>());
template<class... Args> auto operator()(Args&&... args) && -> decltype(!declval<invoke_result_t<FD(Args...)>>());
template<class... Args> auto operator()(Args&&... args) const&& -> decltype(!declval<invoke_result_t<FD const(Args...)>>());
```

The first two are the same as `return !std::invoke(fd, std::forward<Args>(args)...) .` The second two are the same as `return !std::invoke(std::move(fd), std::forward<Args>(args)...) .`

Example

```

// functional_not_fn_.cpp
// compile with: /EHsc /std:c++17
#include <vector>
#include <algorithm>
#include <functional>
#include <iostream>

int main()
{
    std::vector<int> v1 = { 99, 6264, 41, 18467, 6334, 26500, 19169 };
    auto divisible_by_3 = [](int i){ return i % 3 == 0; };

    std::cout << "Vector v1 = ( " ;
    for (const auto& item : v1)
    {
        std::cout << item << " ";
    }
    std::cout << ")" << std::endl;

    // Count the number of vector elements divisible by 3.
    int divisible =
        std::count_if(v1.begin(), v1.end(), divisible_by_3);
    std::cout << "Elements divisible by three: "
        << divisible << std::endl;

    // Count the number of vector elements not divisible by 3.
    int not_divisible =
        std::count_if(v1.begin(), v1.end(), std::not_fn(divisible_by_3));
    std::cout << "Elements not divisible by three: "
        << not_divisible << std::endl;
}

```

```

Vector v1 = ( 99 6264 41 18467 6334 26500 19169 )
Elements divisible by three: 2
Elements not divisible by three: 5

```

ptr_fun

Helper template functions used to convert unary and binary function pointers, respectively, into unary and binary adaptable functions. Deprecated in C++11, removed in C++17.

```

template <class Arg, class Result>
pointer_to_unary_function<Arg, Result, Result (*)(Arg)> ptr_fun(Result (*pfunc)(Arg));

template <class Arg1, class Arg2, class Result>
pointer_to_binary_function<Arg1, Arg2, Result, Result (*)(Arg1, Arg2)> ptr_fun(Result (*pfunc)(Arg1, Arg2));

```

Parameters

pfunc

The unary or binary function pointer to be converted to an adaptable function.

Return Value

The first template function returns the unary function [pointer_to_unary_function](#) < `Arg`, `Result`>(* `pfunc`).

The second template function returns binary function [pointer_to_binary_function](#) < `Arg1`, `Arg2`, `Result`>(* `pfunc`).

Remarks

A function pointer is a function object. It may be passed to any algorithm that expects a function as a parameter, but it isn't adaptable. Information about its nested types is required to use it with an adaptor, for example, to bind a

value to it or to negate it. The conversion of unary and binary function pointers by the `ptr_fun` helper function allows the function adaptors to work with unary and binary function pointers.

Example

```
// functional_ptr_fun.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <cstring>
#include <iostream>

int main( )
{
    using namespace std;
    vector <char*> v1;
    vector <char*>::iterator Iter1, RIter;

    v1.push_back ( "Open" );
    v1.push_back ( "up" );
    v1.push_back ( "the" );
    v1.push_back ( "opalescent" );
    v1.push_back ( "gates" );

    cout << "Original sequence contains: " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; ++Iter1 )
        cout << *Iter1 << " ";
    cout << endl;

    // To search the sequence for "opalescent"
    // use a pointer_to_function conversion
    RIter = find_if( v1.begin( ), v1.end( ),
        not1 ( bind2nd ( ptr_fun ( strcmp ), "opalescent" ) ) );

    if ( RIter != v1.end( ) )
    {
        cout << "Found a match: "
            << *RIter << endl;
    }
}
```

ref

Constructs a `reference_wrapper` from an argument.

```
template <class Ty>
reference_wrapper<Ty> ref(Ty& arg);

template <class Ty>
reference_wrapper<Ty> ref(reference_wrapper<Ty>& arg);
```

Return Value

A reference to `arg`; specifically, `reference_wrapper<Ty>(arg)`.

Example

The following example defines two functions: one bound to a string variable, the other bound to a reference of the string variable computed by a call to `ref`. When the value of the variable changes, the first function continues to use the old value and the second function uses the new value.

```

#include <algorithm>
#include <functional>
#include <iostream>
#include <iterator>
#include <ostream>
#include <string>
#include <vector>
using namespace std;
using namespace std;
using namespace std::placeholders;

bool shorter_than(const string& l, const string& r) {
    return l.size() < r.size();
}

int main() {
    vector<string> v_original;
    v_original.push_back("tiger");
    v_original.push_back("cat");
    v_original.push_back("lion");
    v_original.push_back("cougar");

    copy(v_original.begin(), v_original.end(), ostream_iterator<string>(cout, " "));
    cout << endl;

    string s("meow");

    function<bool (const string&)> f = bind(shorter_than, _1, s);
    function<bool (const string&)> f_ref = bind(shorter_than, _1, ref(s));

    vector<string> v;

    // Remove elements that are shorter than s ("meow")

    v = v_original;
    v.erase(remove_if(v.begin(), v.end(), f), v.end());

    copy(v.begin(), v.end(), ostream_iterator<string>(cout, " "));
    cout << endl;

    // Now change the value of s.
    // f_ref, which is bound to ref(s), will use the
    // new value, while f is still bound to the old value.

    s = "kitty";

    // Remove elements that are shorter than "meow" (f is bound to old value of s)

    v = v_original;
    v.erase(remove_if(v.begin(), v.end(), f), v.end());

    copy(v.begin(), v.end(), ostream_iterator<string>(cout, " "));
    cout << endl;

    // Remove elements that are shorter than "kitty" (f_ref is bound to ref(s))

    v = v_original;
    v.erase(remove_if(v.begin(), v.end(), f_ref), v.end());

    copy(v.begin(), v.end(), ostream_iterator<string>(cout, " "));
    cout << endl;
}

```

```
tiger cat lion cougar
tiger lion cougar
tiger lion cougar
tiger cougar
```

swap

Swaps two `function` objects.

```
template <class FT>
void swap(function<FT>& f1, function<FT>& f2);
```

Parameters

FT

The type controlled by the function objects.

f1

The first function object.

f2

The second function object.

Remarks

The function returns `f1.swap(f2)` .

Example

```
// std_functional_swap.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    std::function<int (int)> fn0(neg);
    std::cout << std::boolalpha << "empty == " << !fn0 << std::endl;
    std::cout << "val == " << fn0(3) << std::endl;

    std::function<int (int)> fn1;
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;
    std::cout << std::endl;

    swap(fn0, fn1);
    std::cout << std::boolalpha << "empty == " << !fn0 << std::endl;
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;
    std::cout << "val == " << fn1(3) << std::endl;

    return (0);
}
```

```
empty == false  
val == -3  
empty == true  
  
empty == true  
empty == false  
val == -3
```

[<functional>](#)

<functional> operators

11/9/2018 • 2 minutes to read • [Edit Online](#)

`operator!=`

`operator==`

operator==

Tests if callable object is empty.

```
template <class Fty>
bool operator==(const function<Fty>& f, nullptr_type npc);

template <class Fty>
bool operator==(nullptr_type npc, const function<Fty>& f);
```

Parameters

Fty

The function type to wrap.

f

The function object

npc

A null pointer.

Remarks

The operators both take an argument that is a reference to a `function` object and an argument that is a null pointer constant. Both return true only if the `function` object is empty.

Example

```
// std_functional_operator_eq.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    std::function<int(int)> fn0;
    std::cout << std::boolalpha << "empty == "
              << (fn0 == 0) << std::endl;

    std::function<int(int)> fn1(neg);
    std::cout << std::boolalpha << "empty == "
              << (fn1 == 0) << std::endl;

    return (0);
}
```

```
empty == true
empty == false
```

operator!=

Tests if callable object is not empty.

```
template <class Fty>
bool operator!=(const function<Fty>& f, null_ptr_type npc);

template <class Fty>
bool operator!=(null_ptr_type npc, const function<Fty>& f);
```

Parameters

Fty

The function type to wrap.

f

The function object

npc

A null pointer.

Remarks

The operators both take an argument that is a reference to a `function` object and an argument that is a null pointer constant. Both return true only if the `function` object is not empty.

Example

```
// std_functional_operator_ne.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    std::function<int (int)> fn0;
    std::cout << std::boolalpha << "not empty == "
              << (fn0 != 0) << std::endl;

    std::function<int (int)> fn1(neg);
    std::cout << std::boolalpha << "not empty == "
              << (fn1 != 0) << std::endl;

    return (0);
}
```

```
not empty == false
not empty == true
```

_1 Object

11/9/2018 • 2 minutes to read • [Edit Online](#)

Placeholders for replaceable arguments.

Syntax

```
namespace placeholders {  
    extern unspecified _1,  
    _2, ... _M  
} // namespace placeholders (within std)
```

Remarks

The objects `_1, _2, ... _M` are placeholders designating the first, second, ..., Mth argument, respectively in a function call to an object returned by `bind`. You use `_N` to specify where the Nth argument should be inserted when the bind expression is evaluated.

In this implementation the value of `_M` is 20.

Example

```
// std__functional_placeholder.cpp  
// compile with: /EHsc  
#include <functional>  
#include <algorithm>  
#include <iostream>  
  
using namespace std::placeholders;  
  
void square(double x)  
{  
    std::cout << x << "^2 == " << x * x << std::endl;  
}  
  
void product(double x, double y)  
{  
    std::cout << x << "*" << y << " == " << x * y << std::endl;  
}  
  
int main()  
{  
    double arg[] = {1, 2, 3};  
  
    std::for_each(&arg[0], &arg[3], square);  
    std::cout << std::endl;  
  
    std::for_each(&arg[0], &arg[3], std::bind(product, _1, 2));  
    std::cout << std::endl;  
  
    std::for_each(&arg[0], &arg[3], std::bind(square, _1));  
  
    return (0);  
}
```

```
1^2 == 1
2^2 == 4
3^2 == 9

1*2 == 2
2*2 == 4
3*2 == 6

1^2 == 1
2^2 == 4
3^2 == 9
```

Requirements

[is_placeholder Class](#)

bad_function_call Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Reports a bad function call.

Syntax

```
class bad_function_call : public std::exception {};
```

Remarks

The class describes an exception thrown to indicate that a call to `operator()` on a [function Class](#)

binary_function Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

An empty base struct that defines types that may be inherited by derived classes that provides a binary function object. Deprecated in C++11, removed in C++17.

Syntax

```
struct binary_function {  
    typedef Arg1 first_argument_type;  
    typedef Arg2 second_argument_type;  
    typedef Result result_type;  
};
```

Remarks

The template struct serves as a base for classes that define a member function of the form:

```
result_type ** operator()( const** first_argument_type&, const second_argument_type& ) const
```

All such binary functions can refer to their first argument type as *first_argument_type*, their second argument type as *second_argument_type*, and their return type as *result_type*.

Example

```

// functional_binary_function.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

template <class Type> class average:
binary_function<Type, Type, Type>
{
public:
    result_type operator( ) ( first_argument_type a,
                              second_argument_type b )
    {
        return (result_type) ( ( a + b ) / 2 );
    }
};

int main( )
{
    vector <double> v1, v2, v3 ( 6 );
    vector <double>::iterator Iter1, Iter2, Iter3;

    for ( int i = 1 ; i <= 6 ; i++ )
        v1.push_back( 11.0 / i );

    for ( int j = 0 ; j <= 5 ; j++ )
        v2.push_back( -2.0 * j );

    cout << "The vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "The vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Finding the element-wise averages of the elements of v1 & v2
    transform ( v1.begin( ), v1.end( ), v2.begin( ), v3.begin( ),
                average<double>( ) );

    cout << "The element-wise averages are: ( " ;
    for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
        cout << *Iter3 << " ";
    cout << ")" << endl;
}
/* Output:
The vector v1 = ( 11 5.5 3.66667 2.75 2.2 1.83333 )
The vector v2 = ( -0 -2 -4 -6 -8 -10 )
The element-wise averages are: ( 5.5 1.75 -0.166667 -1.625 -2.9 -4.08333 )
*/

```

Requirements

Header: <functional>

binary_negate Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

A template class providing a member function that negates the return value of a specified binary function. Deprecated in C++17 in favor of [not_fn](#).

Syntax

```
template <class Operation>
class binary_negate
    : public binaryFunction <typename Operation::first_argument_type,
                           typename Operation::second_argument_type, bool>
{
public:
    explicit binary_negate(const Operation& Func);
    bool operator()(const typename Operation::first_argument_type& left,
                   const typename Operation::second_argument_type& right) const;
};
```

Parameters

Func

The binary function to be negated.

left

The left operand of the binary function to be negated.

right

The right operand of the binary function to be negated.

Return Value

The negation of the binary function.

Remarks

The template class stores a copy of a binary function object *Func*. It defines its member function `operator()` as returning `!Func(left, right)`.

The constructor of `binary_negate` is rarely used directly. The helper function [not2](#) is usually preferred to declare and use the **binary_negator** adaptor predicate.

Example

```

// functional_binary_negate.cpp
// compile with: /EHsc
#define _CRT_RAND_S
#include <stdlib.h>

#include <vector>
#include <algorithm>
#include <functional>
#include <iostream>

int main( )
{
    using namespace std;
    vector<unsigned int> v1;
    vector<unsigned int>::iterator Iter1;

    unsigned int i;
    v1.push_back( 6262 );
    v1.push_back( 6262 );
    unsigned int randVal = 0;
    for ( i = 0 ; i < 5 ; i++ )
    {
        rand_s(&randVal);
        v1.push_back( randVal );
    }

    cout << "Original vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in ascending order,
    // use default binary predicate less<unsigned int>( )
    sort( v1.begin( ), v1.end( ) );
    cout << "Sorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in descending order,
    // use the binary_negate function
    sort( v1.begin( ), v1.end( ),
        binary_negate<less<unsigned int>>(less<unsigned int>( ) ) );

    // The helper function not2 could also have been used
    // in the above line and is usually preferred for convenience
    // sort( v1.begin( ), v1.end( ), not2(less<unsigned int>( ) ) );

    cout << "Resorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
}
/* Output:
Original vector v1 = ( 6262 6262 2233879413 2621500314 580942933 3715465425 3739828298 )
Sorted vector v1 = ( 6262 6262 580942933 2233879413 2621500314 3715465425 3739828298 )
Resorted vector v1 = ( 3739828298 3715465425 2621500314 2233879413 580942933 6262 6262 )
*/

binder1st Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

A template class providing a constructor that converts a binary function object into a unary function object by binding the first argument of the binary function to a specified value. Deprecated in C++11 in favor of [bind](#), and removed in C++17.

Syntax

```
template <class Operation>
class binder1st
    : public unaryFunction <typename Operation::second_argument_type,
                          typename Operation::result_type>
{
public:
    typedef typename Operation::argument_type argument_type;
    typedef typename Operation::result_type result_type;
    binder1st(
        const Operation& binary_fn,
        const typename Operation::first_argument_type& left);

    result_type operator()(const argument_type& right) const;
    result_type operator()(const argument_type& right) const;

protected:
    Operation op;
    typename Operation::first_argument_type value;
};
```

Parameters

binary_fn

The binary function object to be converted to a unary function object.

left

The value to which the first argument of the binary function object is to be bound.

right

The value of the argument that the adapted binary object compares to the fixed value of the second argument.

Return Value

The unary function object that results from binding the first argument of the binary function object to the value *left*.

Remarks

The template class stores a copy of a binary function object *binary_fn* in `op`, and a copy of *left* in `value`. It defines its member function `operator()` as returning `op(value, right)`.

If *binary_fn* is an object of type `Operation` and `c` is a constant, then `bind1st(binary_fn, c)` is a more convenient equivalent to `binder1st<Operation>(binary_fn, c)`. For more information, see [bind1st](#).

Example

```

// functional_binder1st.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main()
{
    vector<int> v1;
    vector<int>::iterator Iter;

    int i;
    for (i = 0; i <= 5; i++)
    {
        v1.push_back(5 * i);
    }

    cout << "The vector v1 = ( ";
    for (Iter = v1.begin(); Iter != v1.end(); Iter++)
        cout << *Iter << " ";
    cout << ")" << endl;

    // Count the number of integers > 10 in the vector
    vector<int>::iterator::difference_type result1;
    result1 = count_if(v1.begin(), v1.end(),
        binder1st<less<int> >(less<int>(), 10));
    cout << "The number of elements in v1 greater than 10 is: "
        << result1 << "." << endl;

    // Compare use of binder2nd fixing 2nd argument:
    // count the number of integers < 10 in the vector
    vector<int>::iterator::difference_type result2;
    result2 = count_if(v1.begin(), v1.end(),
        binder2nd<less<int> >(less<int>(), 10));
    cout << "The number of elements in v1 less than 10 is: "
        << result2 << "." << endl;
}
/* Output:
The vector v1 = ( 0 5 10 15 20 25 )
The number of elements in v1 greater than 10 is: 3.
The number of elements in v1 less than 10 is: 2.
*/

```

Requirements

Header: <functional>

Namespace: std

[C++ Standard Library Reference](#)

binder2nd Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

A template class providing a constructor that converts a binary function object into a unary function object by binding the second argument of the binary function to a specified value. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Operation>
class binder2nd
    : public unaryFunction <typename Operation::first_argument_type,
        typename Operation::result_type>
{
public:
    typedef typename Operation::argument_type argument_type;
    typedef typename Operation::result_type result_type;
    binder2nd(
        const Operation& Func,
        const typename Operation::second_argument_type& right);

    result_type operator()(const argument_type& left) const;
    result_type operator()(argument_type& left) const;

protected:
    Operation op;
    typename Operation::second_argument_type value;
};
```

Parameters

Func

The binary function object to be converted to a unary function object.

right

The value to which the second argument of the binary function object is to be bound.

left

The value of the argument that the adapted binary object compares to the fixed value of the second argument.

Return Value

The unary function object that results from binding the second argument of the binary function object to the value *right*.

Remarks

The template class stores a copy of a binary function object *Func* in `op`, and a copy of *right* in `value`. It defines its member function `operator()` as returning `op(left, value)`.

If `Func` is an object of type `Operation` and `c` is a constant, then `bind2nd (Func, c)` is equivalent to the `binder2nd` class constructor `binder2nd < Operation > (Func, c)` and more convenient.

Example

```

// functional_binder2nd.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main()
{
    vector<int> v1;
    vector<int>::iterator Iter;

    int i;
    for (i = 0; i <= 5; i++)
    {
        v1.push_back(5 * i);
    }

    cout << "The vector v1 = ( ";
    for (Iter = v1.begin(); Iter != v1.end(); Iter++)
        cout << *Iter << " ";
    cout << ")" << endl;

    // Count the number of integers > 10 in the vector
    vector<int>::iterator::difference_type result1;
    result1 = count_if(v1.begin(), v1.end(),
        binder2nd<greater<int> >(greater<int>(), 10));
    cout << "The number of elements in v1 greater than 10 is: "
        << result1 << "." << endl;

    // Compare using binder1st fixing 1st argument:
    // count the number of integers < 10 in the vector
    vector<int>::iterator::difference_type result2;
    result2 = count_if(v1.begin(), v1.end(),
        binder1st<greater<int> >(greater<int>(), 10));
    cout << "The number of elements in v1 less than 10 is: "
        << result2 << "." << endl;
}
/* Output:
The vector v1 = ( 0 5 10 15 20 25 )
The number of elements in v1 greater than 10 is: 3.
The number of elements in v1 less than 10 is: 2.
*/

const_mem_fun_ref_t Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

An adapter class that allows a **const** member function that takes no arguments to be called as a unary function object when initialized with a reference argument. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Result, class Type>
class const_mem_fun_ref_t
: public unary_function<Type, Result>
{
    explicit const_mem_fun_t(Result (Type::* Pm)() const);
    Result operator()(const Type& left) const;
};
```

Parameters

Pm

A pointer to the member function of class `Type` to be converted to a function object.

left

The object that the *Pm* member function is called on.

Return Value

An adaptable unary function.

Remarks

The template class stores a copy of *Pm*, which must be a pointer to a member function of class `Type`, in a private member object. It defines its member function `operator()` as returning `(left.*Pm)() const`.

Example

The constructor of `const_mem_fun_ref_t` is not usually used directly; the helper function `mem_fun_ref` is used to adapt member functions. See [mem_fun_ref](#) for an example of how to use member function adaptors.

const_mem_fun_t Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

An adapter class that allows a const member function that takes no arguments to be called as a unary function object when initialized with a reference argument. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Result, class Type>
class const_mem_fun_t : public unary_function <Type *, Result>
{
    explicit const_mem_fun_t(Result (Type::* Pm)() const);
    Result operator()(const Type* Pleft) const;
};
```

Parameters

Pm

A pointer to the member function of class `Type` to be converted to a function object.

Pleft

The object that the *Pm* member function is called on.

Return Value

An adaptable unary function.

Remarks

The template class stores a copy of *Pm*, which must be a pointer to a member function of class `Type`, in a private member object. It defines its member function `operator()` as returning `(Pleft -> * Pm)() const`.

Example

The constructor of `const_mem_fun_t` is not usually used directly; the helper function `mem_fun` is used to adapt member functions. See [mem_fun](#) for an example of how to use member function adaptors.

const_mem_fun1_ref_t Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

An adapter class that allows a **const** member function that takes a single argument to be called as a binary function object when initialized with a reference argument. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Result, class Type, class Arg>
class const_mem_fun1_ref_t
: public binary_function<Type, Arg, Result>
{
    explicit const_mem_fun1_ref_t(Result (Type::* Pm)(Arg) const);
    Result operator()(const Type& left, Arg right) const;
};
```

Parameters

Pm

A pointer to the member function of class `Type` to be converted to a function object.

left

The **const** object that the *Pm* member function is called on.

right

The argument that is being given to *Pm*.

Return Value

An adaptable binary function.

Remarks

The template class stores a copy of *Pm*, which must be a pointer to a member function of class `Type`, in a private member object. It defines its member function `operator()` as returning `(left.* Pm)(right) const`.

Example

The constructor of `const_mem_fun1_ref_t` is not usually used directly; the helper function `mem_fun_ref` is used to adapt member functions. See [mem_fun_ref](#) for examples of how to use member function adaptors.

Requirements

const_mem_fun1_t Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

An adapter class that allows a **const** member function that takes a single argument to be called as a binary function object when initialized with a pointer argument. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Result, class Type, class Arg>
class const_mem_fun1_t : public binary_function<const Type *, Arg, Result>
{
    explicit const_mem_fun1_t(Result (Type::* member_ptr)(Arg) const);
    Result operator()(const Type* left, Arg right) const;
};
```

Parameters

member_ptr

A pointer to the member function of class `Type` to be converted to a function object.

left

The **const** object that the *member_ptr* member function is called on.

right

The argument that is being given to *member_ptr*.

Return Value

An adaptable binary function.

Remarks

The template class stores a copy of *member_ptr*, which must be a pointer to a member function of class `Type`, in a private member object. It defines its member function `operator()` as returning `(left->member_ptr)(right) const`.

Example

The constructor of `const_mem_fun1_t` is rarely used directly. `mem_fn` is used to adapt member functions. See [mem_fn](#) for an example of how to use member function adaptors.

divides Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A predefined function object that performs the division operation (`operator/`) on its arguments.

Syntax

```
template <class Type = void>
struct divides : public binary_function <Type, Type, Type>
{
    Type operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator/
template <>
struct divides<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const
        -> decltype(std::forward<T>(Left)* std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* A type that supports an `operator/` that takes operands of the specified or inferred types.

Left

The left operand of the division operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the division operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left / Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator/`.

Example

```

// functional_divides.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main( )
{
    vector <double> v1, v2, v3 (6);
    vector <double>::iterator Iter1, Iter2, Iter3;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 7.0 * i );
    }

    int j;
    for ( j = 1 ; j <= 6 ; j++ )
    {
        v2.push_back( 2.0 * j);
    }

    cout << "The vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "The vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Finding the element-wise quotients of the elements of v1 & v2
    transform ( v1.begin( ), v1.end( ), v2.begin( ), v3.begin ( ),
        divides<double>( ) );

    cout << "The element-wise quotients are: ( " ;
    for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
        cout << *Iter3 << " ";
    cout << ")" << endl;
}

/* Output:
The vector v1 = ( 0 7 14 21 28 35 )
The vector v2 = ( 2 4 6 8 10 12 )
The element-wise quotients are: ( 0 1.75 2.33333 2.625 2.8 2.91667 )
*/

```

[C++ Standard Library Reference](#)

equal_to Struct

3/11/2019 • 2 minutes to read • [Edit Online](#)

A binary predicate that performs the equality operation (`operator==`) on its arguments.

Syntax

```
template <class Type = void>
struct equal_to : public binary_function<Type, Type, bool>
{
    bool operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator==
template <>
struct equal_to<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const
        -> decltype(std::forward<T>(Left) == std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator==` that takes operands of the specified or inferred types.

Left

The left operand of the equality operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the equality operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left == Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator==`.

Remarks

The objects of type *Type* must be equality-comparable. This requires that the `operator==` defined on the set of objects satisfies the mathematical properties of an equivalence relation. All of the built-in numeric and pointer types satisfy this requirement.

Example

```

// functional_equal_to.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main( )
{
    vector <double> v1, v2, v3 ( 6 );
    vector <double>::iterator Iter1, Iter2, Iter3;

    int i;
    for ( i = 0 ; i <= 5 ; i+=2 )
    {
        v1.push_back( 2.0 *i );
        v1.push_back( 2.0 * i + 1.0 );
    }

    int j;
    for ( j = 0 ; j <= 5 ; j+=2 )
    {
        v2.push_back( - 2.0 * j );
        v2.push_back( 2.0 * j + 1.0 );
    }

    cout << "The vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "The vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Testing for the element-wise equality between v1 & v2
    transform ( v1.begin( ), v1.end( ), v2.begin( ), v3.begin( ),
        equal_to<double>( ) );

    cout << "The result of the element-wise equal_to comparison\n"
        << "between v1 & v2 is: ( " ;
    for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
        cout << *Iter3 << " ";
    cout << ")" << endl;
}

```

```

The vector v1 = ( 0 1 4 5 8 9 )
The vector v2 = ( -0 1 -4 5 -8 9 )
The result of the element-wise equal_to comparison
between v1 & v2 is: ( 1 1 0 1 0 1 )

```

function Class

11/9/2018 • 9 minutes to read • [Edit Online](#)

Wrapper for a callable object.

Syntax

```
template <class Fty>
class function // Fty of type Ret(T1, T2, ..., TN)
    : public unary_function<T1, Ret>          // when Fty is Ret(T1)
    : public binary_function<T1, T2, Ret>     // when Fty is Ret(T1, T2)
{
public:
    typedef Ret result_type;

    function();
    function(nullptr_t);
    function(const function& right);
    template <class Fty2>
        function(Fty2 fn);
    template <class Fty2, class Alloc>
        function(reference_wrapper<Fty2>, const Alloc& Ax);

    template <class Fty2, class Alloc>
        void assign(Fty2, const Alloc& Ax);
    template <class Fty2, class Alloc>
        void assign(reference_wrapper<Fty2>, const Alloc& Ax);
    function& operator=(nullptr_t);
    function& operator=(const function&);
    template <class Fty2>
        function& operator=(Fty2);
    template <class Fty2>
        function& operator=(reference_wrapper<Fty2>);

    void swap(function&);
    explicit operator bool() const;

    result_type operator()(T1, T2, ....., TN) const;
    const std::type_info& target_type() const;
    template <class Fty2>
        Fty2 *target();

    template <class Fty2>
        const Fty2 *target() const;

    template <class Fty2>
        void operator==(const Fty2&) const = delete;
    template <class Fty2>
        void operator!=(const Fty2&) const = delete;
};
```

Parameters

Fty

The function type to wrap.

Ax

The allocator function.

Remarks

The template class is a call wrapper whose call signature is `Ret(T1, T2, ..., TN)`. You use it to enclose a variety of callable objects in a uniform wrapper.

Some member functions take an operand that names the desired target object. You can specify such an operand in several ways:

`fn` -- the callable object `fn`; after the call the `function` object holds a copy of `fn`

`fnref` -- the callable object named by `fnref.get()`; after the call the `function` object holds a reference to `fnref.get()`

`right` -- the callable object, if any, held by the `function` object `right`

`npc` -- a null pointer; after the call the `function` object is empty

In all cases, `INVOKE(f, t1, t2, ..., tN)`, where `f` is the callable object and `t1, t2, ..., tN` are lvalues of types `T1, T2, ..., TN` respectively, must be well-formed and, if `Ret` is not void, convertible to `Ret`.

An empty `function` object does not hold a callable object or a reference to a callable object.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>function</code>	Constructs a wrapper that either is empty or stores a callable object of arbitrary type with a fixed signature.

Typedefs

TYPE NAME	DESCRIPTION
<code>result_type</code>	The return type of the stored callable object.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>assign</code>	Assigns a callable object to this function object.
<code>swap</code>	Swap two callable objects.
<code>target</code>	Tests if stored callable object is callable as specified.
<code>target_type</code>	Gets type information on the callable object.

Operators

OPERATOR	DESCRIPTION
<code>function::operator unspecified</code>	Tests if stored callable object exists.
<code>function::operator()</code>	Calls a callable object.
<code>function::operator=</code>	Replaces the stored callable object.

Requirements

Header: <functional>

Namespace: std

function::assign

Assigns a callable object to this function object.

```
template <class Fx, class Alloc>
void assign(
    Fx _Func,
    const Alloc& Ax);

template <class Fx, class Alloc>
void assign(
    reference_wrapper<Fx> _Fnref,
    const Alloc& Ax);
```

Parameters

_Func

A callable object.

_Fnref

A reference wrapper that contains a callable object.

Ax

An allocator object.

Remarks

The member functions each replace the `callable object` held by `*this` with the callable object passed as the `operand`. Both allocate storage with the allocator object *Ax*.

function::function

Constructs a wrapper that either is empty or stores a callable object of arbitrary type with a fixed signature.

```
function();
function(nullptr_t npc);
function(const function& right);
template <class Fx>
    function(Fx _Func);
template <class Fx>
    function(reference_wrapper<Fx> _Fnref);
template <class Fx, class Alloc>
    function(
        Fx _Func,
        const Alloc& Ax);

template <class Fx, class Alloc>
    function(
        reference_wrapper<Fx> _Fnref,
        const Alloc& Ax);
```

Parameters

right

The function object to copy.

Fx

The type of the callable object.

_Func

The callable object to wrap.

Alloc

The allocator type.

Ax

The allocator.

_Fnref

The callable object reference to wrap.

Remarks

The first two constructors construct an empty `function` object. The next three constructors construct a `function` object that holds the callable object passed as the operand. The last two constructors allocate storage with the allocator object `Ax`.

Example

```

// std_functional_function_function.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>
#include <vector>

int square(int val)
{
    return val * val;
}

class multiply_by
{
public:
    explicit multiply_by(const int n) : m_n(n) { }

    int operator()(const int x) const
    {
        return m_n * x;
    }

private:
    int m_n;
};

int main()
{
    typedef std::vector< std::function<int (int)> > vf_t;

    vf_t v;
    v.push_back(square);
    v.push_back(std::negate<int>());
    v.push_back(multiply_by(3));

    for (vf_t::const_iterator i = v.begin(); i != v.end(); ++i)
    {
        std::cout << (*i)(10) << std::endl;
    }

    std::function<int (int)> f = v[0];
    std::function<int (int)> g;

    if (f) {
        std::cout << "f is non-empty (correct)." << std::endl;
    } else {
        std::cout << "f is empty (can't happen)." << std::endl;
    }

    if (g) {
        std::cout << "g is non-empty (can't happen)." << std::endl;
    } else {
        std::cout << "g is empty (correct)." << std::endl;
    }

    return 0;
}

```

```

100
-10
30
f is non-empty (correct).
g is empty (correct).

```

function::operator unspecified

Tests if stored callable object exists.

```
operator unspecified();
```

Remarks

The operator returns a value that is convertible to **bool** with a true value only if the object is not empty. You use it to test whether the object is empty.

Example

```
// std_functional_function_operator_bool.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    std::function<int (int)> fn0;
    std::cout << std::boolalpha << "not empty == " << (bool)fn0 << std::endl;

    std::function<int (int)> fn1(neg);
    std::cout << std::boolalpha << "not empty == " << (bool)fn1 << std::endl;

    return (0);
}
```

```
not empty == false
not empty == true
```

function::operator()

Calls a callable object.

```
result_type operator()(
    T1 t1,
    T2 t2, ...,
    TN tN);
```

Parameters

TN

The type of the Nth call argument.

tN

The Nth call argument.

Remarks

The member function returns `INVOKE(fn, t1, t2, ..., tN, Ret)`, where `fn` is the target object stored in `*this`. You use it to call the wrapped callable object.

Example

```
// std_functional_function_operator_call.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    std::function<int (int)> fn1(neg);
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;
    std::cout << "val == " << fn1(3) << std::endl;

    return (0);
}
```

```
empty == false
val == -3
```

function::operator=

Replaces the stored callable object.

```
function& operator=(null_ptr_type npc);
function& operator=(const function& right);
template <class Fty>
    function& operator=(Fty fn);
template <class Fty>
    function& operator=(reference_wrapper<Fty> fnref);
```

Parameters

npc

A null pointer constant.

right

The function object to copy.

fn

The callable object to wrap.

fnref

The callable object reference to wrap.

Remarks

The operators each replace the callable object held by `*this` with the callable object passed as the operand.

Example

```
// std_functional_function_operator_as.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    std::function<int (int)> fn0(neg);
    std::cout << std::boolalpha << "empty == " << !fn0 << std::endl;
    std::cout << "val == " << fn0(3) << std::endl;

    std::function<int (int)> fn1;
    fn1 = 0;
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;

    fn1 = neg;
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;
    std::cout << "val == " << fn1(3) << std::endl;

    fn1 = fn0;
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;
    std::cout << "val == " << fn1(3) << std::endl;

    fn1 = std::cref(fn1);
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;
    std::cout << "val == " << fn1(3) << std::endl;

    return (0);
}
```

```
empty == false
val == -3
empty == true
empty == false
val == -3
empty == false
val == -3
empty == false
val == -3
```

function::result_type

The return type of the stored callable object.

```
typedef Ret result_type;
```

Remarks

The typedef is a synonym for the type `Ret` in the template's call signature. You use it to determine the return type of the wrapped callable object.

Example

```
// std_functional_function_result_type.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    std::function<int (int)> fn1(neg);
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;

    std::function<int (int)>::result_type val = fn1(3);
    std::cout << "val == " << val << std::endl;

    return (0);
}
```

```
empty == false
val == -3
```

function::swap

Swap two callable objects.

```
void swap(function& right);
```

Parameters

right

The function object to swap with.

Remarks

The member function swaps the target objects between `*this` and *right*. It does so in constant time and throws no exceptions.

Example

```
// std_functional_function_swap.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    std::function<int (int)> fn0(neg);
    std::cout << std::boolalpha << "empty == " << !fn0 << std::endl;
    std::cout << "val == " << fn0(3) << std::endl;

    std::function<int (int)> fn1;
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;
    std::cout << std::endl;

    fn0.swap(fn1);
    std::cout << std::boolalpha << "empty == " << !fn0 << std::endl;
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;
    std::cout << "val == " << fn1(3) << std::endl;

    return (0);
}
```

```
empty == false
val == -3
empty == true

empty == true
empty == false
val == -3
```

function::target

Tests if stored callable object is callable as specified.

```
template <class Fty2>
    Fty2 *target();
template <class Fty2>
    const Fty2 *target() const;
```

Parameters

Fty2

The target callable object type to test.

Remarks

The type *Fty2* must be callable for the argument types `T1, T2, ..., TN` and the return type `Ret`. If `target_type() == typeid(Fty2)`, the member template function returns the address of the target object; otherwise, it returns 0.

A type *Fty2* is callable for the argument types `T1, T2, ..., TN` and the return type `Ret` if, for lvalues `fn, t1, t2, ..., tN` of types `Fty2, T1, T2, ..., TN`, respectively, `INVOKE(fn, t1, t2, ..., tN)` is well-formed and, if `Ret` is not **void**, convertible to `Ret`.

Example

```

// std__functional__function_target.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    typedef int (*Myfun)(int);
    std::function<int (int)> fn0(neg);
    std::cout << std::boolalpha << "empty == " << !fn0 << std::endl;
    std::cout << "no target == " << (fn0.target<Myfun>() == 0) << std::endl;

    Myfun *fptr = fn0.target<Myfun>();
    std::cout << "val == " << (*fptr)(3) << std::endl;

    std::function<int (int)> fn1;
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;
    std::cout << "no target == " << (fn1.target<Myfun>() == 0) << std::endl;

    return (0);
}

```

```

empty == false
no target == false
val == -3
empty == true
no target == true

```

function::target_type

Gets type information on the callable object.

```
const std::type_info& target_type() const;
```

Remarks

The member function returns `typeid(void)` if `*this` is empty, otherwise it returns `typeid(T)`, where `T` is the type of the target object.

Example

```

// std__functional__function_target_type.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val)
{
    return (-val);
}

int main()
{
    std::function<int (int)> fn0(neg);
    std::cout << std::boolalpha << "empty == " << !fn0 << std::endl;
    std::cout << "type == " << fn0.target_type().name() << std::endl;

    std::function<int (int)> fn1;
    std::cout << std::boolalpha << "empty == " << !fn1 << std::endl;
    std::cout << "type == " << fn1.target_type().name() << std::endl;

    return (0);
}

```

```

empty == false
type == int (__cdecl*)(int)
empty == true
type == void

```

[reference_wrapper Class](#)

greater Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A binary predicate that performs the greater-than operation (`operator>`) on its arguments.

Syntax

```
template <class Type = void>
struct greater : public binary_function <Type, Type, bool>
{
    bool operator()(
        const Type& Left,
        const Type& Right) const;

};

// specialized transparent functor for operator>
template <>
struct greater<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const
        -> decltype(std::forward<T>(Left) > std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator>` that takes operands of the specified or inferred types.

Left

The left operand of the greater-than operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the greater-than operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left > Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator>`.

Remarks

The binary predicate `greater < Type >` provides a strict weak ordering of a set of element values of type *Type* into equivalence classes, if and only if this type satisfies the standard mathematical requirements for being so ordered. The specializations for any pointer type yield a total ordering of elements, in that all elements of distinct values are ordered with respect to each other.

Example

```

// functional_greater.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <cstdlib>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1;

    int i;
    for ( i = 0 ; i < 8 ; i++ )
    {
        v1.push_back( rand( ) );
    }

    cout << "Original vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in ascending order,
    // use default binary predicate less<int>( )
    sort( v1.begin( ), v1.end( ) );
    cout << "Sorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in descending order,
    // specify binary predicate greater<int>( )
    sort( v1.begin( ), v1.end( ), greater<int>( ) );
    cout << "Resorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
}

```

```

Original vector v1 = (41 18467 6334 26500 19169 15724 11478 29358)
Sorted vector v1 = (41 6334 11478 15724 18467 19169 26500 29358)
Resorted vector v1 = (29358 26500 19169 18467 15724 11478 6334 41)

```

Requirements

Header: <functional>

[C++ Standard Library Reference](#)

greater_equal Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A binary predicate that performs the greater-than-or-equal-to operation (`operator>=`) on its arguments.

Syntax

```
template <class Type = void>
struct greater_equal : public binary_function <Type, Type, bool>
{
    bool operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator>=
template <>
struct greater_equal<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const`
        -> decltype(std::forward<T>(Left)>= std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator>=` that takes operands of the specified or inferred types.

Left

The left operand of the greater-than-or-equal-to operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the greater-than-or-equal-to operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left >= Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator>=`.

Remarks

The binary predicate `greater_equal < Type >` provides a strict weak ordering of a set of element values of type *Type* into equivalence classes, if and only if this type satisfies the standard mathematical requirements for being so ordered. The specializations for any pointer type yield a total ordering of elements, in that all elements of distinct values are ordered with respect to each other.

Example

```

// functional_greater_equal.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <cstdlib>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1;

    int i;
    v1.push_back( 6262 );
    v1.push_back( 6262 );
    for ( i = 0 ; i < 5 ; i++ )
    {
        v1.push_back( rand( ) );
    }

    cout << "Original vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in ascending order,
    // use default binary predicate less<int>( )
    sort( v1.begin( ), v1.end( ) );
    cout << "Sorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in descending order,
    // specify binary predicate greater_equal<int>( )
    sort( v1.begin( ), v1.end( ), greater_equal<int>( ) );
    cout << "Resorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
}

```

```

Original vector v1 = (6262 6262 41 18467 6334 26500 19169)
Sorted vector v1 = (41 6262 6262 6334 18467 19169 26500)
Resorted vector v1 = (26500 19169 18467 6334 6262 6262 41)

```

hash Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Computes hash code for a value.

Syntax

```
template <class Ty>
struct hash {
    size_t operator()(Ty val) const;
};
```

Remarks

The function object defines a hash function, suitable for mapping values of type *Ty* to a distribution of index values.

The member `operator()` returns a hash code for *val*, suitable for use with template classes `unordered_map`, `unordered_multimap`, `unordered_set`, and `unordered_multiset`. The standard library provides specializations for basic types: *Ty* may be any scalar type, including pointer types and enumeration types. In addition, there are specializations for the library types `string`, `wstring`, `u16string`, `u32string`, `string_view`, `wstring_view`, `u16string_view`, `u32string_view`, `bitset`, `error_code`, `error_condition`, `optional`, `shared_ptr`, `thread`, `type_index`, `unique_ptr`, `variant`, and `vector<bool>`.

Example

```
// std_functional_hash.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>
#include <unordered_set>

int main()
{
    std::unordered_set<int, std::hash<int> > c0;
    c0.insert(3);
    std::cout << *c0.find(3) << std::endl;

    return (0);
}
```

3

[<unordered_set>](#)

is_bind_expression Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type generated by calling `bind`.

Syntax

```
template struct is_bind_expression { static const bool value; };
```

Remarks

The constant member `value` is true if the type `Ty` is a type returned by a call to `bind`, otherwise false.

Example

```
// std__functional__is_bind_expression.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

void square(double x)
{
    std::cout << x << "^2 == " << x * x << std::endl;
}

template<class Expr>
void test_for_bind(const Expr&)
{
    std::cout << std::is_bind_expression<Expr>::value << std::endl;
}

int main()
{
    test_for_bind(3.0 * 3.0);
    test_for_bind(std::bind(square, 3));

    return (0);
}
```

```
0
1
```

Requirements

Header: <functional>

Namespace: std

[bind](#)

is_placeholder Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is a placeholder.

Syntax

```
struct is_placeholder { static const int value; };
```

Remarks

The constant value `value` is 0 if the type `Ty` is not a placeholder; otherwise, its value is the position of the function call argument that it binds to. You use it to determine the value `N` for the Nth placeholder `_N`.

Example

```
// std__functional__is_placeholder.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

using namespace std::placeholders;

template<class Expr>
void test_for_placeholder(const Expr&)
{
    std::cout << std::is_placeholder<Expr>::value << std::endl;
}

int main()
{
    test_for_placeholder(3.0);
    test_for_placeholder(_3);

    return (0);
}
```

```
0
3
```

Requirements

Header: <functional>

Namespace: std

[_1 Object](#)

less Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A binary predicate that performs the less-than operation (`operator<`) on its arguments.

Syntax

```
template <class Type = void>
struct less : public binary_function <Type, Type, bool>
{
    bool operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator<
template <>
struct less<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const
        -> decltype(std::forward<T>(Left) < std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator<` that takes operands of the specified or inferred types.

Left

The left operand of the less-than operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the less-than operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left < Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator<`.

Remarks

The binary predicate `less < Type >` provides a strict weak ordering of a set of element values of type *Type* into equivalence classes, if and only if this type satisfies the standard mathematical requirements for being so ordered. The specializations for any pointer type yield a total ordering of elements, in that all elements of distinct values are ordered with respect to each other.

Example

```

// functional_less.cpp
// compile with: /EHsc
#include <vector>
#include <algorithm>
#include <functional>
#include <iostream>

struct MyStruct {
    MyStruct(int i) : m_i(i){}

    bool operator < (const MyStruct & rhs) const {
        return m_i < rhs.m_i;
    }

    int m_i;
};

int main() {
    using namespace std;
    vector <MyStruct> v1;
    vector <MyStruct>::iterator Iter1;
    vector <MyStruct>::reverse_iterator rIter1;

    int i;
    for ( i = 0 ; i < 7 ; i++ )
        v1.push_back( MyStruct(rand()));

    cout << "Original vector v1 = ( " ;
    for ( Iter1 = v1.begin() ; Iter1 != v1.end() ; Iter1++ )
        cout << Iter1->m_i << " ";
    cout << ")" << endl;

    // To sort in ascending order,
    sort( v1.begin( ), v1.end( ), less<MyStruct>());

    cout << "Sorted vector v1 = ( " ;
    for ( Iter1 = v1.begin() ; Iter1 != v1.end() ; Iter1++ )
        cout << Iter1->m_i << " ";
    cout << ")" << endl;
}

```

Output

```

Original vector v1 = (41 18467 6334 26500 19169 15724 11478)
Sorted vector v1 = (41 6334 11478 15724 18467 19169 26500)

```

Requirements

less_equal Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A binary predicate that performs the less-than-or-equal-to operation (`operator<=`) on its arguments.

Syntax

```
template <class Type = void>
struct less_equal : public binary_function <Type, Type, bool>
{
    bool operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator<=
template <>
struct less_equal<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const
        -> decltype(std::forward<T>(Left) <= std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator<=` that takes operands of the specified or inferred types.

Left

The left operand of the less-than-or-equal-to operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the less-than-or-equal-to operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left <= Right`. The specialized template does perfect forwarding of the result, which has the type returned by `operator<=`.

Remarks

The binary predicate `less_equal < Type >` provides a strict weak ordering of a set of element values of type *Type* into equivalence classes, if and only if this type satisfies the standard mathematical requirements for being so ordered. The specializations for any pointer type yield a total ordering of elements, in that all elements of distinct values are ordered with respect to each other.

Example

```

// functional_less_equal.cpp
// compile with: /EHsc
#define _CRT_RAND_S
#include <stdlib.h>
#include <vector>
#include <algorithm>
#include <functional>
#include <cstdlib>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter1;
    vector<int>::reverse_iterator rIter1;
    unsigned int randomNumber;

    int i;
    for ( i = 0 ; i < 5 ; i++ )
    {
        if ( rand_s( &randomNumber ) == 0 )
        {
            // Convert the random number to be between 1 - 50000
            // This is done for readability purposes
            randomNumber = ( unsigned int) ((double)randomNumber /
                (double) UINT_MAX * 50000) + 1;

            v1.push_back( randomNumber );
        }
    }
    for ( i = 0 ; i < 3 ; i++ )
    {
        v1.push_back( 2836 );
    }

    cout << "Original vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // To sort in ascending order,
    // use the binary predicate less_equal<int>( )
    sort( v1.begin( ), v1.end( ), less_equal<int>( ) );
    cout << "Sorted vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;
}

```

Sample Output

```

Original vector v1 = (31247 37154 48755 15251 6205 2836 2836 2836)
Sorted vector v1 = (2836 2836 2836 6205 15251 31247 37154 48755)

```

Requirements

[C++ Standard Library Reference](#)

logical_and Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A predefined function object that performs the logical conjunction operation (`operator&&`) on its arguments.

Syntax

```
template <class Type = void>
struct logical_and : public binary_function<Type, Type, bool>
{
    bool operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator&&
template <>
struct logical_and<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const`
        -> decltype(std::forward<T>(Left) && std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator&&` that takes operands of the specified or inferred types.

Left

The left operand of the logical conjunction operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the logical conjunction operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left && Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator&&`.

Remarks

For user-defined types, there is no short-circuiting of operand evaluation. Both arguments are evaluated by `operator&&`.

Example

```
// functional_logical_and.cpp
// compile with: /EHsc

#define _CRT_RAND_S
#include <stdlib.h>
#include <deque>
```

```

#include <algorithm>
#include <functional>
#include <iostream>

int main( )
{
    using namespace std;
    deque<bool> d1, d2, d3( 7 );
    deque<bool>::iterator iter1, iter2, iter3;

    unsigned int randomValue;

    int i;
    for ( i = 0 ; i < 7 ; i++ )
    {
        if ( rand_s( &randomValue ) == 0 )
        {
            d1.push_back((bool)(( randomValue % 2 ) != 0));
        }
    }

    int j;
    for ( j = 0 ; j < 7 ; j++ )
    {
        if ( rand_s( &randomValue ) == 0 )
        {
            d2.push_back((bool)(( randomValue % 2 ) != 0));
        }
    }

    cout << boolalpha;    // boolalpha I/O flag on

    cout << "Original deque:\n d1 = ( " ;
    for ( iter1 = d1.begin( ) ; iter1 != d1.end( ) ; iter1++ )
        cout << *iter1 << " ";
    cout << ")" << endl;

    cout << "Original deque:\n d2 = ( " ;
    for ( iter2 = d2.begin( ) ; iter2 != d2.end( ) ; iter2++ )
        cout << *iter2 << " ";
    cout << ")" << endl;

    // To find element-wise conjunction of the truth values
    // of d1 & d2, use the logical_and function object
    transform( d1.begin( ), d1.end( ), d2.begin( ),
        d3.begin( ), logical_and<bool>( ) );
    cout << "The deque which is the conjunction of d1 & d2 is:\n d3 = ( " ;
    for ( iter3 = d3.begin( ) ; iter3 != d3.end( ) ; iter3++ )
        cout << *iter3 << " ";
    cout << ")" << endl;
}

/* Output:
Original deque:
d1 = ( true true true true true false false )
Original deque:
d2 = ( true false true true false true false )
The deque which is the conjunction of d1 & d2 is:
d3 = ( true false true true false false false )

logical_not Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A predefined function object that performs the logical not operation (`operator!`) on its argument.

Syntax

```
template <class Type = void>
struct logical_not : public unary_function<Type, bool>
{
    bool operator()(const Type& Left) const;
};

// specialized transparent functor for operator!
template <>
struct logical_not<void>
{
    template <class Type>
    auto operator()(Type&& Left) const`
        -> decltype(!std::forward<Type>(Left));
};
```

Parameters

Type

Any type that supports an `operator!` that takes an operand of the specified or inferred type.

Left

The operand of the logical not operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *Type*.

Return Value

The result of `!Left`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator!`.

Example

```

// functional_logical_not.cpp
// compile with: /EHsc
#include <deque>
#include <algorithm>
#include <functional>
#include <iostream>

int main( )
{
    using namespace std;
    deque<bool> d1, d2 ( 7 );
    deque<bool>::iterator iter1, iter2;

    int i;
    for ( i = 0 ; i < 7 ; i++ )
    {
        d1.push_back((bool)((i % 2) != 0));
    }

    cout << boolalpha;    // boolalpha I/O flag on

    cout << "Original deque:\n d1 = ( " ;
    for ( iter1 = d1.begin( ) ; iter1 != d1.end( ) ; iter1++ )
        cout << *iter1 << " ";
    cout << ")" << endl;

    // To flip all the truth values of the elements,
    // use the logical_not function object
    transform( d1.begin( ), d1.end( ), d2.begin( ), logical_not<bool>( ) );
    cout << "The deque with its values negated is:\n d2 = ( " ;
    for ( iter2 = d2.begin( ) ; iter2 != d2.end( ) ; iter2++ )
        cout << *iter2 << " ";
    cout << ")" << endl;
}
/* Output:
Original deque:
d1 = ( false true false true false true false )
The deque with its values negated is:
d2 = ( true false true false true false true )
*/

```

logical_or Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A predefined function object that performs the logical disjunction operation (`operator||`) on its arguments.

Syntax

```
template <class Type = void>
struct logical_or : public binary_function<Type, Type, bool>
{
    bool operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator||
template <>
struct logical_or<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const`
        -> decltype(std::forward<T>(Left) || std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator||` that takes operands of the specified or inferred types.

Left

The left operand of the logical disjunction operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the logical disjunction operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left || Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator||`.

Remarks

For user-defined types, there is no short-circuiting of operand evaluation. Both arguments are evaluated by `operator||`.

Example

```

// functional_logical_or.cpp
// compile with: /EHsc
#include <deque>
#include <algorithm>
#include <functional>
#include <iostream>

int main( )
{
    using namespace std;
    deque<bool> d1, d2, d3( 7 );
    deque<bool>::iterator iter1, iter2, iter3;

    int i;
    for ( i = 0 ; i < 7 ; i++ )
    {
        d1.push_back((bool)((rand() % 2) != 0));
    }

    int j;
    for ( j = 0 ; j < 7 ; j++ )
    {
        d2.push_back((bool)((rand() % 2) != 0));
    }

    cout << boolalpha;    // boolalpha I/O flag on

    cout << "Original deque:\n d1 = ( " ;
    for ( iter1 = d1.begin( ) ; iter1 != d1.end( ) ; iter1++ )
        cout << *iter1 << " ";
    cout << ")" << endl;

    cout << "Original deque:\n d2 = ( " ;
    for ( iter2 = d2.begin( ) ; iter2 != d2.end( ) ; iter2++ )
        cout << *iter2 << " ";
    cout << ")" << endl;

    // To find element-wise disjunction of the truth values
    // of d1 & d2, use the logical_or function object
    transform( d1.begin( ), d1.end( ), d2.begin( ),
        d3.begin( ), logical_or<bool>( ) );

[Thread Safety in the C++ Standard Library](#)

mem_fun_ref_t Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

An adapter class that allows a `non_const` member function that takes no arguments to be called as a unary function object when initialized with a reference argument. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Result, class Type>
class mem_fun_ref_t : public unary_function<Type, Result> {
    explicit mem_fun_ref_t(
        Result (Type::* _Pm)());

    Result operator()(Type& left) const;
};
```

Parameters

_Pm

A pointer to the member function of class `Type` to be converted to a function object.

left

The object that the *_Pm* member function is called on.

Return Value

An adaptable unary function.

Remarks

The template class stores a copy of *_Pm*, which must be a pointer to a member function of class `Type`, in a private member object. It defines its member function `operator()` as returning `(left.*_Pm)()`.

Example

The constructor of `mem_fun_ref_t` is not usually used directly; the helper function `mem_fun_ref` is used to adapt member functions. See [mem_fun_ref](#) for an example of how to use member function adaptors.

Requirements

Header: <functional>

Namespace: std

mem_fun_t Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

An adapter class that allows a `non_const` member function that takes no arguments to be called as a unary function object when initialized with a pointer argument. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Result, class Type>
class mem_fun_t : public unary_function<Type *, Result> {
    explicit mem_fun_t(Result (Type::* _Pm)());

    Result operator()(Type* _Pleft) const;
};
```

Parameters

_Pm

A pointer to the member function of class `Type` to be converted to a function object.

_Pleft

The object that the *_Pm* member function is called on.

Return Value

An adaptable unary function.

Remarks

The template class stores a copy of *_Pm*, which must be a pointer to a member function of class `Type`, in a private member object. It defines its member function `operator()` as returning `(_Pleft -> * _Pm)()`.

Example

The constructor of `mem_fun_t` is not usually used directly; the helper function `mem_fun` is used to adapt member functions. See [mem_fun](#) for an example of how to use member function adaptors.

mem_fun1_ref_t Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

An adapter class that allows a `non_const` member function that takes a single argument to be called as a binary function object when initialized with a reference argument. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Result, class Type, class Arg>
class mem_fun1_ref_t : public binary_function<Type, Arg, Result> {
    explicit mem_fun1_ref_t(
        Result (Type::* _Pm)(Arg));

    Result operator()(
        Type& left,
        Arg right) const;

};
```

Parameters

_Pm

A pointer to the member function of class `Type` to be converted to a function object.

left

The object that the *_Pm* member function is called on.

right

The argument that is being given to *_Pm*.

Return Value

An adaptable binary function.

Remarks

The template class stores a copy of *_Pm*, which must be a pointer to a member function of class `Type`, in a private member object. It defines its member function `operator()` as returning (**left**.* *_Pm*)(**right**).

Example

The constructor of `mem_fun1_ref_t` is not usually used directly; the helper function `mem_fun_ref` is used to adapt member functions. See [mem_fun_ref](#) for an example of how to use member function adaptors.

Requirements

Header: <functional>

Namespace: std

mem_fun1_t Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

An adapter class that allows a `non_const` member function that takes a single argument to be called as a binary function object when initialized with a pointer argument. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Result, class Type, class Arg>
class mem_fun1_t : public binary_function<Type *, Arg, Result> {
    explicit mem_fun1_t(
        Result (Type::* _Pm)(Arg));

    Result operator()(
        Type* _Pleft,
        Arg right) const;

};
```

Parameters

_Pm

A pointer to the member function of class `Type` to be converted to a function object.

_Pleft

The object that the *_Pm* member function is called on.

right

The argument that is being given to *_Pm*.

Return Value

An adaptable binary function.

Remarks

The template class stores a copy of *_Pm*, which must be a pointer to a member function of class `Type`, in a private member object. It defines its member function `operator()` as returning `(_Pleft->* _Pm)(right)`.

Example

The constructor of `mem_fun1_t` is not usually used directly; the helper function `mem_fun` is used to adapt member functions. See [mem_fun](#) for an example of how to use member function adaptors.

Requirements

Header: <functional>

Namespace: std

minus Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A predefined function object that performs the subtraction operation (binary `operator-`) on its arguments.

Syntax

```
template <class Type = void>
struct minus : public binary_function <Type, Type, Type>
{
    Type operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator-
template <>
struct minus<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const`
        -> decltype(std::forward<T>(Left) - std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* A type that supports a binary `operator-` that takes operands of the specified or inferred types.

Left

The left operand of the operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left - Right`. The specialized template does perfect forwarding of the result, which has the type returned by `operator-`.

Example

```

// functional_minus.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main( )
{
    vector<int> v1, v2, v3 ( 6 );
    vector<int>::iterator Iter1, Iter2, Iter3;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
    {
        v1.push_back( 4 * i + 1);
    }

    int j;
    for ( j = 0 ; j <= 5 ; j++ )
    {
        v2.push_back( 3 * j - 1);
    }

    cout << "The vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "The vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Finding the element-wise difference of the elements of v1 & v2
    transform ( v1.begin( ), v1.end( ), v2.begin( ), v3.begin( ),
        minus<int>( ) );

    cout << "The element-wise differences between v1 and v2 are: ( " ;
    for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
        cout << *Iter3 << " ";
    cout << ")" << endl;
}
/* Output:
The vector v1 = ( 1 5 9 13 17 21 )
The vector v2 = ( -1 2 5 8 11 14 )
The element-wise differences between v1 and v2 are: ( 2 3 4 5 6 7 )
*/

```

Requirements

Header: <functional>

Namespace: std

modulus Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A predefined function object that performs the modulus division operation (`operator%`) on its arguments.

Syntax

```
template <class Type = void>
struct modulus : public binary_function <Type, Type, Type>
{
    Type operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator%
template <>
struct modulus<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const`
        -> decltype(std::forward<T>(Left) % std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator%` that takes operands of the specified or inferred types.

Left

The left operand of the modulus operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the modulus operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left % Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator%`.

Remarks

The `modulus` functor is restricted to integral types for the basic data types, or to user-defined types that implement `operator%`.

Example

```

// functional_modulus.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main( )
{
    vector<int> v1, v2, v3 ( 6 );
    vector<int>::iterator Iter1, Iter2, Iter3;

    int i;
    for ( i = 1 ; i <= 6 ; i++ )
    {
        v1.push_back( 5 * i );
    }

    int j;
    for ( j = 1 ; j <= 6 ; j++ )
    {
        v2.push_back( 3 * j );
    }

    cout << "The vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "The vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Finding the element-wise remainders of the elements of v1 & v2
    transform (v1.begin( ), v1.end( ), v2.begin( ), v3.begin( ),
        modulus<int>() );

    cout << "The element-wise remainders of the modular division\n are: ( " ;
    for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
        cout << *Iter3 << " ";
    cout << ")" << endl;
}
/* Output:
The vector v1 = ( 5 10 15 20 25 30 )
The vector v2 = ( 3 6 9 12 15 18 )
The element-wise remainders of the modular division
are: ( 2 4 6 8 10 12 )
*/

```

Requirements

Header: <functional>

Namespace: std

multiplies Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A predefined function object that performs the multiplication operation (binary `operator*`) on its arguments.

Syntax

```
template <class Type = void>
struct multiplies : public binary_function <Type, Type, Type>
{
    Type operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator*
template <>
struct multiplies<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const`
        -> decltype(std::forward<T>(Left) * std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* A type that supports a binary `operator*` that takes operands of the specified or inferred types.

Left

The left operand of the multiplication operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the multiplication operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left * Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator*`.

Example

```

// functional_multiplies.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main( )
{
    vector<int> v1, v2, v3 ( 6 );
    vector<int>::iterator Iter1, Iter2, Iter3;

    int i;
    for ( i = 1 ; i <= 6 ; i++ )
    {
        v1.push_back( 2 * i );
    }

    int j;
    for ( j = 1 ; j <= 6 ; j++ )
    {
        v2.push_back( 3 * j );
    }

    cout << "The vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "The vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Finding the element-wise products of the elements of v1 & v2
    transform ( v1.begin( ), v1.end( ), v2.begin( ), v3.begin( ),
        multiplies<int>( ) );

    cout << "The element-wise products of vectors V1 & v2\n are: ( " ;
    for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
        cout << *Iter3 << " ";
    cout << ")" << endl;
}
/* Output:
The vector v1 = ( 2 4 6 8 10 12 )
The vector v2 = ( 3 6 9 12 15 18 )
The element-wise products of vectors V1 & v2
are: ( 6 24 54 96 150 216 )
*/

```

negate Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A predefined function object that performs the arithmetic negation operation (unary `operator-`) on its argument.

Syntax

```
template <class Type = void>
struct negate : public unary_function<Type, Type>
{
    Type operator()(const Type& Left) const;
};

// specialized transparent functor for unary operator-
template <>
struct negate<void>
{
    template <class Type>
    auto operator()(Type&& Left) const`
        -> decltype(-std::forward<Type>(Left));
};
```

Parameters

Type

Any type that supports an `operator-` that takes an operand of the specified or inferred type.

Left

The operand to be negated. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *Type*.

Return Value

The result of `-Left`. The specialized template does perfect forwarding of the result, which has the type that's returned by unary `operator-`.

Example

```

// functional_negate.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main( )
{
    vector<int> v1, v2 ( 8 );
    vector<int>::iterator Iter1, Iter2;

    int i;
    for ( i = -2 ; i <= 5 ; i++ )
    {
        v1.push_back( 5 * i );
    }

    cout << "The vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    // Finding the element-wise negatives of the vector v1
    transform ( v1.begin( ), v1.end( ), v2.begin( ), negate<int>( ) );

    cout << "The negated elements of the vector = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;
}
/* Output:
The vector v1 = ( -10 -5 0 5 10 15 20 25 )
The negated elements of the vector = ( 10 5 0 -5 -10 -15 -20 -25 )
*/

```

Requirements

Header: <functional>

Namespace: std

[C++ Standard Library Reference](#)

not_equal_to Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A binary predicate that performs the inequality operation (`operator!=`) on its arguments.

Syntax

```
template <class Type = void>
struct not_equal_to : public binary_function<Type, Type, bool>
{
    bool operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator!=
template <>
struct not_equal_to<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const`
        -> decltype(std::forward<T>(Left) != std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* Any type that supports an `operator!=` that takes operands of the specified or inferred types.

Left

The left operand of the inequality operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the inequality operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left != Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by `operator!=`.

Remarks

The objects of type *Type* must be equality-comparable. This requires that the `operator!=` defined on the set of objects satisfies the mathematical properties of an equivalence relation. All of the built-in numeric and pointer types satisfy this requirement.

Example

```

// functional_not_equal_to.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main( )
{
    vector <double> v1, v2, v3 (6);
    vector <double>::iterator Iter1, Iter2, Iter3;

    int i;
    for ( i = 0 ; i <= 5 ; i+=2 )
    {
        v1.push_back( 2.0 *i );
        v1.push_back( 2.0 * i + 1.0 );
    }

    int j;
    for ( j = 0 ; j <= 5 ; j+=2 )
    {
        v2.push_back( - 2.0 * j );
        v2.push_back( 2.0 * j + 1.0 );
    }

    cout << "The vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "The vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Testing for the element-wise equality between v1 & v2
    transform ( v1.begin( ), v1.end( ), v2.begin( ), v3.begin ( ),
        not_equal_to<double>( ) );

    cout << "The result of the element-wise not_equal_to comparsion\n"
        << "between v1 & v2 is: ( " ;
    for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
        cout << *Iter3 << " ";
    cout << ")" << endl;
}
/* Output:
The vector v1 = ( 0 1 4 5 8 9 )
The vector v2 = ( -0 1 -4 5 -8 9 )
The result of the element-wise not_equal_to comparsion
between v1 & v2 is: ( 0 0 1 0 1 0 )
*/

```

plus Struct

2/28/2019 • 2 minutes to read • [Edit Online](#)

A predefined function object that performs the addition operation (binary `operator+`) on its arguments.

Syntax

```
template <class Type = void>
struct plus : public binary_function <Type, Type, Type>
{
    Type operator()(const Type& Left, const Type& Right) const;
};

// specialized transparent functor for operator+
template <>
struct plus<void>
{
    template <class T, class U>
    auto operator()(T&& Left, U&& Right) const`
        -> decltype(std::forward<T>(Left) + std::forward<U>(Right));
};
```

Parameters

Type, *T*, *U* A type that supports a binary `operator+` that takes operands of the specified or inferred types.

Left

The left operand of the addition operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *T*.

Right

The right operand of the addition operation. The unspecialized template takes an lvalue reference argument of type *Type*. The specialized template does perfect forwarding of lvalue and rvalue reference arguments of inferred type *U*.

Return Value

The result of `Left + Right`. The specialized template does perfect forwarding of the result, which has the type that's returned by binary `operator+`.

Example

```

// functional_plus.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main( )
{
    vector <double> v1, v2, v3 ( 6 );
    vector <double>::iterator Iter1, Iter2, Iter3;

    int i;
    for ( i = 0 ; i <= 5 ; i++ )
        v1.push_back( 4 * i );

    int j;
    for ( j = 0 ; j <= 5 ; j++ )
        v2.push_back( -2.0 * j - 4 );

    cout << "The vector v1 = ( " ;
    for ( Iter1 = v1.begin( ) ; Iter1 != v1.end( ) ; Iter1++ )
        cout << *Iter1 << " ";
    cout << ")" << endl;

    cout << "The vector v2 = ( " ;
    for ( Iter2 = v2.begin( ) ; Iter2 != v2.end( ) ; Iter2++ )
        cout << *Iter2 << " ";
    cout << ")" << endl;

    // Finding the element-wise sums of the elements of v1 & v2
    transform (v1.begin( ), v1.end( ), v2.begin( ), v3.begin( ), plus<double>( ) );

    cout << "The element-wise sums are: ( " ;
    for ( Iter3 = v3.begin( ) ; Iter3 != v3.end( ) ; Iter3++ )
        cout << *Iter3 << " ";
    cout << ")" << endl;
}
/* Output:
The vector v1 = ( 0 4 8 12 16 20 )
The vector v2 = ( -4 -6 -8 -10 -12 -14 )
The element-wise sums are: ( -4 -2 0 2 4 6 )
*/

```

[C++ Standard Library Reference](#)

pointer_to_binary_function Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

Converts a binary function pointer into an adaptable binary function. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Arg1, class Arg2, class Result>
class pointer_to_binary_function
    : public binary_function <Arg1, Arg2, Result>
{
public:
    explicit pointer_to_binary_function(
        Result(*pfunc)(Arg1, Arg2));
    Result operator()(Arg1 left, Arg2 right) const;
};
```

Parameters

pfunc

The binary function to be converted.

left

The left object that the **pfunc* is called on.

right

The right object that the **pfunc* is called on.

Return Value

The template class stores a copy of `pfunc`. It defines its member function `operator()` as returning `(* pfunc)(Left, right)`.

Remarks

A binary function pointer is a function object and may be passed to any C++ Standard Library algorithm that is expecting a binary function as a parameter, but it is not adaptable. To use it with an adaptor, such as binding a value to it or using it with a negator, it must be supplied with the nested types `first_argument_type`, `second_argument_type`, and `result_type` that make such an adaptation possible. The conversion by `pointer_to_binary_function` allows the function adaptors to work with binary function pointers.

Example

The constructor of `pointer_to_binary_function` is rarely used directly. See the helper function `ptr_fun` for an example of how to declare and use the `pointer_to_binary_function` adaptor predicate.

Requirements

Header: <functional>

Namespace: std

See also

[C++ Standard Library Reference](#)

pointer_to_unary_function Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

Converts a unary function pointer into an adaptable unary function. Deprecated in C++11, removed in C++17.

Syntax

```
template <class Arg, class Result>
class pointer_to_unary_function
    : public unary_function<Arg, Result>
{
public:
    explicit pointer_to_unary_function(Result(*pfunc)(Arg));
    Result operator()(Arg left) const;
};
```

Parameters

pfunc

The binary function to be converted.

left

The object that the **pfunc* is called on.

Return Value

The template class stores a copy of `pfunc`. It defines its member function `operator()` as returning `(* pfunc)(Left)`.

Remarks

A unary function pointer is a function object and may be passed to any C++ Standard Library algorithm that is expecting a unary function as a parameter, but it is not adaptable. To use it with an adaptor, such as binding a value to it or using it with a negator, it must be supplied with the nested types `argument_type` and `result_type` that make such an adaptation possible. The conversion by `pointer_to_unary_function` allows the function adaptors to work with binary function pointers.

Example

The constructor of `pointer_to_unary_function` is rarely used directly. See the helper function `ptr_fun` for an example of how to declare and use the `pointer_to_unary_function` adaptor predicate.

Requirements

Header: `<functional>`

Namespace: `std`

[C++ Standard Library Reference](#)

reference_wrapper Class

11/9/2018 • 3 minutes to read • [Edit Online](#)

Wraps a reference.

Syntax

```
template <class Ty>
class reference_wrapper
{
public:
    typedef Ty type;

    reference_wrapper(Ty&) noexcept;
    operator Ty&() const noexcept;
    Ty& get() const noexcept;

    template <class... Types>
    auto operator()(Types&&... args) const ->
        decltype(std::invoke(get(), std::forward<Types>(args)...));

private:
    Ty *ptr; // exposition only
};
```

Remarks

A `reference_wrapper<Ty>` is a copy constructible and copy assignable wrapper around a reference to an object or a function of type `Ty`, and holds a pointer that points to an object of that type. A `reference_wrapper` can be used to store references in standard containers, and to pass objects by reference to `std::bind`.

The type `Ty` must be an object type or a function type, or a static assert fails at compile time.

The helper functions `std::ref` and `std::cref` can be used to create `reference_wrapper` objects.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>reference_wrapper</code>	Constructs a <code>reference_wrapper</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>result_type</code>	The weak result type of the wrapped reference.
<code>type</code>	The type of the wrapped reference.

Member functions

MEMBER FUNCTION	DESCRIPTION
get	Obtains the wrapped reference.

Operators

OPERATOR	DESCRIPTION
reference_wrapper::operator Ty&	Gets a pointer to the wrapped reference.
reference_wrapper::operator()	Calls the wrapped reference.

Requirements

Header: <functional>

Namespace: std

reference_wrapper::get

Obtains the wrapped reference.

```
Ty& get() const noexcept;
```

Remarks

The member function returns the wrapped reference.

Example

```
// std__functional__reference_wrapper_get.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int main() {
    int i = 1;
    std::reference_wrapper<int> rwi(i);

    std::cout << "i = " << i << std::endl;
    std::cout << "rwi = " << rwi << std::endl;
    rwi.get() = -1;
    std::cout << "i = " << i << std::endl;

    return (0);
}
```

```
i = 1
rwi = 1
i = -1
```

reference_wrapper::operator Ty&

Gets the wrapped reference.

```
operator Ty&() const noexcept;
```

Remarks

The member operator returns `*ptr`.

Example

```
// std__functional__reference_wrapper_operator_cast.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int main() {
    int i = 1;
    std::reference_wrapper<int> rwi(i);

    std::cout << "i = " << i << std::endl;
    std::cout << "(int)rwi = " << (int)rwi << std::endl;

    return (0);
}
```

```
i = 1
(int)rwi = 1
```

reference_wrapper::operator()

Calls the wrapped reference.

```
template <class... Types>
auto operator()(Types&&... args);
```

Parameters

Types

The argument list types.

args

The argument list.

Remarks

The template member `operator()` returns `std::invoke(get(), std::forward<Types>(args)...) .`

Example

```
// std_functional_reference_wrapper_operator_call.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val) {
    return (-val);
}

int main() {
    std::reference_wrapper<int (int)> rwi(neg);

    std::cout << "rwi(3) = " << rwi(3) << std::endl;

    return (0);
}
```

```
rwi(3) = -3
```

reference_wrapper::reference_wrapper

Constructs a `reference_wrapper`.

```
reference_wrapper(Ty& val) noexcept;
```

Parameters

Ty

The type to wrap.

val

The value to wrap.

Remarks

The constructor sets the stored value `ptr` to `&val`.

Example

```
// std_functional_reference_wrapper_reference_wrapper.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val) {
    return (-val);
}

int main() {
    int i = 1;
    std::reference_wrapper<int> rwi(i);

    std::cout << "i = " << i << std::endl;
    std::cout << "rwi = " << rwi << std::endl;
    rwi.get() = -1;
    std::cout << "i = " << i << std::endl;

    return (0);
}
```

```
i = 1
rwi = 1
i = -1
```

reference_wrapper::result_type

The weak result type of the wrapped reference.

```
typedef R result_type;
```

Remarks

The `result_type` typedef is a synonym for the weak result type of a wrapped function. This typedef is only meaningful for function types.

Example

```
// std_functional_reference_wrapper_result_type.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val) {
    return (-val);
}

int main() {
    typedef std::reference_wrapper<int (int)> Mywrapper;
    Mywrapper rwi(neg);
    Mywrapper::result_type val = rwi(3);

    std::cout << "val = " << val << std::endl;

    return (0);
}
```

```
val = -3
```

reference_wrapper::type

The type of the wrapped reference.

```
typedef Ty type;
```

Remarks

The typedef is a synonym for the template argument `Ty`.

Example

```
// std_functional_reference_wrapper_type.cpp
// compile with: /EHsc
#include <functional>
#include <iostream>

int neg(int val) {
    return (-val);
}

int main() {
    int i = 1;
    typedef std::reference_wrapper<int> Mywrapper;
    Mywrapper rwi(i);
    Mywrapper::type val = rwi.get();

    std::cout << "i = " << i << std::endl;
    std::cout << "rwi = " << val << std::endl;

    return (0);
}
```

```
i = 1
rwi = 1
```

[ref](#)

unary_function Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

An empty base struct that defines types that may be inherited by derived classes that provides a unary function object.

Syntax

```
struct unary_function
{
    typedef Arg argument_type;
    typedef Result result_type;
};
```

Remarks

The template struct serves as a base for classes that define a member function of the form **result_type** `operator()` (**const** **argument_type**&) **const**.

All such derived unary functions can refer to their sole argument type as **argument_type** and their return type as **result_type**.

Example

```

// functional_unary_function.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

// Creation of a user-defined function object
// that inherits from the unary_function base class
class greaterthan10: unary_function<int, bool>
{
public:
    result_type operator()(argument_type i)
    {
        return (result_type)(i > 10);
    }
};

int main()
{
    vector<int> v1;
    vector<int>::iterator Iter;

    int i;
    for (i = 0; i <= 5; i++)
    {
        v1.push_back(5 * i);
    }

    cout << "The vector v1 = ( " ;
    for (Iter = v1.begin(); Iter != v1.end(); Iter++)
        cout << *Iter << " ";
    cout << ")" << endl;

    vector<int>::iterator::difference_type result1;
    result1 = count_if(v1.begin(), v1.end(), greaterthan10());
    cout << "The number of elements in v1 greater than 10 is: "
        << result1 << "." << endl;
}

/* Output:
The vector v1 = ( 0 5 10 15 20 25 )
The number of elements in v1 greater than 10 is: 3.
*/

```

Requirements

Header: <functional>

Namespace: std

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

unary_negate Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

A template class providing a member function that negates the return value of a specified unary function. Deprecated in C++17 in favor of [not_fn](#).

Syntax

```
template <class Predicate>
class unary_negate
    : public unaryFunction<typename Predicate::argument_type, bool>
{
public:
    explicit unary_negate(const Predicate& Func);
    bool operator()(const typename Predicate::argument_type& left) const;
};
```

Parameters

Func

The unary function to be negated.

left

The operand of the unary function to be negated.

Return Value

The negation of the unary function.

Remarks

The template class stores a copy of a unary function object *_Func*. It defines its member function `operator()` as returning `!_Func(left)`.

The constructor of `unary_negate` is rarely used directly. The helper function [not1](#) provides an easier way to declare and use the **unary_negator** adaptor predicate.

Example

```

// functional_unary_negate.cpp
// compile with: /EHsc
#include <vector>
#include <functional>
#include <algorithm>
#include <iostream>

using namespace std;

int main()
{
    vector<int> v1;
    vector<int>::iterator Iter;

    int i;
    for (i = 0; i <= 7; i++)
    {
        v1.push_back(5 * i);
    }

    cout << "The vector v1 = ( ";
    for (Iter = v1.begin(); Iter != v1.end(); Iter++)
        cout << *Iter << " ";
    cout << ")" << endl;

    vector<int>::iterator::difference_type result1;
    // Count the elements greater than 10
    result1 = count_if(v1.begin(), v1.end(), bind2nd(greater<int>(), 10));
    cout << "The number of elements in v1 greater than 10 is: "
        << result1 << "." << endl;

    vector<int>::iterator::difference_type result2;
    // Use the negator to count the elements less than or equal to 10
    result2 = count_if(v1.begin(), v1.end(),
        unary_negate<bindefun2nd <greater<int> > >(bind2nd(greater<int>(), 10))));

    // The following helper function not1 also works for the above line
    // not1(bind2nd(greater<int>(), 10));

    cout << "The number of elements in v1 not greater than 10 is: "
        << result2 << "." << endl;
}
/* Output:
The vector v1 = ( 0 5 10 15 20 25 30 35 )
The number of elements in v1 greater than 10 is: 5.
The number of elements in v1 not greater than 10 is: 3.
*/

```

Requirements

Header: `<functional>`

Namespace: `std`

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

<future>

10/31/2018 • 3 minutes to read • [Edit Online](#)

Include the standard header <future> to define template classes and supporting templates that simplify running a function—possibly in a separate thread—and retrieving its result. The result is either the value that is returned by the function or an exception that is emitted by the function but is not caught in the function.

This header uses Concurrency Runtime (ConcRT) so that you can use it together with other ConcRT mechanisms. For more information about ConcRT, see [Concurrency Runtime](#).

Syntax

```
#include <future>
```

Remarks

NOTE

In code that is compiled by using **/clr**, this header is blocked.

An *asynchronous provider* stores the result of a function call. An *asynchronous return object* is used to retrieve the result of a function call. An *associated asynchronous state* provides communication between an asynchronous provider and one or more asynchronous return objects.

A program does not directly create any associated asynchronous state objects. The program creates an asynchronous provider whenever it needs one and from that it creates an asynchronous return object that shares its associated asynchronous state with the provider. Asynchronous providers and asynchronous return objects manage the objects that hold their shared associated asynchronous state. When the last object that references the associated asynchronous state releases it, the object that holds the associated asynchronous state is destroyed.

An asynchronous provider or an asynchronous return object that has no associated asynchronous state is *empty*.

An associated asynchronous state is *ready* only if its asynchronous provider has stored a return value or stored an exception.

The template function `async` and the template classes `promise` and `packaged_task` are asynchronous providers. The template classes `future` and `shared_future` describe asynchronous return objects.

Each of the template classes `promise`, `future`, and `shared_future` has a specialization for the type **void** and a partial specialization for storing and retrieving a value by reference. These specializations differ from the primary template only in the signatures and semantics of the functions that store and retrieve the returned value.

The template classes `future` and `shared_future` never block in their destructors, except in one case that's preserved for backward compatibility: Unlike all other futures, for a `future`—or the last `shared_future`—that's attached to a task started with `std::async`, the destructor blocks if the task has not completed; that is, it blocks if this thread did not yet call `.get()` or `.wait()` and the task is still running. The following usability note has been added to the description of `std::async` in the draft standard: "[Note: If a future obtained from `std::async` is moved outside the local scope, other code that uses the future must be aware that the future's destructor may block for the shared state to become ready.—end note]" In all other cases, `future` and `shared_future` destructors are required and are guaranteed to never block.

Members

Classes

NAME	DESCRIPTION
future Class	Describes an asynchronous return object.
future_error Class	Describes an exception object that can be thrown by methods of types that manage <code>future</code> objects.
packaged_task Class	Describes an asynchronous provider that is a call wrapper and whose call signature is <code>Ty(ArgTypes...)</code> . Its associated asynchronous state holds a copy of its callable object in addition to the potential result.
promise Class	Describes an asynchronous provider.
shared_future Class	Describes an asynchronous return object. In contrast with a <code>future</code> object, an asynchronous provider can be associated with any number of <code>shared_future</code> objects.

Structures

NAME	DESCRIPTION
is_error_code_enum Structure	Specialization that indicates that <code>future_errc</code> is suitable for storing an <code>error_code</code> .
uses_allocator Structure	Specialization that always holds true.

Functions

NAME	DESCRIPTION
async	Represents an asynchronous provider.
future_category	Returns a reference to the <code>error_category</code> object that characterizes errors that are associated with <code>future</code> objects.
make_error_code	Creates an <code>error_code</code> that has the <code>error_category</code> object that characterizes <code>future</code> errors.
make_error_condition	Creates an <code>error_condition</code> that has the <code>error_category</code> object that characterizes <code>future</code> errors.
swap	Exchanges the associated asynchronous state of one <code>promise</code> object with that of another.

Enumerations

NAME	DESCRIPTION
future_errc	Supplies symbolic names for the errors that are reported by the <code>future_error</code> class.
future_status	Supplies symbolic names for the reasons that a timed wait function can return.
launch	Represents a bitmask type that describes the possible modes for the template function <code>async</code> .

[Header Files Reference](#)

<future> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

async	future_category	make_error_code
make_error_condition	swap	

async

Represents an *asynchronous provider*.

```
template <class Fn, class... ArgTypes>
future<typename result_of<Fn(ArgTypes...)>::type>
    async(Fn&& fn, ArgTypes&&... args);

template <class Fn, class... ArgTypes>
future<typename result_of<Fn(ArgTypes...)>::type>
    async(launch policy, Fn&& fn, ArgTypes&&... args);
```

Parameters

policy

A [launch](#) value.

Remarks

Definitions of abbreviations:

<i>dfn</i>	The result of calling <code>decay_copy(forward<Fn>(fn))</code> .
<i>dargs</i>	The results of the calls <code>decay_copy(forward<ArgTypes>(args...))</code> .
<i>Ty</i>	The type <code>result_of<Fn(ArgTypes...)>::type</code> .

The first template function returns `async(launch::any, fn, args...)`.

The second function returns a `future<Ty>` object whose *associated asynchronous state* holds a result together with the values of *dfn* and *dargs* and a thread object to manage a separate thread of execution.

Unless `decay<Fn>::type` is a type other than `launch`, the second function does not participate in overload resolution.

The C++ standard states that if `policy` is `launch::async`, the function creates a new thread. However the Microsoft implementation is currently non-conforming. It obtains its threads from the Windows ThreadPool, which in some cases may provide a recycled thread rather than a new one. This means that the `launch::async` policy is actually implemented as `launch::async|launch::deferred`. Another implication of the ThreadPool-based implementation is that there is no guarantee that thread-local variables will be destroyed when the thread completes. If the thread is recycled and provided to a new call to `async`, the old variables will still exist. We therefore recommend that you do

not use thread-local variables with `async`.

If *policy* is `launch::deferred`, the function marks its associated asynchronous state as holding a *deferred function* and returns. The first call to any non-timed function that waits for the associated asynchronous state to be ready in effect calls the deferred function by evaluating `INVOKE(dfn, dargs..., Ty)`.

In all cases, the associated asynchronous state of the `future` object is not set to *ready* until the evaluation of `INVOKE(dfn, dargs..., Ty)` completes, either by throwing an exception or by returning normally. The result of the associated asynchronous state is an exception if one was thrown, or any value that's returned by the evaluation.

NOTE

For a `future`—or the last `shared_future`—that's attached to a task started with `std::async`, the destructor blocks if the task has not completed; that is, it blocks if this thread did not yet call `.get()` or `.wait()` and the task is still running. If a `future` obtained from `std::async` is moved outside the local scope, other code that uses it must be aware that its destructor may block for the shared state to become ready.

The pseudo-function `INVOKE` is defined in [<functional>](#).

future_category

Returns a reference to the `error_category` object that characterizes errors that are associated with `future` objects.

```
const error_category& future_category() noexcept;
```

make_error_code

Creates an `error_code` together with the `error_category` object that characterizes `future` errors.

```
inline error_code make_error_code(future_errc Errno) noexcept;
```

Parameters

Errno

A `future_errc` value that identifies the reported error.

Return Value

```
error_code(static_cast<int>(Errno), future_category());
```

make_error_condition

Creates an `error_condition` together with the `error_category` object that characterizes `future` errors.

```
inline error_condition make_error_condition(future_errc Errno) noexcept;
```

Parameters

Errno

A `future_errc` value that identifies the reported error.

Return Value

```
error_condition(static_cast<int>(Errno), future_category());
```

swap

Exchanges the *associated asynchronous state* of one `promise` object with that of another.

```
template <class Ty>
void swap(promise<Ty>& Left, promise<Ty>& Right) noexcept;

template <class Ty, class... ArgTypes>
void swap(packaged_task<Ty(ArgTypes...)>& Left, packaged_task<Ty(ArgTypes...)>& Right) noexcept;
```

Parameters

Left

The left `promise` object.

Right

The right `promise` object.

[<future>](#)

<future> enums

10/31/2018 • 2 minutes to read • [Edit Online](#)

future_errc	future_status	launch

future_errc Enumeration

Supplies symbolic names for all of the errors that are reported by the [future_error](#) class.

```
class future_errc {
    broken_promise,
    future_already_retrieved,
    promise_already_satisfied,
    no_state
};
```

future_status Enumeration

Supplies symbolic names for the reasons that a timed wait function can return.

```
enum future_status{
    ready,
    timeout,
    deferred
};
```

launch Enumeration

Represents a bitmask type that describes the possible modes for the template function [async](#).

```
class launch{
    async,
    deferred
};
```

See also

[<future>](#)

future Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an *asynchronous return object*.

Syntax

```
template <class Ty>
class future;
```

Remarks

Each standard *asynchronous provider* returns an object whose type is an instantiation of this template. A `future` object provides the only access to the asynchronous provider that it is associated with. If you need multiple asynchronous return objects that are associated with the same asynchronous provider, copy the `future` object to a `shared_future` object.

Members

Public Constructors

NAME	DESCRIPTION
<code>future</code>	Constructs a <code>future</code> object.

Public Methods

NAME	DESCRIPTION
<code>get</code>	Retrieves the result that is stored in the associated asynchronous state.
<code>share</code>	Converts the object to a <code>shared_future</code> .
<code>valid</code>	Specifies whether the object is not empty.
<code>wait</code>	Blocks the current thread until the associated asynchronous state is ready.
<code>wait_for</code>	Blocks until the associated asynchronous state is ready or until the specified time has elapsed.
<code>wait_until</code>	Blocks until the associated asynchronous state is ready or until a specified point in time.

Public Operators

NAME	DESCRIPTION
<code>future::operator=</code>	Transfers the associated asynchronous state from a specified object.

Requirements

Header: `<future>`

Namespace: `std`

future::future Constructor

Constructs a `future` object.

```
future() noexcept;
future(future&& Other) noexcept;
```

Parameters

Other

A `future` object.

Remarks

The first constructor constructs a `future` object that has no associated asynchronous state.

The second constructor constructs a `future` object and transfers the associated asynchronous state from *Other*. *Other* no longer has an associated asynchronous state.

future::get

Retrieves the result that is stored in the associated asynchronous state.

```
Ty get();
```

Return Value

If the result is an exception, the method rethrows it. Otherwise, the result is returned.

Remarks

Before it retrieves the result, this method blocks the current thread until the associated asynchronous state is ready.

For the partial specialization `future<Ty&>`, the stored value is effectively a reference to the object that was passed to the asynchronous provider as the return value.

Because no stored value exists for the specialization `future<void>`, the method returns **void**.

In other specializations, the method moves its return value from the stored value. Therefore, call this method only once.

future::operator=

Transfers an associated asynchronous state from a specified object.

```
future& operator=(future&& Right) noexcept;
```

Parameters

Right

A `future` object.

Return Value

`*this`

Remarks

After the transfer, *Right* no longer has an associated asynchronous state.

future::share

Converts the object to a [shared_future](#) object.

```
shared_future<Ty> share();
```

Return Value

`shared_future(move(*this))`

future::valid

Specifies whether the object has an associated asynchronous state.

```
bool valid() noexcept;
```

Return Value

true if the object has an associated asynchronous state; otherwise, **false**.

future::wait

Blocks the current thread until the associated asynchronous state is *ready*.

```
void wait() const;
```

Remarks

An associated asynchronous state is *ready* only if its asynchronous provider has stored a return value or stored an exception.

future::wait_for

Blocks the current thread until the associated asynchronous state is *ready* or until a specified time interval has elapsed.

```
template <class Rep, class Period>  
future_status wait_for(const chrono::duration<Rep, Period>& Rel_time) const;
```

Parameters

Rel_time

A [chrono::duration](#) object that specifies a maximum time interval that the thread blocks.

Return Value

A [future_status](#) that indicates the reason for returning.

Remarks

An associated asynchronous state is ready only if its asynchronous provider has stored a return value or stored an exception.

future::wait_until

Blocks the current thread until the associated asynchronous state is *ready* or until after a specified time point.

```
template <class Clock, class Duration>
future_status wait_until(const chrono::time_point<Clock, Duration>& Abs_time) const;
```

Parameters

Abs_time

A [chrono::time_point](#) object that specifies a time after which the thread can unblock.

Return Value

A [future_status](#) that indicates the reason for returning.

Remarks

An associated asynchronous state is *ready* only if its asynchronous provider has stored a return value or stored an exception.

packaged_task Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

Describes an *asynchronous provider* that is a call wrapper whose call signature is `Ty(ArgTypes...)`. Its *associated asynchronous state* holds a copy of its callable object in addition to the potential result.

Syntax

```
template <class>
class packaged_task;
```

Members

Public Constructors

NAME	DESCRIPTION
<code>packaged_task</code>	Constructs a <code>packaged_task</code> object.
<code>packaged_task::~~packaged_task</code> Destructor	Destroys a <code>packaged_task</code> object.

Public Methods

NAME	DESCRIPTION
<code>get_future</code>	Returns a <code>future</code> object that has the same associated asynchronous state.
<code>make_ready_at_thread_exit</code>	Calls the callable object that's stored in the associated asynchronous state and atomically stores the returned value.
<code>reset</code>	Replaces the associated asynchronous state.
<code>swap</code>	Exchanges the associated asynchronous state with that of a specified object.
<code>valid</code>	Specifies whether the object has an associated asynchronous state.

Public Operators

NAME	DESCRIPTION
<code>packaged_task::operator=</code>	Transfers an associated asynchronous state from a specified object.
<code>packaged_task::operator()</code>	Calls the callable object that's stored in the associated asynchronous state, atomically stores the returned value, and sets the state to <i>ready</i> .

NAME	DESCRIPTION
<code>packaged_task::operator bool</code>	Specifies whether the object has an associated asynchronous state.

Requirements

Header: `<future>`

Namespace: `std`

`packaged_task::get_future`

Returns an object of type `future<Ty>` that has the same *associated asynchronous state*.

```
future<Ty> get_future();
```

Remarks

If the `packaged_task` object does not have an associated asynchronous state, this method throws a `future_error` that has an error code of `no_state`.

If this method has already been called for a `packaged_task` object that has the same associated asynchronous state, the method throws a `future_error` that has an error code of `future_already_retrieved`.

`packaged_task::make_ready_at_thread_exit`

Calls the callable object that's stored in the *associated asynchronous state* and atomically stores the returned value.

```
void make_ready_at_thread_exit(AngTypes... args);
```

Remarks

If the `packaged_task` object doesn't have an associated asynchronous state, this method throws a `future_error` that has an error code of `no_state`.

If this method or `make_ready_at_thread_exit` has already been called for a `packaged_task` object that has the same associated asynchronous state, the method throws a `future_error` that has an error code of `promise_already_satisfied`.

Otherwise, this operator calls `INVOKE(fn, args..., Ty)`, where *fn* is the callable object that's stored in the associated asynchronous state. Any returned value is stored atomically as the returned result of the associated asynchronous state.

In contrast to `packaged_task::operator()`, the associated asynchronous state is not set to `ready` until after all thread-local objects in the calling thread have been destroyed. Typically, threads that are blocked on the associated asynchronous state are not unblocked until the calling thread exits.

`packaged_task::operator=`

Transfers the *associated asynchronous state* from a specified object.

```
packaged_task& operator=(packaged_task&& Right);
```

Parameters

Right

A `packaged_task` object.

Return Value

`*this`

Remarks

After the operation, *Right* no longer has an associated asynchronous state.

packaged_task::operator()

Calls the callable object that's stored in the *associated asynchronous state*, atomically stores the returned value, and sets the state to *ready*.

```
void operator()(ArgTypes... args);
```

Remarks

If the `packaged_task` object doesn't have an associated asynchronous state, this method throws a `future_error` that has an error code of `no_state`.

If this method or `make_ready_at_thread_exit` has already been called for a `packaged_task` object that has the same associated asynchronous state, the method throws a `future_error` that has an error code of `promise_already_satisfied`.

Otherwise, this operator calls `INVOKE(fn, args..., Ty)`, where *fn* is the callable object that's stored in the associated asynchronous state. Any returned value is stored atomically as the returned result of the associated asynchronous state, and the state is set to *ready*. As a result, any threads that are blocked on the associated asynchronous state become unblocked.

packaged_task::operator bool

Specifies whether the object has an `associated asynchronous state`.

```
operator bool() const noexcept;
```

Return Value

true if the object has an associated asynchronous state; otherwise, **false**.

packaged_task::packaged_task Constructor

Constructs a `packaged_task` object.

```
packaged_task() noexcept;
packaged_task(packaged_task&& Right) noexcept;
template <class Fn>
    explicit packaged_task(Fn&& fn);

template <class Fn, class Alloc>
    explicit packaged_task(
        allocator_arg_t, const Alloc& alloc, Fn&& fn);
```

Parameters

Right

A `packaged_task` object.

alloc

A memory allocator. For more information, see [<allocators>](#).

fn

A function object.

Remarks

The first constructor constructs a `packaged_task` object that has no *associated asynchronous state*.

The second constructor constructs a `packaged_task` object and transfers the associated asynchronous state from *Right*. After the operation, *Right* no longer has an associated asynchronous state.

The third constructor constructs a `packaged_task` object that has a copy of *fn* stored in its associated asynchronous state.

The fourth constructor constructs a `packaged_task` object that has a copy of *fn* stored in its associated asynchronous state, and uses `alloc` for memory allocation.

`packaged_task::~~packaged_task` Destructor

Destroys a `packaged_task` object.

```
~packaged_task();
```

Remarks

If the *associated asynchronous state* is not *ready*, the destructor stores a [future_error](#) exception that has an error code of `broken_promise` as the result in the associated asynchronous state, and any threads that are blocked on the associated asynchronous state become unblocked.

`packaged_task::reset`

Uses a new *associated asynchronous state* to replace the existing associated asynchronous state.

```
void reset();
```

Remarks

In effect, this method executes `*this = packaged_task(move(fn))`, where *fn* is the function object that's stored in the associated asynchronous state for this object. Therefore, the state of the object is cleared, and [get_future](#), [operator\(\)](#), and [make_ready_at_thread_exit](#) can be called as if on a newly-constructed object.

`packaged_task::swap`

Exchanges the associated asynchronous state with that of a specified object.

```
void swap(packaged_task& Right) noexcept;
```

Parameters

Right

A `packaged_task` object.

packaged_task::valid

Specifies whether the object has an `associated asynchronous state`.

```
bool valid() const;
```

Return Value

true if the object has an associated asynchronous state; otherwise, **false**.

[<future>](#)

promise Class

10/31/2018 • 5 minutes to read • [Edit Online](#)

Describes an *asynchronous provider*.

Syntax

```
template <class Ty>
class promise;
```

Members

Public Constructors

NAME	DESCRIPTION
promise	Constructs a <code>promise</code> object.

Public Methods

NAME	DESCRIPTION
get_future	Returns a future associated with this promise.
set_exception	Atomically sets the result of this promise to indicate an exception.
set_exception_at_thread_exit	Atomically sets the result of this promise to indicate an exception, and delivers the notification only after all thread-local objects in the current thread have been destroyed (usually at thread exit).
set_value	Atomically sets the result of this promise to indicate a value.
set_value_at_thread_exit	Atomically sets the result of this promise to indicate a value, and delivers the notification only after all thread-local objects in the current thread have been destroyed (usually at thread exit).
swap	Exchanges the <i>associated asynchronous state</i> of this promise with that of a specified promise object.

Public Operators

NAME	DESCRIPTION
promise::operator=	Assignment of the shared state of this promise object.

Inheritance Hierarchy

promise

Requirements

Header: <future>

Namespace: std

promise::get_future

Returns a [future](#) object that has the same *associated asynchronous state* as this promise.

```
future<Ty> get_future();
```

Remarks

If the promise object is empty, this method throws a [future_error](#) that has an [error_code](#) of `no_state`.

If this method has already been called for a promise object that has the same associated asynchronous state, the method throws a `future_error` that has an [error_code](#) of `future_already_retrieved`.

promise::operator=

Transfers the *associated asynchronous state* from a specified `promise` object.

```
promise& operator=(promise&& Other) noexcept;
```

Parameters

Other

A `promise` object.

Return Value

`*this`

Remarks

This operator transfers the associated asynchronous state from *Other*. After the transfer, *Other* is *empty*.

promise::promise Constructor

Constructs a `promise` object.

```
promise();  
template <class Alloc>  
promise(allocator_arg_t, const Alloc& Al);  
promise(promise&& Other) noexcept;
```

Parameters

Al

A memory allocator. See [<allocators>](#) for more information.

Other

A `promise` object.

Remarks

The first constructor constructs an *empty* `promise` object.

The second constructor constructs an empty `promise` object and uses *Al* for memory allocation.

The third constructor constructs a `promise` object and transfers the associated asynchronous state from *Other*, and leaves *Other* empty.

promise::set_exception

Atomically stores an exception as the result of this `promise` object and sets the *associated asynchronous state* to *ready*.

```
void set_exception(exception_ptr Exc);
```

Parameters

Exc

An `exception_ptr` that's stored by this method as the exception result.

Remarks

If the `promise` object has no associated asynchronous state, this method throws a `future_error` that has an error code of `no_state`.

If `set_exception`, `set_exception_at_thread_exit`, `set_value`, or `set_value_at_thread_exit` has already been called for a `promise` object that has the same associated asynchronous state, this method throws a `future_error` that has an error code of `promise_already_satisfied`.

As a result of this method, any threads that are blocked on the associated asynchronous state become unblocked.

promise::set_exception_at_thread_exit

Atomically sets the result of this `promise` to indicate an exception, delivering the notification only after all thread-local objects in the current thread have been destroyed (usually at thread exit).

```
void set_exception_at_thread_exit(exception_ptr Exc);
```

Parameters

Exc

An `exception_ptr` that's stored by this method as the exception result.

Remarks

If the promise object has no *associated asynchronous state*, this method throws a `future_error` that has an error code of `no_state`.

If `set_exception`, `set_exception_at_thread_exit`, `set_value`, or `set_value_at_thread_exit` has already been called for a `promise` object that has the same associated asynchronous state, this method throws a `future_error` that has an error code of `promise_already_satisfied`.

In contrast to `set_exception`, this method does not set the associated asynchronous state to ready until after all thread-local objects in the current thread have been destroyed. Typically, threads that are blocked on the associated asynchronous state are not unblocked until the current thread exits.

promise::set_value

Atomically stores a value as the result of this `promise` object and sets the *associated asynchronous state* to *ready*.

```
void promise::set_value(const Ty& Val);
void promise::set_value(Ty&& Val);
void promise<Ty&>::set_value(Ty& Val);
void promise<void>::set_value();
```

Parameters

Val

The value to be stored as the result.

Remarks

If the `promise` object has no associated asynchronous state, this method throws a `future_error` that has an error code of `no_state`.

If `set_exception`, `set_exception_at_thread_exit`, `set_value`, or `set_value_at_thread_exit` has already been called for a `promise` object that has the same associated asynchronous state, this method throws a `future_error` that has an error code of `promise_already_satisfied`.

As a result of this method, any threads that are blocked on the associated asynchronous state become unblocked.

The first method also throws any exception that is thrown when *Val* is copied into the associated asynchronous state. In this situation, the associated asynchronous state is not set to ready.

The second method also throws any exception that is thrown when *Val* is moved into the associated asynchronous state. In this situation, the associated asynchronous state is not set to ready.

For the partial specialization `promise<Ty&>`, the stored value is in effect a reference to *Val*.

For the specialization `promise<void>`, no stored value exists.

promise::set_value_at_thread_exit

Atomically stores a value as the result of this `promise` object.

```
void promise::set_value_at_thread_exit(const Ty& Val);
void promise::set_value_at_thread_exit(Ty&& Val);
void promise<Ty&>::set_value_at_thread_exit(Ty& Val);
void promise<void>::set_value_at_thread_exit();
```

Parameters

Val

The value to be stored as the result.

Remarks

If the `promise` object has no *associated asynchronous state*, this method throws a `future_error` that has an error code of `no_state`.

If `set_exception`, `set_exception_at_thread_exit`, `set_value`, or `set_value_at_thread_exit` has already been called for a `promise` object that has the same associated asynchronous state, this method throws a `future_error` that has an error code of `promise_already_satisfied`.

In contrast to `set_value`, the associated asynchronous state is not set to ready until after all thread-local objects in the current thread have been destroyed. Typically, threads that are blocked on the associated asynchronous state are not unblocked until the current thread exits.

The first method also throws any exception that is thrown when *Val* is copied into the associated asynchronous state.

The second method also throws any exception that is thrown when *Val* is moved into the associated asynchronous state.

For the partial specialization `promise<Ty&>`, the stored value is effectively a reference to *Val*.

For the specialization `promise<void>`, no stored value exists.

promise::swap

Exchanges the *associated asynchronous state* of this promise object with that of a specified object.

```
void swap(promise& Other) noexcept;
```

Parameters

Other

A `promise` object.

[Header Files Reference](#)

shared_future Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Describes an *asynchronous return object*. In contrast with a [future](#) object, an *asynchronous provider* can be associated with any number of `shared_future` objects.

Syntax

```
template <class Ty>
class shared_future;
```

Remarks

Do not call any methods other than `valid`, `operator=`, and the destructor on a `shared_future` object that's *empty*.

`shared_future` objects are not synchronized. Calling methods on the same object from multiple threads introduces a data race that has unpredictable results.

Members

Public Constructors

NAME	DESCRIPTION
shared_future	Constructs a <code>shared_future</code> object.

Public Methods

NAME	DESCRIPTION
get	Retrieves the result that's stored in the <i>associated asynchronous state</i> .
valid	Specifies whether the object is not empty.
wait	Blocks the current thread until the associated asynchronous state is ready.
wait_for	Blocks until the associated asynchronous state is ready or until the specified time has elapsed.
wait_until	Blocks until the associated asynchronous state is ready or until a specified point in time.

Public Operators

NAME	DESCRIPTION
shared_future::operator=	Assigns a new associated asynchronous state.

Requirements

Header: <future>

Namespace: std

shared_future::get

Retrieves the result that's stored in the *associated asynchronous state*.

```
const Ty& get() const;

Ty& get() const;

void get() const;
```

Remarks

If the result is an exception, the method rethrows it. Otherwise, the result is returned.

Before it retrieves the result, this method blocks the current thread until the associated asynchronous state is ready.

For the partial specialization `shared_future<Ty>`, the stored value is effectively a reference to the object that was passed to the *asynchronous provider* as the return value.

Because no stored value exists for the specialization `shared_future<void>`, the method returns **void**.

shared_future::operator=

Transfers an *associated asynchronous state* from a specified object.

```
shared_future& operator=(shared_future&& Right) noexcept;
shared_future& operator=(const shared_future& Right);
```

Parameters

Right

A `shared_future` object.

Return Value

`*this`

Remarks

For the first operator, *Right* no longer has an associated asynchronous state after the operation.

For the second method, *Right* maintains its associated asynchronous state.

shared_future::shared_future Constructor

Constructs a `shared_future` object.

```
shared_future() noexcept;
shared_future(future<Ty>&& Right) noexcept;
shared_future(shared_future&& Right) noexcept;
shared_future(const shared_future& Right);
```

Parameters

Right

A [future](#) or `shared_future` object.

Remarks

The first constructor constructs a `shared_future` object that has no *associated asynchronous state*.

The second and third constructors construct a `shared_future` object and transfer the associated asynchronous state from *Right*. *Right* no longer has an associated asynchronous state.

The fourth constructor constructs a `shared_future` object that has the same associated asynchronous state as *Right*.

shared_future::valid

Specifies whether the object has an *associated asynchronous state*.

```
bool valid() noexcept;
```

Return Value

true if the object has an associated asynchronous state; otherwise, **false**.

shared_future::wait

Blocks the current thread until the *associated asynchronous state* is *ready*.

```
void wait() const;
```

Remarks

An associated asynchronous state is *ready* only if its asynchronous provider has stored a return value or stored an exception.

shared_future::wait_for

Blocks the current thread until the associated asynchronous state is *ready* or until a specified time has elapsed.

```
template <class Rep, class Period>
future_status wait_for(
    const chrono::duration<Rep, Period>& Rel_time) const;
```

Parameters

Rel_time

A [chrono::duration](#) object that specifies a maximum time interval that the thread blocks.

Return Value

A [future_status](#) that indicates the reason for returning.

Remarks

An associated asynchronous state is *ready* only if its asynchronous provider has stored a return value or stored an exception.

shared_future::wait_until

Blocks the current thread until the associated asynchronous state is *ready* or until after a specified time point.

```
template <class Clock, class Duration>
future_status wait_until(
    const chrono::time_point<Clock, Duration>& Abs_time) const;
```

Parameters

Abs_time

A [chrono::time_point](#) object that specifies a time after which the thread can unblock.

Return Value

A [future_status](#) that indicates the reason for returning.

Remarks

An associated asynchronous state is ready only if its asynchronous provider has stored a return value or stored an exception.

<hash_map>

11/9/2018 • 2 minutes to read • [Edit Online](#)

NOTE

This header is obsolete. The alternative is [<unordered_map>](#).

Defines the container template classes `hash_map` and `hash_multimap` and their supporting templates.

Syntax

```
#include <hash_map>
```

Operators

HASH_MAP VERSION	HASH_MULTIMAP VERSION	DESCRIPTION
operator!= (hash_map)	operator!= (hash_multimap)	Tests if the <code>hash_map</code> or <code>hash_multimap</code> object on the left side of the operator is not equal to the <code>hash_map</code> or <code>hash_multimap</code> object on the right side.
operator== (hash_map)	operator== (hash_multimap)	Tests if the <code>hash_map</code> or <code>hash_multimap</code> object on the left side of the operator is equal to the <code>hash_map</code> or <code>hash_multimap</code> object on the right side.

Specialized Template Functions

HASH_MAP VERSION	HASH_MULTIMAP VERSION	DESCRIPTION
swap (hash_map)	swap (hash_multimap)	Exchanges the elements of two <code>hash_maps</code> or <code>hash_multimaps</code> .

Classes

CLASS	DESCRIPTION
hash_compare Class	Describes an object that can be used by any of the hash associative containers — <code>hash_map</code> , <code>hash_multimap</code> , <code>hash_set</code> , or <code>hash_multiset</code> — as a default <code>Traits</code> parameter object to order and hash the elements they contain.
value_compare Class	Provides a function object that can compare the elements of a <code>hash_map</code> by comparing the values of their keys to determine their relative order in the <code>hash_map</code> .
hash_map Class	Used for the storage and fast retrieval of data from a collection in which each element is a pair that has a sort key whose value is unique and an associated data value.

CLASS	DESCRIPTION
hash_multimap Class	Used for the storage and fast retrieval of data from a collection in which each element is a pair that has a sort key whose value need not be unique and an associated data value.

Requirements

Header: `<hash_map>`

<hash_map> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

swap	swap (hash_map)

swap (hash_map)

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Exchanges the elements of two hash_maps.

```
void swap(  
    hash_map <Key, Type, Traits, Allocator>& left,  
    hash_map <Key, Type, Traits, Allocator>& right);
```

Parameters

right

The hash_map whose elements are to be exchanged with those of the map *left*.

left

The hash_map whose elements are to be exchanged with those of the map *right*.

Remarks

The template function is an algorithm specialized on the container class hash_map to execute the member function `left.swap(right)`. This is an instance of the partial ordering of function templates by the compiler. When template functions are overloaded in such a way that the match of the template with the function call is not unique, then the compiler will select the most specialized version of the template function. The general version of the template function, **template <class T> void swap(T&, T&)**, in the algorithm header file works by assignment and is a slow operation. The specialized version in each container is much faster as it can work with the internal representation of the container class.

swap

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Exchanges the elements of two hash_multimaps.

```
void swap(  
    hash_multimap <Key, Type, Traits, Allocator>& left,  
    hash_multimap <Key, Type, Traits, Allocator>& right);
```

Parameters

right

The hash_multimap whose elements are to be exchanged with those of the map *left*.

left

The hash_multimap whose elements are to be exchanged with those of the map *right*.

Remarks

The template function is an algorithm specialized on the container class hash_multimap to execute the member function `left.swap(right)`. This is an instance of the partial ordering of function templates by the compiler.

When template functions are overloaded in such a way that the match of the template with the function call is not unique, then the compiler will select the most specialized version of the template function. The general version of the template function, **template <class T> void swap(T&, T&)**, in the algorithm header file works by assignment and is a slow operation. The specialized version in each container is much faster as it can work with the internal representation of the container class.

<hash_map> operators

10/31/2018 • 5 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator!= (multimap)</code>
<code>operator==</code>	<code>operator== (multimap)</code>

operator!=

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Tests if the hash_map object on the left side of the operator is not equal to the hash_map object on the right side.

```
bool operator!=(const hash_map <Key, Type, Traits, Allocator>& left, const hash_map <Key, Type, Traits, Allocator>& right);
```

Parameters

left

An object of type `hash_map`.

right

An object of type `hash_map`.

Return Value

true if the hash_maps are not equal; **false** if hash_maps are equal.

Remarks

The comparison between hash_map objects is based on a pairwise comparison of their elements. Two hash_maps are equal if they have the same number of elements and their respective elements have the same values.

Otherwise, they are unequal.

Members of the `<hash_map>` and `<hash_set>` header files in the [stdext Namespace](#).

Example

```

// hash_map_op_ne.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1, hm2, hm3;
    int i;
    typedef pair <int, int> Int_Pair;

    for ( i = 0 ; i < 3 ; i++ )
    {
        hm1.insert ( Int_Pair ( i, i ) );
        hm2.insert ( Int_Pair ( i, i * i ) );
        hm3.insert ( Int_Pair ( i, i ) );
    }

    if ( hm1 != hm2 )
        cout << "The hash_maps hm1 and hm2 are not equal." << endl;
    else
        cout << "The hash_maps hm1 and hm2 are equal." << endl;

    if ( hm1 != hm3 )
        cout << "The hash_maps hm1 and hm3 are not equal." << endl;
    else
        cout << "The hash_maps hm1 and hm3 are equal." << endl;
}

```

The hash_maps hm1 and hm2 are not equal.
The hash_maps hm1 and hm3 are equal.

operator==

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Tests if the hash_map object on the left side of the operator is equal to the hash_map object on the right side.

```

bool operator==(const hash_map <Key, Type, Traits, Allocator>& left, const hash_map <Key, Type, Traits,
Allocator>& right);

```

Parameters

left

An object of type `hash_map`.

right

An object of type `hash_map`.

Return Value

true if the hash_map on the left side of the operator is equal to the hash_map on the right side of the operator;
otherwise **false**.

Remarks

The comparison between `hash_map` objects is based on a pairwise comparison of their elements. Two `hash_maps` are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// hash_map_op_eq.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1, hm2, hm3;
    int i;
    typedef pair <int, int> Int_Pair;

    for ( i = 0 ; i < 3 ; i++ )
    {
        hm1.insert ( Int_Pair ( i, i ) );
        hm2.insert ( Int_Pair ( i, i * i ) );
        hm3.insert ( Int_Pair ( i, i ) );
    }

    if ( hm1 == hm2 )
        cout << "The hash_maps hm1 and hm2 are equal." << endl;
    else
        cout << "The hash_maps hm1 and hm2 are not equal." << endl;

    if ( hm1 == hm3 )
        cout << "The hash_maps hm1 and hm3 are equal." << endl;
    else
        cout << "The hash_maps hm1 and hm3 are not equal." << endl;
}
```

```
The hash_maps hm1 and hm2 are not equal.
The hash_maps hm1 and hm3 are equal.
```

operator!= (hash_multimap)

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Tests if the `hash_multimap` object on the left side of the operator is not equal to the `hash_multimap` object on the right side.

```
bool operator!=(const hash_multimap <Key, Type, Traits, Allocator>& left, const hash_multimap <Key, Type,
Traits, Allocator>& right);
```

Parameters

left

An object of type `hash_multimap`.

right

An object of type `hash_multimap`.

Return Value

true if the hash_multimaps are not equal; **false** if hash_multimaps are equal.

Remarks

The comparison between hash_multimap objects is based on a pairwise comparison of their elements. Two hash_multimaps are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// hash_multimap_op_ne.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1, hm2, hm3;
    int i;
    typedef pair <int, int> Int_Pair;

    for ( i = 0 ; i < 3 ; i++ )
    {
        hm1.insert ( Int_Pair ( i, i ) );
        hm2.insert ( Int_Pair ( i, i * i ) );
        hm3.insert ( Int_Pair ( i, i ) );
    }

    if ( hm1 != hm2 )
        cout << "The hash_multimaps hm1 and hm2 are not equal." << endl;
    else
        cout << "The hash_multimaps hm1 and hm2 are equal." << endl;

    if ( hm1 != hm3 )
        cout << "The hash_multimaps hm1 and hm3 are not equal." << endl;
    else
        cout << "The hash_multimaps hm1 and hm3 are equal." << endl;
}
```

```
The hash_multimaps hm1 and hm2 are not equal.
The hash_multimaps hm1 and hm3 are equal.
```

operator==(hash_multimap)

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Tests if the hash_multimap object on the left side of the operator is equal to the hash_multimap object on the right side.

```
bool operator==(const hash_multimap <Key, Type, Traits, Allocator>& left, const hash_multimap <Key, Type,
Traits, Allocator>& right);
```

Parameters

left

An object of type `hash_multimap`.

right

An object of type `hash_multimap`.

Return Value

true if the `hash_multimap` on the left side of the operator is equal to the `hash_multimap` on the right side of the operator; otherwise **false**.

Remarks

The comparison between `hash_multimap` objects is based on a pairwise comparison of their elements. Two `hash_multimaps` are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// hash_multimap_op_eq.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap<int, int> hm1, hm2, hm3;
    int i;
    typedef pair<int, int> Int_Pair;

    for (i = 0; i < 3; i++)
    {
        hm1.insert(Int_Pair(i, i));
        hm2.insert(Int_Pair(i, i*i));
        hm3.insert(Int_Pair(i, i));
    }

    if ( hm1 == hm2 )
        cout << "The hash_multimaps hm1 and hm2 are equal." << endl;
    else
        cout << "The hash_multimaps hm1 and hm2 are not equal." << endl;

    if ( hm1 == hm3 )
        cout << "The hash_multimaps hm1 and hm3 are equal." << endl;
    else
        cout << "The hash_multimaps hm1 and hm3 are not equal." << endl;
}
```

```
The hash_multimaps hm1 and hm2 are not equal.
The hash_multimaps hm1 and hm3 are equal.
```

[`<hash_map>`](#)

hash_compare Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The template class describes an object that can be used by any of the hash associative containers — `hash_map`, `hash_multimap`, `hash_set`, or `hash_multiset` — as a default **Traits** parameter object to order and hash the elements they contain.

Syntax

```
class hash_compare { Traits comp; public: const size_t bucket_size = 4; const size_t min_buckets = 8;
hash_compare(); hash_compare(Traits pred); size_t operator()(const Key& key) const; bool operator()( const Key&
key1, const Key& key2) const; };
```

Remarks

Each hash associative container stores a hash traits object of type `Traits` (a template parameter). You can derive a class from a specialization of `hash_compare` to selectively override certain functions and objects, or you can supply your own version of this class if you meet certain minimum requirements. Specifically, for an object `hash_comp` of type `hash_compare<Key, Traits>`, the following behavior is required by the above containers:

- For all values `key` of type `Key`, the call **hash_comp**(`key`) serves as a hash function, which yields a distribution of values of type `size_t`. The function supplied by `hash_compare` returns `key`.
- For any value `key1` of type `Key` that precedes `key2` in the sequence and has the same hash value (value returned by the hash function), **hash_comp**(`key2`, `key1`) is false. The function must impose a total ordering on values of type `Key`. The function supplied by `hash_compare` returns `comp(key2, key1)`, where `comp` is a stored object of type `Traits` that you can specify when you construct the object `hash_comp`. For the default `Traits` parameter type `less<Key>`, sort keys never decrease in value.
- The integer constant `bucket_size` specifies the mean number of elements per "bucket" (hash-table entry) that the container should try not to exceed. It must be greater than zero. The value supplied by `hash_compare` is 4.
- The integer constant `min_buckets` specifies the minimum number of buckets to maintain in the hash table. It must be a power of two and greater than zero. The value supplied by `hash_compare` is 8.

Example

See examples for [hash_map::hash_map](#), [hash_multimap::hash_multimap](#), [hash_set::hash_set](#), and [hash_multiset::hash_multiset](#), for examples of how to declare and use `hash_compare`.

Requirements

Header: `<hash_map>`

Namespace: `stdext`

hash_map Class

11/14/2018 • 60 minutes to read • [Edit Online](#)

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Stores and retrieves data quickly from a collection in which each element is a pair that has a sort key whose value is unique and an associated data value.

Syntax

```
template <class Key,  
          class Type,  
          class Traits=hash_compare<Key, less<Key>>,  
          class Allocator=allocator<pair <const Key, Type>>>  
class hash_map
```

Parameters

Key

The key data type to be stored in the hash_map.

Type

The element data type to be stored in the hash_map.

Traits

The type which includes two function objects, one of class compare able to compare two element values as sort keys to determine their relative order and a hash function that is a unary predicate mapping key values of the elements to unsigned integers of type `size_t`. This argument is optional, and `hash_compare<Key, less<Key>>` is the default value.

Allocator

The type that represents the stored allocator object that encapsulates details about the hash_map's allocation and deallocation of memory. This argument is optional, and the default value is `allocator<pair <const Key, Type>>`.

Remarks

The hash_map is:

- An associative container, which is a variable size container that supports the efficient retrieval of element values based on an associated key value.
- Reversible, because it provides a bidirectional iterator to access its elements.
- Hashed, because its elements are grouped into buckets based on the value of a hash function applied to the key values of the elements.
- Unique in the sense that each of its elements must have a unique key.
- A pair associative container, because its element data values are distinct from its key values.
- A template class, because the functionality it provides is generic and so independent of the specific type of

data contained as elements or keys. The data types to be used for elements and keys are, instead, specified as parameters in the class template along with the comparison function and allocator.

The main advantage of hashing over sorting is greater efficiency; a successful hashing performs insertions, deletions, and finds in constant average time as compared with a time proportional to the logarithm of the number of elements in the container for sorting techniques. The value of an element in a `hash_map`, but not its associated key value, may be changed directly. Instead, key values associated with old elements must be deleted and new key values associated with new elements inserted.

The choice of container type should be based in general on the type of searching and inserting required by the application. Hashed associative containers are optimized for the operations of lookup, insertion and removal. The member functions that explicitly support these operations are efficient when used with a well-designed hash function, performing them in a time that is on average constant and not dependent on the number of elements in the container. A well-designed hash function produces a uniform distribution of hashed values and minimizes the number of collisions, where a collision is said to occur when distinct key values are mapped into the same hashed value. In the worst case, with the worst possible hash function, the number of operations is proportional to the number of elements in the sequence (linear time).

The `hash_map` should be the associative container of choice when the conditions associating the values with their keys are satisfied by the application. A model for this type of structure is an ordered list of uniquely occurring keywords with associated string values providing, say, definitions. If, instead, the words had more than one correct definition, so that keys were not unique, then a `hash_multimap` would be the container of choice. If, on the other hand, just the list of words were being stored, then a `hash_set` would be the correct container. If multiple occurrences of the words were allowed, then a `hash_multiset` would be the appropriate container structure.

The `hash_map` orders the sequence it controls by calling a stored hash *Traits* object of class `value_compare`. This stored object may be accessed by calling the member function `key_comp`. Such a function object must behave the same as an object of class `hash_compare<Key, less<Key>>`. Specifically, for all values *Key* of type *Key*, the call `Traits (Key)` yields a distribution of values of type `size_t`.

In general, the elements need be merely less than comparable to establish this order: so that, given any two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. On a more technical note, the comparison function is a binary predicate that induces a strict weak ordering in the standard mathematical sense. A binary predicate $f(x, y)$ is a function object that has two argument objects `x` and `y` and a return value of **true** or **false**. An ordering imposed on a `hash_map` is a strict weak ordering if the binary predicate is irreflexive, antisymmetric, and transitive and if equivalence is transitive, where two objects *x* and *y* are defined to be equivalent when both $f(x, y)$ and $f(y, x)$ are false. If the stronger condition of equality between keys replaces that of equivalence, then the ordering becomes total (in the sense that all the elements are ordered with respect to each other) and the keys matched will be indiscernible from each other.

The actual order of elements in the controlled sequence depends on the hash function, the ordering function, and the current size of the hash table stored in the container object. You cannot determine the current size of the hash table, so you cannot in general predict the order of elements in the controlled sequence. Inserting elements invalidates no iterators, and removing elements invalidates only those iterators that had specifically pointed at the removed elements.

The iterator provided by the `hash_map` class is a bidirectional iterator, but the class member functions `insert` and `hash_map` have versions that take as template parameters a weaker input iterator, whose functionality requirements are more minimal than those guaranteed by the class of bidirectional iterators. The different iterator concepts form a family related by refinements in their functionality. Each iterator concept has its own set of requirements, and the algorithms that work with them must limit their assumptions to the requirements provided by that type of iterator. It may be assumed that an input iterator may be dereferenced to refer to some object and that it may be incremented to the next iterator in the sequence. This is a minimal set of functionality, but it is enough to be able to talk meaningfully about a range of iterators `[First, Last)` in the context of the class

member functions.

Constructors

CONSTRUCTOR	DESCRIPTION
hash_map	Constructs a <code>hash_map</code> that is empty or that is a copy of all or part of some other <code>hash_map</code> .

Typedefs

TYPE NAME	DESCRIPTION
allocator_type	A type that represents the <code>allocator</code> class for the <code>hash_map</code> object.
const_iterator	A type that provides a bidirectional iterator that can read a <code>const</code> element in the <code>hash_map</code> .
const_pointer	A type that provides a pointer to a const element in a <code>hash_map</code> .
const_reference	A type that provides a reference to a const element stored in a <code>hash_map</code> for reading and performing const operations.
const_reverse_iterator	A type that provides a bidirectional iterator that can read any const element in the <code>hash_map</code> .
difference_type	A signed integer type that can be used to represent the number of elements of a <code>hash_map</code> in a range between elements pointed to by iterators.
iterator	A type that provides a bidirectional iterator that can read or modify any element in a <code>hash_map</code> .
key_compare	A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the <code>hash_map</code> .
key_type	A type describes the sort key object that constitutes each element of the <code>hash_map</code> .
mapped_type	A type that represents the data type stored in a <code>hash_map</code> .
pointer	A type that provides a pointer to an element in a <code>hash_map</code> .
reference	A type that provides a reference to an element stored in a <code>hash_map</code> .
reverse_iterator	A type that provides a bidirectional iterator that can read or modify an element in a reversed <code>hash_map</code> .
size_type	An unsigned integer type that can represent the number of elements in a <code>hash_map</code> .

TYPE NAME	DESCRIPTION
<code>value_type</code>	A type that provides a function object that can compare two elements as sort keys to determine their relative order in the <code>hash_map</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>at</code>	Finds an element in a <code>hash_map</code> with a specified key value.
<code>begin</code>	Returns an iterator addressing the first element in the <code>hash_map</code> .
<code>cbegin</code>	Returns a const iterator addressing the first element in the <code>hash_map</code> .
<code>cend</code>	Returns a const iterator that addresses the location succeeding the last element in a <code>hash_map</code> .
<code>clear</code>	Erases all the elements of a <code>hash_map</code> .
<code>count</code>	Returns the number of elements in a <code>hash_map</code> whose key matches a parameter-specified key.
<code>crbegin</code>	Returns a const iterator addressing the first element in a reversed <code>hash_map</code> .
<code>crend</code>	Returns a const iterator that addresses the location succeeding the last element in a reversed <code>hash_map</code> .
<code>emplace</code>	Inserts an element constructed in place into a <code>hash_map</code> .
<code>emplace_hint</code>	Inserts an element constructed in place into a <code>hash_map</code> , with a placement hint.
<code>empty</code>	Tests if a <code>hash_map</code> is empty.
<code>end</code>	Returns an iterator that addresses the location succeeding the last element in a <code>hash_map</code> .
<code>equal_range</code>	Returns a pair of iterators, respectively, to the first element in a <code>hash_map</code> with a key that is greater than a specified key and to the first element in the <code>hash_map</code> with a key that is equal to or greater than the key.
<code>erase</code>	Removes an element or a range of elements in a <code>hash_map</code> from specified positions
<code>find</code>	Returns an iterator addressing the location of an element in a <code>hash_map</code> that has a key equivalent to a specified key.

MEMBER FUNCTION	DESCRIPTION
get_allocator	Returns a copy of the <code>allocator</code> object used to construct the <code>hash_map</code> .
insert	Inserts an element or a range of elements into a <code>hash_map</code> .
key_comp	Returns an iterator to the first element in a <code>hash_map</code> with a key value that is equal to or greater than that of a specified key.
lower_bound	Returns an iterator to the first element in a <code>hash_map</code> with a key value that is equal to or greater than that of a specified key.
max_size	Returns the maximum length of the <code>hash_map</code> .
rbegin	Returns an iterator addressing the first element in a reversed <code>hash_map</code> .
rend	Returns an iterator that addresses the location succeeding the last element in a reversed <code>hash_map</code> .
size	Returns the number of elements in the <code>hash_map</code> .
swap	Exchanges the elements of two <code>hash_map</code> s.
upper_bound	Returns an iterator to the first element in a <code>hash_map</code> that with a key value that is greater than that of a specified key.
value_comp	Retrieves a copy of the comparison object used to order element values in a <code>hash_map</code> .

Operators

OPERATOR	DESCRIPTION
operator[]	Inserts an element into a <code>hash_map</code> with a specified key value.
hash_map::operator=	Replaces the elements of a <code>hash_map</code> with a copy of another <code>hash_map</code> .

Requirements

Header: `<hash_map>`

Namespace: `stdext`

`hash_map::allocator_type`

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that represents the allocator class for the hash_map object.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::allocator_type allocator_type;
```

Example

See example for [get_allocator](#) for an example using `allocator_type`.

hash_map::at

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Finds an element in a hash_map with a specified key value.

```
Type& at(const Key& key);  
  
const Type& at(const Key& key) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>key</i>	The key value of the element that is to be found.

Return Value

A reference to the data value of the element found.

Remarks

If the argument key value is not found, then the function throws an object of class [out_of_range Class](#).

Example

```

// hash_map_at.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    typedef pair <const int, int> cInt2Int;
    hash_map <int, int> hm1;

    // Insert data values
    hm1.insert ( cInt2Int ( 1, 10 ) );
    hm1.insert ( cInt2Int ( 2, 20 ) );
    hm1.insert ( cInt2Int ( 3, 30 ) );

    cout << "The values of the mapped elements are:";
    for ( int i = 1 ; i <= hm1.size() ; i++ )
        cout << " " << hm1.at(i);
    cout << "." << endl;
}

```

hash_map::begin

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns an iterator addressing the first element in the hash_map.

```

const_iterator begin() const;

iterator begin();

```

Return Value

A bidirectional iterator addressing the first element in the hash_map or the location succeeding an empty hash_map.

Example

```

// hash_map_begin.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;

    hash_map <int, int> :: iterator hm1_Iter;
    hash_map <int, int> :: const_iterator hm1_cIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 0, 0 ) );
    hm1.insert ( Int_Pair ( 1, 1 ) );
    hm1.insert ( Int_Pair ( 2, 4 ) );

    hm1_cIter = hm1.begin ( );
    cout << "The first element of hm1 is "
         << hm1_cIter -> first << "." << endl;

    hm1_Iter = hm1.begin ( );
    hm1.erase ( hm1_Iter );

    // The following 2 lines would err because the iterator is const
    // hm1_cIter = hm1.begin ( );
    // hm1.erase ( hm1_cIter );

    hm1_cIter = hm1.begin( );
    cout << "The first element of hm1 is now "
         << hm1_cIter -> first << "." << endl;
}

```

```

The first element of hm1 is 0.
The first element of hm1 is now 1.

```

hash_map::cbegin

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns a const iterator addressing the first element in the hash_map.

```
const_iterator cbegin() const;
```

Return Value

A const bidirectional iterator addressing the first element in the [hash_map](#) or the location succeeding an empty

`hash_map`.

Example

```

// hash_map_cbegin.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;

    hash_map <int, int> :: const_iterator hm1_cIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 2, 4 ) );

    hm1_cIter = hm1.cbegin ( );
    cout << "The first element of hm1 is "
         << hm1_cIter -> first << "." << endl;
}

```

The first element of hm1 is 2.

hash_map::cend

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns a const iterator that addresses the location succeeding the last element in a hash_map.

```
const_iterator cend() const;
```

Return Value

A const bidirectional iterator that addresses the location succeeding the last element in a [hash_map](#). If the

`hash_map` is empty, then `hash_map::cend == hash_map::begin`.

Remarks

`cend` is used to test whether an iterator has reached the end of its `hash_map`.

The value returned by `cend` should not be dereferenced.

Example

```
// hash_map_cend.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;

    hash_map <int, int> :: const_iterator hm1_cIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_cIter = hm1.cend( );
    hm1_cIter--;
    cout << "The value of last element of hm1 is "
         << hm1_cIter -> second << "." << endl;
}
```

The value of last element of hm1 is 30.

hash_map::clear

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Erases all the elements of a hash_map.

```
void clear();
```

Remarks

Example

The following example demonstrates the use of the hash_map::clear member function.

```
// hash_map_clear.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map<int, int> hm1;
    hash_map<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    hm1.insert(Int_Pair(1, 1));
    hm1.insert(Int_Pair(2, 4));

    i = hm1.size();
    cout << "The size of the hash_map is initially "
         << i << "." << endl;

    hm1.clear();
    i = hm1.size();
    cout << "The size of the hash_map after clearing is "
         << i << "." << endl;
}
```

The size of the hash_map is initially 2.
The size of the hash_map after clearing is 0.

hash_map::const_iterator

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that provides a bidirectional iterator that can read a **const** element in the hash_map.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::const_iterator const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

The `const_iterator` defined by hash_map points to elements that are objects of [value_type](#), that is of type `pair< const Key, Type >`, whose first member is the key to the element and whose second member is the mapped datum held by the element.

To dereference a `const_iterator` `cIter` pointing to an element in a hash_map, use the `->` operator.

To access the value of the key for the element, use `cIter->first`, which is equivalent to `(*cIter).first`. To access the value of the mapped datum for the element, use `cIter->second`, which is equivalent to `(*cIter).second`.

Example

See example for [begin](#) for an example using `const_iterator`.

hash_map::const_pointer

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that provides a pointer to a **const** element in a hash_map.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a hash_map object.

hash_map::const_reference

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that provides a reference to a **const** element stored in a hash_map for reading and performing **const** operations.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::const_reference  
const_reference;
```

Remarks

Example

```

// hash_map_const_ref.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map<int, int> hm1;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );

    // Declare and initialize a const_reference &Ref1
    // to the key of the first element
    const int &Ref1 = ( hm1.begin( ) -> first );

    // The following line would cause an error because the
    // non-const_reference cannot be used to access the key
    // int &Ref1 = ( hm1.begin( ) -> first );

    cout << "The key of the first element in the hash_map is "
         << Ref1 << "." << endl;

    // Declare and initialize a reference &Ref2
    // to the data value of the first element
    int &Ref2 = ( hm1.begin( ) -> second );

    cout << "The data value of the first element in the hash_map is "
         << Ref2 << "." << endl;
}

```

The key of the first element in the hash_map is 1.
The data value of the first element in the hash_map is 10.

hash_map::const_reverse_iterator

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that provides a bidirectional iterator that can read any **const** element in the hash_map.

```

typedef list<typename Traits::value_type, typename Traits::allocator_type>::const_reverse_iterator
const_reverse_iterator;

```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is use to iterate through the hash_map in reverse.

The `const_reverse_iterator` defined by hash_map points to elements that are objects of [value_type](#), that is of type `pair < const Key, Type>`, whose first member is the key to the element and whose second member is the mapped datum held by the element.

To dereference a `const_reverse_iterator` `crIter` pointing to an element in a hash_map, use the `->` operator.

To access the value of the key for the element, use `crIter -> first`, which is equivalent to `(* crIter).first`. To access the value of the mapped datum for the element, use `crIter -> second`, which is equivalent to `(* crIter).second`.

Example

See the example for [rend](#) for an example of how to declare and use the `const_reverse_iterator`.

hash_map::count

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns the number of elements in a hash_map whose key matches a parameter-specified key.

```
size_type count(const Key& key) const;
```

Parameters

key

The key value of the elements to be matched from the hash_map.

Return Value

1 if the hash_map contains an element whose sort key matches the parameter key; 0 if the hash_map doesn't contain an element with a matching key.

Remarks

The member function returns the number of elements *x* in the range

`[lower_bound(key), upper_bound(key))`

which is 0 or 1 in the case of hash_map, which is a unique associative container.

Example

The following example demonstrates the use of the hash_map::count member function.

```

// hash_map_count.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_map<int, int> hm1;
    hash_map<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    hm1.insert(Int_Pair (1, 1));
    hm1.insert(Int_Pair (2, 1));
    hm1.insert(Int_Pair (1, 4));
    hm1.insert(Int_Pair (2, 1));

    // Keys must be unique in hash_map, so duplicates are ignored
    i = hm1.count(1);
    cout << "The number of elements in hm1 with a sort key of 1 is: "
         << i << "." << endl;

    i = hm1.count(2);
    cout << "The number of elements in hm1 with a sort key of 2 is: "
         << i << "." << endl;

    i = hm1.count(3);
    cout << "The number of elements in hm1 with a sort key of 3 is: "
         << i << "." << endl;
}

```

```

The number of elements in hm1 with a sort key of 1 is: 1.
The number of elements in hm1 with a sort key of 2 is: 1.
The number of elements in hm1 with a sort key of 3 is: 0.

```

hash_map::crbegin

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns a const iterator addressing the first element in a reversed hash_map.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse bidirectional iterator addressing the first element in a reversed [hash_map](#) or addressing what had been the last element in the unreversed `hash_map`.

Remarks

`crbegin` is used with a reversed hash_map just as [begin](#) is used with a `hash_map`.

With the return value of `crbegin`, the `hash_map` object cannot be modified.

`crbegin` can be used to iterate through a `hash_map` backwards.

Example

```

// hash_map_crbegin.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;

    hash_map <int, int> :: const_reverse_iterator hm1_crIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_crIter = hm1.crbegin( );
    cout << "The first element of the reversed hash_map hm1 is "
         << hm1_crIter -> first << "." << endl;
}

```

The first element of the reversed hash_map hm1 is 3.

hash_map::crend

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns a const iterator that addresses the location succeeding the last element in a reversed hash_map.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse bidirectional iterator that addresses the location succeeding the last element in a reversed [hash_map](#) (the location that had preceded the first element in the unreversed `hash_map`).

Remarks

`crend` is used with a reversed `hash_map` just as [hash_map::end](#) is used with a `hash_map`.

With the return value of `crend`, the `hash_map` object cannot be modified.

`crend` can be used to test to whether a reverse iterator has reached the end of its `hash_map`.

The value returned by `crend` should not be dereferenced.

Example

```

// hash_map_crend.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;

    hash_map <int, int> :: const_reverse_iterator hm1_crIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_crIter = hm1.crend( );
    hm1_crIter--;
    cout << "The last element of the reversed hash_map hm1 is "
         << hm1_crIter -> first << "." << endl;
}

```

The last element of the reversed hash_map hm1 is 3.

hash_map::difference_type

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A signed integer type that can be used to represent the number of elements of a hash_map in a range between elements pointed to by iterators.

```

typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::difference_type
difference_type;

```

Example

```

// hash_map_diff_type.cpp
// compile with: /EHsc
#include <iostream>
#include <hash_map>
#include <algorithm>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 3, 20 ) );

    // The following won't insert, because map keys are unique
    hm1.insert ( Int_Pair ( 2, 30 ) );

    hash_map <int, int>::iterator hm1_Iter, hm1_bIter, hm1_eIter;
    hm1_bIter = hm1.begin( );
    hm1_eIter = hm1.end( );

    // Count the number of elements in a hash_map
    hash_map <int, int>::difference_type df_count = 0;
    hm1_Iter = hm1.begin( );
    while ( hm1_Iter != hm1_eIter)
    {
        df_count++;
        hm1_Iter++;
    }

    cout << "The number of elements in the hash_map hm1 is: "
         << df_count << "." << endl;

    cout << "The keys of the mapped elements are:";
    for ( hm1_Iter= hm1.begin( ) ; hm1_Iter!= hm1.end( ) ;
          hm1_Iter++)
        cout << " " << hm1_Iter-> first;
    cout << "." << endl;

    cout << "The values of the mapped elements are:";
    for ( hm1_Iter= hm1.begin( ) ; hm1_Iter!= hm1.end( ) ;
          hm1_Iter++)
        cout << " " << hm1_Iter-> second;
    cout << "." << endl;
}

```

```

The number of elements in the hash_map hm1 is: 3.
The keys of the mapped elements are: 1 2 3.
The values of the mapped elements are: 10 20 20.

```

hash_map::emplace

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Inserts an element constructed in place into a hash_map.

```
template <class ValTy>
pair <iterator, bool>
emplace(
    ValTy&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value used to move construct an element to be inserted into the <code>hash_map</code> unless the <code>hash_map</code> already contains that element (or, more generally, an element whose key is equivalently ordered).

Return Value

The `emplace` member function returns a pair whose bool component returns true if an insertion was made and false if the `hash_map` already contained an element whose key had an equivalent value in the ordering, and whose iterator component returns the address where a new element was inserted or where the element was already located.

To access the iterator component of a pair `pr` returned by this member function, use `pr.first`, and to dereference it, use `*(pr.first)`. To access the **bool** component of a pair `pr` returned by this member function, use `pr.second`, and to dereference it, use `*(pr.second)`.

Remarks

The `hash_map::value_type` of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

Example

```
// hash_map_emplace.cpp
// compile with: /EHsc
#include<hash_map>
#include<iostream>
#include <string>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_map<int, string> hm1;
    typedef pair<int, string> is1(1, "a");

    hm1.emplace(move(is1));
    cout << "After the emplace insertion, hm1 contains:" << endl
         << " " << hm1.begin()->first
         << " => " << hm1.begin()->second
         << endl;
}
```

```
After the emplace insertion, hm1 contains:
1 => a
```

hash_map::emplace_hint

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Inserts an element constructed in place into a `hash_map`, with a placement hint.

```
template <class ValTy>
iterator emplace_hint(
    const_iterator _Where,
    ValTy&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value used to move construct an element to be inserted into the hash_map unless the <code>hash_map</code> already contains that element (or, more generally, an element whose key is equivalently ordered).
<i>_Where</i>	A hint regarding the place to start searching for the correct point of insertion.

Return Value

The [hash_multimap::emplace](#) member function returns an iterator that points to the position where the new element was inserted into the `hash_map`, or where the existing element with equivalent ordering is located.

Remarks

The [hash_map::value_type](#) of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

Insertion can occur in amortized constant time, instead of logarithmic time, if the insertion point immediately follows *_Where*.

Example

```
// hash_map_emplace_hint.cpp
// compile with: /EHsc
#include<hash_map>
#include<iostream>
#include <string>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_map<int, string> hm1;
    typedef pair<int, string> is1(1, "a");

    hm1.emplace(hm1.begin(), move(is1));
    cout << "After the emplace, hm1 contains:" << endl
         << " " << hm1.begin()->first
         << " => " << hm1.begin()->second
         << endl;
}
```

After the emplace insertion, hm1 contains:
1 => a

hash_map::empty

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Tests if a hash_map is empty.

```
bool empty() const;
```

Return Value

true if the hash_map is empty; **false** if the hash_map is nonempty.

Remarks

Example

```
// hash_map_empty.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1, hm2;

    typedef pair <int, int> Int_Pair;
    hm1.insert ( Int_Pair ( 1, 1 ) );

    if ( hm1.empty( ) )
        cout << "The hash_map hm1 is empty." << endl;
    else
        cout << "The hash_map hm1 is not empty." << endl;

    if ( hm2.empty( ) )
        cout << "The hash_map hm2 is empty." << endl;
    else
        cout << "The hash_map hm2 is not empty." << endl;
}
```

```
The hash_map hm1 is not empty.
The hash_map hm2 is empty.
```

hash_map::end

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns an iterator that addresses the location succeeding the last element in a hash_map.

```
const_iterator end() const;

iterator end();
```

Return Value

A bidirectional iterator that addresses the location succeeding the last element in a `hash_map`. If the `hash_map` is empty, then `hash_map::end == hash_map::begin`.

Remarks

`end` is used to test whether an iterator has reached the end of its `hash_map`.

The value returned by `end` should not be dereferenced.

Example

```
// hash_map_end.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;

    hash_map <int, int> :: iterator hm1_Iter;
    hash_map <int, int> :: const_iterator hm1_cIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_cIter = hm1.end( );
    hm1_cIter--;
    cout << "The value of last element of hm1 is "
         << hm1_cIter -> second << "." << endl;

    hm1_Iter = hm1.end( );
    hm1_Iter--;
    hm1.erase ( hm1_Iter );

    // The following 2 lines would err because the iterator is const
    // hm1_cIter = hm1.end ( );
    // hm1_cIter--;
    // hm1.erase ( hm1_cIter );

    hm1_cIter = hm1.end( );
    hm1_cIter--;
    cout << "The value of last element of hm1 is now "
         << hm1_cIter -> second << "." << endl;
}
```

```
The value of last element of hm1 is 30.
The value of last element of hm1 is now 20.
```

hash_map::equal_range

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns a pair of iterators respectively to the first element in a hash_map with a key that is greater than a specified key and to the first element in the hash_map with a key that is equal to or greater than the key.

```
pair <const_iterator, const_iterator> equal_range (const Key& key) const;  
  
pair <iterator, iterator> equal_range (const Key& key);
```

Parameters

key

The argument key value to be compared with the sort key of an element from the hash_map being searched.

Return Value

A pair of iterators such that the first is the [lower_bound](#) of the key and the second is the [upper_bound](#) of the key.

To access the first iterator of a pair `pr` returned by the member function, use `pr.first` and to dereference the lower bound iterator, use `*(pr.first)`. To access the second iterator of a pair `pr` returned by the member function, use `pr.second` and to dereference the upper bound iterator, use `*(pr.second)`.

Remarks

Example

```

// hash_map_equal_range.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    typedef hash_map <int, int> IntMap;
    IntMap hm1;
    hash_map <int, int> :: const_iterator hm1_RcIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    pair <IntMap::const_iterator, IntMap::const_iterator> p1, p2;
    p1 = hm1.equal_range( 2 );

    cout << "The lower bound of the element with "
         << "a key of 2 in the hash_map hm1 is: "
         << p1.first -> second << "." << endl;

    cout << "The upper bound of the element with "
         << "a key of 2 in the hash_map hm1 is: "
         << p1.second -> second << "." << endl;

    // Compare the upper_bound called directly
    hm1_RcIter = hm1.upper_bound( 2 );

    cout << "A direct call of upper_bound( 2 ) gives "
         << hm1_RcIter -> second << "," << endl
         << "matching the 2nd element of the pair"
         << " returned by equal_range( 2 )." << endl;

    p2 = hm1.equal_range( 4 );

    // If no match is found for the key,
    // both elements of the pair return end( )
    if ( ( p2.first == hm1.end( ) ) && ( p2.second == hm1.end( ) ) )
        cout << "The hash_map hm1 doesn't have an element "
             << "with a key less than 40." << endl;
    else
        cout << "The element of hash_map hm1 with a key >= 40 is: "
             << p1.first -> first << "." << endl;
}

```

The lower bound of the element with a key of 2 in the hash_map hm1 is: 20.
 The upper bound of the element with a key of 2 in the hash_map hm1 is: 30.
 A direct call of upper_bound(2) gives 30,
 matching the 2nd element of the pair returned by equal_range(2).
 The hash_map hm1 doesn't have an element with a key less than 40.

hash_map::erase

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Removes an element or a range of elements in a hash_map from specified positions or removes elements that

match a specified key.

```
iterator erase(iterator _Where);

iterator erase(iterator first, iterator last);

size_type erase(const key_type& key);
```

Parameters

_Where

Position of the element to be removed from the hash_map.

first

Position of the first element removed from the hash_map.

last

Position just beyond the last element removed from the hash_map.

key

The key value of the elements to be removed from the hash_map.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or a pointer to the end of the hash_map if no such element exists.

For the third member function, returns the number of elements that have been removed from the hash_map.

Remarks

The member functions never throw an exception.

Example

The following example demonstrates the use of the hash_map::erase member function.

```
// hash_map_erase.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_map<int, int> hm1, hm2, hm3;
    hash_map<int, int> :: iterator pIter, Iter1, Iter2;
    int i;
    hash_map<int, int>::size_type n;
    typedef pair<int, int> Int_Pair;

    for (i = 1; i < 5; i++)
    {
        hm1.insert(Int_Pair (i, i));
        hm2.insert(Int_Pair (i, i*i));
        hm3.insert(Int_Pair (i, i-1));
    }

    // The 1st member function removes an element at a given position
    Iter1 = ++hm1.begin();
    hm1.erase(Iter1);

    cout << "After the 2nd element is deleted, the hash_map hm1 is:";
    for (pIter = hm1.begin(); pIter != hm1.end(); pIter++)
        cout << " " << *pIter << " second:";
```

```

        cout << " " << pIter -> second;
        cout << "." << endl;

        // The 2nd member function removes elements
        // in the range [ first, last)
        Iter1 = ++hm2.begin();
        Iter2 = --hm2.end();
        hm2.erase(Iter1, Iter2);

        cout << "After the middle two elements are deleted, "
              << "the hash_map hm2 is:";
        for (pIter = hm2.begin(); pIter != hm2.end(); pIter++)
            cout << " " << pIter -> second;
        cout << "." << endl;

        // The 3rd member function removes elements with a given key
        n = hm3.erase(2);

        cout << "After the element with a key of 2 is deleted,\n"
              << "the hash_map hm3 is:";
        for (pIter = hm3.begin(); pIter != hm3.end(); pIter++)
            cout << " " << pIter -> second;
        cout << "." << endl;

        // The 3rd member function returns the number of elements removed
        cout << "The number of elements removed from hm3 is: "
              << n << "." << endl;

        // The dereferenced iterator can also be used to specify a key
        Iter1 = ++hm3.begin();
        hm3.erase(Iter1);

        cout << "After another element with a key equal to that"
              << endl;
        cout << "of the 2nd element is deleted, "
              << "the hash_map hm3 is:";
        for (pIter = hm3.begin(); pIter != hm3.end(); pIter++)
            cout << " " << pIter -> second;
        cout << "." << endl;
    }
}

```

After the 2nd element is deleted, the hash_map hm1 is: 1 3 4.
 After the middle two elements are deleted, the hash_map hm2 is: 1 16.
 After the element with a key of 2 is deleted,
 the hash_map hm3 is: 0 2 3.
 The number of elements removed from hm3 is: 1.
 After another element with a key equal to that
 of the 2nd element is deleted, the hash_map hm3 is: 0 3.

hash_map::find

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns an iterator addressing the location of an element in a hash_map that has a key equivalent to a specified key.

```

iterator find(const Key& key);

const_iterator find(const Key& key) const;

```

Parameters

key

The key value to be matched by the sort key of an element from the hash_map being searched.

Return Value

An iterator that addresses the location of an element with a specified key, or the location succeeding the last element in the hash_map if no match is found for the key.

Remarks

`find` returns an iterator that addresses an element in the hash_map whose sort key is equivalent to the argument key under a binary predicate that induces an ordering based on a less than comparability relation.

If the return value of `find` is assigned to a [const_iterator](#), the hash_map object cannot be modified. If the return value of `find` is assigned to an [iterator](#), the hash_map object can be modified

Example

```
// hash_map_find.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;
    hash_map <int, int> :: const_iterator hm1_AcIter, hm1_RcIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_RcIter = hm1.find( 2 );
    cout << "The element of hash_map hm1 with a key of 2 is: "
         << hm1_RcIter -> second << "." << endl;

    // If no match is found for the key, end( ) is returned
    hm1_RcIter = hm1.find( 4 );

    if ( hm1_RcIter == hm1.end( ) )
        cout << "The hash_map hm1 doesn't have an element "
             << "with a key of 4." << endl;
    else
        cout << "The element of hash_map hm1 with a key of 4 is: "
             << hm1_RcIter -> second << "." << endl;

    // The element at a specific location in the hash_map can be found
    // using a dereferenced iterator addressing the location
    hm1_AcIter = hm1.end( );
    hm1_AcIter--;
    hm1_RcIter = hm1.find( hm1_AcIter -> first );
    cout << "The element of hm1 with a key matching "
         << "that of the last element is: "
         << hm1_RcIter -> second << "." << endl;
}
```

The element of hash_map hm1 with a key of 2 is: 20.
The hash_map hm1 doesn't have an element with a key of 4.
The element of hm1 with a key matching that of the last element is: 30.

hash_map::get_allocator

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns a copy of the allocator object used to construct the hash_map.

```
Allocator get_allocator() const;
```

Return Value

The allocator used by the hash_map.

Remarks

Allocators for the hash_map class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```

// hash_map_get_allocator.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int>::allocator_type hm1_Alloc;
    hash_map <int, int>::allocator_type hm2_Alloc;
    hash_map <int, double>::allocator_type hm3_Alloc;
    hash_map <int, int>::allocator_type hm4_Alloc;

    // The following lines declare objects
    // that use the default allocator.
    hash_map <int, int> hm1;
    hash_map <int, int> hm2;
    hash_map <int, double> hm3;

    hm1_Alloc = hm1.get_allocator( );
    hm2_Alloc = hm2.get_allocator( );
    hm3_Alloc = hm3.get_allocator( );

    cout << "The number of integers that can be allocated"
         << endl << "before free memory is exhausted: "
         << hm2.max_size( ) << "." << endl;

    cout << "The number of doubles that can be allocated"
         << endl << "before free memory is exhausted: "
         << hm3.max_size( ) << "." << endl;

    // The following line creates a hash_map hm4
    // with the allocator of hash_map hm1.
    hash_map <int, int> hm4( less<int>( ), hm1_Alloc );

    hm4_Alloc = hm4.get_allocator( );

    // Two allocators are interchangeable if
    // storage allocated from each can be
    // deallocated with the other
    if( hm1_Alloc == hm4_Alloc )
    {
        cout << "The allocators are interchangeable."
             << endl;
    }
    else
    {
        cout << "The allocators are not interchangeable."
             << endl;
    }
}

```

hash_map::hash_map

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Constructs a hash_map that is empty or is a copy of all or part of some other hash_map.

```

hash_map();

explicit hash_map(
    const Traits& Comp);

hash_map(
    const Traits& Comp,
    const Allocator& Al);

hash_map(
    const hash_map& Right);

hash_map(
    hash_map&& Right);

hash_map(
    initializer_list<Type> IList);hash_map(initializer_list<Type> IList,
    const key_compare& Comp);

hash_map(
    initializer_list<Type> IList,
    const key_compare& Comp,
    const allocator_type& Al);

template <class InputIterator>
hash_map(
    InputIterator First,
    InputIterator Last);

template <class InputIterator>
hash_map(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp);

template <class InputIterator>
hash_map(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp,
    const Allocator& Al

```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The storage allocator class to be used for this hash_map object, which defaults to <code>Allocator</code> .
<i>Comp</i>	The comparison function of type <code>const Traits</code> used to order the elements in the hash_map, which defaults to <code>hash_compare</code> .
<i>Right</i>	The hash_map of which the constructed map is to be a copy.
<i>First</i>	The position of the first element in the range of elements to be copied.
<i>Last</i>	The position of the first element beyond the range of elements to be copied.

PARAMETER	DESCRIPTION
<i>lList</i>	The initializer_list

Remarks

All constructors store a type of allocator object that manages memory storage for the hash_map and can later be returned by calling [get_allocator](#). The allocator parameter is often omitted in the class declarations and preprocessing macros used to substitute alternative allocators.

All constructors initialize their hash_map.

All constructors store a function object of type `Traits` that is used to establish an order among the keys of the hash_map and that can later be returned by calling [key_comp](#).

The first three constructors specify an empty initial hash_map, in addition, the second specifies the type of comparison function (*Comp*) to be used in establishing the order of the elements and the third explicitly specifies the allocator type (*Al*) to be used. The keyword **explicit** suppresses certain kinds of automatic type conversion.

The fourth constructor specifies a copy of the hash_map *Right*.

The next three constructors copy the range `[First, Last)` of a hash_map with increasing explicitness in specifying the type of comparison function of class `Traits` and allocator.

The last constructor moves the hash_map *Right*.

hash_map::insert

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Inserts an element or a range of elements into a hash_map.

```
pair <iterator, bool> insert(
    const value_type& val);

iterator insert(
    const_iterator _Where,
    const value_type& val);

template <class InputIterator>
void insert(
    InputIterator first,
    InputIterator last);

template <class ValTy>
pair <iterator, bool>
insert(
    ValTy&& val);

template <class ValTy>
iterator insert(
    const_iterator _Where,
    ValTy&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value of an element to be inserted into the hash_map unless the hash_map already contains that element (or, more generally, an element whose key is equivalently ordered).
<i>_Where</i>	A hint regarding the place to start searching for the correct point of insertion.
<i>first</i>	The position of the first element to be copied from a hash_map.
<i>last</i>	The position just beyond the last element to be copied from a hash_map.

Return Value

The first `insert` member function returns a pair whose `bool` component returns true if an insertion was made and false if the hash_map already contained an element whose key had an equivalent value in the ordering, and whose iterator component returns the address where a new element was inserted or where the element was already located.

To access the iterator component of a pair `pr` returned by this member function, use `pr.first`, and to dereference it, use `*(pr.first)`. To access the `bool` component of a pair `pr` returned by this member function, use `pr.second`, and to dereference it, use `*(pr.second)`.

The second `insert` member function, the hint version, returns an iterator that points to the position where the new element was inserted into the hash_map.

The last two `insert` member functions behave the same as the first two, except that they move construct the inserted value.

Remarks

The `value_type` of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

Insertion can occur in amortized constant time for the hint version of `insert`, instead of logarithmic time, if the insertion point immediately follows `_Where`.

The third member function inserts the sequence of element values into a hash_map corresponding to each element addressed by an iterator of in the range `[First, Last)` of a specified set.

Example

```
// hash_map_insert.cpp
// compile with: /EHsc
#include<hash_map>
#include<iostream>
#include <string>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_map<int, int>::iterator hm1_pIter, hm2_pIter;

    hash_map<int, int> hm1, hm2;
    typedef pair<int, int> Int_Pair;

    hm1.insert(Int_Pair(1, 10));
    hm1.insert(Int_Pair(2, 20));
```

```

hm1.insert(Int_Pair(2, 20));
hm1.insert(Int_Pair(3, 30));
hm1.insert(Int_Pair(4, 40));

cout << "The original elements (Key => Value) of hm1 are:";
for (hm1_pIter = hm1.begin(); hm1_pIter != hm1.end(); hm1_pIter++)
    cout << endl << " " << hm1_pIter -> first << " => "
        << hm1_pIter->second;
cout << endl;

pair< hash_map<int,int>::iterator, bool > pr;
pr = hm1.insert(Int_Pair(1, 10));

if (pr.second == true)
{
    cout << "The element 10 was inserted in hm1 successfully."
        << endl;
}
else
{
    cout << "The element 10 already exists in hm1\n"
        << "with a key value of "
        << "((pr.first) -> first) = " << (pr.first)->first
        << "." << endl;
}

// The hint version of insert
hm1.insert(--hm1.end(), Int_Pair(5, 50));

cout << "After the insertions, the elements of hm1 are:";
for (hm1_pIter = hm1.begin(); hm1_pIter != hm1.end(); hm1_pIter++)
    cout << endl << hm1_pIter -> first << " => "
        << hm1_pIter->second;
cout << endl;

hm2.insert(Int_Pair(10, 100));

// The templated version inserting a range
hm2.insert( ++hm1.begin(), --hm1.end() );

cout << "After the insertions, the elements of hm2 are:";
for (hm2_pIter = hm2.begin(); hm2_pIter != hm2.end(); hm2_pIter++)
    cout << endl << hm2_pIter -> first << " => "
        << hm2_pIter->second;
cout << endl;

// The templated versions move constructing elements
hash_map<int, string> hm3, hm4;
pair<int, string> is1(1, "a"), is2(2, "b");

hm3.insert(move(is1));
cout << "After the move insertion, hm3 contains:" << endl
    << hm3.begin()->first
    << " => " << hm3.begin()->second
    << endl;

hm4.insert(hm4.begin(), move(is2));
cout << "After the move insertion, hm4 contains:" << endl
    << hm4.begin()->first
    << " => " << hm4.begin()->second
    << endl;
}

```

The original elements (Key => Value) of hm1 are:

```
1 => 10
2 => 20
3 => 30
4 => 40
```

The element 10 already exists in hm1
with a key value of ((pr.first) -> first) = 1.

After the insertions, the elements of hm1 are:

```
1 => 10
2 => 20
3 => 30
4 => 40
5 => 50
```

After the insertions, the elements of hm2 are:

```
2 => 20
10 => 100
3 => 30
4 => 40
```

After the move insertion, hm3 contains:

```
1 => a
```

After the move insertion, hm4 contains:

```
2 => b
```

hash_map::iterator

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that provides a bidirectional iterator that can read or modify any element in a hash_map.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::iterator iterator;
```

Remarks

The `iterator` defined by hash_map points to elements that are objects of `value_type`, that is of type **pair<const Key, Type>**, whose first member is the key to the element and whose second member is the mapped datum held by the element.

To dereference an **iterator** `Iter` pointing to an element in a multimap, use the `->` operator.

To access the value of the key for the element, use `Iter -> first`, which is equivalent to `(* Iter).first`. To access the value of the mapped datum for the element, use `Iter -> second`, which is equivalent to `(* Iter).second`.

A type `iterator` can be used to modify the value of an element.

Example

See example for [begin](#) for an example of how to declare and use the `iterator`.

hash_map::key_comp

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Retrieves a copy of the comparison object used to order keys in a hash_map.

```
key_compare key_comp() const;
```

Return Value

Returns the function object that a hash_map uses to order its elements.

Remarks

The stored object defines the member function

bool operator(const Key& left, const Key& right);

that returns **true** if left precedes and is not equal to right in the sort order.

Example

```
// hash_map_key_comp.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;

    hash_map <int, int, hash_compare<int, less<int> > > > hm1;
    hash_map <int, int, hash_compare<int, less<int> > >::key_compare
        kc1 = hm1.key_comp( ) ;

    // Operator stored in kc1 tests order & returns bool value
    bool result1 = kc1( 2, 3 ) ;
    if( result1 == true )
    {
        cout << "kc1( 2,3 ) returns value of true,"
            << "\n where kc1 is the function object of hm1"
            << " of type key_compare." << endl;
    }
    else
    {
        cout << "kc1( 2,3 ) returns value of false"
            << "\n where kc1 is the function object of hm1"
            << " of type key_compare." << endl;
    }

    hash_map <int, int, hash_compare<int, greater<int> > > > hm2;
    hash_map <int, int, hash_compare<int, greater<int> > >
        ::key_compare kc2 = hm2.key_comp( );

    // Operator stored in kc2 tests order & returns bool value
    bool result2 = kc2( 2, 3 ) ;
    if( result2 == true )
    {
        cout << "kc2( 2,3 ) returns value of true,"
            << "\n where kc2 is the function object of hm2"
            << " of type key_compare." << endl;
    }
    else
    {
        cout << "kc2( 2,3 ) returns value of false,"
            << "\n where kc2 is the function object of hm2"
            << " of type key_compare." << endl;
    }
}
```

hash_map::key_compare

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the map.

```
typedef Traits key_compare;
```

Remarks

`key_compare` is a synonym for the template parameter `Traits`.

For more information on `Traits` see the [hash_map Class](#) topic.

Example

See example for [key_comp](#) for an example of how to declare and use `key_compare`.

hash_map::key_type

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type describes the sort key object that constitutes each element of the hash_map.

```
typedef Key key_type;
```

Remarks

`key_type` is a synonym for the template parameter `Key`.

For more information on `key`, see the Remarks section of the [hash_map Class](#) topic.

Example

See example for [value_type](#) for an example of how to declare and use `key_type`.

hash_map::lower_bound

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns an iterator to the first element in a hash_map with a key value that is equal to or greater than that of a specified key.

```
iterator lower_bound(const Key& key);  
  
const_iterator lower_bound(const Key& key) const;
```

Parameters

key

The argument key value to be compared with the sort key of an element from the hash_map being searched.

Return Value

An [iterator](#) or [const_iterator](#) that addresses the location of an element in a hash_map that with a key that is equal to or greater than the argument key, or that addresses the location succeeding the last element in the hash_map if no match is found for the key.

If the return value of `lower_bound` is assigned to a `const_iterator`, the hash_map object cannot be modified. If the return value of `lower_bound` is assigned to a `iterator`, the hash_map object can be modified.

Remarks

Example

```
// hash_map_lower_bound.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;
    hash_map <int, int> :: const_iterator hm1_AcIter, hm1_RcIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_RcIter = hm1.lower_bound( 2 );
    cout << "The first element of hash_map hm1 with a key of 2 is: "
         << hm1_RcIter -> second << "." << endl;

    // If no match is found for the key, end( ) is returned
    hm1_RcIter = hm1.lower_bound ( 4 );

    if ( hm1_RcIter == hm1.end( ) )
        cout << "The hash_map hm1 doesn't have an element "
             << "with a key of 4." << endl;
    else
        cout << "The element of hash_map hm1 with a key of 4 is: "
             << hm1_RcIter -> second << "." << endl;

    // An element at a specific location in the hash_map can be
    // found using a dereferenced iterator addressing the location
    hm1_AcIter = hm1.end( );
    hm1_AcIter--;
    hm1_RcIter = hm1.lower_bound ( hm1_AcIter -> first );
    cout << "The element of hm1 with a key matching "
         << "that of the last element is: "
         << hm1_RcIter -> second << "." << endl;
}
```

The first element of hash_map hm1 with a key of 2 is: 20.
The hash_map hm1 doesn't have an element with a key of 4.
The element of hm1 with a key matching that of the last element is: 30.

hash_map::mapped_type

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that represents the data type stored in a hash_map.

```
typedef Type mapped_type;
```

Remarks

The type `mapped_type` is a synonym for the template parameter `Type`.

For more information on `Type` see the [hash_map Class](#) topic.

Example

See example for [value_type](#) for an example of how to declare and use `key_type`.

hash_map::max_size

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns the maximum length of the hash_map.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the hash_map.

Remarks

Example

```
// hash_map_max_size.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map<int, int> hm1;
    hash_map<int, int> :: size_type i;

    i = hm1.max_size( );
    cout << "The maximum possible length "
        << "of the hash_map is " << i << "."
        << endl << "(Magnitude is machine specific.);";
}
```

hash_map::operator[]

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Inserts an element into a `hash_map` with a specified key value.

```
Type& operator[](const Key& key);
```

```
Type& operator[](Key&& key);
```

Parameters

PARAMETER	DESCRIPTION
<i>key</i>	The key value of the element that is to be inserted.

Return Value

A reference to the data value of the inserted element.

Remarks

If the argument key value is not found, then it is inserted along with the default value of the data type.

`operator[]` may be used to insert elements into a `hash_map m` using

```
m[ key] = DataValue ;
```

where `DataValue` is the value of the `mapped_type` of the element with a key value of *key*.

When using `operator[]` to insert elements, the returned reference does not indicate whether an insertion is changing a preexisting element or creating a new one. The member functions [find](#) and [insert](#) can be used to determine whether an element with a specified key is already present before an insertion.

Example

```

// hash_map_op_ref.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    using namespace stdext;
    typedef pair <const int, int> cInt2Int;
    hash_map <int, int> hm1;
    hash_map <int, int> :: iterator pIter;

    // Insert a data value of 10 with a key of 1
    // into a hash_map using the operator[] member function
    hm1[ 1 ] = 10;

    // Compare other ways to insert objects into a hash_map
    hm1.insert ( hash_map <int, int> :: value_type ( 2, 20 ) );
    hm1.insert ( cInt2Int ( 3, 30 ) );

    cout << "The keys of the mapped elements are:";
    for ( pIter = hm1.begin( ) ; pIter != hm1.end( ) ; pIter++ )
        cout << " " << pIter -> first;
    cout << "." << endl;

    cout << "The values of the mapped elements are:";
    for ( pIter = hm1.begin( ) ; pIter != hm1.end( ) ; pIter++ )
        cout << " " << pIter -> second;
    cout << "." << endl;

    // If the key already exists, operator[]
    // changes the value of the datum in the element
    hm1[ 2 ] = 40;

    // operator[] will also insert the value of the data
    // type's default constructor if the value is unspecified
    hm1[5];

    cout << "The keys of the mapped elements are now:";
    for ( pIter = hm1.begin( ) ; pIter != hm1.end( ) ; pIter++ )
        cout << " " << pIter -> first;
    cout << "." << endl;

    cout << "The values of the mapped elements are now:";
    for ( pIter = hm1.begin( ) ; pIter != hm1.end( ) ; pIter++ )
        cout << " " << pIter -> second;
    cout << "." << endl;

    // operator[] will also insert by moving a key
    hash_map <string, int> hm2;
    string str("a");
    hm2[move(str)] = 1;
    cout << "The moved key is " << hm2.begin()->first
        << ", with value " << hm2.begin()->second << endl;
}

```

hash_map::operator=

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Replaces the elements of the `hash_map` with a copy of another `hash_map`.

```
hash_map& operator=(const hash_map& right);

hash_map& operator=(hash_map&& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The hash_map Class being copied into the <code>hash_map</code> .

Remarks

After erasing any existing elements in a `hash_map`, `operator=` either copies or moves the contents of *right* into the `hash_map`.

Example

```
// hash_map_operator_as.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map<int, int> v1, v2, v3;
    hash_map<int, int>::iterator iter;

    v1.insert(pair<int, int>(1, 10));

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;
}
```

hash_map::pointer

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that provides a pointer to an element in a `hash_map`.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::pointer pointer;
```

Remarks

A type `pointer` can be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a `hash_map` object.

hash_map::rbegin

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns an iterator addressing the first element in a reversed `hash_map`.

```
const_reverse_iterator rbegin() const;  
  
reverse_iterator rbegin();
```

Return Value

A reverse bidirectional iterator addressing the first element in a reversed `hash_map` or addressing what had been the last element in the unreversed `hash_map`.

Remarks

`rbegin` is used with a reversed `hash_map` just as [begin](#) is used with a `hash_map`.

If the return value of `rbegin` is assigned to a [const_reverse_iterator](#), then the `hash_map` object cannot be modified. If the return value of `rbegin` is assigned to a [reverse_iterator](#), then the `hash_map` object can be modified.

`rbegin` can be used to iterate through a `hash_map` backwards.

Example

```

// hash_map_rbegin.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;

    hash_map <int, int> :: iterator hm1_Iter;
    hash_map <int, int> :: reverse_iterator hm1_rIter;
    hash_map <int, int> :: const_reverse_iterator hm1_crIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_rIter = hm1.rbegin( );
    cout << "The first element of the reversed hash_map hm1 is "
         << hm1_rIter -> first << "." << endl;

    // begin can be used to start an iteration
    // through a hash_map in a forward order
    cout << "The hash_map is: ";
    for ( hm1_Iter = hm1.begin( ) ; hm1_Iter != hm1.end( ); hm1_Iter++)
        cout << hm1_Iter -> first << " ";
    cout << "." << endl;

    // rbegin can be used to start an iteration
    // through a hash_map in a reverse order
    cout << "The reversed hash_map is: ";
    for ( hm1_rIter = hm1.rbegin( ) ; hm1_rIter != hm1.rend( ); hm1_rIter++)
        cout << hm1_rIter -> first << " ";
    cout << "." << endl;

    // A hash_map element can be erased by dereferencing to its key
    hm1_rIter = hm1.rbegin( );
    hm1.erase ( hm1_rIter -> first );

    hm1_rIter = hm1.rbegin( );
    cout << "After the erasure, the first element "
         << "in the reversed hash_map is "
         << hm1_rIter -> first << "." << endl;
}

```

```

The first element of the reversed hash_map hm1 is 3.
The hash_map is: 1 2 3 .
The reversed hash_map is: 3 2 1 .
After the erasure, the first element in the reversed hash_map is 2.

```

hash_map::reference

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that provides a reference to an element stored in a hash_map.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::reference reference;
```

Remarks

Example

```
// hash_map_reference.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );

    // Declare and initialize a const_reference &Ref1
    // to the key of the first element
    const int &Ref1 = ( hm1.begin( ) -> first );

    // The following line would cause an error as the
    // non-const_reference cannot be used to access the key
    // int &Ref1 = ( hm1.begin( ) -> first );

    cout << "The key of first element in the hash_map is "
         << Ref1 << "." << endl;

    // Declare and initialize a reference &Ref2
    // to the data value of the first element
    int &Ref2 = ( hm1.begin( ) -> second );

    cout << "The data value of first element in the hash_map is "
         << Ref2 << "." << endl;

    // The non-const_reference can be used to modify the
    // data value of the first element
    Ref2 = Ref2 + 5;
    cout << "The modified data value of first element is "
         << Ref2 << "." << endl;
}
```

```
The key of first element in the hash_map is 1.
The data value of first element in the hash_map is 10.
The modified data value of first element is 15.
```

hash_map::rend

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns an iterator that addresses the location succeeding the last element in a reversed hash_map.

```
const_reverse_iterator rend() const;
```

```
reverse_iterator rend();
```

Return Value

A reverse bidirectional iterator that addresses the location succeeding the last element in a reversed hash_map (the location that had preceded the first element in the unreversed hash_map).

Remarks

`rend` is used with a reversed hash_map just as `end` is used with a hash_map.

If the return value of `rend` is assigned to a `const_reverse_iterator`, then the hash_map object cannot be modified.

If the return value of `rend` is assigned to a `reverse_iterator`, then the hash_map object can be modified.

`rend` can be used to test to whether a reverse iterator has reached the end of its hash_map.

The value returned by `rend` should not be dereferenced.

Example

```

// hash_map_rend.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;

    hash_map <int, int> :: iterator hm1_Iter;
    hash_map <int, int> :: reverse_iterator hm1_rIter;
    hash_map <int, int> :: const_reverse_iterator hm1_crIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_rIter = hm1.rend( );
    hm1_rIter--;
    cout << "The last element of the reversed hash_map hm1 is "
         << hm1_rIter -> first << "." << endl;

    // begin can be used to start an iteration
    // through a hash_map in a forward order
    cout << "The hash_map is: ";
    for ( hm1_Iter = hm1.begin( ) ; hm1_Iter != hm1.end( );
          hm1_Iter++)
        cout << hm1_Iter -> first << " ";
    cout << "." << endl;

    // rbegin can be used to start an iteration
    // through a hash_map in a reverse order
    cout << "The reversed hash_map is: ";
    for ( hm1_rIter = hm1.rbegin( ) ; hm1_rIter != hm1.rend( );
          hm1_rIter++)
        cout << hm1_rIter -> first << " ";
    cout << "." << endl;

    // A hash_map element can be erased by dereferencing to its key
    hm1_rIter = --hm1.rend( );
    hm1.erase ( hm1_rIter -> first );

    hm1_rIter = hm1.rend( );
    hm1_rIter--;
    cout << "After the erasure, the last element "
         << "in the reversed hash_map is "
         << hm1_rIter -> first << "." << endl;
}

```

```

The last element of the reversed hash_map hm1 is 1.
The hash_map is: 1 2 3 .
The reversed hash_map is: 3 2 1 .
After the erasure, the last element in the reversed hash_map is 2.

```

hash_map::reverse_iterator

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that provides a bidirectional iterator that can read or modify an element in a reversed hash_map.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::reverse_iterator
reverse_iterator;
```

Remarks

A type `reverse_iterator` cannot modify the value of an element and is use to iterate through the hash_map in reverse.

The `reverse_iterator` defined by hash_map points to elements that are objects of [value_type](#), that is of type **pair<const Key, Type>**, whose first member is the key to the element and whose second member is the mapped datum held by the element.

To dereference a `reverse_iterator` `rIter` pointing to an element in a hash_map, use the `->` operator.

To access the value of the key for the element, use `rIter -> first`, which is equivalent to `(* rIter).first`. To access the value of the mapped datum for the element, use `rIter -> second`, which is equivalent to `(* rIter).second`.

Example

See example for [rbegin](#) for an example of how to declare and use `reverse_iterator`.

hash_map::size

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns the number of elements in the hash_map.

```
size_type size() const;
```

Return Value

The current length of the hash_map.

Remarks

Example

The following example demonstrates the use of the hash_map::size member function.

```
// hash_map_size.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map<int, int> hm1, hm2;
    hash_map<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    hm1.insert(Int_Pair(1, 1));
    i = hm1.size();
    cout << "The hash_map length is " << i << "." << endl;

    hm1.insert(Int_Pair(2, 4));
    i = hm1.size();
    cout << "The hash_map length is now " << i << "." << endl;
}
```

```
The hash_map length is 1.
The hash_map length is now 2.
```

hash_map::size_type

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

An unsigned integer type that can represent the number of elements in a hash_map.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::size_type size_type;
```

Remarks

Example

See example for [size](#) for an example of how to declare and use `size_type`

hash_map::swap

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Exchanges the elements of two hash_maps.

```
void swap(hash_map& right);
```

Parameters

right

The argument hash_map providing the elements to be swapped with the target hash_map.

Remarks

The member function invalidates no references, pointers, or iterators that designate elements in the two hash_maps whose elements are being exchanged.

Example

```
// hash_map_swap.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1, hm2, hm3;
    hash_map <int, int>::iterator hm1_Iter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );
    hm2.insert ( Int_Pair ( 10, 100 ) );
    hm2.insert ( Int_Pair ( 20, 200 ) );
    hm3.insert ( Int_Pair ( 30, 300 ) );

    cout << "The original hash_map hm1 is:";
    for ( hm1_Iter = hm1.begin( ); hm1_Iter != hm1.end( ); hm1_Iter++ )
        cout << " " << hm1_Iter -> second;
    cout << "." << endl;

    // This is the member function version of swap
    // hm2 is said to be the argument hash_map;
    // hm1 is said to be the target hash_map
    hm1.swap( hm2 );

    cout << "After swapping with hm2, hash_map hm1 is:";
    for ( hm1_Iter = hm1.begin( ); hm1_Iter != hm1.end( ); hm1_Iter++ )
        cout << " " << hm1_Iter -> second;
    cout << "." << endl;

    // This is the specialized template version of swap
    swap( hm1, hm3 );

    cout << "After swapping with hm3, hash_map hm1 is:";
    for ( hm1_Iter = hm1.begin( ); hm1_Iter != hm1.end( ); hm1_Iter++ )
        cout << " " << hm1_Iter -> second;
    cout << "." << endl;
}
```

The original hash_map hm1 is: 10 20 30.
After swapping with hm2, hash_map hm1 is: 100 200.
After swapping with hm3, hash_map hm1 is: 300.

hash_map::upper_bound

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns an iterator to the first element in a hash_map that with a key having a value that is greater than that of a

specified key.

```
iterator upper_bound(const Key& key);  
  
const_iterator upper_bound(const Key& key) const;
```

Parameters

key

The argument key value to be compared with the sort key value of an element from the hash_map being searched.

Return Value

An [iterator](#) or [const_iterator](#) that addresses the location of an element in a hash_map that with a key that is greater than the argument key, or that addresses the location succeeding the last element in the hash_map if no match is found for the key.

If the return value is assigned to a `const_iterator`, the hash_map object cannot be modified. If the return value is assigned to an `iterator`, the hash_map object can be modified.

Remarks

Example

```

// hash_map_upper_bound.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_map <int, int> hm1;
    hash_map <int, int> :: const_iterator hm1_AcIter, hm1_RcIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_RcIter = hm1.upper_bound( 2 );
    cout << "The first element of hash_map hm1 with a key "
        << "greater than 2 is: "
        << hm1_RcIter -> second << "." << endl;

    // If no match is found for the key, end is returned
    hm1_RcIter = hm1.upper_bound ( 4 );

    if ( hm1_RcIter == hm1.end( ) )
        cout << "The hash_map hm1 doesn't have an element "
            << "with a key greater than 4." << endl;
    else
        cout << "The element of hash_map hm1 with a key > 4 is: "
            << hm1_RcIter -> second << "." << endl;

    // The element at a specific location in the hash_map can be found
    // using a dereferenced iterator addressing the location
    hm1_AcIter = hm1.begin( );
    hm1_RcIter = hm1.upper_bound ( hm1_AcIter -> first );
    cout << "The 1st element of hm1 with a key greater than that\n"
        << "of the initial element of hm1 is: "
        << hm1_RcIter -> second << "." << endl;
}

```

The first element of hash_map hm1 with a key greater than 2 is: 30.
 The hash_map hm1 doesn't have an element with a key greater than 4.
 The 1st element of hm1 with a key greater than that
 of the initial element of hm1 is: 20.

hash_map::value_comp

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

Returns a function object that determines the order of elements in a hash_map by comparing their key values.

```
value_compare value_comp() const;
```

Return Value

Returns the comparison function object that a hash_map uses to order its elements.

Remarks

For a hash_map m , if two elements $e1$ ($k1, d1$) and $e2$ ($k2, d2$) are objects of type `value_type`, where $k1$ and $k2$ are their keys of type `key_type` and $d1$ and $d2$ are their data of type `mapped_type`, then `m.value_comp()(e1, e2)` is equivalent to `m.key_comp()(k1, k2)`. A stored object defines the member function

```
bool operator(value_type& left, value_type& right);
```

which returns **true** if the key value of `left` precedes and is not equal to the key value of `right` in the sort order.

Example

```
// hash_map_value_comp.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;

    hash_map <int, int, hash_compare<int, less<int> > > > hm1;
    hash_map <int, int, hash_compare<int, less<int> > >
    ::value_compare vc1 = hm1.value_comp( );
    pair< hash_map<int,int>::iterator, bool > pr1, pr2;

    pr1= hm1.insert ( hash_map <int, int> :: value_type ( 1, 10 ) );
    pr2= hm1.insert ( hash_map <int, int> :: value_type ( 2, 5 ) );

    if( vc1( *pr1.first, *pr2.first ) == true )
    {
        cout << "The element ( 1,10 ) precedes the element ( 2,5 )."
              << endl;
    }
    else
    {
        cout << "The element ( 1,10 ) does not precede the element ( 2,5 )."
              << endl;
    }

    if( vc1 ( *pr2.first, *pr1.first ) == true )
    {
        cout << "The element ( 2,5 ) precedes the element ( 1,10 )."
              << endl;
    }
    else
    {
        cout << "The element ( 2,5 ) does not precede the element ( 1,10 )."
              << endl;
    }
}
```

hash_map::value_type

NOTE

This API is obsolete. The alternative is [unordered_map Class](#).

A type that represents the type of object stored in a hash_map.

```
typedef pair<const Key, Type> value_type;
```

Remarks

`value_type` is declared to be `pair<const key_type, mapped_type>` and not `pair<key_type, mapped_type>` because the keys of an associative container may not be changed using a nonconstant iterator or reference.

Example

```
// hash_map_value_type.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    typedef pair <const int, int> cInt2Int;
    hash_map <int, int> hm1;
    hash_map <int, int> :: key_type key1;
    hash_map <int, int> :: mapped_type mapped1;
    hash_map <int, int> :: value_type value1;
    hash_map <int, int> :: iterator pIter;

    // value_type can be used to pass the correct type
    // explicitly to avoid implicit type conversion
    hm1.insert ( hash_map <int, int> :: value_type ( 1, 10 ) );

    // Compare other ways to insert objects into a hash_map
    hm1.insert ( cInt2Int ( 2, 20 ) );
    hm1[ 3 ] = 30;

    // Initializing key1 and mapped1
    key1 = ( hm1.begin( ) -> first );
    mapped1 = ( hm1.begin( ) -> second );

    cout << "The key of first element in the hash_map is "
          << key1 << "." << endl;

    cout << "The data value of first element in the hash_map is "
          << mapped1 << "." << endl;

    // The following line would cause an error because
    // the value_type is not assignable
    // value1 = cInt2Int ( 4, 40 );

    cout << "The keys of the mapped elements are:";
    for ( pIter = hm1.begin( ) ; pIter != hm1.end( ) ; pIter++ )
        cout << " " << pIter -> first;
    cout << "." << endl;

    cout << "The values of the mapped elements are:";
    for ( pIter = hm1.begin( ) ; pIter != hm1.end( ) ; pIter++ )
        cout << " " << pIter -> second;
    cout << "." << endl;
}
```

The key of first element in the hash_map is 1.
The data value of first element in the hash_map is 10.
The keys of the mapped elements are: 1 2 3.
The values of the mapped elements are: 10 20 30.

hash_multimap Class

11/14/2018 • 56 minutes to read • [Edit Online](#)

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

The container class `hash_multimap` is an extension of the C++ Standard Library and is used for the storage and fast retrieval of data from a collection in which each element is a pair that has a sort key whose value need not be unique and an associated data value.

Syntax

```
template <class Key,
          class Type,
          class Traits=hash_compare <Key, less <Key>>,
          class Allocator=allocator <pair <const Key, Type>>>
class hash_multimap
```

Parameters

Key

The key data type to be stored in the `hash_multimap`.

Type

The element data type to be stored in the `hash_multimap`.

Traits

The type that includes two function objects, one of class *Traits* that is able to compare two element values as sort keys to determine their relative order and a hash function that is a unary predicate mapping key values of the elements to unsigned integers of type `size_t`. This argument is optional, and the `hash_compare<Key, less<Key>>` is the default value.

Allocator

The type that represents the stored allocator object that encapsulates details about the `hash_multimap`'s allocation and deallocation of memory. This argument is optional, and the default value is

```
allocator<pair <const Key, Type>> .
```

Remarks

The `hash_multimap` is:

- An associative container, which is a variable size container that supports the efficient retrieval of element values based on an associated key value.
- Reversible, because it provides a bidirectional iterator to access its elements.
- Hashed, because its elements are grouped into buckets based on the value of a hash function applied to the key values of the elements.
- Multiple, because its elements do not need to have a unique key, so that one key value may have many element data values associated with it.

- A pair associative container, because its element values are distinct from its key values.
- A template class, because the functionality it provides is generic and so independent of the specific type of data contained as elements or keys. The data types to be used for elements and keys are, instead, specified as parameters in the class template along with the comparison function and allocator.

The main advantage of hashing over sorting is greater efficiency; a successful hashing performs insertions, deletions, and finds in constant average time as compared with a time proportional to the logarithm of the number of elements in the container for sorting techniques. The value of an element in a `hash_multimap`, but not its associated key value, may be changed directly. Instead, key values associated with old elements must be deleted and new key values associated with new elements inserted.

The choice of container type should be based in general on the type of searching and inserting required by the application. Hashed associative containers are optimized for the operations of lookup, insertion and removal. The member functions that explicitly support these operations are efficient when used with a well-designed hash function, performing them in a time that is on average constant and not dependent on the number of elements in the container. A well-designed hash function produces a uniform distribution of hashed values and minimizes the number of collisions, where a collision is said to occur when distinct key values are mapped into the same hashed value. In the worst case, with the worst possible hash function, the number of operations is proportional to the number of elements in the sequence (linear time).

The `hash_multimap` should be the associative container of choice when the conditions associating the values with their keys are satisfied by the application. A model for this type of structure is an ordered list of key words with associated string values providing, say, definitions, where the words were not always uniquely defined. If, instead, the keywords were uniquely defined so that keys were unique, then a `hash_map` would be the container of choice. If, on the other hand, just the list of words were being stored, then a `hash_set` would be the correct container. If multiple occurrences of the words were allowed, then a `hash_multiset` would be the appropriate container structure.

The `hash_multimap` orders the sequence it controls by calling a stored hash `Traits` object of type `value_compare`. This stored object may be accessed by calling the member function `key_comp`. Such a function object must behave the same as an object of class `hash_compare<Key, less<Key>>`. Specifically, for all values `key` of type `Key`, the call `Traits (Key)` yields a distribution of values of type `size_t`.

In general, the elements need be merely less than comparable to establish this order: so that, given any two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the non-equivalent elements. On a more technical note, the comparison function is a binary predicate that induces a strict weak ordering in the standard mathematical sense. A binary predicate $f(x, y)$ is a function object that has two argument objects `x` and `y` and a return value of **true** or **false**. An ordering imposed on a `hash_multimap` is a strict weak ordering if the binary predicate is irreflexive, antisymmetric, and transitive and if equivalence is transitive, where two objects `x` and `y` are defined to be equivalent when both $f(x, y)$ and $f(y, x)$ are **false**. If the stronger condition of equality between keys replaces that of equivalence, then the ordering becomes total (in the sense that all the elements are ordered with respect to each other) and the keys matched will be indiscernible from each other.

The actual order of elements in the controlled sequence depends on the hash function, the ordering function, and the current size of the hash table stored in the container object. You cannot determine the current size of the hash table, so you cannot in general predict the order of elements in the controlled sequence. Inserting elements invalidates no iterators, and removing elements invalidates only those iterators that had specifically pointed at the removed elements.

The iterator provided by the `hash_multimap` class is a bidirectional iterator, but the class member functions `insert` and `hash_multimap` have versions that take as template parameters a weaker input iterator, whose functionality requirements are more minimal than those guaranteed by the class of bidirectional iterators. The different iterator concepts form a family related by refinements in their functionality. Each iterator concept has its own

hash_multimap of requirements, and the algorithms that work with them must limit their assumptions to the requirements provided by that type of iterator. It may be assumed that an input iterator may be dereferenced to refer to some object and that it may be incremented to the next iterator in the sequence. This is a minimal hash_multimap of functionality, but it is enough to be able to talk meaningfully about a range of iterators [First, Last) in the context of the member functions.

Constructors

CONSTRUCTOR	DESCRIPTION
hash_multimap	Constructs a list of a specific size or with elements of a specific value or with a specific <code>allocator</code> or as a copy of some other <code>hash_multimap</code> .

Typedefs

TYPE NAME	DESCRIPTION
allocator_type	A type that represents the <code>allocator</code> class for the <code>hash_multimap</code> object.
const_iterator	A type that provides a bidirectional iterator that can read a <code>const</code> element in the <code>hash_multimap</code> .
const_pointer	A type that provides a pointer to a const element in a <code>hash_multimap</code> .
const_reference	A type that provides a reference to a const element stored in a <code>hash_multimap</code> for reading and performing const operations.
const_reverse_iterator	A type that provides a bidirectional iterator that can read any const element in the <code>hash_multimap</code> .
difference_type	A signed integer type that can be used to represent the number of elements of a <code>hash_multimap</code> in a range between elements pointed to by iterators.
iterator	A type that provides a bidirectional iterator that can read or modify any element in a <code>hash_multimap</code> .
key_compare	A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the <code>hash_multimap</code> .
key_type	A type that describes the sort key object that constitutes each element of the <code>hash_multimap</code> .
mapped_type	A type that represents the data type stored in a <code>hash_multimap</code> .
pointer	A type that provides a pointer to an element in a <code>hash_multimap</code> .

TYPE NAME	DESCRIPTION
reference	A type that provides a reference to an element stored in a <code>hash_multimap</code> .
reverse_iterator	A type that provides a bidirectional iterator that can read or modify an element in a reversed <code>hash_multimap</code> .
size_type	An unsigned integer type that can represent the number of elements in a <code>hash_multimap</code> .
value_type	A type that provides a function object that can compare two elements as sort keys to determine their relative order in the <code>hash_multimap</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
begin	Returns an iterator addressing the first element in the <code>hash_multimap</code> .
cbegin	Returns a const iterator addressing the first element in the <code>hash_multimap</code> .
cend	Returns a const iterator that addresses the location succeeding the last element in a <code>hash_multimap</code> .
clear	Erases all the elements of a <code>hash_multimap</code> .
count	Returns the number of elements in a <code>hash_multimap</code> whose key matches a parameter-specified key.
crbegin	Returns a const iterator addressing the first element in a reversed <code>hash_multimap</code> .
crend	Returns a const iterator that addresses the location succeeding the last element in a reversed <code>hash_multimap</code> .
emplace	Inserts an element constructed in place into a <code>hash_multimap</code> .
emplace_hint	Inserts an element constructed in place into a <code>hash_multimap</code> , with a placement hint.
empty	Tests if a <code>hash_multimap</code> is empty.
end	Returns an iterator that addresses the location succeeding the last element in a <code>hash_multimap</code> .
equal_range	Returns an iterator that addresses the location succeeding the last element in a <code>hash_multimap</code> .

MEMBER FUNCTION	DESCRIPTION
erase	Removes an element or a range of elements in a <code>hash_multimap</code> from specified positions
find	Returns an iterator addressing the location of an element in a <code>hash_multimap</code> that has a key equivalent to a specified key.
get_allocator	Returns a copy of the <code>allocator</code> object used to construct the <code>hash_multimap</code> .
insert	Inserts an element or a range of elements into the <code>hash_multimap</code> at a specified position.
key_comp	Retrieves a copy of the comparison object used to order keys in a <code>hash_multimap</code> .
lower_bound	Returns an iterator to the first element in a <code>hash_multimap</code> that with a key value that is equal to or greater than that of a specified key.
max_size	Returns the maximum length of the <code>hash_multimap</code> .
rbegin	Returns an iterator addressing the first element in a reversed <code>hash_multimap</code> .
rend	Returns an iterator that addresses the location succeeding the last element in a reversed <code>hash_multimap</code> .
size	Specifies a new size for a <code>hash_multimap</code> .
swap	Exchanges the elements of two <code>hash_multimap</code> s.
upper_bound	Returns an iterator to the first element in a <code>hash_multimap</code> that with a key value that is greater than that of a specified key.
value_comp	Retrieves a copy of the comparison object used to order element values in a <code>hash_multimap</code> .

Operators

OPERATOR	DESCRIPTION
hash_multimap::operator=	Replaces the elements of a <code>hash_multimap</code> with a copy of another <code>hash_multimap</code> .

Requirements

Header: `<hash_map>`

Namespace: `stdext`

`hash_multimap::allocator_type`

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that represents the allocator class for the hash_multimap object.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::allocator_type allocator_type;
```

Remarks

`allocator_type` is a synonym for the template parameter `Allocator`.

For more information on `Allocator`, see the Remarks section of the [hash_multimap Class](#) topic.

Example

See the example for [get_allocator](#) for an example using `allocator_type`.

hash_multimap::begin

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns an iterator addressing the first element in the hash_multimap.

```
const_iterator begin() const;  
  
iterator begin();
```

Return Value

A bidirectional iterator addressing the first element in the hash_multimap or the location succeeding an empty hash_multimap.

Remarks

If the return value of `begin` is assigned to a `const_iterator`, the elements in the hash_multimap object cannot be modified. If the return value of `begin` is assigned to an `iterator`, the elements in the hash_multimap object can be modified.

Example

```

// hash_multimap_begin.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;

    hash_multimap <int, int> :: iterator hm1_Iter;
    hash_multimap <int, int> :: const_iterator hm1_cIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 0, 0 ) );
    hm1.insert ( Int_Pair ( 1, 1 ) );
    hm1.insert ( Int_Pair ( 2, 4 ) );

    hm1_cIter = hm1.begin ( );
    cout << "The first element of hm1 is " << hm1_cIter -> first
         << "." << endl;

    hm1_Iter = hm1.begin ( );
    hm1.erase ( hm1_Iter );

    // The following 2 lines would err because the iterator is const
    // hm1_cIter = hm1.begin ( );
    // hm1.erase ( hm1_cIter );

    hm1_cIter = hm1.begin( );
    cout << "The first element of hm1 is now " << hm1_cIter -> first
         << "." << endl;
}

```

```

The first element of hm1 is 0.
The first element of hm1 is now 1.

```

hash_multimap::cbegin

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns a const iterator addressing the first element in the hash_multimap.

```
const_iterator cbegin() const;
```

Return Value

A const bidirectional iterator addressing the first element in the [hash_multimap](#) or the location succeeding an empty `hash_multimap`.

Example

```
// hash_multimap_cbegin.cpp
// compile with: /EHsc
#include <hash_multimap>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;

    hash_multimap <int, int> :: const_iterator hm1_cIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 2, 4 ) );

    hm1_cIter = hm1.cbegin ( );
    cout << "The first element of hm1 is "
         << hm1_cIter -> first << "." << endl;
}
```

The first element of hm1 is 2.

hash_multimap::cend

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns a const iterator that addresses the location succeeding the last element in a hash_multimap.

```
const_iterator cend() const;
```

Return Value

A const bidirectional iterator that addresses the location succeeding the last element in a [hash_multimap](#). If the `hash_multimap` is empty, then `hash_multimap::cend == hash_multimap::begin`.

Remarks

`cend` is used to test whether an iterator has reached the end of its hash_multimap.

The value returned by `cend` should not be dereferenced.

Example

```
// hash_multimap_cend.cpp
// compile with: /EHsc
#include <hash_multimap>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;

    hash_multimap <int, int> :: const_iterator hm1_cIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_cIter = hm1.cend( );
    hm1_cIter--;
    cout << "The value of last element of hm1 is "
         << hm1_cIter -> second << "." << endl;
}
```

The value of last element of hm1 is 30.

hash_multimap::clear

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Erases all the elements of a hash_multimap.

```
void clear();
```

Remarks

Example

The following example demonstrates the use of the hash_multimap::clear member function.

```
// hash_multimap_clear.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_multimap<int, int> hm1;
    hash_multimap<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    hm1.insert(Int_Pair(1, 1));
    hm1.insert(Int_Pair(2, 4));

    i = hm1.size();
    cout << "The size of the hash_multimap is initially "
         << i << "." << endl;

    hm1.clear();
    i = hm1.size();
    cout << "The size of the hash_multimap after clearing is "
         << i << "." << endl;
}
```

The size of the hash_multimap is initially 2.
The size of the hash_multimap after clearing is 0.

hash_multimap::const_iterator

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that provides a bidirectional iterator that can read a **const** element in the hash_multimap.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::const_iterator const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

The `const_iterator` defined by hash_multimap points to objects of [value_type](#), which are of type `pair<const Key, Type>`. The value of the key is available through the first member pair, and the value of the mapped element is available through the second member of the pair.

To dereference a `const_iterator` `cIter` pointing to an element in a hash_multimap, use the `->` operator.

To access the value of the key for the element, use `cIter->first`, which is equivalent to `(*cIter).first`. To access the value of the mapped datum for the element, use `cIter->second`, which is equivalent to `(*cIter).second`.

Example

See the example for [begin](#) for an example using `const_iterator`.

hash_multimap::const_pointer

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that provides a pointer to a **const** element in a hash_multimap.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a hash_multimap object.

hash_multimap::const_reference

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that provides a reference to a **const** element stored in a hash_multimap for reading and performing **const** operations.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::const_reference  
const_reference;
```

Remarks

Example

```

// hash_multimap_const_ref.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap<int, int> hm1;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );

    // Declare and initialize a const_reference &Ref1
    // to the key of the first element
    const int &Ref1 = ( hm1.begin( ) -> first );

    // The following line would cause an error because the
    // non-const_reference cannot be used to access the key
    // int &Ref1 = ( hm1.begin( ) -> first );

    cout << "The key of first element in the hash_multimap is "
         << Ref1 << "." << endl;

    // Declare and initialize a reference &Ref2
    // to the data value of the first element
    int &Ref2 = ( hm1.begin() -> second );

    cout << "The data value of 1st element in the hash_multimap is "
         << Ref2 << "." << endl;
}

```

```

The key of first element in the hash_multimap is 1.
The data value of 1st element in the hash_multimap is 10.

```

hash_multimap::const_reverse_iterator

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that provides a bidirectional iterator that can read any **const** element in the hash_multimap.

```

typedef list<typename Traits::value_type, typename Traits::allocator_type>::const_reverse_iterator
const_reverse_iterator;

```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is use to iterate through the hash_multimap in reverse.

The `const_reverse_iterator` defined by hash_multimap points to objects of [value_type](#), which are of type `pair<const Key, Type>`, whose first member is the key to the element and whose second member is the mapped datum held by the element.

To dereference a `const_reverse_iterator` `crIter` pointing to an element in a hash_multimap, use the `->` operator.

To access the value of the key for the element, use `crIter->first`, which is equivalent to `(*crIter).first`. To access the value of the mapped datum for the element, use `crIter->second`, which is equivalent to `(*crIter).second`.

Example

See the example for [rend](#) for an example of how to declare and use the `const_reverse_iterator`.

hash_multimap::count

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns the number of elements in a hash_multimap whose key matches a parameter-specified key.

```
size_type count(const Key& key) const;
```

Parameters

key

The key of the elements to be matched from the hash_multimap.

Return Value

1 if the hash_multimap contains an element whose sort key matches the parameter key; 0 if the hash_multimap doesn't contain an element with a matching key.

Remarks

The member function returns the number of elements in the range

`[lower_bound (key), upper_bound (key))`

which have a key value *key*.

Example

The following example demonstrates the use of the hash_multimap::count member function.

```

// hash_multimap_count.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap<int, int> hm1;
    hash_multimap<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    hm1.insert(Int_Pair(1, 1));
    hm1.insert(Int_Pair(2, 1));
    hm1.insert(Int_Pair(1, 4));
    hm1.insert(Int_Pair(2, 1));

    // Elements do not need to have unique keys in hash_multimap,
    // so duplicates are allowed and counted
    i = hm1.count(1);
    cout << "The number of elements in hm1 with a sort key of 1 is: "
         << i << "." << endl;

    i = hm1.count(2);
    cout << "The number of elements in hm1 with a sort key of 2 is: "
         << i << "." << endl;

    i = hm1.count(3);
    cout << "The number of elements in hm1 with a sort key of 3 is: "
         << i << "." << endl;
}

```

```

The number of elements in hm1 with a sort key of 1 is: 2.
The number of elements in hm1 with a sort key of 2 is: 2.
The number of elements in hm1 with a sort key of 3 is: 0.

```

hash_multimap::crbegin

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns a const iterator addressing the first element in a reversed hash_multimap.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse bidirectional iterator addressing the first element in a reversed [hash_multimap](#) or addressing what had been the last element in the unreversed `hash_multimap`.

Remarks

`crbegin` is used with a reversed hash_multimap just as [hash_multimap::begin](#) is used with a `hash_multimap`.

With the return value of `crbegin`, the `hash_multimap` object cannot be modified.

`crbegin` can be used to iterate through a `hash_multimap` backwards.

Example

```
// hash_multimap_crbegin.cpp
// compile with: /EHsc
#include <hash_multimap>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;

    hash_multimap <int, int> :: const_reverse_iterator hm1_crIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_crIter = hm1.crbegin( );
    cout << "The first element of the reversed hash_multimap hm1 is "
         << hm1_crIter -> first << "." << endl;
}
```

The first element of the reversed hash_multimap hm1 is 3.

hash_multimap::crend

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns a const iterator that addresses the location succeeding the last element in a reversed hash_multimap.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse bidirectional iterator that addresses the location succeeding the last element in a reversed [hash_multimap](#) (the location that had preceded the first element in the unreversed `hash_multimap`).

Remarks

`crend` is used with a reversed hash_multimap just as [hash_multimap::end](#) is used with a hash_multimap.

With the return value of `crend`, the `hash_multimap` object cannot be modified.

`crend` can be used to test to whether a reverse iterator has reached the end of its hash_multimap.

The value returned by `crend` should not be dereferenced.

Example

```
// hash_multimap_crend.cpp
// compile with: /EHsc
#include <hash_multimap>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;

    hash_multimap <int, int> :: const_reverse_iterator hm1_crIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_crIter = hm1.crend( );
    hm1_crIter--;
    cout << "The last element of the reversed hash_multimap hm1 is "
         << hm1_crIter -> first << "." << endl;
}
```

The last element of the reversed hash_multimap hm1 is 3.

hash_multimap::difference_type

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A signed integer type that can be used to represent the number of elements of a hash_multimap in a range between elements pointed to by iterators.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::difference_type
difference_type;
```

Remarks

The `difference_type` is the type returned when subtracting or incrementing through iterators of the container. The `difference_type` is typically used to represent the number of elements in the range $[first, last)$ between the iterators `first` and `last`, includes the element pointed to by `first` and the range of elements up to, but not including, the element pointed to by `last`.

Note that although `difference_type` is available for all iterators that satisfy the requirements of an input iterator, which includes the class of bidirectional iterators supported by reversible containers such as set, subtraction between iterators is only supported by random-access iterators provided by a random-access container such as vector.

Example

```

// hash_multimap_difference_type.cpp
// compile with: /EHsc
#include <iostream>
#include <hash_map>
#include <algorithm>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_multimap<int, int> hm1;
    typedef pair<int, int> Int_Pair;

    hm1.insert(Int_Pair(2, 20));
    hm1.insert(Int_Pair(1, 10));
    hm1.insert(Int_Pair(3, 20));

    // The following will insert, because map keys
    // do not need to be unique
    hm1.insert(Int_Pair(2, 30));

    hash_multimap<int, int>::iterator hm1_Iter, hm1_bIter, hm1_eIter;
    hm1_bIter = hm1.begin();
    hm1_eIter = hm1.end();

    // Count the number of elements in a hash_multimap
    hash_multimap<int, int>::difference_type df_count = 0;
    hm1_Iter = hm1.begin();
    while (hm1_Iter != hm1_eIter)
    {
        df_count++;
        hm1_Iter++;
    }

    cout << "The number of elements in the hash_multimap hm1 is: "
         << df_count << "." << endl;

    cout << "The keys of the mapped elements are:";
    for (hm1_Iter= hm1.begin() ; hm1_Iter!= hm1.end();
         hm1_Iter++)
        cout << " " << hm1_Iter-> first;
    cout << "." << endl;

    cout << "The values of the mapped elements are:";
    for (hm1_Iter= hm1.begin() ; hm1_Iter!= hm1.end();
         hm1_Iter++)
        cout << " " << hm1_Iter-> second;
    cout << "." << endl;
}

```

The number of elements in the hash_multimap hm1 is: 4.
 The keys of the mapped elements are: 1 2 2 3.
 The values of the mapped elements are: 10 20 30 20.

hash_multimap::emplace

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Inserts an element constructed in place into a hash_multimap.

```
template <class ValTy>
iterator emplace(ValTy&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value used to move construct an element to be inserted into the hash_multimap .

Return Value

The `emplace` member function returns an iterator that points to the position where the new element was inserted.

Remarks

The [hash_multimap::value_type](#) of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

Example

```
// hash_multimap_emplace.cpp
// compile with: /EHsc
#include<hash_multimap>
#include<iostream>
#include <string>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_multimap<int, string> hm1;
    typedef pair<int, string> is1(1, "a");

    hm1.emplace(move(is1));
    cout << "After the emplace, hm1 contains:" << endl
    << " " << hm1.begin()->first
    << " => " << hm1.begin()->second
    << endl;
}
```

```
After the emplace insertion, hm1 contains:
1 => a
```

hash_multimap::emplace_hint

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Inserts an element constructed in place into a `hash_multimap`, with a placement hint.

```
template <class ValTy>
iterator emplace_hint(
    const_iterator _Where,
    ValTy&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value used to move construct an element to be inserted into the hash_multimap unless the <code>hash_multimap</code> already contains that element (or, more generally, an element whose key is equivalently ordered).
<i>_Where</i>	A hint regarding the place to start searching for the correct point of insertion.

Return Value

The [hash_multimap::emplace](#) member function returns an iterator that points to the position where the new element was inserted into the `hash_multimap`.

Remarks

The [hash_multimap::value_type](#) of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

Insertion can occur in amortized constant time, instead of logarithmic time, if the insertion point immediately follows *_Where*.

Example

```
// hash_multimap_emplace_hint.cpp
// compile with: /EHsc
#include<hash_multimap>
#include<iostream>
#include <string>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_multimap<int, string> hm1;
    typedef pair<int, string> is1(1, "a");

    hm1.emplace(hm1.begin(), move(is1));
    cout << "After the emplace insertion, hm1 contains:" << endl
         << " " << hm1.begin()->first
         << " => " << hm1.begin()->second
         << endl;
}
```

```
After the emplace insertion, hm1 contains:
1 => a
```

hash_multimap::empty

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Tests if a `hash_multimap` is empty.

```
bool empty() const;
```

Return Value

true if the hash_multimap is empty; **false** if the hash_multimap is nonempty.

Remarks

Example

```
// hash_multimap_empty.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1, hm2;

    typedef pair <int, int> Int_Pair;
    hm1.insert ( Int_Pair ( 1, 1 ) );

    if ( hm1.empty( ) )
        cout << "The hash_multimap hm1 is empty." << endl;
    else
        cout << "The hash_multimap hm1 is not empty." << endl;

    if ( hm2.empty( ) )
        cout << "The hash_multimap hm2 is empty." << endl;
    else
        cout << "The hash_multimap hm2 is not empty." << endl;
}
```

```
The hash_multimap hm1 is not empty.
The hash_multimap hm2 is empty.
```

hash_multimap::end

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns an iterator that addresses the location succeeding the last element in a hash_multimap.

```
const_iterator end() const;

iterator end();
```

Return Value

A bidirectional iterator that addresses the location succeeding the last element in a hash_multimap. If the hash_multimap is empty, then hash_multimap::end == hash_multimap::begin.

Remarks

`end` is used to test whether an iterator has reached the end of its hash_multimap.

The value returned by `end` should not be dereferenced.

Example

```
// hash_multimap_end.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;

    hash_multimap <int, int> :: iterator hm1_Iter;
    hash_multimap <int, int> :: const_iterator hm1_cIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_cIter = hm1.end( );
    hm1_cIter--;
    cout << "The value of last element of hm1 is "
         << hm1_cIter -> second << "." << endl;

    hm1_Iter = hm1.end( );
    hm1_Iter--;
    hm1.erase ( hm1_Iter );

    // The following 2 lines would err because the iterator is const
    // hm1_cIter = hm1.end( );
    // hm1_cIter--;
    // hm1.erase ( hm1_cIter );

    hm1_cIter = hm1.end( );
    hm1_cIter--;
    cout << "The value of last element of hm1 is now "
         << hm1_cIter -> second << "." << endl;
}
```

```
The value of last element of hm1 is 30.
The value of last element of hm1 is now 20.
```

hash_multimap::equal_range

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns a pair of iterators respectively to the first element in a hash_multimap with a key that is greater than a specified key and to the first element in the hash_multimap with a key that is equal to or greater than the key.

```
pair <const_iterator, const_iterator> equal_range (const Key& key) const;

pair <iterator, iterator> equal_range (const Key& key);
```

Parameters

key

The argument key to be compared with the sort key of an element from the hash_multimap being searched.

Return Value

A pair of iterators such that the first is the [lower_bound](#) of the key and the second is the [upper_bound](#) of the key.

To access the first iterator of a pair `pr` returned by the member function, use `pr.first` and to dereference the lower bound iterator, use `*(pr.first)`. To access the second iterator of a pair `pr` returned by the member function, use `pr.second` and to dereference the upper bound iterator, use `*(pr.second)`.

Remarks

Example

```
// hash_multimap_equal_range.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    typedef hash_multimap <int, int> IntMMap;
    IntMMap hm1;
    hash_multimap <int, int> :: const_iterator hm1_RcIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    pair <IntMMap::const_iterator, IntMMap::const_iterator> p1, p2;
    p1 = hm1.equal_range( 2 );

    cout << "The lower bound of the element with a key of 2\n"
         << "in the hash_multimap hm1 is: "
         << p1.first -> second << "." << endl;

    cout << "The upper bound of the element with a key of 2\n"
         << "in the hash_multimap hm1 is: "
         << p1.second -> second << "." << endl;

    // Compare the upper_bound called directly
    hm1_RcIter = hm1.upper_bound( 2 );

    cout << "A direct call of upper_bound( 2 ) gives "
         << hm1_RcIter -> second << "," << endl
         << "matching the 2nd element of the pair "
         << "returned by equal_range( 2 )." << endl;

    p2 = hm1.equal_range( 4 );

    // If no match is found for the key,
    // both elements of the pair return end( )
    if ( ( p2.first == hm1.end( ) ) && ( p2.second == hm1.end( ) ) )
        cout << "The hash_multimap hm1 doesn't have an element "
             << "with a key less than 4." << endl;
    else
        cout << "The element of hash_multimap hm1 with a key >= 40 is: "
             << p1.first -> first << "." << endl;
}
```

The lower bound of the element with a key of 2
in the hash_multimap hm1 is: 20.
The upper bound of the element with a key of 2
in the hash_multimap hm1 is: 30.
A direct call of upper_bound(2) gives 30,
matching the 2nd element of the pair returned by equal_range(2).
The hash_multimap hm1 doesn't have an element with a key less than 4.

hash_multimap::erase

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Removes an element or a range of elements in a hash_multimap from specified positions or removes elements that match a specified key.

```
iterator erase(iterator _Where);  
  
iterator erase(iterator first, iterator last);  
  
size_type erase(const key_type& key);
```

Parameters

_Where

Position of the element to be removed from the hash_multimap.

first

Position of the first element removed from the hash_multimap.

last

Position just beyond the last element removed from the hash_multimap.

key

The key of the elements to be removed from the hash_multimap.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or a pointer to the end of the hash_multimap if no such element exists.

For the third member function, returns the number of elements that have been removed from the hash_multimap.

Remarks

The member functions never throw an exception.

Example

The following example demonstrates the use of the hash_multimap::erase member function.

```
// hash_multimap_erase.cpp  
// compile with: /EHsc  
#include <hash_map>  
#include <iostream>  
  
int main()  
{
```

```

using namespace std;
using namespace stdext;
hash_multimap<int, int> hm1, hm2, hm3;
hash_multimap<int, int> :: iterator pIter, Iter1, Iter2;
int i;
hash_multimap<int, int>::size_type n;
typedef pair<int, int> Int_Pair;

for (i = 1; i < 5; i++)
{
    hm1.insert(Int_Pair (i, i) );
    hm2.insert(Int_Pair (i, i*i) );
    hm3.insert(Int_Pair (i, i-1) );
}

// The 1st member function removes an element at a given position
Iter1 = ++hm1.begin();
hm1.erase(Iter1);

cout << "After the 2nd element is deleted, "
    << "the hash_multimap hm1 is:";
for (pIter = hm1.begin(); pIter != hm1.end(); pIter++)
    cout << " " << pIter -> second;
cout << "." << endl;

// The 2nd member function removes elements
// in the range [ first, last)
Iter1 = ++hm2.begin();
Iter2 = --hm2.end();
hm2.erase(Iter1, Iter2);

cout << "After the middle two elements are deleted, "
    << "the hash_multimap hm2 is:";
for (pIter = hm2.begin(); pIter != hm2.end(); pIter++)
    cout << " " << pIter -> second;
cout << "." << endl;

// The 3rd member function removes elements with a given key
hm3.insert(Int_Pair (2, 5));
n = hm3.erase(2);

cout << "After the element with a key of 2 is deleted,\n"
    << "the hash_multimap hm3 is:";
for (pIter = hm3.begin(); pIter != hm3.end(); pIter++)
    cout << " " << pIter -> second;
cout << "." << endl;

// The 3rd member function returns the number of elements removed
cout << "The number of elements removed from hm3 is: "
    << n << "." << endl;

// The dereferenced iterator can also be used to specify a key
Iter1 = ++hm3.begin();
hm3.erase(Iter1);

cout << "After another element with a key equal to that of the"
    << endl;
cout << "2nd element is deleted, "
    << "the hash_multimap hm3 is:";
for (pIter = hm3.begin(); pIter != hm3.end(); pIter++)
    cout << " " << pIter -> second;
cout << "." << endl;
}

```

After the 2nd element is deleted, the hash_multimap hm1 is: 1 3 4.
After the middle two elements are deleted, the hash_multimap hm2 is: 1 16.
After the element with a key of 2 is deleted,
the hash_multimap hm3 is: 0 2 3.
The number of elements removed from hm3 is: 2.
After another element with a key equal to that of the
2nd element is deleted, the hash_multimap hm3 is: 0 3.

hash_multimap::find

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns an iterator addressing the first location of an element in a hash_multimap that has a key equivalent to a specified key.

```
iterator find(const Key& key);  
  
const_iterator find(const Key& key) const;
```

Parameters

key

The key to be matched by the sort key of an element from the hash_multimap being searched.

Return Value

An iterator that addresses the first location of an element with a specified key, or the location succeeding the last element in the hash_multimap if no match is found for the key.

Remarks

The member function returns an iterator that addresses an element in the hash_multimap whose sort key is `equivalent` to the argument key under a binary predicate that induces an ordering based on a less than comparability relation.

If the return value of `find` is assigned to a `const_iterator`, the hash_multimap object cannot be modified. If the return value of `find` is assigned to an `iterator`, the hash_multimap object can be modified.

Example

```

// hash_multimap_find.cpp
// compile with: /EHsc
#include <iostream>
#include <hash_map>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_multimap<int, int> hm1;
    hash_multimap<int, int> :: const_iterator hm1_AcIter, hm1_RcIter;
    typedef pair<int, int> Int_Pair;

    hm1.insert(Int_Pair(1, 10));
    hm1.insert(Int_Pair(2, 20));
    hm1.insert(Int_Pair(3, 20));
    hm1.insert(Int_Pair(3, 30));

    hm1_RcIter = hm1.find(2);
    cout << "The element of hash_multimap hm1 with a key of 2 is: "
         << hm1_RcIter -> second << "." << endl;

    hm1_RcIter = hm1.find(3);
    cout << "The first element of hash_multimap hm1 with a key of 3 is: "
         << hm1_RcIter -> second << "." << endl;

    // If no match is found for the key, end() is returned
    hm1_RcIter = hm1.find(4);

    if (hm1_RcIter == hm1.end())
        cout << "The hash_multimap hm1 doesn't have an element "
             << "with a key of 4." << endl;
    else
        cout << "The element of hash_multimap hm1 with a key of 4 is: "
             << hm1_RcIter -> second << "." << endl;

    // The element at a specific location in the hash_multimap can be
    // found using a dereferenced iterator addressing the location
    hm1_AcIter = hm1.end();
    hm1_AcIter--;
    hm1_RcIter = hm1.find(hm1_AcIter -> first);
    cout << "The first element of hm1 with a key matching"
         << endl << "that of the last element is: "
         << hm1_RcIter -> second << "." << endl;

    // Note that the first element with a key equal to
    // the key of the last element is not the last element
    if (hm1_RcIter == --hm1.end())
        cout << "This is the last element of hash_multimap hm1."
             << endl;
    else
        cout << "This is not the last element of hash_multimap hm1."
             << endl;
}

```

```

The element of hash_multimap hm1 with a key of 2 is: 20.
The first element of hash_multimap hm1 with a key of 3 is: 20.
The hash_multimap hm1 doesn't have an element with a key of 4.
The first element of hm1 with a key matching
that of the last element is: 20.
This is not the last element of hash_multimap hm1.

```

hash_multimap::get_allocator

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns a copy of the allocator object used to construct the hash_multimap.

```
Allocator get_allocator() const;
```

Return Value

The allocator used by the hash_multimap.

Remarks

Allocators for the hash_multimap class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```

// hash_multimap_get_allocator.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int>::allocator_type hm1_Alloc;
    hash_multimap <int, int>::allocator_type hm2_Alloc;
    hash_multimap <int, double>::allocator_type hm3_Alloc;
    hash_multimap <int, int>::allocator_type hm4_Alloc;

    // The following lines declare objects
    // that use the default allocator.
    hash_multimap <int, int> hm1;
    hash_multimap <int, int> hm2;
    hash_multimap <int, double> hm3;

    hm1_Alloc = hm1.get_allocator( );
    hm2_Alloc = hm2.get_allocator( );
    hm3_Alloc = hm3.get_allocator( );

    cout << "The number of integers that can be allocated"
         << endl << " before free memory is exhausted: "
         << hm2.max_size( ) << "." << endl;

    cout << "The number of doubles that can be allocated"
         << endl << " before free memory is exhausted: "
         << hm3.max_size( ) << "." << endl;

    // The following line creates a hash_multimap hm4
    // with the allocator of hash_multimap hm1.
    hash_multimap <int, int> hm4( less<int>( ), hm1_Alloc );

    hm4_Alloc = hm4.get_allocator( );

    // Two allocators are interchangeable if
    // storage allocated from each can be
    // deallocated by the other
    if( hm1_Alloc == hm4_Alloc )
    {
        cout << "The allocators are interchangeable."
             << endl;
    }
    else
    {
        cout << "The allocators are not interchangeable."
             << endl;
    }
}

```

hash_multimap::hash_multimap

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Constructs a hash_multimap that is empty or is a copy of all or part of some other hash_multimap.

```

hash_multimap();

explicit hash_multimap(
    const Compare& Comp);

hash_multimap(
    const Compare& Comp,
    const Allocator& Al);

hash_multimap(
    const hash_multimap& Right);

hash_multimap(
    hash_multimap&& Right);

hash_multimap(
    initializer_list<Type> IList);

hash_multimap(
    initializer_list<Type> IList,
    const Compare& Comp);

hash_multimap(
    initializer_list<Type> IList,
    const Compare& Comp,
    const Allocator& Al);

template <class InputIterator>
hash_multimap(
    InputIterator First,
    InputIterator Last);

template <class InputIterator>
hash_multimap(
    InputIterator First,
    InputIterator Last,
    const Compare& Comp);

template <class InputIterator>
hash_multimap(
    InputIterator First,
    InputIterator Last,
    const Compare& Comp,
    const Allocator& Al);

```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The storage allocator class to be used for this hash_multimap object, which defaults to <code>Allocator</code> .
<i>Comp</i>	The comparison function of type <code>const Traits</code> used to order the elements in the map, which defaults to <code>Traits</code> .
<i>Right</i>	The map of which the constructed set is to be a copy.
<i>First</i>	The position of the first element in the range of elements to be copied.
<i>Last</i>	The position of the first element beyond the range of elements to be copied.

PARAMETER	DESCRIPTION
<i>lList</i>	The initializer_list to copy from.

Remarks

All constructors store a type of allocator object that manages memory storage for the hash_multimap and that can later be returned by calling [get_allocator](#). The allocator parameter is often omitted in the class declarations and preprocessing macros are used to substitute alternative allocators.

All constructors initialize their hash_multimap.

All constructors store a function object of type `Traits` that is used to establish an order among the keys of the hash_multimap and can later be returned by calling [key_comp](#).

The first three constructors specify an empty initial hash_multimap; the second specifies the type of comparison function (*Comp*) to be used in establishing the order of the elements and the third explicitly specifies the allocator type (`_Al`) to be used. The keyword `explicit` suppresses certain kinds of automatic type conversion.

The fourth constructor specifies a copy of the hash_multimap `Right`.

The next three constructors copy the range `First, Last` of a map with increasing explicitness in specifying the type of comparison function of class `Traits` and allocator.

The eighth constructor moves the hash_multimap `Right`.

The final three constructors use an initializer_list.

hash_multimap::insert

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Inserts an element or a range of elements into a hash_multimap.

```

iterator insert(
    const value_type& Val);

iterator insert(
    const_iterator Where,
    const value_type& Val); void insert(
    initializer_list<value_type> lList);

template <class InputIterator>
void insert(
    InputIterator First,
    InputIterator Last);

template <class ValTy>
iterator insert(
    ValTy&& Val);

template <class ValTy>
iterator insert(
    const_iterator Where,
    ValTy&& Val);

```

Parameters

PARAMETER	DESCRIPTION
<i>Val</i>	The value of an element to be inserted into the hash_multimap unless it already contains that element, or more generally, unless it already contains an element whose key is equivalently ordered.
<i>Where</i>	A hint about where to start searching for the correct point of insertion.
<i>First</i>	The position of the first element to be copied from a map.
<i>Last</i>	The position just beyond the last element to be copied from a map.

Return Value

The first two `insert` member functions return an iterator that points to the position where the new element was inserted.

The third member function uses an `initializer_list` for the elements to be inserted.

The fourth member function inserts the sequence of element values into a map that corresponds to each element addressed by an iterator in the range `[First, Last)` of a specified set.

The last two `insert` member functions behave the same as the first two, except that they move-construct the inserted value.

Remarks

The `value_type` of an element is a pair, so that the value of an element will be an ordered pair in which the first component is equal to the key value and the second component is equal to the data value of the element.

Insertion can occur in amortized constant time for the hint version of `insert`, instead of logarithmic time, if the insertion point immediately follows *Where*.

hash_multimap::iterator

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that provides a bidirectional iterator that can read or modify any element in a hash_multimap.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::iterator iterator;
```

Remarks

The `iterator` defined by hash_multimap points to objects of `value_type`, which are of type `pair<const Key, Type>`, whose first member is the key to the element and whose second member is the mapped datum held by the element.

To dereference an **iterator** `Iter` pointing to an element in a hash_multimap, use the `->` operator.

To access the value of the key for the element, use `Iter -> first`, which is equivalent to `(*Iter).first`. To access the value of the mapped datum for the element, use `Iter -> second`, which is equivalent to `(*Iter).first`.

A type `iterator` can be used to modify the value of an element.

Example

See the example for [begin](#) for an example of how to declare and use `iterator`.

hash_multimap::key_comp

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Retrieves a copy of the comparison object used to order keys in a hash_multimap.

```
key_compare key_comp() const;
```

Return Value

Returns the function object that a hash_multimap uses to order its elements.

Remarks

The stored object defines the member function

bool operator(const Key& `left` , const Key& `right`);

which returns **true** if `left` precedes and is not equal to `right` in the sort order.

Example

```

// hash_multimap_key_comp.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;

    hash_multimap <int, int, hash_compare<int, less<int>>> hm1;
    hash_multimap <int, int, hash_compare<int, less<int>>
        >::key_compare kc1 = hm1.key_comp( ) ;
    bool result1 = kc1( 2, 3 ) ;
    if( result1 == true )
    {
        cout << "kc1( 2,3 ) returns value of true,\n"
            << "where kc1 is the function object of hm1.\n"
            << endl;
    }
    else
    {
        cout << "kc1( 2,3 ) returns value of false,\n"
            << "where kc1 is the function object of hm1.\n"
            << endl;
    }

    hash_multimap <int, int, hash_compare<int, greater<int>>> hm2;
    hash_multimap <int, int, hash_compare<int, greater<int>>
        >::key_compare kc2 = hm2.key_comp( ) ;
    bool result2 = kc2( 2, 3 ) ;
    if( result2 == true )
    {
        cout << "kc2( 2,3 ) returns value of true,\n"
            << "where kc2 is the function object of hm2."
            << endl;
    }
    else
    {
        cout << "kc2( 2,3 ) returns value of false,\n"
            << "where kc2 is the function object of hm2."
            << endl;
    }
}

```

hash_multimap::key_compare

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the hash_multimap.

```
typedef Traits key_compare;
```

Remarks

`key_compare` is a synonym for the template parameter *Traits*.

For more information on *Traits* see the [hash_multimap Class](#) topic.

Example

See the example for [key_comp](#) for an example of how to declare and use `key_compare`.

hash_multimap::key_type

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that describes the sort key object that constitutes each element of the hash_multimap.

```
typedef Key key_type;
```

Remarks

`key_type` is a synonym for the template parameter *Key*.

For more information on *Key*, see the Remarks section of the [hash_multimap Class](#) topic.

Example

See the example for [value_type](#) for an example of how to declare and use `key_compare`.

hash_multimap::lower_bound

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns an iterator to the first element in a hash_multimap with a key that is equal to or greater than a specified key.

```
iterator lower_bound(const Key& key);  
  
const_iterator lower_bound(const Key& key) const;
```

Parameters

key

The argument key to be compared with the sort key of an element from the hash_multimap being searched.

Return Value

An [iterator](#) or [const_iterator](#) that addresses the location of an element in a hash_multimap with a key that is equal to or greater than the argument key, or that addresses the location succeeding the last element in the hash_multimap if no match is found for the key.

If the return value of `lower_bound` is assigned to a `const_iterator`, the hash_multimap object cannot be modified. If the return value of `lower_bound` is assigned to an `iterator`, the hash_multimap object can be modified.

Remarks

Example

```

// hash_multimap_lower_bound.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;
    hash_multimap <int, int> :: const_iterator hm1_AcIter,
        hm1_RcIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_RcIter = hm1.lower_bound( 2 );
    cout << "The element of hash_multimap hm1 with a key of 2 is: "
        << hm1_RcIter -> second << "." << endl;

    hm1_RcIter = hm1.lower_bound( 3 );
    cout << "The first element of hash_multimap hm1 with a key of 3 is: "
        << hm1_RcIter -> second << "." << endl;

    // If no match is found for the key, end( ) is returned
    hm1_RcIter = hm1.lower_bound( 4 );

    if ( hm1_RcIter == hm1.end( ) )
        cout << "The hash_multimap hm1 doesn't have an element "
            << "with a key of 4." << endl;
    else
        cout << "The element of hash_multimap hm1 with a key of 4 is: "
            << hm1_RcIter -> second << "." << endl;

    // The element at a specific location in the hash_multimap can be
    // found using a dereferenced iterator addressing the location
    hm1_AcIter = hm1.end( );
    hm1_AcIter--;
    hm1_RcIter = hm1.lower_bound( hm1_AcIter -> first );
    cout << "The first element of hm1 with a key matching"
        << endl << "that of the last element is: "
        << hm1_RcIter -> second << "." << endl;

    // Note that the first element with a key equal to
    // the key of the last element is not the last element
    if ( hm1_RcIter == --hm1.end( ) )
        cout << "This is the last element of hash_multimap hm1."
            << endl;
    else
        cout << "This is not the last element of hash_multimap hm1."
            << endl;
}

```

The element of hash_multimap hm1 with a key of 2 is: 20.
 The first element of hash_multimap hm1 with a key of 3 is: 20.
 The hash_multimap hm1 doesn't have an element with a key of 4.
 The first element of hm1 with a key matching
 that of the last element is: 20.
 This is not the last element of hash_multimap hm1.

hash_multimap::mapped_type

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that represents the data type stored in a hash_multimap.

```
typedef Type mapped_type;
```

Remarks

`mapped_type` is a synonym for the template parameter *Type*.

For more information on *Type* see the [hash_multimap Class](#) topic.

Example

See the example for [value_type](#) for an example of how to declare and use `key_type`.

hash_multimap::max_size

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns the maximum length of the hash_multimap.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the hash_multimap.

Remarks

Example

```
// hash_multimap_max_size.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;
    hash_multimap <int, int> :: size_type i;

    i = hm1.max_size( );
    cout << "The maximum possible length "
         << "of the hash_multimap is " << i << "." << endl;
}
```

hash_multimap::operator=

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Replaces the elements of the `hash_multimap` with a copy of another `hash_multimap`.

```
hash_multimap& operator=(const hash_multimap& right);

hash_multimap& operator=(hash_multimap&& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The hash_multimap being copied into the <code>hash_multimap</code> .

Remarks

After erasing any existing elements in a `hash_multimap`, `operator=` either copies or moves the contents of *right* into the `hash_multimap`.

Example

```
// hash_multimap_operator_as.cpp
// compile with: /EHsc
#include <hash_multimap>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap<int, int> v1, v2, v3;
    hash_multimap<int, int>::iterator iter;

    v1.insert(pair<int, int>(1, 10));

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;
}
```

hash_multimap::pointer

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that provides a pointer to an element in a hash_multimap.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::pointer pointer;
```

Remarks

A type `pointer` can be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a hash_multimap object.

hash_multimap::rbegin

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns an iterator addressing the first element in a reversed hash_multimap.

```
const_reverse_iterator rbegin() const;  
  
reverse_iterator rbegin();
```

Return Value

A reverse bidirectional iterator addressing the first element in a reversed hash_multimap or addressing what had been the last element in the unreversed hash_multimap.

Remarks

`rbegin` is used with a reversed hash_multimap just as [begin](#) is used with a hash_multimap.

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, then the hash_multimap object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, then the hash_multimap object can be modified.

`rbegin` can be used to iterate through a hash_multimap backwards.

Example

```

// hash_multimap_rbegin.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;

    hash_multimap <int, int> :: iterator hm1_Iter;
    hash_multimap <int, int> :: reverse_iterator hm1_rIter;
    hash_multimap <int, int> :: const_reverse_iterator hm1_crIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_rIter = hm1.rbegin( );
    cout << "The first element of the reversed hash_multimap hm1 is "
         << hm1_rIter -> first << "." << endl;

    // begin can be used to start an iteration
    // through a hash_multimap in a forward order
    cout << "The hash_multimap is: ";
    for ( hm1_Iter = hm1.begin( ); hm1_Iter != hm1.end( ); hm1_Iter++)
        cout << hm1_Iter -> first << " ";
    cout << "." << endl;

    // rbegin can be used to start an iteration
    // through a hash_multimap in a reverse order
    cout << "The reversed hash_multimap is: ";
    for ( hm1_rIter = hm1.rbegin( ); hm1_rIter != hm1.rend( ); hm1_rIter++)
        cout << hm1_rIter -> first << " ";
    cout << "." << endl;

    // A hash_multimap element can be erased by dereferencing its key
    hm1_rIter = hm1.rbegin( );
    hm1.erase ( hm1_rIter -> first );

    hm1_rIter = hm1.rbegin( );
    cout << "After the erasure, the first element\n"
         << "in the reversed hash_multimap is "
         << hm1_rIter -> first << "." << endl;
}

```

```

The first element of the reversed hash_multimap hm1 is 3.
The hash_multimap is: 1 2 3 .
The reversed hash_multimap is: 3 2 1 .
After the erasure, the first element
in the reversed hash_multimap is 2.

```

hash_multimap::reference

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that provides a reference to an element stored in a hash_multimap.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::reference reference;
```

Remarks

Example

```
// hash_multimap_reference.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );

    // Declare and initialize a const_reference &Ref1
    // to the key of the first element
    const int &Ref1 = ( hm1.begin( ) -> first );

    // The following line would cause an error as the
    // non-const_reference cannot be used to access the key
    // int &Ref1 = ( hm1.begin( ) -> first );

    cout << "The key of first element in the hash_multimap is "
         << Ref1 << "." << endl;

    // Declare and initialize a reference &Ref2
    // to the data value of the first element
    int &Ref2 = ( hm1.begin( ) -> second );

    cout << "The data value of first element in the hash_multimap is "
         << Ref2 << "." << endl;

    //The non-const_reference can be used to modify the
    //data value of the first element
    Ref2 = Ref2 + 5;
    cout << "The modified data value of first element is "
         << Ref2 << "." << endl;
}
```

```
The key of first element in the hash_multimap is 1.
The data value of first element in the hash_multimap is 10.
The modified data value of first element is 15.
```

hash_multimap::rend

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns an iterator that addresses the location succeeding the last element in a reversed hash_multimap.

```
const_reverse_iterator rend() const;  
  
reverse_iterator rend();
```

Return Value

A reverse bidirectional iterator that addresses the location succeeding the last element in a reversed hash_multimap (the location that had preceded the first element in the unreversed hash_multimap).

Remarks

`rend` is used with a reversed hash_multimap just as `end` is used with a hash_multimap.

If the return value of `rend` is assigned to a `const_reverse_iterator`, then the hash_multimap object cannot be modified. If the return value of `rend` is assigned to a `reverse_iterator`, then the hash_multimap object can be modified.

`rend` can be used to test to whether a reverse iterator has reached the end of its hash_multimap.

The value returned by `rend` should not be dereferenced.

Example

```

// hash_multimap_rend.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;

    hash_multimap <int, int> :: iterator hm1_Iter;
    hash_multimap <int, int> :: reverse_iterator hm1_rIter;
    hash_multimap <int, int> :: const_reverse_iterator hm1_crIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );

    hm1_rIter = hm1.rend( );
    hm1_rIter--;
    cout << "The last element of the reversed hash_multimap hm1 is "
         << hm1_rIter -> first << "." << endl;

    // begin can be used to start an iteration
    // through a hash_multimap in a forward order
    cout << "The hash_multimap is: ";
    for ( hm1_Iter = hm1.begin( ) ; hm1_Iter != hm1.end( ); hm1_Iter++)
        cout << hm1_Iter -> first << " ";
    cout << "." << endl;

    // rbegin can be used to start an iteration
    // through a hash_multimap in a reverse order
    cout << "The reversed hash_multimap is: ";
    for ( hm1_rIter = hm1.rbegin( ) ; hm1_rIter != hm1.rend( ); hm1_rIter++)
        cout << hm1_rIter -> first << " ";
    cout << "." << endl;

    // A hash_multimap element can be erased by dereferencing its key
    hm1_rIter = --hm1.rend( );
    hm1.erase ( hm1_rIter -> first );

    hm1_rIter = hm1.rend( );
    hm1_rIter--;
    cout << "After the erasure, the last element "
         << "in the reversed hash_multimap is "
         << hm1_rIter -> first << "." << endl;
}

```

```

The last element of the reversed hash_multimap hm1 is 1.
The hash_multimap is: 1 2 3 .
The reversed hash_multimap is: 3 2 1 .
After the erasure, the last element in the reversed hash_multimap is 2.

```

hash_multimap::reverse_iterator

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that provides a bidirectional iterator that can read or modify an element in a reversed hash_multimap.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::reverse_iterator
reverse_iterator;
```

Remarks

A type `reverse_iterator` is used to iterate through the `hash_multimap` in reverse.

The `reverse_iterator` defined by `hash_multimap` points to objects of `value_type`, which are of type `pair<const Key, Type>`. The value of the key is available through the first member `pair` and the value of the mapped element is available through the second member of the `pair`.

Example

See the example for [rbegin](#) for an example of how to declare and use `reverse_iterator`.

hash_multimap::size

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns the number of elements in the `hash_multimap`.

```
size_type size() const;
```

Return Value

The current length of the `hash_multimap`.

Remarks

Example

The following example demonstrates the use of the `hash_multimap::size` member function.

```
// hash_multimap_size.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap<int, int> hm1, hm2;
    hash_multimap<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    hm1.insert(Int_Pair(1, 1));
    i = hm1.size();
    cout << "The hash_multimap length is " << i << "." << endl;

    hm1.insert(Int_Pair(2, 4));
    i = hm1.size();
    cout << "The hash_multimap length is now " << i << "." << endl;
}
```

```
The hash_multimap length is 1.  
The hash_multimap length is now 2.
```

hash_multimap::size_type

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

An unsigned integer type that counts the number of elements in a hash_multimap.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::size_type size_type;
```

Remarks

Example

See the example for [size](#) for an example of how to declare and use `size_type`

hash_multimap::swap

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Exchanges the elements of two hash_multimaps.

```
void swap(hash_multimap& right);
```

Parameters

right

The hash_multimap providing the elements to be swapped or the hash_multimap whose elements are to be exchanged with those of the hash_multimap.

Remarks

The member function invalidates no references, pointers, or iterators that designate elements in the two hash_multimaps whose elements are being exchanged.

Example

```

// hash_multimap_swap.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1, hm2, hm3;
    hash_multimap <int, int>::iterator hm1_Iter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );
    hm2.insert ( Int_Pair ( 10, 100 ) );
    hm2.insert ( Int_Pair ( 20, 200 ) );
    hm3.insert ( Int_Pair ( 30, 300 ) );

    cout << "The original hash_multimap hm1 is:";
    for ( hm1_Iter = hm1.begin( ); hm1_Iter != hm1.end( ); hm1_Iter++ )
        cout << " " << hm1_Iter -> second;
    cout << "." << endl;

    // This is the member function version of swap
    hm1.swap( hm2 );

    cout << "After swapping with hm2, hash_multimap hm1 is:";
    for ( hm1_Iter = hm1.begin( ); hm1_Iter != hm1.end( ); hm1_Iter++ )
        cout << " " << hm1_Iter -> second;
    cout << "." << endl;

    // This is the specialized template version of swap
    swap( hm1, hm3 );

    cout << "After swapping with hm3, hash_multimap hm1 is:";
    for ( hm1_Iter = hm1.begin( ); hm1_Iter != hm1.end( ); hm1_Iter++ )
        cout << " " << hm1_Iter -> second;
    cout << "." << endl;
}

```

The original hash_multimap hm1 is: 10 20 30.
 After swapping with hm2, hash_multimap hm1 is: 100 200.
 After swapping with hm3, hash_multimap hm1 is: 300.

hash_multimap::upper_bound

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

Returns an iterator to the first element in a hash_multimap with a key that is greater than a specified key.

```

iterator upper_bound(const Key& key);

const_iterator upper_bound(const Key& key) const;

```

Parameters

key

The argument key to be compared with the sort key of an element from the hash_multimap being searched.

Return Value

An [iterator](#) or [const_iterator](#) that addresses the location of an element in a hash_multimap with a key that is greater than the argument key, or that addresses the location succeeding the last element in the hash_multimap if no match is found for the key.

If the return value of `upper_bound` is assigned to a `const_iterator`, the hash_multimap object cannot be modified. If the return value of `upper_bound` is assigned to a `iterator`, the hash_multimap object can be modified.

Remarks

Example

```
// hash_multimap_upper_bound.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multimap <int, int> hm1;
    hash_multimap <int, int> :: const_iterator hm1_AcIter, hm1_RcIter;
    typedef pair <int, int> Int_Pair;

    hm1.insert ( Int_Pair ( 1, 10 ) );
    hm1.insert ( Int_Pair ( 2, 20 ) );
    hm1.insert ( Int_Pair ( 3, 30 ) );
    hm1.insert ( Int_Pair ( 3, 40 ) );

    hm1_RcIter = hm1.upper_bound( 1 );
    cout << "The 1st element of hash_multimap hm1 with "
        << "a key greater than 1 is: "
        << hm1_RcIter -> second << "." << endl;

    hm1_RcIter = hm1.upper_bound( 2 );
    cout << "The first element of hash_multimap hm1\n"
        << "with a key greater than 2 is: "
        << hm1_RcIter -> second << "." << endl;

    // If no match is found for the key, end( ) is returned
    hm1_RcIter = hm1.lower_bound( 4 );

    if ( hm1_RcIter == hm1.end( ) )
        cout << "The hash_multimap hm1 doesn't have an element "
            << "with a key of 4." << endl;
    else
        cout << "The element of hash_multimap hm1 with a key of 4 is: "
            << hm1_RcIter -> second << "." << endl;

    // The element at a specific location in the hash_multimap can be
    // found using a dereferenced iterator addressing the location
    hm1_AcIter = hm1.begin( );
    hm1_RcIter = hm1.upper_bound( hm1_AcIter -> first );
    cout << "The first element of hm1 with a key greater than"
        << endl << "that of the initial element of hm1 is: "
        << hm1_RcIter -> second << "." << endl;
}
```

The 1st element of hash_multimap hm1 with a key greater than 1 is: 20.
The first element of hash_multimap hm1
with a key greater than 2 is: 30.
The hash_multimap hm1 doesn't have an element with a key of 4.
The first element of hm1 with a key greater than
that of the initial element of hm1 is: 20.

hash_multimap::value_comp

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

The member function returns a function object that determines the order of elements in a hash_multimap by comparing their key values.

```
value_compare value_comp() const;
```

Return Value

Returns the comparison function object that a hash_multimap uses to order its elements.

Remarks

For a hash_multimap m , if two elements $e1(k1, d1)$ and $e2(k2, d2)$ are objects of type [value_type](#), where $k1$ and $k2$ are their keys of type [key_type](#) and $d1$ and $d2$ are their data of type [mapped_type](#), then

`m.value_comp()(e1, e2)` is equivalent to `m.key_comp()(k1, k2)`. A stored object defines the member function

```
bool operator( value_type& left, value_type& right);
```

which returns **true** if the key value of `left` precedes and is not equal to the key value of `right` in the sort order.

Example

```

// hash_multimap_value_comp.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;

    hash_multimap <int, int, hash_compare<int, less<int>>> hm1;
    hash_multimap <int, int, hash_compare<int, less<int>>
        >::value_compare vc1 = hm1.value_comp( );
    hash_multimap <int,int>::iterator Iter1, Iter2;

    Iter1= hm1.insert ( hash_multimap <int, int> :: value_type ( 1, 10 ) );
    Iter2= hm1.insert ( hash_multimap <int, int> :: value_type ( 2, 5 ) );

    if( vc1( *Iter1, *Iter2 ) == true )
    {
        cout << "The element ( 1,10 ) precedes the element ( 2,5 )."
            << endl;
    }
    else
    {
        cout << "The element ( 1,10 ) does "
            << "not precede the element ( 2,5 )."
            << endl;
    }

    if( vc1( *Iter2, *Iter1 ) == true )
    {
        cout << "The element ( 2,5 ) precedes the element ( 1,10 )."
            << endl;
    }
    else
    {
        cout << "The element ( 2,5 ) does "
            << "not precede the element ( 1,10 )."
            << endl;
    }
}

```

hash_multimap::value_type

NOTE

This API is obsolete. The alternative is [unordered_multimap Class](#).

A type that represents the type of object stored in a hash_multimap.

```
typedef pair<const Key, Type> value_type;
```

Remarks

`value_type` is declared to be `pair<const key_type, mapped_type>` and not `pair<key_type, mapped_type>` because the keys of an associative container may not be changed using a nonconstant iterator or reference.

Example

```

// hash_multimap_value_type.cpp
// compile with: /EHsc
#include <hash_map>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    typedef pair <const int, int> cInt2Int;
    hash_multimap <int, int> hm1;
    hash_multimap <int, int> :: key_type key1;
    hash_multimap <int, int> :: mapped_type mapped1;
    hash_multimap <int, int> :: value_type value1;
    hash_multimap <int, int> :: iterator pIter;

    // value_type can be used to pass the correct type
    // explicitly to avoid implicit type conversion
    hm1.insert ( hash_multimap <int, int> :: value_type ( 1, 10 ) );

    // Compare another way to insert objects into a hash_multimap
    hm1.insert ( cInt2Int ( 2, 20 ) );

    // Initializing key1 and mapped1
    key1 = ( hm1.begin( ) -> first );
    mapped1 = ( hm1.begin( ) -> second );

    cout << "The key of first element in the hash_multimap is "
         << key1 << "." << endl;

    cout << "The data value of first element in the hash_multimap is "
         << mapped1 << "." << endl;

    // The following line would cause an error because
    // the value_type is not assignable
    // value1 = cInt2Int ( 4, 40 );

    cout << "The keys of the mapped elements are:";
    for ( pIter = hm1.begin( ) ; pIter != hm1.end( ) ; pIter++ )
        cout << " " << pIter -> first;
    cout << "." << endl;

    cout << "The values of the mapped elements are:";
    for ( pIter = hm1.begin( ) ; pIter != hm1.end( ) ; pIter++ )
        cout << " " << pIter -> second;
    cout << "." << endl;
}

```

```

The key of first element in the hash_multimap is 1.
The data value of first element in the hash_multimap is 10.
The keys of the mapped elements are: 1 2.
The values of the mapped elements are: 10 20.

```

See also

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

value_compare Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Provides a function object that can compare the elements of a `hash_map` by comparing the values of their keys to determine their relative order in the `hash_map`.

Syntax

```
class value_compare
: std::public binary_function<value_type, value_type, bool>
{
public:
    bool operator()(
        const value_type& left,
        const value_type& right) const
    {
        return (comp(left.first, right.first));
    }

protected:
    value_compare(const key_compare& c) : comp (c) { }
    key_compare comp;
};
```

Remarks

The comparison criteria provided by `value_compare` between `value_types` of whole elements contained by a `hash_map` is induced from a comparison between the keys of the respective elements by the auxiliary class construction. The member function operator uses the object `comp` of type `key_compare` stored in the function object provided by `value_compare` to compare the sort-key components of two elements.

For `hash_sets` and `hash_multisets`, which are simple containers where the key values are identical to the element values, `value_compare` is equivalent to `key_compare`; for `hash_maps` and `hash_multimaps` they are not, because the value of the type `pair` elements is not identical to the value of the element's key.

Example

See the example for [hash_map::value_comp](#) for an example of how to declare and use `value_compare`.

Requirements

Header: `<hash_map>`

Namespace: `stdext`

<hash_set>

11/9/2018 • 2 minutes to read • [Edit Online](#)

NOTE

This header is obsolete. The alternative is [<unordered_set>](#).

Defines the container template classes `hash_set` and `hash_multiset` and their supporting templates.

Syntax

```
#include <hash_set>
```

Remarks

Operators

HASH_SET VERSION	HASH_MULTISSET VERSION	DESCRIPTION
operator!= (hash_set)	operator!= (hash_multiset)	Tests if the <code>hash_set</code> or <code>hash_multiset</code> object on the left side of the operator is not equal to the <code>hash_set</code> or <code>hash_multiset</code> object on the right side.
operator== (hash_set)	operator== (hash_multiset)	Tests if the <code>hash_set</code> or <code>hash_multiset</code> object on the left side of the operator is equal to the <code>hash_set</code> or <code>hash_multiset</code> object on the right side.

Specialized Template Functions

HASH_SET VERSION	HASH_MULTISSET VERSION	DESCRIPTION
swap (hash_set)	swap (hash_multiset)	Exchanges the elements of two <code>hash_sets</code> or <code>hash_multisets</code> .

Classes

CLASS	DESCRIPTION
hash_compare Class	Describes an object that can be used by any of the hash associative containers — <code>hash_map</code> , <code>hash_multimap</code> , <code>hash_set</code> , or <code>hash_multiset</code> — as a default <code>Traits</code> parameter object to order and hash the elements they contain.
hash_set Class	Used for the storage and fast retrieval of data from a collection in which the values of the elements contained are unique and serve as the key values.

CLASS	DESCRIPTION
hash_multiset Class	Used for the storage and fast retrieval of data from a collection in which the values of the elements contained are unique and serve as the key values.

hash_set Class

11/14/2018 • 50 minutes to read • [Edit Online](#)

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

The container class `hash_set` is an extension of the C++ Standard Library and is used for the storage and fast retrieval of data from a collection in which the values of the elements contained are unique and serve as the key values.

Syntax

```
template <class Key,  
          class Traits=hash_compare<Key, less<Key>>,  
          class Allocator=allocator<Key>>  
class hash_set
```

Parameters

Key

The element data type to be stored in the `hash_set`.

Traits

The type which includes two function objects, one of class `compare` that is a binary predicate able to compare two element values as sort keys to determine their relative order and a hash function that is a unary predicate mapping key values of the elements to unsigned integers of type `size_t`. This argument is optional, and the `hash_compare<Key, less<Key> >` is the default value.

Allocator

The type that represents the stored allocator object that encapsulates details about the `hash_set`'s allocation and deallocation of memory. This argument is optional, and the default value is `allocator<Key>`.

Remarks

The `hash_set` is:

- An associative container, which is a variable size container that supports the efficient retrieval of element values based on an associated key value. Further, it is a simple associative container because its element values are its key values.
- Reversible, because it provides a bidirectional iterator to access its elements.
- Hashed, because its elements are grouped into buckets based on the value of a hash function applied to the key values of the elements.
- Unique in the sense that each of its elements must have a unique key. Because `hash_set` is also a simple associative container, its elements are also unique.
- A template class because the functionality it provides is generic and so independent of the specific type of data contained as elements or keys. The data types to be used for elements and keys are, instead, specified as parameters in the class template along with the comparison function and allocator.

The main advantage of hashing over sorting is greater efficiency; a successful hashing performs insertions, deletions, and finds in constant average time as compared with a time proportional to the logarithm of the number of elements in the container for sorting techniques. The value of an element in a set may not be changed directly. Instead, you must delete old values and insert elements with new values.

The choice of container type should be based in general on the type of searching and inserting required by the application. Hashed associative containers are optimized for the operations of lookup, insertion and removal. The member functions that explicitly support these operations are efficient when used with a well-designed hash function, performing them in a time that is on average constant and not dependent on the number of elements in the container. A well-designed hash function produces a uniform distribution of hashed values and minimizes the number of collisions, where a collision is said to occur when distinct key values are mapped into the same hashed value. In the worst case, with the worst possible hash function, the number of operations is proportional to the number of elements in the sequence (linear time).

The `hash_set` should be the associative container of choice when the conditions associating the values with their keys are satisfied by the application. The elements of a `hash_set` are unique and serve as their own sort keys. A model for this type of structure is an ordered list of, say, words in which the words may occur only once. If multiple occurrences of the words were allowed, then a `hash_multiset` would be the appropriate container structure. If values need to be attached to a list of unique key words, then a `hash_map` would be an appropriate structure to contain this data. If instead the keys are not unique, then a `hash_multimap` would be the container of choice.

The `hash_set` orders the sequence it controls by calling a stored hash `Traits` object of type `value_compare`. This stored object may be accessed by calling the member function `key_comp`. Such a function object must behave the same as an object of class `hash_compare<Key, less<Key> >`. Specifically, for all values `key` of type `Key`, the call `Trait(key)` yields a distribution of values of type `size_t`.

In general, the elements need be merely less than comparable to establish this order: so that, given any two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the non-equivalent elements. On a more technical note, the comparison function is a binary predicate that induces a strict weak ordering in the standard mathematical sense. A binary predicate $f(x, y)$ is a function object that has two argument objects x and y and a return value of true or false. An ordering imposed on a `hash_set` is a strict weak ordering if the binary predicate is irreflexive, antisymmetric, and transitive and if equivalence is transitive, where two objects x and y are defined to be equivalent when both $f(x, y)$ and $f(y, x)$ are false. If the stronger condition of equality between keys replaces that of equivalence, then the ordering becomes total (in the sense that all the elements are ordered with respect to each other) and the keys matched will be indiscernible from each other.

The actual order of elements in the controlled sequence depends on the hash function, the ordering function, and the current size of the hash table stored in the container object. You cannot determine the current size of the hash table, so you cannot in general predict the order of elements in the controlled sequence. Inserting elements invalidates no iterators, and removing elements invalidates only those iterators that had specifically pointed at the removed elements.

The iterator provided by the `hash_set` class is a bidirectional iterator, but the class member functions `insert` and `hash_set` have versions that take as template parameters a weaker input iterator, whose functionality requirements are more minimal than those guaranteed by the class of bidirectional iterators. The different iterator concepts form a family related by refinements in their functionality. Each iterator concept has its own set of requirements, and the algorithms that work with them must limit their assumptions to the requirements provided by that type of iterator. It may be assumed that an input iterator may be dereferenced to refer to some object and that it may be incremented to the next iterator in the sequence. This is a minimal set of functionality, but it is enough to be able to talk meaningfully about a range of iterators [`first`, `last`) in the context of the class member functions.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>hash_set</code>	Constructs a <code>hash_set</code> that is empty or that is a copy of all or part of some other <code>hash_set</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>allocator_type</code>	A type that represents the <code>allocator</code> class for the <code>hash_set</code> object.
<code>const_iterator</code>	A type that provides a bidirectional iterator that can read a <code>const</code> element in the <code>hash_set</code> .
<code>const_pointer</code>	A type that provides a pointer to a const element in a <code>hash_set</code> .
<code>const_reference</code>	A type that provides a reference to a const element stored in a <code>hash_set</code> for reading and performing const operations.
<code>const_reverse_iterator</code>	A type that provides a bidirectional iterator that can read any const element in the <code>hash_set</code> .
<code>difference_type</code>	A signed integer type that can be used to represent the number of elements of a <code>hash_set</code> in a range between elements pointed to by iterators.
<code>iterator</code>	A type that provides a bidirectional iterator that can read or modify any element in a <code>hash_set</code> .
<code>key_compare</code>	A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the <code>hash_set</code> .
<code>key_type</code>	A type that describes an object stored as an element of a <code>hash_set</code> in its capacity as sort key.
<code>pointer</code>	A type that provides a pointer to an element in a <code>hash_set</code> .
<code>reference</code>	A type that provides a reference to an element stored in a <code>hash_set</code> .
<code>reverse_iterator</code>	A type that provides a bidirectional iterator that can read or modify an element in a reversed <code>hash_set</code> .
<code>size_type</code>	An unsigned integer type that can represent the number of elements in a <code>hash_set</code> .
<code>value_compare</code>	A type that provides two function objects, a binary predicate of class <code>compare</code> that can compare two element values of a <code>hash_set</code> to determine their relative order and a unary predicate that hashes the elements.

TYPE NAME	DESCRIPTION
<code>value_type</code>	A type that describes an object stored as an element of a <code>hash_set</code> in its capacity as a value.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>begin</code>	Returns an iterator that addresses the first element in the <code>hash_set</code> .
<code>cbegin</code>	Returns a const iterator addressing the first element in the <code>hash_set</code> .
<code>cend</code>	Returns a const iterator that addresses the location succeeding the last element in a <code>hash_set</code> .
<code>clear</code>	Erases all the elements of a <code>hash_set</code> .
<code>count</code>	Returns the number of elements in a <code>hash_set</code> whose key matches a parameter-specified key.
<code>crbegin</code>	Returns a const iterator addressing the first element in a reversed <code>hash_set</code> .
<code>crend</code>	Returns a const iterator that addresses the location succeeding the last element in a reversed <code>hash_set</code> .
<code>emplace</code>	Inserts an element constructed in place into a <code>hash_set</code> .
<code>emplace_hint</code>	Inserts an element constructed in place into a <code>hash_set</code> , with a placement hint.
<code>empty</code>	Tests if a <code>hash_set</code> is empty.
<code>end</code>	Returns an iterator that addresses the location succeeding the last element in a <code>hash_set</code> .
<code>equal_range</code>	Returns a pair of iterators respectively to the first element in a <code>hash_set</code> with a key that is greater than a specified key and to the first element in the <code>hash_set</code> with a key that is equal to or greater than the key.
<code>erase</code>	Removes an element or a range of elements in a <code>hash_set</code> from specified positions or removes elements that match a specified key.
<code>find</code>	Returns an iterator addressing the location of an element in a <code>hash_set</code> that has a key equivalent to a specified key.
<code>get_allocator</code>	Returns a copy of the <code>allocator</code> object used to construct the <code>hash_set</code> .

MEMBER FUNCTION	DESCRIPTION
insert	Inserts an element or a range of elements into a <code>hash_set</code> .
key_comp	Retrieves a copy of the comparison object used to order keys in a <code>hash_set</code> .
lower_bound	Returns an iterator to the first element in a <code>hash_set</code> with a key that is equal to or greater than a specified key.
max_size	Returns the maximum length of the <code>hash_set</code> .
rbegin	Returns an iterator addressing the first element in a reversed <code>hash_set</code> .
rend	Returns an iterator that addresses the location succeeding the last element in a reversed <code>hash_set</code> .
size	Returns the number of elements in the <code>hash_set</code> .
swap	Exchanges the elements of two <code>hash_set</code> s.
upper_bound	Returns an iterator to the first element in a <code>hash_set</code> that with a key that is equal to or greater than a specified key.
value_comp	Retrieves a copy of the hash traits object used to hash and order element key values in a <code>hash_set</code> .

Operators

OPERATOR	DESCRIPTION
hash_set::operator=	Replaces the elements of a <code>hash_set</code> with a copy of another <code>hash_set</code> .

Requirements

Header: `<hash_set>`

Namespace: `stdext`

hash_set::allocator_type

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that represents the allocator class for the `hash_set` object.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::allocator_type allocator_type;
```

Remarks

`allocator_type` is a synonym for the template parameter *Allocator*.

For more information on *Allocator*, see the Remarks section of the [hash_set Class](#) topic.

Example

See example for [get_allocator](#) for an example that uses `allocator_type`.

hash_set::begin

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns an iterator that addresses the first element in the hash_set.

```
const_iterator begin() const;

iterator begin();
```

Return Value

A bidirectional iterator addressing the first element in the hash_set or the location succeeding an empty hash_set.

Remarks

If the return value of `begin` is assigned to a `const_iterator`, the elements in the hash_set object cannot be modified. If the return value of `begin` is assigned to an `iterator`, the elements in the hash_set object can be modified.

Example

```
// hash_set_begin.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int>::iterator hs1_Iter;
    hash_set <int>::const_iterator hs1_cIter;

    hs1.insert( 1 );
    hs1.insert( 2 );
    hs1.insert( 3 );

    hs1_Iter = hs1.begin( );
    cout << "The first element of hs1 is " << *hs1_Iter << endl;

    hs1_Iter = hs1.begin( );
    hs1.erase( hs1_Iter );

    // The following 2 lines would err because the iterator is const
    // hs1_cIter = hs1.begin( );
    // hs1.erase( hs1_cIter );

    hs1_cIter = hs1.begin( );
    cout << "The first element of hs1 is now " << *hs1_cIter << endl;
}
```

```
The first element of hs1 is 1
The first element of hs1 is now 2
```

hash_set::cbegin

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns a const iterator that addresses the first element in the hash_set.

```
const_iterator cbegin() const;
```

Return Value

A const bidirectional iterator addressing the first element in the [hash_set](#) or the location succeeding an empty `hash_set`.

Remarks

With the return value of `cbegin`, the elements in the `hash_set` object cannot be modified.

Example

```
// hash_set_cbegin.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int>::const_iterator hs1_cIter;

    hs1.insert( 1 );
    hs1.insert( 2 );
    hs1.insert( 3 );

    hs1_cIter = hs1.cbegin( );
    cout << "The first element of hs1 is " << *hs1_cIter << endl;
}
```

```
The first element of hs1 is 1
```

hash_set::cend

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns a const iterator that addresses the location succeeding the last element in a hash_set.

```
const_iterator cend() const;
```

Return Value

A const bidirectional iterator that addresses the location succeeding the last element in a [hash_set](#). If the `hash_set` is empty, then `hash_set::cend == hash_set::begin`.

Remarks

`cend` is used to test whether an iterator has reached the end of its `hash_set`. The value returned by `cend` should not be dereferenced.

Example

```
// hash_set_cend.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int> :: const_iterator hs1_cIter;

    hs1.insert( 1 );
    hs1.insert( 2 );
    hs1.insert( 3 );

    hs1_cIter = hs1.cend( );
    hs1_cIter--;
    cout << "The last element of hs1 is " << *hs1_cIter << endl;
}
```

```
The last element of hs1 is 3
```

hash_set::clear

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Erases all the elements of a `hash_set`.

```
void clear();
```

Remarks

Example

```
// hash_set_clear.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;

    hs1.insert( 1 );
    hs1.insert( 2 );

    cout << "The size of the hash_set is initially " << hs1.size( )
         << "." << endl;

    hs1.clear( );
    cout << "The size of the hash_set after clearing is "
         << hs1.size( ) << "." << endl;
}
```

The size of the hash_set is initially 2.
The size of the hash_set after clearing is 0.

hash_set::const_iterator

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that provides a bidirectional iterator that can read a **const** element in the hash_set.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::const_iterator const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

Example

See example for [begin](#) for an example that uses `const_iterator`.

hash_set::const_pointer

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that provides a pointer to a **const** element in a hash_set.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element.

In most cases, a [const_iterator](#) should be used to access the elements in a **const** hash_set object.

hash_set::const_reference

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that provides a reference to a **const** element stored in a hash_set for reading and performing **const** operations.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::const_reference const_reference;
```

Remarks

Example

```
// hash_set_const_ref.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;

    hs1.insert( 10 );
    hs1.insert( 20 );

    // Declare and initialize a const_reference &Ref1
    // to the 1st element
    const int &Ref1 = *hs1.begin( );

    cout << "The first element in the hash_set is "
         << Ref1 << "." << endl;

    // The following line would cause an error because the
    // const_reference cannot be used to modify the hash_set
    // Ref1 = Ref1 + 5;
}
```

```
The first element in the hash_set is 10.
```

hash_set::const_reverse_iterator

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that provides a bidirectional iterator that can read any **const** element in the hash_set.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::const_reverse_iterator
const_reverse_iterator;
```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is use to iterate through the `hash_set` in reverse.

Example

See the example for [rend](#) for an example of how to declare and use the `const_reverse_iterator`

hash_set::count

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns the number of elements in a `hash_set` whose key matches a parameter-specified key.

```
size_type count(const Key& key) const;
```

Parameters

key

The key of the elements to be matched from the `hash_set`.

Return Value

1 if the `hash_set` contains an element whose sort key matches the parameter key.

0 if the `hash_set` does not contain an element with a matching key.

Remarks

The member function returns the number of elements in the following range:

[`lower_bound(key)`, `upper_bound(key)`).

Example

The following example demonstrates the use of the `hash_set::count` member function.

```
// hash_set_count.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set<int> hs1;
    hash_set<int>::size_type i;

    hs1.insert(1);
    hs1.insert(1);

    // Keys must be unique in hash_set, so duplicates are ignored.
    i = hs1.count(1);
    cout << "The number of elements in hs1 with a sort key of 1 is: "
         << i << "." << endl;

    i = hs1.count(2);
    cout << "The number of elements in hs1 with a sort key of 2 is: "
         << i << "." << endl;
}
```

```
The number of elements in hs1 with a sort key of 1 is: 1.
The number of elements in hs1 with a sort key of 2 is: 0.
```

hash_set::crbegin

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns a const iterator addressing the first element in a reversed hash_set.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse bidirectional iterator addressing the first element in a reversed [hash_set](#) or addressing what had been the last element in the unreversed `hash_set`.

Remarks

`crbegin` is used with a reversed hash_set just as [hash_set::begin](#) is used with a hash_set.

With the return value of `crbegin`, the `hash_set` object cannot be modified.

`crbegin` can be used to iterate through a `hash_set` backwards.

Example

```
// hash_set_crbegin.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int>::const_reverse_iterator hs1_crIter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );

    hs1_crIter = hs1.crbegin( );
    cout << "The first element in the reversed hash_set is "
         << *hs1_crIter << "." << endl;
}
```

The first element in the reversed hash_set is 30.

hash_set::crend

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns a const iterator that addresses the location succeeding the last element in a reversed hash_set.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse bidirectional iterator that addresses the location succeeding the last element in a reversed [hash_set](#) (the location that had preceded the first element in the unreversed `hash_set`).

Remarks

`crend` is used with a reversed `hash_set` just as [hash_set::end](#) is used with a `hash_set`.

With the return value of `crend`, the `hash_set` object cannot be modified.

`crend` can be used to test to whether a reverse iterator has reached the end of its `hash_set`.

Example

```
// hash_set_crend.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int>::const_reverse_iterator hs1_crIter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );

    hs1_crIter = hs1.crend( );
    hs1_crIter--;
    cout << "The last element in the reversed hash_set is "
         << *hs1_crIter << "." << endl;
}
```

The last element in the reversed hash_set is 10.

hash_set::difference_type

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A signed integer type that can be used to represent the number of elements of a hash_set in a range between elements pointed to by iterators.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::difference_type difference_type;
```

Remarks

The `difference_type` is the type returned when subtracting or incrementing through iterators of the container.

The `difference_type` is typically used to represent the number of elements in the range [`first`, `last`) between the iterators `first` and `last`, includes the element pointed to by `first` and the range of elements up to, but not including, the element pointed to by `last`.

Note that although `difference_type` is available for all iterators that satisfy the requirements of an input iterator, which includes the class of bidirectional iterators supported by reversible containers such as set, subtraction between iterators is only supported by random-access iterators provided by a random access container, such as vector or deque.

Example

```

// hash_set_diff_type.cpp
// compile with: /EHsc
#include <iostream>
#include <hash_set>
#include <algorithm>

int main( )
{
    using namespace std;
    using namespace stdext;

    hash_set <int> hs1;
    hash_set <int>::iterator hs1_iter, hs1_bIter, hs1_eIter;

    hs1.insert( 20 );
    hs1.insert( 10 );
    hs1.insert( 20 ); // Won't insert as hash_set elements are unique

    hs1_bIter = hs1.begin( );
    hs1_eIter = hs1.end( );

    hash_set <int>::difference_type df_typ5, df_typ10, df_typ20;

    df_typ5 = count( hs1_bIter, hs1_eIter, 5 );
    df_typ10 = count( hs1_bIter, hs1_eIter, 10 );
    df_typ20 = count( hs1_bIter, hs1_eIter, 20 );

    // The keys, and hence the elements, of a hash_set are unique,
    // so there is at most one of a given value
    cout << "The number '5' occurs " << df_typ5
        << " times in hash_set hs1.\n";
    cout << "The number '10' occurs " << df_typ10
        << " times in hash_set hs1.\n";
    cout << "The number '20' occurs " << df_typ20
        << " times in hash_set hs1.\n";

    // Count the number of elements in a hash_set
    hash_set <int>::difference_type df_count = 0;
    hs1_iter = hs1.begin( );
    while ( hs1_iter != hs1_eIter)
    {
        df_count++;
        hs1_iter++;
    }

    cout << "The number of elements in the hash_set hs1 is: "
        << df_count << "." << endl;
}

```

```

The number '5' occurs 0 times in hash_set hs1.
The number '10' occurs 1 times in hash_set hs1.
The number '20' occurs 1 times in hash_set hs1.
The number of elements in the hash_set hs1 is: 2.

```

hash_set::emplace

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Inserts an element constructed in place into a hash_set.

```
template <class ValTy>
pair <iterator, bool>
emplace(
    ValTy&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value of an element to be inserted into the hash_set unless the hash_set already contains that element or, more generally, an element whose key is equivalently ordered.

Return Value

The [emplace](#) member function returns a pair whose **bool** component returns **true** if an insertion was make and **false** if the [hash_set](#) already contained an element whose key had an equivalent value in the ordering, and whose iterator component returns the address where a new element was inserted or where the element was already located.

Remarks

Example

```
// hash_set_emplace.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set<string> hs3;
    string str1("a");

    hs3.emplace(move(str1));
    cout << "After the emplace insertion, hs3 contains "
        << *hs3.begin() << "." << endl;
}
```

After the `emplace` insertion, `hs3` contains `a`.

hash_set::emplace_hint

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Inserts an element constructed in place into a `hash_set`.

```
template <class ValTy>
iterator emplace(
    const_iterator _where,
    ValTy&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value of an element to be inserted into the hash_set unless the <code>hash_set</code> already contains that element or, more generally, an element whose key is equivalently ordered.
<i>_Where</i>	The place to start searching for the correct point of insertion. (Insertion can occur in amortized constant time, instead of logarithmic time, if the insertion point immediately follows <i>_Where</i> .)

Return Value

The [hash_set::emplace](#) member function returns an iterator that points to the position where the new element was inserted into the `hash_set`, or where the existing element with equivalent ordering is located.

Remarks

Insertion can occur in amortized constant time, instead of logarithmic time, if the insertion point immediately follows *_Where*.

Example

```
// hash_set_emplace_hint.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set<string> hs3;
    string str1("a");

    hs3.insert(hs3.begin(), move(str1));
    cout << "After the emplace insertion, hs3 contains "
         << *hs3.begin() << "." << endl;
}
```

After the emplace insertion, hs3 contains a.

hash_set::empty

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Tests if a `hash_set` is empty.

```
bool empty() const;
```

Return Value

true if the `hash_set` is empty; **false** if the `hash_set` is nonempty.

Remarks

Example

```
// hash_set_empty.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1, hs2;
    hs1.insert ( 1 );

    if ( hs1.empty( ) )
        cout << "The hash_set hs1 is empty." << endl;
    else
        cout << "The hash_set hs1 is not empty." << endl;

    if ( hs2.empty( ) )
        cout << "The hash_set hs2 is empty." << endl;
    else
        cout << "The hash_set hs2 is not empty." << endl;
}
```

```
The hash_set hs1 is not empty.
The hash_set hs2 is empty.
```

hash_set::end

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns an iterator that addresses the location succeeding the last element in a hash_set.

```
const_iterator end() const;

iterator end();
```

Return Value

A bidirectional iterator that addresses the location succeeding the last element in a hash_set. If the hash_set is empty, then hash_set::end == hash_set::begin.

Remarks

`end` is used to test whether an iterator has reached the end of its hash_set. The value returned by `end` should not be dereferenced.

Example

```
// hash_set_end.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int> :: iterator hs1_Iter;
    hash_set <int> :: const_iterator hs1_cIter;

    hs1.insert( 1 );
    hs1.insert( 2 );
    hs1.insert( 3 );

    hs1_Iter = hs1.end( );
    hs1_Iter--;
    cout << "The last element of hs1 is " << *hs1_Iter << endl;

    hs1.erase( hs1_Iter );

    // The following 3 lines would err because the iterator is const:
    // hs1_cIter = hs1.end( );
    // hs1_cIter--;
    // hs1.erase( hs1_cIter );

    hs1_cIter = hs1.end( );
    hs1_cIter--;
    cout << "The last element of hs1 is now " << *hs1_cIter << endl;
}
```

```
The last element of hs1 is 3
The last element of hs1 is now 2
```

hash_set::equal_range

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns a pair of iterators respectively to the first element in a hash set with a key that is equal to a specified key and to the first element in the hash set with a key that is greater than the key.

```
pair <const_iterator, const_iterator> equal_range (const Key& key) const;

pair <iterator, iterator> equal_range (const Key& key);
```

Parameters

key

The argument key to be compared with the sort key of an element from the hash_set being searched.

Return Value

A pair of iterators where the first is the [lower_bound](#) of the key and the second is the [upper_bound](#) of the key.

To access the first iterator of a pair pr returned by the member function, use `pr.first`, and to dereference the

lower bound iterator, use `*(pr.first)`. To access the second iterator of a pair `pr` returned by the member function, use `pr.second`, and to dereference the upper bound iterator, use `*(pr.second)`.

Remarks

Example

```
// hash_set_equal_range.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    typedef hash_set<int> IntHSet;
    IntHSet hs1;
    hash_set<int> :: const_iterator hs1_RcIter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );

    pair <IntHSet::const_iterator, IntHSet::const_iterator> p1, p2;
    p1 = hs1.equal_range( 20 );

    cout << "The upper bound of the element with "
         << "a key of 20 in the hash_set hs1 is: "
         << *(p1.second) << "." << endl;

    cout << "The lower bound of the element with "
         << "a key of 20 in the hash_set hs1 is: "
         << *(p1.first) << "." << endl;

    // Compare the upper_bound called directly
    hs1_RcIter = hs1.upper_bound( 20 );
    cout << "A direct call of upper_bound( 20 ) gives "
         << *hs1_RcIter << "," << endl
         << "matching the 2nd element of the pair"
         << " returned by equal_range( 20 )." << endl;

    p2 = hs1.equal_range( 40 );

    // If no match is found for the key,
    // both elements of the pair return end( )
    if ( ( p2.first == hs1.end( ) ) && ( p2.second == hs1.end( ) ) )
        cout << "The hash_set hs1 doesn't have an element "
             << "with a key greater than or equal to 40." << endl;
    else
        cout << "The element of hash_set hs1 with a key >= 40 is: "
             << *(p1.first) << "." << endl;
}
```

The upper bound of the element with a key of 20 in the hash_set hs1 is: 30.
The lower bound of the element with a key of 20 in the hash_set hs1 is: 20.
A direct call of upper_bound(20) gives 30,
matching the 2nd element of the pair returned by equal_range(20).
The hash_set hs1 doesn't have an element with a key greater than or equal to 40.

hash_set::erase

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Removes an element or a range of elements in a `hash_set` from specified positions or removes elements that match a specified key.

```
iterator erase(iterator _Where);

iterator erase(iterator first, iterator last);

size_type erase(const key_type& key);
```

Parameters

_Where

Position of the element to be removed from the `hash_set`.

first

Position of the first element removed from the `hash_set`.

last

Position just beyond the last element removed from the `hash_set`.

key

The key of the elements to be removed from the `hash_set`.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or a pointer to the end of the `hash_set` if no such element exists. For the third member function, the number of elements that have been removed from the `hash_set`.

Remarks

The member functions never throw an exception.

Example

The following example demonstrates the use of the `hash_set::erase` member function.

```
// hash_set_erase.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_set<int> hs1, hs2, hs3;
    hash_set<int>::iterator pIter, Iter1, Iter2;
    int i;
    hash_set<int>::size_type n;

    for (i = 1; i < 5; i++)
    {
        hs1.insert (i);
        hs2.insert (i * i);
        hs3.insert (i - 1);
    }

    // The 1st member function removes an element at a given position
```

```

Iter1 = ++hs1.begin();
hs1.erase(Iter1);

cout << "After the 2nd element is deleted, the hash_set hs1 is:";
for (pIter = hs1.begin(); pIter != hs1.end(); pIter++)
    cout << " " << *pIter;
cout << "." << endl;

// The 2nd member function removes elements
// in the range [ first, last)
Iter1 = ++hs2.begin();
Iter2 = --hs2.end();
hs2.erase(Iter1, Iter2);

cout << "After the middle two elements are deleted, "
    << "the hash_set hs2 is:";
for (pIter = hs2.begin(); pIter != hs2.end(); pIter++)
    cout << " " << *pIter;
cout << "." << endl;

// The 3rd member function removes elements with a given key
n = hs3.erase(2);

cout << "After the element with a key of 2 is deleted, "
    << "the hash_set hs3 is:";
for (pIter = hs3.begin(); pIter != hs3.end(); pIter++)
    cout << " " << *pIter;
cout << "." << endl;

// The 3rd member function returns the number of elements removed
cout << "The number of elements removed from hs3 is: "
    << n << "." << endl;

// The dereferenced iterator can also be used to specify a key
Iter1 = ++hs3.begin();
hs3.erase(Iter1);

cout << "After another element (unique for hash_set) with a key "
    << endl;
cout << "equal to that of the 2nd element is deleted, "
    << "the hash_set hs3 is:";
for (pIter = hs3.begin(); pIter != hs3.end(); pIter++)
    cout << " " << *pIter;
cout << "." << endl;
}

```

After the 2nd element is deleted, the hash_set hs1 is: 1 3 4.
 After the middle two elements are deleted, the hash_set hs2 is: 16 4.
 After the element with a key of 2 is deleted, the hash_set hs3 is: 0 1 3.
 The number of elements removed from hs3 is: 1.
 After another element (unique for hash_set) with a key
 equal to that of the 2nd element is deleted, the hash_set hs3 is: 0 3.

hash_set::find

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns an iterator addressing the location of an element in a hash_set that has a key equivalent to a specified key.

```
iterator find(const Key& key);

const_iterator find(const Key& key) const;
```

Parameters

key

The argument key to be matched by the sort key of an element from the hash_set being searched.

Return Value

An `iterator` or `const_iterator` that addresses the location of an element equivalent to a specified key or that addresses the location succeeding the last element in the hash_set if no match is found for the key.

Remarks

The member function returns an iterator that addresses an element in the hash_set whose sort key is `equivalent` to the argument key under a binary predicate that induces an ordering based on a less-than comparability relation.

If the return value of `find` is assigned to a `const_iterator`, the hash_set object cannot be modified. If the return value of `find` is assigned to an `iterator`, the hash_set object can be modified.

Example

```
// hash_set_find.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int> :: const_iterator hs1_AcIter, hs1_RcIter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );

    hs1_RcIter = hs1.find( 20 );
    cout << "The element of hash_set hs1 with a key of 20 is: "
         << *hs1_RcIter << "." << endl;

    hs1_RcIter = hs1.find( 40 );

    // If no match is found for the key, end( ) is returned
    if ( hs1_RcIter == hs1.end( ) )
        cout << "The hash_set hs1 doesn't have an element "
             << "with a key of 40." << endl;
    else
        cout << "The element of hash_set hs1 with a key of 40 is: "
             << *hs1_RcIter << "." << endl;

    // The element at a specific location in the hash_set can be found
    // by using a dereferenced iterator addressing the location
    hs1_AcIter = hs1.end( );
    hs1_AcIter--;
    hs1_RcIter = hs1.find( *hs1_AcIter );
    cout << "The element of hs1 with a key matching "
         << "that of the last element is: "
         << *hs1_RcIter << "." << endl;
}
```

```
The element of hash_set hs1 with a key of 20 is: 20.  
The hash_set hs1 doesn't have an element with a key of 40.  
The element of hs1 with a key matching that of the last element is: 30.
```

hash_set::get_allocator

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns a copy of the allocator object used to construct the hash_set.

```
Allocator get_allocator() const;
```

Return Value

The allocator used by the hash_set to manage memory, which is the template parameter *Allocator*.

For more information on *Allocator*, see the Remarks section of the [hash_set Class](#) topic.

Remarks

Allocators for the hash_set class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```

// hash_set_get_allocator.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;

    // The following lines declare objects
    // that use the default allocator.
    hash_set <int, hash_compare <int, less<int> > > hs1;
    hash_set <int, hash_compare <int, greater<int> > > hs2;
    hash_set <double, hash_compare <double,
        less<double> >, allocator<double> > hs3;

    hash_set <int, hash_compare <int,
        greater<int> > >::allocator_type hs2_Alloc;
    hash_set <double>::allocator_type hs3_Alloc;
    hs2_Alloc = hs2.get_allocator( );

    cout << "The number of integers that can be allocated"
        << endl << "before free memory is exhausted: "
        << hs1.max_size( ) << "." << endl;

    cout << "The number of doubles that can be allocated"
        << endl << "before free memory is exhausted: "
        << hs3.max_size( ) << "." << endl;

    // The following lines create a hash_set hs4
    // with the allocator of hash_set hs1.
    hash_set <int>::allocator_type hs4_Alloc;
    hash_set <int> hs4;
    hs4_Alloc = hs2.get_allocator( );

    // Two allocators are interchangeable if
    // storage allocated from each can be
    // deallocated by the other
    if( hs2_Alloc == hs4_Alloc )
    {
        cout << "The allocators are interchangeable."
            << endl;
    }
    else
    {
        cout << "The allocators are not interchangeable."
            << endl;
    }
}

```

hash_set::hash_set

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Constructs a `hash_set` that is empty or that is a copy of all or part of some other `hash_set`.

```

hash_set();

explicit hash_set(
    const Traits& Comp);

hash_set(
    const Traits& Comp,
    const Allocator& Al);

hash_set(
    const hash_set<Key, Traits, Allocator>& Right);

hash_set(
    hash_set&& Right);

hash_set(
    initializer_list<Type> IList);

hash_set(
    initializer_list<Type> IList,
    const Compare& Comp);

hash_set(
    initializer_list<value_type> IList,
    const Compare& Comp,
    const Allocator& Al);

template <class InputIterator>
hash_set(
    InputIterator First,
    InputIterator Last);

template <class InputIterator>
hash_set(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp);

template <class InputIterator>
hash_set(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp,
    const Allocator& Al);

```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The storage allocator class to be used for this <code>hash_set</code> object, which defaults to <code>Allocator</code> .
<i>Comp</i>	The comparison function of type <code>const Traits</code> used to order the elements in the <code>hash_set</code> , which defaults to <code>hash_compare</code> .
<i>Right</i>	The <code>hash_set</code> of which the constructed <code>hash_set</code> is to be a copy.
<i>First</i>	The position of the first element in the range of elements to be copied.

PARAMETER	DESCRIPTION
<i>Last</i>	The position of the first element beyond the range of elements to be copied.

Remarks

All constructors store a type of allocator object that manages memory storage for the `hash_set` and that can later be returned by calling `hash_set::get_allocator`. The allocator parameter is often omitted in the class declarations and preprocessing macros used to substitute alternative allocators.

All constructors initialize their `hash_sets`.

All constructors store a function object of type `Traits` that is used to establish an order among the keys of the `hash_set` and that can later be returned by calling `hash_set::key_comp`. For more information on `Traits` see the [hash_set Class](#) topic.

The first constructor creates an empty initial `hash_set`. The second specifies the type of comparison function (`Comp`) to be used in establishing the order of the elements, and the third explicitly specifies the allocator type (`Al`) to be used. The key word `explicit` suppresses certain kinds of automatic type conversion.

The fourth and fifth constructors specify a copy of the `hash_set` `Right` .

The last sixth, seventh, and eighth constructors use an `initializer_list` for the elements.

The last constructors copy the range [`First` , `Last`) of a `hash_set` with increasing explicitness in specifying the type of comparison function of class `Traits` and allocator.

The eighth constructor moves the `hash_set` `Right` .

The actual order of elements in a `hash_set` container depends on the hash function, the ordering function and the current size of the hash table and cannot, in general, be predicted as it could with the `set` container, where it was determined by the ordering function alone.

hash_set::insert

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Inserts an element or a range of elements into a `hash_set` .

```
pair<iterator, bool> insert(
    const value_type& Val);

iterator insert(
    iterator Where,
    const value_type& Val);

void insert(
    initializer_list<value_type> Ilist)
template <class InputIterator>
void insert(
    InputIterator First,
    InputIterator Last);
```

Parameters

PARAMETER	DESCRIPTION
<i>Val</i>	The value of an element to be inserted into the <code>hash_set</code> unless the <code>hash_set</code> already contains that element or, more generally, an element whose key is equivalently ordered.
<i>Where</i>	The place to start searching for the correct point of insertion. (Insertion can occur in amortized constant time, instead of logarithmic time, if the insertion point immediately follows <code>_where</code> .)
<i>First</i>	The position of the first element to be copied from a <code>hash_set</code> .
<i>Last</i>	The position just beyond the last element to be copied from a <code>hash_set</code> .
<i>lList</i>	The initializer_list from which to copy the elements.

Return Value

The first `insert` member function returns a pair whose **bool** component returns **true** if an insertion was made and **false** if the `hash_set` already contained an element whose key had an equivalent value in the ordering, and whose iterator component returns the address where a new element was inserted or where the element was already located.

To access the iterator component of a pair `pr` returned by this member function, use `pr.first` and to dereference it, use `*(pr.first)`. To access the **bool** component of a pair `pr` returned by this member function, use `pr.second`, and to dereference it, use `*(pr.second)`.

The second `insert` member function returns an iterator that points to the position where the new element was inserted into the `hash_set`.

Remarks

The third member function inserts the elements in an initializer_list.

The third member function inserts the sequence of element values into a `hash_set` corresponding to each element addressed by an iterator of in the range [`First`, `Last`) of a specified `hash_set`.

hash_set::iterator

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that provides a bidirectional iterator that can read or modify any element in a `hash_set`.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::iterator iterator;
```

Remarks

A type `iterator` can be used to modify the value of an element.

Example

See the example for [begin](#) for an example of how to declare and use `iterator`.

hash_set::key_comp

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Retrieves a copy of the hash traits object used to hash and order element key values in a `hash_set`.

```
key_compare key_comp() const;
```

Return Value

Returns the function object that a `hash_set` uses to order its elements, which is the template parameter *Traits*.

For more information on *Traits* see the [hash_set Class](#) topic.

Remarks

The stored object defines the member function:

```
bool operator( const Key& _xVal, const Key& _yVal );
```

which returns **true** if `_xVal` precedes and is not equal to `_yVal` in the sort order.

Note that both [key_compare](#) and [value_compare](#) are synonyms for the template parameter *Traits*. Both types are provided for the `hash_set` and `hash_multiset` classes, where they are identical, for compatibility with the `hash_map` and `hash_multimap` classes, where they are distinct.

Example

```

// hash_set_key_comp.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;

    hash_set <int, hash_compare < int, less<int> > > hs1;
    hash_set<int, hash_compare < int, less<int> > >::key_compare kc1
        = hs1.key_comp( ) ;
    bool result1 = kc1( 2, 3 ) ;
    if( result1 == true )
    {
        cout << "kc1( 2,3 ) returns value of true, "
              << "where kc1 is the function object of hs1."
              << endl;
    }
    else
    {
        cout << "kc1( 2,3 ) returns value of false "
              << "where kc1 is the function object of hs1."
              << endl;
    }

    hash_set <int, hash_compare < int, greater<int> > > hs2;
    hash_set<int, hash_compare < int, greater<int> > >::key_compare
        kc2 = hs2.key_comp( ) ;
    bool result2 = kc2( 2, 3 ) ;
    if(result2 == true)
    {
        cout << "kc2( 2,3 ) returns value of true, "
              << "where kc2 is the function object of hs2."
              << endl;
    }
    else
    {
        cout << "kc2( 2,3 ) returns value of false, "
              << "where kc2 is the function object of hs2."
              << endl;
    }
}

```

hash_set::key_compare

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the `hash_set`.

```
typedef Traits key_compare;
```

Remarks

`key_compare` is a synonym for the template parameter *Traits*.

For more information on *Traits* see the [hash_set Class](#) topic.

Note that both `key_compare` and `value_compare` are synonyms for the template parameter *Traits*. Both types are provided for the set and multiset classes, where they are identical, for compatibility with the map and multimap classes, where they are distinct.

Example

See the example for `key_comp` for an example of how to declare and use `key_compare`.

hash_set::key_type

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that describes an object stored as an element of a hash_set in its capacity as sort key.

```
typedef Key key_type;
```

Remarks

`key_type` is a synonym for the template parameter *Key*.

For more information on *Key*, see the Remarks section of the [hash_set Class](#) topic.

Note that both `key_type` and `value_type` are synonyms for the template parameter *Key*. Both types are provided for the hash_set and hash_multiset classes, where they are identical, for compatibility with the hash_map and hash_multimap classes, where they are distinct.

Example

See the example for `value_type` for an example of how to declare and use `key_type`.

hash_set::lower_bound

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns an iterator to the first element in a hash_set with a key that is equal to or greater than a specified key.

```
const_iterator lower_bound(const Key& key) const;  
  
iterator lower_bound(const Key& key);
```

Parameters

key

The argument key to be compared with the sort key of an element from the hash_set being searched.

Return Value

An `iterator` or `const_iterator` that addresses the location of an element in a hash_set that with a key that is equal to or greater than the argument key or that addresses the location succeeding the last element in the hash_set if no match is found for the key.

Remarks

Example

```

// hash_set_lower_bound.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int> :: const_iterator hs1_AcIter, hs1_RcIter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );

    hs1_RcIter = hs1.lower_bound( 20 );
    cout << "The element of hash_set hs1 with a key of 20 is: "
         << *hs1_RcIter << "." << endl;

    hs1_RcIter = hs1.lower_bound( 40 );

    // If no match is found for the key, end( ) is returned
    if ( hs1_RcIter == hs1.end( ) )
        cout << "The hash_set hs1 doesn't have an element "
             << "with a key of 40." << endl;
    else
        cout << "The element of hash_set hs1 with a key of 40 is: "
             << *hs1_RcIter << "." << endl;

    // An element at a specific location in the hash_set can be found
    // by using a dereferenced iterator that addresses the location
    hs1_AcIter = hs1.end( );
    hs1_AcIter--;
    hs1_RcIter = hs1.lower_bound( *hs1_AcIter );
    cout << "The element of hs1 with a key matching "
         << "that of the last element is: "
         << *hs1_RcIter << "." << endl;
}

```

The element of hash_set hs1 with a key of 20 is: 20.
 The hash_set hs1 doesn't have an element with a key of 40.
 The element of hs1 with a key matching that of the last element is: 30.

hash_set::max_size

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns the maximum length of the hash_set.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the hash_set.

Remarks

Example

```
// hash_set_max_size.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int>::size_type i;

    i = hs1.max_size( );
    cout << "The maximum possible length "
         << "of the hash_set is " << i << "." << endl;
}
```

hash_set::operator=

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Replaces the elements of the hash_set with a copy of another hash_set.

```
hash_set& operator=(const hash_set& right);

hash_set& operator=(hash_set&& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The hash_set being copied into the <code>hash_set</code> .

Remarks

After erasing any existing elements in a `hash_set`, `operator=` either copies or moves the contents of *right* into the `hash_set`.

Example

```

// hash_set_operator_as.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set<int> v1, v2, v3;
    hash_set<int>::iterator iter;

    v1.insert(10);

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << iter << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter << " ";
    cout << endl;
}

```

hash_set::pointer

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that provides a pointer to an element in a hash_set.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::pointer pointer;
```

Remarks

A type `pointer` can be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a hash_set object.

hash_set::rbegin

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns an iterator addressing the first element in a reversed hash_set.

```
const_reverse_iterator rbegin() const;
```

```
reverse_iterator rbegin();
```

Return Value

A reverse bidirectional iterator addressing the first element in a reversed hash_set or addressing what had been the last element in the unreversed hash_set.

Remarks

`rbegin` is used with a reversed hash_set just as `begin` is used with a hash_set.

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, then the hash_set object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, then the hash_set object can be modified.

`rbegin` can be used to iterate through a hash_set backwards.

Example

```

// hash_set_rbegin.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int>::iterator hs1_Iter;
    hash_set <int>::reverse_iterator hs1_rIter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );

    hs1_rIter = hs1.rbegin( );
    cout << "The first element in the reversed hash_set is "
         << *hs1_rIter << "." << endl;

    // begin can be used to start an iteration
    // through a hash_set in a forward order
    cout << "The hash_set is: ";
    for ( hs1_Iter = hs1.begin( ) ; hs1_Iter != hs1.end( );
          hs1_Iter++ )
        cout << *hs1_Iter << " ";
    cout << endl;

    // rbegin can be used to start an iteration
    // through a hash_set in a reverse order
    cout << "The reversed hash_set is: ";
    for ( hs1_rIter = hs1.rbegin( ) ; hs1_rIter != hs1.rend( );
          hs1_rIter++ )
        cout << *hs1_rIter << " ";
    cout << endl;

    // A hash_set element can be erased by dereferencing to its key
    hs1_rIter = hs1.rbegin( );
    hs1.erase ( *hs1_rIter );

    hs1_rIter = hs1.rbegin( );
    cout << "After the erasure, the first element "
         << "in the reversed hash_set is "<< *hs1_rIter << "."
         << endl;
}

```

```

The first element in the reversed hash_set is 30.
The hash_set is: 10 20 30
The reversed hash_set is: 30 20 10
After the erasure, the first element in the reversed hash_set is 20.

```

hash_set::reference

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that provides a reference to an element stored in a hash_set.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::reference reference;
```

Remarks

Example

```
// hash_set_reference.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;

    hs1.insert( 10 );
    hs1.insert( 20 );

    // Declare and initialize a reference &Ref1 to the 1st element
    int &Ref1 = *hs1.begin( );

    cout << "The first element in the hash_set is "
         << Ref1 << "." << endl;

    // The value of the 1st element of the hash_set can be changed
    // by operating on its (non-const) reference
    Ref1 = Ref1 + 5;

    cout << "The first element in the hash_set is now "
         << *hs1.begin() << "." << endl;
}
```

```
The first element in the hash_set is 10.
The first element in the hash_set is now 15.
```

hash_set::rend

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns an iterator that addresses the location succeeding the last element in a reversed hash_set.

```
const_reverse_iterator rend() const;

reverse_iterator rend();
```

Return Value

A reverse bidirectional iterator that addresses the location succeeding the last element in a reversed hash_set (the location that had preceded the first element in the unreversed hash_set).

Remarks

`rend` is used with a reversed hash_set just as [end](#) is used with a hash_set.

If the return value of `rend` is assigned to a `const_reverse_iterator`, then the `hash_set` object cannot be modified. If the return value of `rend` is assigned to a `reverse_iterator`, then the `hash_set` object can be modified. The value returned by `rend` should not be dereferenced.

`rend` can be used to test to whether a reverse iterator has reached the end of its `hash_set`.

Example

```
// hash_set_rend.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int>::iterator hs1_iter;
    hash_set <int>::reverse_iterator hs1_rIter;
    hash_set <int>::const_reverse_iterator hs1_crIter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );

    hs1_rIter = hs1.rend( );
    hs1_rIter--;
    cout << "The last element in the reversed hash_set is "
         << *hs1_rIter << "." << endl;

    // end can be used to terminate an iteration
    // through a hash_set in a forward order
    cout << "The hash_set is: ";
    for ( hs1_iter = hs1.begin( ) ; hs1_iter != hs1.end( );
          hs1_iter++ )
        cout << *hs1_iter << " ";
    cout << "." << endl;

    // rend can be used to terminate an iteration
    // through a hash_set in a reverse order
    cout << "The reversed hash_set is: ";
    for ( hs1_rIter = hs1.rbegin( ) ; hs1_rIter != hs1.rend( );
          hs1_rIter++ )
        cout << *hs1_rIter << " ";
    cout << "." << endl;

    hs1_rIter = hs1.rend( );
    hs1_rIter--;
    hs1.erase ( *hs1_rIter );

    hs1_rIter = hs1.rend( );
    hs1_rIter--;
    cout << "After the erasure, the last element in the "
         << "reversed hash_set is " << *hs1_rIter << "."
         << endl;
}
```

The last element in the reversed hash_set is 10.
The hash_set is: 10 20 30 .
The reversed hash_set is: 30 20 10 .
After the erasure, the last element in the reversed hash_set is 20.

hash_set::reverse_iterator

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that provides a bidirectional iterator that can read or modify an element in a reversed hash_set.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::reverse_iterator
reverse_iterator;
```

Remarks

A type `reverse_iterator` is use to iterate through the hash_set in reverse.

Example

See the example for [rbegin](#) for an example of how to declare and use `reverse_iterator`.

hash_set::size

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns the number of elements in the hash_set.

```
size_type size() const;
```

Return Value

The current length of the hash_set.

Remarks

Example

```
// hash_set_size.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set<int> hs1;
    hash_set<int> :: size_type i;

    hs1.insert( 1 );
    i = hs1.size( );
    cout << "The hash_set length is " << i << "." << endl;

    hs1.insert( 2 );
    i = hs1.size( );
    cout << "The hash_set length is now " << i << "." << endl;
}
```

```
The hash_set length is 1.  
The hash_set length is now 2.
```

hash_set::size_type

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

An unsigned integer type that can represent the number of elements in a hash_set.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::size_type size_type;
```

Remarks

Example

See the example for [size](#) for an example of how to declare and use `size_type`

hash_set::swap

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Exchanges the elements of two hash_sets.

```
void swap(hash_set& right);
```

Parameters

right

The argument hash_set providing the elements to be swapped with the target hash_set.

Remarks

The member function invalidates no references, pointers, or iterators that designate elements in the two hash_sets whose elements are being exchanged.

Example

```

// hash_set_swap.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1, hs2, hs3;
    hash_set <int>::iterator hs1_Iter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );
    hs2.insert( 100 );
    hs2.insert( 200 );
    hs3.insert( 300 );

    cout << "The original hash_set hs1 is:";
    for ( hs1_Iter = hs1.begin( ); hs1_Iter != hs1.end( );
          hs1_Iter++ )
        cout << " " << *hs1_Iter;
    cout << "." << endl;

    // This is the member function version of swap
    hs1.swap( hs2 );

    cout << "After swapping with hs2, list hs1 is:";
    for ( hs1_Iter = hs1.begin( ); hs1_Iter != hs1.end( );
          hs1_Iter++ )
        cout << " " << *hs1_Iter;
    cout << "." << endl;

    // This is the specialized template version of swap
    swap( hs1, hs3 );

    cout << "After swapping with hs3, list hs1 is:";
    for ( hs1_Iter = hs1.begin( ); hs1_Iter != hs1.end( );
          hs1_Iter++ )
        cout << " " << *hs1_Iter;
    cout << "." << endl;
}

```

```

The original hash_set hs1 is: 10 20 30.
After swapping with hs2, list hs1 is: 200 100.
After swapping with hs3, list hs1 is: 300.

```

hash_set::upper_bound

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Returns an iterator to the first element in a hash_set that with a key that is greater than a specified key.

```

const_iterator upper_bound(const Key& key) const;

iterator upper_bound(const Key& key);

```

Parameters

key

The argument key to be compared with the sort key of an element from the hash_set being searched.

Return Value

An `iterator` or `const_iterator` that addresses the location of an element in a hash_set that with a key that is equal to or greater than the argument key, or that addresses the location succeeding the last element in the hash_set if no match is found for the key.

Remarks

Example

```
// hash_set_upper_bound.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int> :: const_iterator hs1_AcIter, hs1_RcIter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );

    hs1_RcIter = hs1.upper_bound( 20 );
    cout << "The first element of hash_set hs1 with a key greater "
         << "than 20 is: " << *hs1_RcIter << "." << endl;

    hs1_RcIter = hs1.upper_bound( 30 );

    // If no match is found for the key, end( ) is returned
    if ( hs1_RcIter == hs1.end( ) )
        cout << "The hash_set hs1 doesn't have an element "
             << "with a key greater than 30." << endl;
    else
        cout << "The element of hash_set hs1 with a key > 40 is: "
             << *hs1_RcIter << "." << endl;

    // An element at a specific location in the hash_set can be found
    // by using a dereferenced iterator addressing the location
    hs1_AcIter = hs1.begin( );
    hs1_RcIter = hs1.upper_bound( *hs1_AcIter );
    cout << "The first element of hs1 with a key greater than "
         << endl << "that of the initial element of hs1 is: "
         << *hs1_RcIter << "." << endl;
}
```

```
The first element of hash_set hs1 with a key greater than 20 is: 30.
The hash_set hs1 doesn't have an element with a key greater than 30.
The first element of hs1 with a key greater than
that of the initial element of hs1 is: 20.
```

hash_set::value_comp

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Retrieves a copy of the comparison object used to order element values in a `hash_set`.

```
value_compare value_comp() const;
```

Return Value

Returns the function object that a `hash_set` uses to order its elements, which is the template parameter *Compare*.

For more information on *Compare*, see the Remarks section of the [hash_set Class](#) topic.

Remarks

The stored object defines the member function:

```
bool operator( const Key& _xVal, const Key& _yVal );
```

which returns **true** if `_xVal` precedes and is not equal to `_yval` in the sort order.

Note that both [value_compare](#) and [key_compare](#) are synonyms for the template parameter *Compare*. Both types are provided for the `hash_set` and `hash_multiset` classes, where they are identical, for compatibility with the `hash_map` and `hash_multimap` classes, where they are distinct.

Example

```

// hash_set_value_comp.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;

    hash_set <int, hash_compare < int, less<int> > > hs1;
    hash_set <int, hash_compare < int, less<int> > >::value_compare
        vc1 = hs1.value_comp( );
    bool result1 = vc1( 2, 3 );
    if( result1 == true )
    {
        cout << "vc1( 2,3 ) returns value of true, "
            << "where vc1 is the function object of hs1."
            << endl;
    }
    else
    {
        cout << "vc1( 2,3 ) returns value of false, "
            << "where vc1 is the function object of hs1."
            << endl;
    }

    hash_set <int, hash_compare < int, greater<int> > > hs2;
    hash_set<int, hash_compare < int, greater<int> > >::value_compare
        vc2 = hs2.value_comp( );
    bool result2 = vc2( 2, 3 );
    if( result2 == true )
    {
        cout << "vc2( 2,3 ) returns value of true, "
            << "where vc2 is the function object of hs2."
            << endl;
    }
    else
    {
        cout << "vc2( 2,3 ) returns value of false, "
            << "where vc2 is the function object of hs2."
            << endl;
    }
}

```

hash_set::value_compare

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that provides two function objects, a binary predicate of class compare that can compare two element values of a hash_set to determine their relative order and a unary predicate that hashes the elements.

```
typedef key_compare value_compare;
```

Remarks

`value_compare` is a synonym for the template parameter *Traits*.

For more information on *Traits* see the [hash_set Class](#) topic.

Note that both [key_compare](#) and `value_compare` are synonyms for the template parameter *Traits*. Both types are provided for the `hash_set` and `hash_multiset` classes, where they are identical, for compatibility with the `hash_map` and `hash_multimap` classes, where they are distinct.

Example

See the example for [value_comp](#) for an example of how to declare and use `value_compare`.

hash_set::value_type

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

A type that describes an object stored as an element of a `hash_set` in its capacity as a value.

```
typedef Key value_type;
```

Example

```
// hash_set_value_type.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1;
    hash_set <int>::iterator hs1_Iter;

    hash_set <int> :: value_type hsvt_Int;  // Declare value_type
    hsvt_Int = 10;                        // Initialize value_type

    hash_set <int> :: key_type hskt_Int;    // Declare key_type
    hskt_Int = 20;                        // Initialize key_type

    hs1.insert( hsvt_Int );                // Insert value into hs1
    hs1.insert( hskt_Int );                // Insert key into hs1

    // A hash_set accepts key_types or value_types as elements
    cout << "The hash_set has elements:";
    for ( hs1_Iter = hs1.begin( ) ; hs1_Iter != hs1.end( ); hs1_Iter++)
        cout << " " << *hs1_Iter;
    cout << "." << endl;
}
```

```
The hash_set has elements: 10 20.
```

hash_multiset Class

11/14/2018 • 50 minutes to read • [Edit Online](#)

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

The container class `hash_multiset` is an extension of the C++ Standard Library and is used for the storage and fast retrieval of data from a collection in which the values of the elements contained serve as the key values and are not required to be unique.

Syntax

```
template <class Key, class Traits =hash_compare<Key, less<Key>>, class Allocator =allocator<Key>>
class hash_multiset
```

Parameters

Key

The element data type to be stored in the `hash_multiset`.

Traits

The type which includes two function objects, one of class `compare` that is a binary predicate able to compare two element values as sort keys to determine their relative order and a hash function that is a unary predicate mapping key values of the elements to unsigned integers of type `size_t`. This argument is optional, and the

`hash_compare<Key, less<Key>>` is the default value.

Allocator

The type that represents the stored allocator object that encapsulates details about the `hash_multiset`'s allocation and deallocation of memory. This argument is optional, and the default value is `allocator<Key>`.

Remarks

The `hash_multiset` is:

- An associative container, which is a variable size container that supports the efficient retrieval of element values based on an associated key value. Further, it is a simple associative container because its element values are its key values.
- Reversible, because it provides a bidirectional iterator to access its elements.
- Hashed, because its elements are grouped into buckets based on the value of a hash function applied to the key values of the elements.
- Unique in the sense that each of its elements must have a unique key. Because `hash_multiset` is also a simple associative container, its elements are also unique.
- A template class because the functionality it provides is generic and so independent of the specific type of data contained as elements or keys. The data types to be used for elements and keys are, instead, specified as parameters in the class template along with the comparison function and allocator.

The main advantage of hashing over sorting is greater efficiency: a successful hashing performs insertions,

deletions, and finds in constant average time as compared with a time proportional to the logarithm of the number of elements in the container for sorting techniques. The value of an element in a set may not be changed directly. Instead, you must delete old values and insert elements with new values.

The choice of container type should be based in general on the type of searching and inserting required by the application. Hashed associative containers are optimized for the operations of lookup, insertion and removal. The member functions that explicitly support these operations are efficient when used with a well-designed hash function, performing them in a time that is on average constant and not dependent on the number of elements in the container. A well-designed hash function produces a uniform distribution of hashed values and minimizes the number of collisions, where a collision is said to occur when distinct key values are mapped into the same hashed value. In the worst case, with the worst possible hash function, the number of operations is proportional to the number of elements in the sequence (linear time).

The `hash_multiset` should be the associative container of choice when the conditions associating the values with their keys are satisfied by the application. The elements of a `hash_multiset` may be multiple and serve as their own sort keys, so keys are not unique. A model for this type of structure is an ordered list of, say, words in which the words may occur more than once. Had multiple occurrences of the words not been allowed, then a `hash_set` would have been the appropriate container structure. If unique definitions were attached as values to the list of unique keywords, then a `hash_map` would be an appropriate structure to contain this data. If instead the definitions were not unique, then a `hash_multimap` would be the container of choice.

The `hash_multiset` orders the sequence it controls by calling a stored hash traits object of type `value_compare`. This stored object may be accessed by calling the member function `key_comp`. Such a function object must behave the same as an object of class `hash_compare<Key, less<Key> >`. Specifically, for all values `Key` of type `Key`, the call `Trait(Key)` yields a distribution of values of type `size_t`.

In general, the elements need be merely less than comparable to establish this order: so that, given any two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. On a more technical note, the comparison function is a binary predicate that induces a strict weak ordering in the standard mathematical sense. A binary predicate $f(x, y)$ is a function object that has two argument objects x and y and a return value of true or false. An ordering imposed on a `hash_multiset` is a strict weak ordering if the binary predicate is irreflexive, antisymmetric, and transitive and if equivalence is transitive, where two objects x and y are defined to be equivalent when both $f(x, y)$ and $f(y, x)$ are false. If the stronger condition of equality between keys replaces that of equivalence, then the ordering becomes total (in the sense that all the elements are ordered with respect to each other) and the keys matched will be indiscernible from each other.

The actual order of elements in the controlled sequence depends on the hash function, the ordering function, and the current size of the hash table stored in the container object. You cannot determine the current size of the hash table, so you cannot in general predict the order of elements in the controlled sequence. Inserting elements invalidates no iterators, and removing elements invalidates only those iterators that had specifically pointed at the removed elements.

The iterator provided by the `hash_multiset` class is a bidirectional iterator, but the class member functions `insert` and `hash_multiset` have versions that take as template parameters a weaker input iterator, whose functionality requirements are more minimal than those guaranteed by the class of bidirectional iterators. The different iterator concepts form a family related by refinements in their functionality. Each iterator concept has its own `hash_multiset` of requirements, and the algorithms that work with them must limit their assumptions to the requirements provided by that type of iterator. It may be assumed that an input iterator may be dereferenced to refer to some object and that it may be incremented to the next iterator in the sequence. This is a minimal `hash_multiset` of functionality, but it is enough to be able to talk meaningfully about a range of iterators [`first`, `last`) in the context of the class member functions.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>hash_multiset</code>	Constructs a <code>hash_multiset</code> that is empty or that is a copy of all or part of some other <code>hash_multiset</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>allocator_type</code>	A type that represents the <code>allocator</code> class for the <code>hash_multiset</code> object.
<code>const_iterator</code>	A type that provides a bidirectional iterator that can read a const element in the <code>hash_multiset</code> .
<code>const_pointer</code>	A type that provides a pointer to a const element in a <code>hash_multiset</code> .
<code>const_reference</code>	A type that provides a reference to a const element stored in a <code>hash_multiset</code> for reading and performing const operations.
<code>const_reverse_iterator</code>	A type that provides a bidirectional iterator that can read any const element in the <code>hash_multiset</code> .
<code>difference_type</code>	A signed integer type that provides the difference between two iterators that address elements within the same <code>hash_multiset</code> .
<code>iterator</code>	A type that provides a bidirectional iterator that can read or modify any element in a <code>hash_multiset</code> .
<code>key_compare</code>	A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the <code>hash_multiset</code> .
<code>key_type</code>	A type that describes an object stored as an element of a <code>hash_set</code> in its capacity as sort key.
<code>pointer</code>	A type that provides a pointer to an element in a <code>hash_multiset</code> .
<code>reference</code>	A type that provides a reference to an element stored in a <code>hash_multiset</code> .
<code>reverse_iterator</code>	A type that provides a bidirectional iterator that can read or modify an element in a reversed <code>hash_multiset</code> .
<code>size_type</code>	An unsigned integer type that can represent the number of elements in a <code>hash_multiset</code> .
<code>value_compare</code>	A type that provides two function objects, a binary predicate of class <code>compare</code> that can compare two element values of a <code>hash_multiset</code> to determine their relative order and a unary predicate that hashes the elements.

TYPE NAME	DESCRIPTION
<code>value_type</code>	A type that describes an object stored as an element of a <code>hash_multiset</code> in its capacity as a value.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>begin</code>	Returns an iterator that addresses the first element in the <code>hash_multiset</code> .
<code>cbegin</code>	Returns a const iterator addressing the first element in the <code>hash_multiset</code> .
<code>cend</code>	Returns a const iterator that addresses the location succeeding the last element in a <code>hash_multiset</code> .
<code>clear</code>	Erases all the elements of a <code>hash_multiset</code> .
<code>count</code>	Returns the number of elements in a <code>hash_multiset</code> whose key matches a parameter-specified key
<code>crbegin</code>	Returns a const iterator addressing the first element in a reversed <code>hash_multiset</code> .
<code>crend</code>	Returns a const iterator that addresses the location succeeding the last element in a reversed <code>hash_multiset</code> .
<code>emplace</code>	Inserts an element constructed in place into a <code>hash_multiset</code> .
<code>emplace_hint</code>	Inserts an element constructed in place into a <code>hash_multiset</code> , with a placement hint.
<code>empty</code>	Tests if a <code>hash_multiset</code> is empty.
<code>end</code>	Returns an iterator that addresses the location succeeding the last element in a <code>hash_multiset</code> .
<code>equal_range</code>	Returns a pair of iterators respectively to the first element in a <code>hash_multiset</code> with a key that is greater than a specified key and to the first element in the <code>hash_multiset</code> with a key that is equal to or greater than the key.
<code>erase</code>	Removes an element or a range of elements in a <code>hash_multiset</code> from specified positions or removes elements that match a specified key.
<code>find</code>	Returns an iterator addressing the location of an element in a <code>hash_multiset</code> that has a key equivalent to a specified key.
<code>get_allocator</code>	Returns a copy of the <code>allocator</code> object used to construct the <code>hash_multiset</code> .

MEMBER FUNCTION	DESCRIPTION
insert	Inserts an element or a range of elements into a <code>hash_multiset</code> .
key_comp	Retrieves a copy of the comparison object used to order keys in a <code>hash_multiset</code> .
lower_bound	Returns an iterator to the first element in a <code>hash_multiset</code> with a key that is equal to or greater than a specified key.
max_size	Returns the maximum length of the <code>hash_multiset</code> .
rbegin	Returns an iterator addressing the first element in a reversed <code>hash_multiset</code> .
rend	Returns an iterator that addresses the location succeeding the last element in a reversed <code>hash_multiset</code> .
size	Returns the number of elements in the <code>hash_multiset</code> .
swap	Exchanges the elements of two <code>hash_multiset</code> s.
upper_bound	Returns an iterator to the first element in a <code>hash_multiset</code> that with a key that is equal to or greater than a specified key.
value_comp	Retrieves a copy of the hash traits object used to hash and order element key values in a <code>hash_multiset</code> .

Operators

OPERATOR	DESCRIPTION
hash_multiset::operator=	Replaces the elements of the <code>hash_multiset</code> with a copy of another <code>hash_multiset</code> .

Requirements

Header: `<hash_set>`

Namespace: `stdext`

`hash_multiset::allocator_type`

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that represents the allocator class for the `hash_multiset` object.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::allocator_type allocator_type;
```

Example

See example for [get_allocator](#) for an example using `allocator_type`

hash_multiset::begin

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns an iterator that addresses the first element in the hash_multiset.

```
const_iterator begin() const;

iterator begin();
```

Return Value

A bidirectional iterator addressing the first element in the hash_multiset or the location succeeding an empty hash_multiset.

Remarks

If the return value of `begin` is assigned to a `const_iterator`, the elements in the hash_multiset object cannot be modified. If the return value of `begin` is assigned to an `iterator`, the elements in the hash_multiset object can be modified.

Example

```
// hash_multiset_begin.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;
    hash_multiset <int>::iterator hms1_Iter;
    hash_multiset <int>::const_iterator hms1_cIter;

    hms1.insert( 1 );
    hms1.insert( 2 );
    hms1.insert( 3 );

    hms1_Iter = hms1.begin( );
    cout << "The first element of hms1 is " << *hms1_Iter << endl;

    hms1_Iter = hms1.begin( );
    hms1.erase( hms1_Iter );

    // The following 2 lines would err because the iterator is const
    // hms1_cIter = hms1.begin( );
    // hms1.erase( hms1_cIter );

    hms1_cIter = hms1.begin( );
    cout << "The first element of hms1 is now " << *hms1_cIter << endl;
}
```

```
The first element of hms1 is 1
The first element of hms1 is now 2
```

hash_multiset::cbegin

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns a const iterator that addresses the first element in the hash_multiset.

```
const_iterator cbegin() const;
```

Return Value

A const bidirectional iterator addressing the first element in the [hash_multiset](#) or the location succeeding an empty `hash_multiset`.

Remarks

With the return value of `cbegin`, the elements in the `hash_multiset` object cannot be modified.

Example

```
// hash_multiset_cbegin.cpp
// compile with: /EHsc
#include <hash_multiset>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hs1;
    hash_multiset <int>::const_iterator hs1_cIter;

    hs1.insert( 1 );
    hs1.insert( 2 );
    hs1.insert( 3 );

    hs1_cIter = hs1.cbegin( );
    cout << "The first element of hs1 is " << *hs1_cIter << endl;
}
```

```
The first element of hs1 is 1
```

hash_multiset::cend

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns a const iterator that addresses the location succeeding the last element in a hash_multiset.

```
const_iterator cend() const;
```

Return Value

A const bidirectional iterator that addresses the location succeeding the last element in a [hash_multiset](#). If the `hash_multiset` is empty, then `hash_multiset::cend == hash_multiset::begin`.

Remarks

`cend` is used to test whether an iterator has reached the end of its `hash_multiset`. The value returned by `cend` should not be dereferenced.

Example

```
// hash_multiset_cend.cpp
// compile with: /EHsc
#include <hash_multiset>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hs1;
    hash_multiset <int> :: const_iterator hs1_cIter;

    hs1.insert( 1 );
    hs1.insert( 2 );
    hs1.insert( 3 );

    hs1_cIter = hs1.cend( );
    hs1_cIter--;
    cout << "The last element of hs1 is " << *hs1_cIter << endl;
}
```

```
The last element of hs1 is 3
```

hash_multiset::clear

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Erases all the elements of a `hash_multiset`.

```
void clear();
```

Remarks

Example

```
// hash_multiset_clear.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;

    hms1.insert( 1 );
    hms1.insert( 2 );

    cout << "The size of the hash_multiset is initially " << hms1.size( )
        << "." << endl;

    hms1.clear( );
    cout << "The size of the hash_multiset after clearing is "
        << hms1.size( ) << "." << endl;
}
```

```
The size of the hash_multiset is initially 2.
The size of the hash_multiset after clearing is 0.
```

hash_multiset::const_iterator

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides a bidirectional iterator that can read a **const** element in the hash_multiset.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::const_iterator const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

Example

See example for [begin](#) for an example using `const_iterator`.

hash_multiset::const_pointer

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides a pointer to a **const** element in a hash_multiset.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element.

In most cases, a [const_iterator](#) should be used to access the elements in a **const** hash_multiset object.

hash_multiset::const_reference

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides a reference to a **const** element stored in a hash_multiset for reading and performing **const** operations.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::const_reference
const_reference;
```

Remarks

Example

```
// hash_multiset_const_reference.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;

    hms1.insert( 10 );
    hms1.insert( 20 );

    // Declare and initialize a const_reference &Ref1
    // to the 1st element
    const int &Ref1 = *hms1.begin( );

    cout << "The first element in the hash_multiset is "
         << Ref1 << "." << endl;

    // The following line would cause an error because the
    // const_reference cannot be used to modify the hash_multiset
    // Ref1 = Ref1 + 5;
}
```

```
The first element in the hash_multiset is 10.
```

hash_multiset::const_reverse_iterator

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides a bidirectional iterator that can read any **const** element in the hash_multiset.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::const_reverse_iterator
const_reverse_iterator;
```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is use to iterate through the `hash_multiset` in reverse.

Example

See the example for [rend](#) for an example of how to declare and use the `const_reverse_iterator`.

hash_multiset::count

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns the number of elements in a `hash_multiset` whose key matches a parameter-specified key.

```
size_type count(const Key& key) const;
```

Parameters

key

The key of the elements to be matched from the `hash_multiset`.

Return Value

The number of elements in the `hash_multiset` with the parameter-specified key.

Remarks

The member function returns the number of elements in the following range:

[`lower_bound(key)`, `upper_bound(key)`).

Example

The following example demonstrates the use of the `hash_multiset::count` member function.

```

// hash_multiset_count.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset<int> hms1;
    hash_multiset<int>::size_type i;

    hms1.insert(1);
    hms1.insert(1);

    // Keys do not need to be unique in hash_multiset,
    // so duplicates may exist.
    i = hms1.count(1);
    cout << "The number of elements in hms1 with a sort key of 1 is: "
         << i << "." << endl;

    i = hms1.count(2);
    cout << "The number of elements in hms1 with a sort key of 2 is: "
         << i << "." << endl;
}

```

```

The number of elements in hms1 with a sort key of 1 is: 2.
The number of elements in hms1 with a sort key of 2 is: 0.

```

hash_multiset::crbegin

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns a const iterator addressing the first element in a reversed hash_multiset.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse bidirectional iterator addressing the first element in a reversed [hash_multiset](#) or addressing what had been the last element in the unreversed `hash_multiset`.

Remarks

`crbegin` is used with a reversed `hash_multiset` just as [hash_multiset::begin](#) is used with a `hash_multiset`.

With the return value of `crbegin`, the `hash_multiset` object cannot be modified.

`crbegin` can be used to iterate through a `hash_multiset` backwards.

Example

```
// hash_multiset_crbegin.cpp
// compile with: /EHsc
#include <hash_multiset>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hs1;
    hash_multiset <int>::const_reverse_iterator hs1_crIter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );

    hs1_crIter = hs1.crbegin( );
    cout << "The first element in the reversed hash_multiset is "
         << *hs1_crIter << "." << endl;
}
```

The first element in the reversed hash_multiset is 30.

hash_multiset::crend

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns a const iterator that addresses the location succeeding the last element in a reversed hash_multiset.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse bidirectional iterator that addresses the location succeeding the last element in a reversed [hash_multiset](#) (the location that had preceded the first element in the unreversed `hash_multiset`).

Remarks

`crend` is used with a reversed `hash_multiset` just as [hash_multiset::end](#) is used with a `hash_multiset`.

With the return value of `crend`, the `hash_multiset` object cannot be modified.

`crend` can be used to test to whether a reverse iterator has reached the end of its hash_multiset.

Example

```
// hash_multiset_crend.cpp
// compile with: /EHsc
#include <hash_multiset>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hs1;
    hash_multiset <int>::const_reverse_iterator hs1_crIter;

    hs1.insert( 10 );
    hs1.insert( 20 );
    hs1.insert( 30 );

    hs1_crIter = hs1.crend( );
    hs1_crIter--;
    cout << "The last element in the reversed hash_multiset is "
         << *hs1_crIter << "." << endl;
}
```

The last element in the reversed hash_multiset is 10.

hash_multiset::difference_type

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A signed integer type that provides the difference between two iterators that address elements within the same hash_multiset.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::difference_type
difference_type;
```

Remarks

The `difference_type` is the type returned when subtracting or incrementing through iterators of the container.

The `difference_type` is typically used to represent the number of elements in the range [`first`, `last`) between the iterators `first` and `last`, includes the element pointed to by `first` and the range of elements up to, but not including, the element pointed to by `last`.

Note that although `difference_type` is available for all iterators that satisfy the requirements of an input iterator, which includes the class of bidirectional iterators supported by reversible containers such as set. Subtraction between iterators is only supported by random-access iterators provided by a random-access container such as vector or deque.

Example

```

// hash_multiset_diff_type.cpp
// compile with: /EHsc
#include <iostream>
#include <hash_set>
#include <algorithm>

int main( )
{
    using namespace std;
    using namespace stdext;

    hash_multiset <int> hms1;
    hash_multiset <int>::iterator hms1_iter, hms1_bIter, hms1_eIter;

    hms1.insert( 20 );
    hms1.insert( 10 );

    // hash_multiset elements need not be unique
    hms1.insert( 20 );

    hms1_bIter = hms1.begin( );
    hms1_eIter = hms1.end( );

    hash_multiset <int>::difference_type df_typ5, df_typ10,
        df_typ20;

    df_typ5 = count( hms1_bIter, hms1_eIter, 5 );
    df_typ10 = count( hms1_bIter, hms1_eIter, 10 );
    df_typ20 = count( hms1_bIter, hms1_eIter, 20 );

    // The keys & hence the elements of a hash_multiset
    // need not be unique and may occur multiple times
    cout << "The number '5' occurs " << df_typ5
        << " times in hash_multiset hms1.\n";
    cout << "The number '10' occurs " << df_typ10
        << " times in hash_multiset hms1.\n";
    cout << "The number '20' occurs " << df_typ20
        << " times in hash_multiset hms1.\n";

    // Count the number of elements in a hash_multiset
    hash_multiset <int>::difference_type df_count = 0;
    hms1_iter = hms1.begin( );
    while ( hms1_iter != hms1_eIter)
    {
        df_count++;
        hms1_iter++;
    }

    cout << "The number of elements in the hash_multiset hms1 is "
        << df_count << "." << endl;
}

```

The number '5' occurs 0 times in hash_multiset hms1.
 The number '10' occurs 1 times in hash_multiset hms1.
 The number '20' occurs 2 times in hash_multiset hms1.
 The number of elements in the hash_multiset hms1 is 3.

hash_multiset::emplace

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Inserts an element constructed in place into a `hash_multiset`.

```
template <class ValTy>
iterator insert(ValTy&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value of an element to be inserted into the hash_multiset unless the <code>hash_multiset</code> already contains that element or, more generally, an element whose key is equivalently ordered.

Return Value

The `emplace` member function returns an iterator that points to the position where the new element was inserted.

Remarks

Example

```
// hash_multiset_emplace.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset<string> hms3;
    string str1("a");

    hms3.emplace(move(str1));
    cout << "After the emplace insertion, hms3 contains "
         << *hms3.begin() << "." << endl;
}
```

After the `emplace` insertion, `hms3` contains `a`.

hash_multiset::emplace_hint

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Inserts an element constructed in place into a `hash_multiset`, with a placement hint.

```
template <class ValTy>
iterator insert(
    const_iterator _where,
    ValTy&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The value of an element to be inserted into the hash_multiset unless the <code>hash_multiset</code> already contains that element or, more generally, an element whose key is equivalently ordered.
<i>_Where</i>	The place to start searching for the correct point of insertion. (Insertion can occur in amortized constant time, instead of logarithmic time, if the insertion point immediately follows <i>_Where</i> .)

Return Value

The [hash_multiset::emplace](#) member function returns an iterator that points to the position where the new element was inserted into the `hash_multiset`.

Remarks

Insertion can occur in amortized constant time, instead of logarithmic time, if the insertion point immediately follows *_Where*.

Example

```
// hash_multiset_emplace_hint.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset<string> hms1;
    string str1("a");

    hms1.insert(hms1.begin(), move(str1));
    cout << "After the emplace insertion, hms1 contains "
         << *hms1.begin() << "." << endl;
}
```

After the emplace insertion, hms1 contains a.

hash_multiset::empty

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Tests if a `hash_multiset` is empty.

```
bool empty() const;
```

Return Value

true if the hash_multiset is empty; **false** if the hash_multiset is nonempty.

Remarks

Example

```
// hash_multiset_empty.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1, hms2;
    hms1.insert ( 1 );

    if ( hms1.empty( ) )
        cout << "The hash_multiset hms1 is empty." << endl;
    else
        cout << "The hash_multiset hms1 is not empty." << endl;

    if ( hms2.empty( ) )
        cout << "The hash_multiset hms2 is empty." << endl;
    else
        cout << "The hash_multiset hms2 is not empty." << endl;
}
```

```
The hash_multiset hms1 is not empty.
The hash_multiset hms2 is empty.
```

hash_multiset::end

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns an iterator that addresses the location succeeding the last element in a hash_multiset.

```
const_iterator end() const;

iterator end();
```

Return Value

A bidirectional iterator that addresses the location succeeding the last element in a hash_multiset. If the hash_multiset is empty, then hash_multiset::end == hash_multiset::begin.

Remarks

`end` is used to test whether an iterator has reached the end of its hash_multiset. The value returned by `end` should not be dereferenced.

Example

```

// hash_multiset_end.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;
    hash_multiset <int> :: iterator hms1_Iter;
    hash_multiset <int> :: const_iterator hms1_cIter;

    hms1.insert( 1 );
    hms1.insert( 2 );
    hms1.insert( 3 );

    hms1_Iter = hms1.end( );
    hms1_Iter--;
    cout << "The last element of hms1 is " << *hms1_Iter << endl;

    hms1.erase( hms1_Iter );

    // The following 3 lines would err because the iterator is const
    // hms1_cIter = hms1.end( );
    // hms1_cIter--;
    // hms1.erase( hms1_cIter );

    hms1_cIter = hms1.end( );
    hms1_cIter--;
    cout << "The last element of hms1 is now " << *hms1_cIter << endl;
}

```

```

The last element of hms1 is 3
The last element of hms1 is now 2

```

hash_multiset::equal_range

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns a pair of iterators respectively to the first element in a hash_multiset with a key that is greater than a specified key and to the first element in the hash_multiset with a key that is equal to or greater than the key.

```

pair <const_iterator, const_iterator> equal_range (const Key& key) const;

pair <iterator, iterator> equal_range (const Key& key);

```

Parameters

key

The argument key to be compared with the sort key of an element from the hash_multiset being searched.

Return Value

A pair of iterators where the first is the [lower_bound](#) of the key and the second is the [upper_bound](#) of the key.

To access the first iterator of a pair `pr` returned by the member function, use `pr.first` and to dereference the

lower bound iterator, use `*(pr.first)`. To access the second iterator of a pair `pr` returned by the member function, use `pr.second` and to dereference the upper bound iterator, use `*(pr.second)`.

Example

```
// hash_multiset_equal_range.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    typedef hash_multiset<int> IntHSet;
    IntHSet hms1;
    hash_multiset <int> :: const_iterator hms1_RcIter;

    hms1.insert( 10 );
    hms1.insert( 20 );
    hms1.insert( 30 );

    pair <IntHSet::const_iterator, IntHSet::const_iterator> p1, p2;
    p1 = hms1.equal_range( 20 );

    cout << "The upper bound of the element with "
         << "a key of 20\nin the hash_multiset hms1 is: "
         << *(p1.second) << "." << endl;

    cout << "The lower bound of the element with "
         << "a key of 20\nin the hash_multiset hms1 is: "
         << *(p1.first) << "." << endl;

    // Compare the upper_bound called directly
    hms1_RcIter = hms1.upper_bound( 20 );
    cout << "A direct call of upper_bound( 20 ) gives "
         << *hms1_RcIter << "," << endl
         << "matching the 2nd element of the pair"
         << " returned by equal_range( 20 )." << endl;

    p2 = hms1.equal_range( 40 );

    // If no match is found for the key,
    // both elements of the pair return end( )
    if ( ( p2.first == hms1.end( ) )
        && ( p2.second == hms1.end( ) ) )
        cout << "The hash_multiset hms1 doesn't have an element "
             << "with a key less than 40." << endl;
    else
        cout << "The element of hash_multiset hms1"
             << "with a key >= 40 is: "
             << *(p1.first) << "." << endl;
}
```

The upper bound of the element with a key of 20
in the hash_multiset hms1 is: 30.
The lower bound of the element with a key of 20
in the hash_multiset hms1 is: 20.
A direct call of upper_bound(20) gives 30,
matching the 2nd element of the pair returned by equal_range(20).
The hash_multiset hms1 doesn't have an element with a key less than 40.

hash_multiset::erase

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Removes an element or a range of elements in a `hash_multiset` from specified positions or removes elements that match a specified key.

```
iterator erase(iterator _Where);

iterator erase(iterator first, iterator last);

size_type erase(const key_type& key);
```

Parameters

_Where

Position of the element to be removed from the `hash_multiset`.

first

Position of the first element removed from the `hash_multiset`.

last

Position just beyond the last element removed from the `hash_multiset`.

key

The key of the elements to be removed from the `hash_multiset`.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or a pointer to the end of the `hash_multiset` if no such element exists. For the third member function, the number of elements that have been removed from the `hash_multiset`.

Remarks

The member functions never throw an exception.

Example

The following example demonstrates the use of the `hash_multiset::erase` member function.

```
// hash_multiset_erase.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main()
{
    using namespace std;
    using namespace stdext;
    hash_multiset<int> hms1, hms2, hms3;
    hash_multiset<int> :: iterator pIter, Iter1, Iter2;
    int i;
    hash_multiset<int>::size_type n;

    for (i = 1; i < 5; i++)
    {
        hms1.insert(i);
        hms2.insert(i * i);
        hms3.insert(i - 1);
    }

    // The 1st member function removes an element at a given position
```

```

Iter1 = ++hms1.begin();
hms1.erase(Iter1);

cout << "After the 2nd element is deleted,\n"
      << "the hash_multiset hms1 is:" ;
for (pIter = hms1.begin(); pIter != hms1.end(); pIter++)
    cout << " " << *pIter;
cout << "." << endl;

// The 2nd member function removes elements
// in the range [ first, last)
Iter1 = ++hms2.begin();
Iter2 = --hms2.end();
hms2.erase(Iter1, Iter2);

cout << "After the middle two elements are deleted,\n"
      << "the hash_multiset hms2 is:" ;
for (pIter = hms2.begin(); pIter != hms2.end(); pIter++)
    cout << " " << *pIter;
cout << "." << endl;

// The 3rd member function removes elements with a given key
n = hms3.erase(2);

cout << "After the element with a key of 2 is deleted,\n"
      << "the hash_multiset hms3 is:" ;
for (pIter = hms3.begin(); pIter != hms3.end(); pIter++)
    cout << " " << *pIter;
cout << "." << endl;

// The 3rd member function returns the number of elements removed
cout << "The number of elements removed from hms3 is: "
      << n << "." << endl;

// The dereferenced iterator can also be used to specify a key
Iter1 = ++hms3.begin();
hms3.erase(Iter1);

cout << "After another element with a key "
      << "equal to that of the 2nd element\n"
      << "is deleted, the hash_multiset hms3 is:" ;
for (pIter = hms3.begin(); pIter != hms3.end(); pIter++)
    cout << " " << *pIter;
cout << "." << endl;
}

```

```

After the 2nd element is deleted,
the hash_multiset hms1 is: 1 3 4.
After the middle two elements are deleted,
the hash_multiset hms2 is: 16 4.
After the element with a key of 2 is deleted,
the hash_multiset hms3 is: 0 1 3.
The number of elements removed from hms3 is: 1.
After another element with a key equal to that of the 2nd element
is deleted, the hash_multiset hms3 is: 0 3.

```

hash_multiset::find

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns an iterator addressing the location of an element in a hash_multiset that has a key equivalent to a

specified key.

```
iterator find(const Key& key);  
  
const_iterator find(const Key& key) const;
```

Parameters

key

The argument key to be matched by the sort key of an element from the hash_multiset being searched.

Return Value

An [iterator](#) or [const_iterator](#) that addresses the location of an element equivalent to a specified key or that addresses the location succeeding the last element in the hash_multiset if no match is found for the key.

Remarks

The member function returns an iterator that addresses an element in the hash_multiset whose sort key is [equivalent](#) to the argument key under a binary predicate that induces an ordering based on a less-than comparability relation.

If the return value of [find](#) is assigned to a [const_iterator](#), the hash_multiset object cannot be modified. If the return value of [find](#) is assigned to an [iterator](#), the hash_multiset object can be modified.

Example

```

// hash_multiset_find.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;
    hash_multiset <int> :: const_iterator hms1_AcIter, hms1_RcIter;

    hms1.insert( 10 );
    hms1.insert( 20 );
    hms1.insert( 30 );

    hms1_RcIter = hms1.find( 20 );
    cout << "The element of hash_multiset hms1 with a key of 20 is: "
         << *hms1_RcIter << "." << endl;

    hms1_RcIter = hms1.find( 40 );

    // If no match is found for the key, end( ) is returned
    if ( hms1_RcIter == hms1.end( ) )
        cout << "The hash_multiset hms1 doesn't have an element "
             << "with a key of 40." << endl;
    else
        cout << "The element of hash_multiset hms1 with a key of 40 is: "
             << *hms1_RcIter << "." << endl;

    // The element at a specific location in the hash_multiset can be found
    // by using a dereferenced iterator addressing the location
    hms1_AcIter = hms1.end( );
    hms1_AcIter--;
    hms1_RcIter = hms1.find( *hms1_AcIter );
    cout << "The element of hms1 with a key matching "
         << "that of the last element is: "
         << *hms1_RcIter << "." << endl;
}

```

```

The element of hash_multiset hms1 with a key of 20 is: 20.
The hash_multiset hms1 doesn't have an element with a key of 40.
The element of hms1 with a key matching that of the last element is: 30.

```

hash_multiset::get_allocator

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns a copy of the allocator object used to construct the hash_multiset.

```
Allocator get_allocator() const;
```

Return Value

The allocator used by the hash_multiset to manage memory, which is the class's template parameter `Allocator`.

For more information on `Allocator`, see the Remarks section of the [hash_multiset Class](#) topic.

Remarks

Allocators for the `hash_multiset` class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```
// hash_multiset_get_allocator.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;

    // The following lines declare objects
    // that use the default allocator.
    hash_multiset <int, hash_compare <int, less<int> > > hms1;
    hash_multiset <int, hash_compare <int, greater<int> > > hms2;
    hash_multiset <double, hash_compare <double,
        less<double> >, allocator<double> > hms3;

    hash_multiset <int, hash_compare <int,
        greater<int> > >::allocator_type hms2_Alloc;
    hash_multiset <double>::allocator_type hms3_Alloc;
    hms2_Alloc = hms2.get_allocator( );

    cout << "The number of integers that can be allocated"
        << endl << "before free memory is exhausted: "
        << hms1.max_size( ) << "." << endl;

    cout << "The number of doubles that can be allocated"
        << endl << "before free memory is exhausted: "
        << hms3.max_size( ) << "." << endl;

    // The following lines create a hash_multiset hms4
    // with the allocator of hash_multiset hms1.
    hash_multiset <int>::allocator_type hms4_Alloc;
    hash_multiset <int> hms4;
    hms4_Alloc = hms2.get_allocator( );

    // Two allocators are interchangeable if
    // storage allocated from each can be
    // deallocated by the other
    if( hms2_Alloc == hms4_Alloc )
    {
        cout << "The allocators are interchangeable."
            << endl;
    }
    else
    {
        cout << "The allocators are not interchangeable."
            << endl;
    }
}
```

`hash_multiset::hash_multiset`

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Constructs a `hash_multiset` that is empty or that is a copy of all or part of some other `hash_multiset`.

```
hash_multiset();

explicit hash_multiset(
    const Traits& Comp);

hash_multiset(
    const Traits& Comp,
    const Allocator& Al);

hash_multiset(
    const hash_multiset<Key, Traits, Allocator>& Right);

hash_multiset(
    hash_multiset&& Right
);
hash_multiset (initializer_list<Type> IList);

hash_multiset(
    initializer_list<Tu[e> IList, const Compare& Comp):
hash_multiset(
    initializer_list<Type> IList, const Compare& Comp, const Allocator& Al);

template <class InputIterator>
hash_multiset(
    InputIterator First,
    InputIterator Last);

template <class InputIterator>
hash_multiset(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp);

template <class InputIterator>
hash_multiset(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp,
    const Allocator& Al);
```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The storage allocator class to be used for this <code>hash_multiset</code> object, which defaults to <code>Allocator</code> .
<i>Comp</i>	The comparison function of type <code>const Traits</code> used to order the elements in the <code>hash_multiset</code> , which defaults to <code>hash_compare</code> .
<i>Right</i>	The <code>hash_multiset</code> of which the constructed <code>hash_multiset</code> is to be a copy.

PARAMETER	DESCRIPTION
<i>First</i>	The position of the first element in the range of elements to be copied.
<i>Last</i>	The position of the first element beyond the range of elements to be copied.
<i>lList</i>	The initializer_list that contains the elements to be copied.

Remarks

All constructors store a type of allocator object that manages memory storage for the `hash_multiset` and that can later be returned by calling `hash_multiset::get_allocator`. The allocator parameter is often omitted in the class declarations and preprocessing macros used to substitute alternative allocators.

All constructors initialize their `hash_multisets`.

All constructors store a function object of type `Traits` that is used to establish an order among the keys of the `hash_multiset` and that can later be returned by calling `hash_multiset::key_comp`. For more information on `Traits` see the [hash_multiset Class](#) topic.

The first three constructors specify an empty initial `hash_multiset`, the second specifying the type of comparison function (*Comp*) to be used in establishing the order of the elements and the third explicitly specifying the allocator type (*Al*) to be used. The keyword **explicit** suppresses certain kinds of automatic type conversion.

The fourth constructor moves the `hash_multiset` `Right`.

The fifth, sixth, and seventh constructors use an `initializer_list`.

The last three constructors copy the range [`First`, `Last`) of a `hash_multiset` with increasing explicitness in specifying the type of comparison function of class `Compare` and allocator.

The actual order of elements in a hashed set container depends on the hash function, the ordering function and the current size of the hash table and cannot, in general, be predicted as it could with the set container, where it was determined by the ordering function alone.

hash_multiset::insert

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Inserts an element or a range of elements into a `hash_multiset`.

```

iterator insert(
    const Type& Val);

iterator insert(
    iterator Where,
    const Type& Al);

void insert(
    initializer_list<Type> IList);

iterator insert(
    const Type& Val);

iterator insert(
    Iterator Where,
    const Type& Val);

template <class InputIterator>
void insert(
    InputIterator First,
    InputIterator Last);

template <class ValTy>
iterator insert(
    ValTy&& Val);

template <class ValTy>
iterator insert(
    const_iterator Where,
    ValTy&& Val);

```

Parameters

PARAMETER	DESCRIPTION
<i>Val</i>	The value of an element to be inserted into the hash_multiset unless the hash_multiset already contains that element or, more generally, an element whose key is equivalently ordered.
<i>Where</i>	The place to start searching for the correct point of insertion. (Insertion can occur in amortized constant time, instead of logarithmic time, if the insertion point immediately follows <code>_where</code> .)
<i>First</i>	The position of the first element to be copied from a hash_multiset.
<i>Last</i>	The position just beyond the last element to be copied from a hash_multiset.
<i>IList</i>	The initializer_list that contains the elements to copy.

Return Value

The first two insert member functions return an iterator that points to the position where the new element was inserted.

The next three member functions use an initializer_list.

The third member function inserts the sequence of element values into a hash_multiset corresponding to each element addressed by an iterator of in the range [`First` , `Last`) of a specified hash_multiset.

Remarks

Insertion can occur in amortized constant time for the hint version of `insert`, instead of logarithmic time, if the insertion point immediately follows *Where*.

hash_multiset::iterator

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides a bidirectional iterator that can read or modify any element in a `hash_multiset`.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::iterator iterator;
```

Remarks

A type `iterator` can be used to modify the value of an element.

Example

See example for [begin](#) for an example of how to declare and use `iterator`.

hash_multiset::key_comp

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Retrieves a copy of the comparison object used to order keys in a `hash_multiset`.

```
key_compare key_comp() const;
```

Return Value

Returns the `hash_multiset` template parameter *Traits*, which contains function objects that are used to hash and to order the elements of the container.

For more information on *Traits* see the [hash_multiset Class](#) topic.

Remarks

The stored object defines a member function:

```
bool operator( const Key& _xVal, const Key& _yVal );
```

which returns **true** if `_xVal` precedes and is not equal to `_yVal` in the sort order.

Note that both [key_compare](#) and [value_compare](#) are synonyms for the template parameter *Traits*. Both types are provided for the `hash_multiset` and `hash_multiset` classes, where they are identical, for compatibility with the `hash_map` and `hash_multimap` classes, where they are distinct.

Example

```

// hash_multiset_key_comp.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;

    hash_multiset <int, hash_compare < int, less<int> > >hms1;
    hash_multiset<int, hash_compare < int, less<int> > >::key_compare kc1
        = hms1.key_comp( ) ;
    bool result1 = kc1( 2, 3 ) ;
    if( result1 == true )
    {
        cout << "kc1( 2,3 ) returns value of true, "
            << "where kc1 is the function object of hms1."
            << endl;
    }
    else
    {
        cout << "kc1( 2,3 ) returns value of false "
            << "where kc1 is the function object of hms1."
            << endl;
    }

    hash_multiset <int, hash_compare < int, greater<int> > > hms2;
    hash_multiset<int, hash_compare < int, greater<int> > >::key_compare
        kc2 = hms2.key_comp( ) ;
    bool result2 = kc2( 2, 3 ) ;
    if( result2 == true )
    {
        cout << "kc2( 2,3 ) returns value of true, "
            << "where kc2 is the function object of hms2."
            << endl;
    }
    else
    {
        cout << "kc2( 2,3 ) returns value of false, "
            << "where kc2 is the function object of hms2."
            << endl;
    }
}

```

hash_multiset::key_compare

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides two function objects, a binary predicate of class compare that can compare two element values of a hash_multiset to determine their relative order and a unary predicate that hashes the elements.

```
typedef Traits key_compare;
```

Remarks

`key_compare` is a synonym for the template parameter *Traits*.

For more information on *Traits* see the [hash_multiset Class](#) topic.

Note that both `key_compare` and `value_compare` are synonyms for the template parameter *Traits*. Both types are provided for the `hash_set` and `hash_multiset` classes, where they are identical, for compatibility with the `hash_map` and `hash_multimap` classes, where they are distinct.

Example

See example for [key_comp](#) for an example of how to declare and use `key_compare`.

hash_multiset::key_type

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides a function object that can compare sort keys to determine the relative order of two elements in the `hash_multiset`.

```
typedef Key key_type;
```

Remarks

`key_type` is a synonym for the template parameter *Key*.

Note that both `key_type` and `value_type` are synonyms for the template parameter *Key*. Both types are provided for the `set` and `multiset` classes, where they are identical, for compatibility with the `map` and `multimap` classes, where they are distinct.

For more information on *Key*, see the Remarks section of the [hash_multiset Class](#) topic.

Example

See example for [value_type](#) for an example of how to declare and use `key_type`.

hash_multiset::lower_bound

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns an iterator to the first element in a `hash_multiset` with a key that is equal to or greater than a specified key.

```
const_iterator lower_bound(const Key& key) const;  
  
iterator lower_bound(const Key& key);
```

Parameters

key

The argument key to be compared with the sort key of an element from the `hash_multiset` being searched.

Return Value

An [iterator](#) or [const_iterator](#) that addresses the location of the first element in a `hash_multiset` with a key that is equal to or greater than the argument key, or that addresses the location succeeding the last element in the `hash_multiset` if no match is found for the key.

Remarks

Example

```
// hash_multiset_lower_bound.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main() {
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;
    hash_multiset <int> :: const_iterator hms1_AcIter, hms1_RcIter;

    hms1.insert( 10 );
    hms1.insert( 20 );
    hms1.insert( 30 );

    hms1_RcIter = hms1.lower_bound( 20 );
    cout << "The element of hash_multiset hms1 with a key of 20 is: "
         << *hms1_RcIter << "." << endl;

    hms1_RcIter = hms1.lower_bound( 40 );

    // If no match is found for the key, end( ) is returned
    if ( hms1_RcIter == hms1.end( ) )
        cout << "The hash_multiset hms1 doesn't have an element "
             << "with a key of 40." << endl;
    else
        cout << "The element of hash_multiset hms1 with a key of 40 is: "
             << *hms1_RcIter << "." << endl;

    // An element at a specific location in the hash_multiset can be found
    // by using a dereferenced iterator that addresses the location
    hms1_AcIter = hms1.end( );
    hms1_AcIter--;
    hms1_RcIter = hms1.lower_bound( *hms1_AcIter );
    cout << "The element of hms1 with a key matching "
         << "that of the last element is: "
         << *hms1_RcIter << "." << endl;
}
```

hash_multiset::max_size

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns the maximum length of the hash_multiset.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the hash_multiset.

Remarks

Example

```

// hash_multiset_max_size.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;
    hash_multiset <int>::size_type i;

    i = hms1.max_size( );
    cout << "The maximum possible length "
         << "of the hash_multiset is " << i << "." << endl;
}

```

hash_multiset::operator=

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Replaces the elements of the hash_multiset with a copy of another hash_multiset.

```

hash_multiset& operator=(const hash_multiset& right);

hash_multiset& operator=(hash_multiset&& right);

```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The hash_multiset being copied into the <code>hash_multiset</code> .

Remarks

After erasing any existing elements in a `hash_multiset`, `operator=` either copies or moves the contents of *right* into the `hash_multiset`.

Example

```

// hash_multiset_operator_as.cpp
// compile with: /EHsc
#include <hash_multiset>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset<int> v1, v2, v3;
    hash_multiset<int>::iterator iter;

    v1.insert(10);

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << iter << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter << " ";
    cout << endl;
}

```

hash_multiset::pointer

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides a pointer to an element in a hash_multiset.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::pointer pointer;
```

Remarks

A type `pointer` can be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a multiset object.

hash_multiset::rbegin

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns an iterator addressing the first element in a reversed hash_multiset.

```
const_reverse_iterator rbegin() const;
```

```
reverse_iterator rbegin();
```

Return Value

A reverse bidirectional iterator addressing the first element in a reversed hash_multiset or addressing what had been the last element in the unreversed hash_multiset.

Remarks

`rbegin` is used with a reversed hash_multiset just as `begin` is used with a hash_multiset.

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, then the hash_multiset object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, then the hash_multiset object can be modified.

`rbegin` can be used to iterate through a hash_multiset backwards.

Example

```

// hash_multiset_rbegin.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;
    hash_multiset <int>::iterator hms1_Iter;
    hash_multiset <int>::reverse_iterator hms1_rIter;

    hms1.insert( 10 );
    hms1.insert( 20 );
    hms1.insert( 30 );

    hms1_rIter = hms1.rbegin( );
    cout << "The first element in the reversed hash_multiset is "
         << *hms1_rIter << "." << endl;

    // begin can be used to start an iteration
    // through a hash_multiset in a forward order
    cout << "The hash_multiset is: ";
    for ( hms1_Iter = hms1.begin( ) ; hms1_Iter != hms1.end( ) ;
          hms1_Iter++ )
        cout << *hms1_Iter << " ";
    cout << endl;

    // rbegin can be used to start an iteration
    // through a hash_multiset in a reverse order
    cout << "The reversed hash_multiset is: ";
    for ( hms1_rIter = hms1.rbegin( ) ; hms1_rIter != hms1.rend( ) ;
          hms1_rIter++ )
        cout << *hms1_rIter << " ";
    cout << endl;

    // A hash_multiset element can be erased by dereferencing to its key
    hms1_rIter = hms1.rbegin( );
    hms1.erase ( *hms1_rIter );

    hms1_rIter = hms1.rbegin( );
    cout << "After the erasure, the first element "
         << "in the reversed hash_multiset is "<< *hms1_rIter << "."
         << endl;
}

```

```

The first element in the reversed hash_multiset is 30.
The hash_multiset is: 10 20 30
The reversed hash_multiset is: 30 20 10
After the erasure, the first element in the reversed hash_multiset is 20.

```

hash_multiset::reference

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides a reference to an element stored in a hash_multiset.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::reference reference;
```

Remarks

Example

```
// hash_multiset_reference.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;

    hms1.insert( 10 );
    hms1.insert( 20 );

    // Declare and initialize a reference &Ref1 to the 1st element
    int &Ref1 = *hms1.begin( );

    cout << "The first element in the hash_multiset is "
         << Ref1 << "." << endl;

    // The value of the 1st element of the hash_multiset can be
    // changed by operating on its (non const) reference
    Ref1 = Ref1 + 5;

    cout << "The first element in the hash_multiset is now "
         << *hms1.begin() << "." << endl;
}
```

```
The first element in the hash_multiset is 10.
The first element in the hash_multiset is now 15.
```

hash_multiset::rend

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns an iterator that addresses the location succeeding the last element in a reversed hash_multiset.

```
const_reverse_iterator rend() const;

reverse_iterator rend();
```

Return Value

A reverse bidirectional iterator that addresses the location succeeding the last element in a reversed hash_multiset (the location that had preceded the first element in the unreversed hash_multiset).

Remarks

`rend` is used with a reversed hash_multiset just as `end` is used with a hash_multiset.

If the return value of `rend` is assigned to a `const_reverse_iterator`, then the `hash_multiset` object cannot be modified. If the return value of `rend` is assigned to a `reverse_iterator`, then the `hash_multiset` object can be modified. The value returned by `rend` should not be dereferenced.

`rend` can be used to test to whether a reverse iterator has reached the end of its `hash_multiset`.

Example

```
// hash_multiset_rend.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;
    hash_multiset <int>::iterator hms1_Iter;
    hash_multiset <int>::reverse_iterator hms1_rIter;
    hash_multiset <int>::const_reverse_iterator hms1_crIter;

    hms1.insert( 10 );
    hms1.insert( 20 );
    hms1.insert( 30 );

    hms1_rIter = hms1.rend( );
    hms1_rIter--;
    cout << "The last element in the reversed hash_multiset is "
         << *hms1_rIter << "." << endl;

    // end can be used to terminate an iteration
    // through a hash_multiset in a forward order
    cout << "The hash_multiset is: ";
    for ( hms1_Iter = hms1.begin( ) ; hms1_Iter != hms1.end( ) ;
          hms1_Iter++ )
        cout << *hms1_Iter << " ";
    cout << "." << endl;

    // rend can be used to terminate an iteration
    // through a hash_multiset in a reverse order
    cout << "The reversed hash_multiset is: ";
    for ( hms1_rIter = hms1.rbegin( ) ; hms1_rIter != hms1.rend( ) ;
          hms1_rIter++ )
        cout << *hms1_rIter << " ";
    cout << "." << endl;

    hms1_rIter = hms1.rend( );
    hms1_rIter--;
    hms1.erase ( *hms1_rIter );

    hms1_rIter = hms1.rend( );
    hms1_rIter--;
    cout << "After the erasure, the last element in the "
         << "reversed hash_multiset is " << *hms1_rIter << "."
         << endl;
}
```

The last element in the reversed hash_multiset is 10.
The hash_multiset is: 10 20 30 .
The reversed hash_multiset is: 30 20 10 .
After the erasure, the last element in the reversed hash_multiset is 20.

hash_multiset::reverse_iterator

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides a bidirectional iterator that can read or modify an element in a reversed hash_multiset.

```
typedef list<typename Traits::value_type, typename Traits::allocator_type>::reverse_iterator
reverse_iterator;
```

Remarks

A type `reverse_iterator` is use to iterate through the hash_multiset in reverse.

Example

See example for [rbegin](#) for an example of how to declare and use `reverse_iterator`.

hash_multiset::size

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns the number of elements in the hash_multiset.

```
size_type size() const;
```

Return Value

The current length of the hash_multiset.

Remarks

Example

```
// hash_multiset_size.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;
    hash_multiset <int> :: size_type i;

    hms1.insert( 1 );
    i = hms1.size( );
    cout << "The hash_multiset length is " << i << "." << endl;

    hms1.insert( 2 );
    i = hms1.size( );
    cout << "The hash_multiset length is now " << i << "." << endl;
}
```

```
The hash_multiset length is 1.  
The hash_multiset length is now 2.
```

hash_multiset::size_type

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

An unsigned integer type that can represent the number of elements in a hash_multiset.

```
typedef list<typename _Traits::value_type, typename _Traits::allocator_type>::size_type size_type;
```

Remarks

Example

See example for [size](#) for an example of how to declare and use `size_type`

hash_multiset::swap

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Exchanges the elements of two hash_multisets.

```
void swap(hash_multiset& right);
```

Parameters

right

The argument hash_multiset providing the elements to be swapped with the target hash_multiset.

Remarks

The member function invalidates no references, pointers, or iterators that designate elements in the two hash_multisets whose elements are being exchanged.

Example

```

// hash_multiset_swap.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1, hms2, hms3;
    hash_multiset <int>::iterator hms1_Iter;

    hms1.insert( 10 );
    hms1.insert( 20 );
    hms1.insert( 30 );
    hms2.insert( 100 );
    hms2.insert( 200 );
    hms3.insert( 300 );

    cout << "The original hash_multiset hms1 is:";
    for ( hms1_Iter = hms1.begin( ); hms1_Iter != hms1.end( );
          hms1_Iter++ )
        cout << " " << *hms1_Iter;
    cout << "." << endl;

    // This is the member function version of swap
    hms1.swap( hms2 );

    cout << "After swapping with hms2, list hms1 is:";
    for ( hms1_Iter = hms1.begin( ); hms1_Iter != hms1.end( );
          hms1_Iter++ )
        cout << " " << *hms1_Iter;
    cout << "." << endl;

    // This is the specialized template version of swap
    swap( hms1, hms3 );

    cout << "After swapping with hms3, list hms1 is:";
    for ( hms1_Iter = hms1.begin( ); hms1_Iter != hms1.end( );
          hms1_Iter++ )
        cout << " " << *hms1_Iter;
    cout << "." << endl;
}

```

The original hash_multiset hms1 is: 10 20 30.
 After swapping with hms2, list hms1 is: 200 100.
 After swapping with hms3, list hms1 is: 300.

hash_multiset::upper_bound

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Returns an iterator to the first element in a hash_multiset with a key that is greater than a specified key.

```

const_iterator upper_bound(const Key& key) const;

iterator upper_bound(const Key& key);

```

Parameters

key

The argument key to be compared with the sort key of an element from the hash_multiset being searched.

Return Value

An [iterator](#) or [const_iterator](#) that addresses the location of the first element in a hash_multiset with a key greater than the argument key, or that addresses the location succeeding the last element in the hash_multiset if no match is found for the key.

Remarks

Example

```
// hash_multiset_upper_bound.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;
    hash_multiset <int> :: const_iterator hms1_AcIter, hms1_RcIter;

    hms1.insert( 10 );
    hms1.insert( 20 );
    hms1.insert( 30 );

    hms1_RcIter = hms1.upper_bound( 20 );
    cout << "The first element of hash_multiset hms1" << endl
         << "with a key greater than 20 is: "
         << *hms1_RcIter << "." << endl;

    hms1_RcIter = hms1.upper_bound( 30 );

    // If no match is found for the key, end( ) is returned
    if ( hms1_RcIter == hms1.end( ) )
        cout << "The hash_multiset hms1 doesn't have an element\n"
             << "with a key greater than 30." << endl;
    else
        cout << "The element of hash_multiset hms1"
             << "with a key > 40 is: "
             << *hms1_RcIter << "." << endl;

    // An element at a specific location in the hash_multiset can be
    // found by using a dereferenced iterator addressing the location
    hms1_AcIter = hms1.begin( );
    hms1_RcIter = hms1.upper_bound( *hms1_AcIter );
    cout << "The first element of hms1 with a key greater than "
         << endl << "that of the initial element of hms1 is: "
         << *hms1_RcIter << "." << endl;
}
```

```
The first element of hash_multiset hms1
with a key greater than 20 is: 30.
The hash_multiset hms1 doesn't have an element
with a key greater than 30.
The first element of hms1 with a key greater than
that of the initial element of hms1 is: 20.
```

hash_multiset::value_comp

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

Retrieves a copy of the comparison object used to order element values in a `hash_multiset`.

```
value_compare value_comp() const;
```

Return Value

Returns the `hash_multiset` template parameter *Traits*, which contains function objects that are used to hash and to order elements of the container.

For more information on *Traits* see the [hash_multiset Class](#) topic.

Remarks

The stored object defines a member function:

```
bool operator( constKey& _xVal , const Key& _yVal);
```

which returns **true** if `_xVal` precedes and is not equal to `_yVal` in the sort order.

Note that both [key_compare](#) and [value_compare](#) are synonyms for the template parameter *Traits*. Both types are provided for the `hash_multiset` and `hash_multiset` classes, where they are identical, for compatibility with the `hash_map` and `hash_multimap` classes, where they are distinct.

Example

```

// hash_multiset_value_comp.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;

    hash_multiset <int, hash_compare < int, less<int> > > hms1;
    hash_multiset <int, hash_compare < int, less<int> > >::value_compare
        vc1 = hms1.value_comp( );
    bool result1 = vc1( 2, 3 );
    if( result1 == true )
    {
        cout << "vc1( 2,3 ) returns value of true, "
            << "where vc1 is the function object of hms1."
            << endl;
    }
    else
    {
        cout << "vc1( 2,3 ) returns value of false, "
            << "where vc1 is the function object of hms1."
            << endl;
    }

    hash_multiset <int, hash_compare < int, greater<int> > > hms2;
    hash_multiset<int, hash_compare < int, greater<int> > >::
        value_compare vc2 = hms2.value_comp( );
    bool result2 = vc2( 2, 3 );
    if( result2 == true )
    {
        cout << "vc2( 2,3 ) returns value of true, "
            << "where vc2 is the function object of hms2."
            << endl;
    }
    else
    {
        cout << "vc2( 2,3 ) returns value of false, "
            << "where vc2 is the function object of hms2."
            << endl;
    }
}

```

```

vc1( 2,3 ) returns value of true, where vc1 is the function object of hms1.
vc2( 2,3 ) returns value of false, where vc2 is the function object of hms2.

```

hash_multiset::value_compare

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that provides two function objects, a binary predicate of class compare that can compare two element values of a hash_multiset to determine their relative order and a unary predicate that hashes the elements.

```
typedef key_compare value_compare;
```

Remarks

`value_compare` is a synonym for the template parameter *Traits*.

For more information on *Traits* see the [hash_multiset Class](#) topic.

Note that both [key_compare](#) and `value_compare` are synonyms for the template parameter *Traits*. Both types are provided for the classes `set` and `multiset`, where they are identical, for compatibility with the classes `map` and `multimap`, where they are distinct.

Example

See example for [value_comp](#) for an example of how to declare and use `value_compare`.

hash_multiset::value_type

NOTE

This API is obsolete. The alternative is [unordered_multiset Class](#).

A type that describes an object stored as an element as a `hash_multiset` in its capacity as a value.

```
typedef Key value_type;
```

Example

```
// hash_multiset_value_type.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hms1;
    hash_multiset <int>::iterator hms1_Iter;

    // Declare value_type
    hash_multiset <int> :: value_type hmsvt_Int;

    hmsvt_Int = 10;    // Initialize value_type

    // Declare key_type
    hash_multiset <int> :: key_type hmskt_Int;
    hmskt_Int = 20;    // Initialize key_type

    hms1.insert( hmsvt_Int );    // Insert value into s1
    hms1.insert( hmskt_Int );    // Insert key into s1

    // A hash_multiset accepts key_types or value_types as elements
    cout << "The hash_multiset has elements:";
    for ( hms1_Iter = hms1.begin() ; hms1_Iter != hms1.end( );
          hms1_Iter++)
        cout << " " << *hms1_Iter;
    cout << "." << endl;
}
```

```
The hash_multiset has elements: 10 20.
```

<hash_set> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

swap

swap (hash_multiset)

swap

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Exchanges the elements of two hash_sets.

```
void swap(  
    hash_set <Key, Traits, Allocator>& left,  
    hash_set <Key, Traits, Allocator>& right);
```

Parameters

right

The hash_set providing the elements to be swapped, or the hash_set whose elements are to be exchanged with those of the hash_set *left*.

left

The hash_set whose elements are to be exchanged with those of the hash_set *right*.

Remarks

The `swap` template function is an algorithm specialized on the container class `hash_set` to execute the member function `left.swap(right)`. This is an instance of the partial ordering of function templates by the compiler. When template functions are overloaded in such a way that the match of the template with the function call is not unique, then the compiler will select the most specialized version of the template function. The general version of the template function

template <class T> void swap(T&, T&),

in the algorithm class works by assignment and is a slow operation. The specialized version in each container is much faster as it can work with the internal representation of the container class.

Example

See the code example for the member class [hash_set::swap](#) for an example that uses the template version of `swap`.

swap (hash_multiset)

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Exchanges the elements of two hash_multisets.

```
void swap(hash_multiset <Key, Traits, Allocator>& left, hash_multiset <Key, Traits, Allocator>& right);
```

Parameters

right

The hash_multiset providing the elements to be swapped, or the hash_multiset whose elements are to be exchanged with those of the hash_multiset *left*.

left

The hash_multiset whose elements are to be exchanged with those of the hash_multiset *right*.

Remarks

The `swap` template function is an algorithm specialized on the container class `hash_multiset` to execute the member function `left.swap(right)`. This is an instance of the partial ordering of function templates by the compiler. When template functions are overloaded in such a way that the match of the template with the function call is not unique, then the compiler will select the most specialized version of the template function. The general version of the template function

template <class T> void swap(T&, T&),

in the algorithm class works by assignment and is a slow operation. The specialized version in each container is much faster as it can work with the internal representation of the container class.

Example

See the code example for the member class `hash_multiset::swap` for an example that uses the template version of `swap`.

<hash_set> operators

3/28/2019 • 4 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator!= (hash_multiset)</code>	<code>operator==</code>
<code>operator== (hash_multiset)</code>		

operator!=

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Tests if the `hash_set` object on the left side of the operator is not equal to the `hash_set` object on the right side.

```
bool operator!=(const hash_set <Key, Traits, Allocator>& left, const hash_set <Key, Traits, Allocator>& right);
```

Parameters

left

An object of type `hash_set`.

right

An object of type `hash_set`.

Return Value

true if the `hash_sets` are not equal; **false** if `hash_sets` are equal.

Remarks

The comparison between `hash_set` objects is based on a pairwise comparison between their elements. Two `hash_sets` are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Members of the `<hash_map>` and `<hash_set>` header files are in the [stdext Namespace](#).

Example

```

// hash_set_op_ne.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> hs1, hs2, hs3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        hs1.insert ( i );
        hs2.insert ( i * i );
        hs3.insert ( i );
    }

    if ( hs1 != hs2 )
        cout << "The hash_sets hs1 and hs2 are not equal." << endl;
    else
        cout << "The hash_sets hs1 and hs2 are equal." << endl;

    if ( hs1 != hs3 )
        cout << "The hash_sets hs1 and hs3 are not equal." << endl;
    else
        cout << "The hash_sets hs1 and hs3 are equal." << endl;
}

```

The hash_sets hs1 and hs2 are not equal.
The hash_sets hs1 and hs3 are equal.

operator==

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Tests if the hash_set object on the left side of the operator is equal to the hash_set object on the right side.

```

bool operator!=(const hash_set <Key, Traits, Allocator>& left, const hash_set <Key, Traits, Allocator>&
right);

```

Parameters

left

An object of type `hash_set`.

right

An object of type `hash_set`.

Return Value

true if the hash_set on the left side of the operator is equal to the hash_set on the right side of the operator;
otherwise **false**.

Remarks

The comparison between hash_set objects is based on a pairwise comparison of their elements. Two hash_sets are

equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// hash_set_op_eq.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_set <int> s1, s2, s3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i );
    }

    if ( s1 == s2 )
        cout << "The hash_sets s1 and s2 are equal." << endl;
    else
        cout << "The hash_sets s1 and s2 are not equal." << endl;

    if ( s1 == s3 )
        cout << "The hash_sets s1 and s3 are equal." << endl;
    else
        cout << "The hash_sets s1 and s3 are not equal." << endl;
}
```

```
The hash_sets s1 and s2 are not equal.
The hash_sets s1 and s3 are equal.
```

operator!= (hash_multiset)

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Tests if the hash_multiset object on the left side of the operator is not equal to the hash_multiset object on the right side.

```
bool operator!=(const hash_multiset <Key, Traits, Allocator>& left, const hash_multiset <Key, Traits,
Allocator>& right);
```

Parameters

left

An object of type `hash_multiset`.

right

An object of type `hash_multiset`.

Return Value

true if the hash_multisets are not equal; **false** if hash_multisets are equal.

Remarks

The comparison between hash_multiset objects is based on a pairwise comparison between their elements. Two hash_multisets are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// hashset_op_ne.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset <int> hs1, hs2, hs3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        hs1.insert ( i );
        hs2.insert ( i * i );
        hs3.insert ( i );
    }

    if ( hs1 != hs2 )
        cout << "The hash_multisets hs1 and hs2 are not equal." << endl;
    else
        cout << "The hash_multisets hs1 and hs2 are equal." << endl;

    if ( hs1 != hs3 )
        cout << "The hash_multisets hs1 and hs3 are not equal." << endl;
    else
        cout << "The hash_multisets hs1 and hs3 are equal." << endl;
}
```

```
The hash_multisets hs1 and hs2 are not equal.
The hash_multisets hs1 and hs3 are equal.
```

operator== (hash_multiset)

NOTE

This API is obsolete. The alternative is [unordered_set Class](#).

Tests if the hash_multiset object on the left side of the operator is equal to the hash_multiset object on the right side.

```
bool operator!=(const hash_multiset <Key, Traits, Allocator>& left, const hash_multiset <Key, Traits,
Allocator>& right);
```

Parameters

left

An object of type `hash_multiset`.

right

An object of type `hash_multiset`.

Return Value

true if the `hash_multiset` on the left side of the operator is equal to the `hash_multiset` on the right side of the operator; otherwise **false**.

Remarks

The comparison between `hash_multiset` objects is based on a pairwise comparison of their elements. Two `hash_multisets` are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// hash_multiset_op_eq.cpp
// compile with: /EHsc
#include <hash_set>
#include <iostream>

int main( )
{
    using namespace std;
    using namespace stdext;
    hash_multiset<int> s1, s2, s3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i );
    }

    if ( s1 == s2 )
        cout << "The hash_multisets s1 and s2 are equal." << endl;
    else
        cout << "The hash_multisets s1 and s2 are not equal." << endl;

    if ( s1 == s3 )
        cout << "The hash_multisets s1 and s2 are equal." << endl;
    else
        cout << "The hash_multisets s1 and s2 are not equal." << endl;
}
```

```
The hash_multisets s1 and s2 are not equal.
The hash_multisets s1 and s2 are equal.
```

<initializer_list>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template class `initializer_list` and several supporting templates.

Syntax

```
#include <initializer_list>
```

Classes

CLASS	DESCRIPTION
initializer_list	Provides access to an array of elements in which each member is of the specified type.

See also

[Header Files Reference](#)

initializer_list Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Provides access to an array of elements in which each member is of the specified type.

Syntax

```
template <class Type>
class initializer_list
```

Parameters

PARAMETER	DESCRIPTION
<i>Type</i>	The element data type to be stored in the <code>initializer_list</code> .

Remarks

An `initializer_list` can be constructed using a braced initializer list:

```
initializer_list<int> i1{ 1, 2, 3, 4 };
```

The compiler transforms braced initializer lists with homogeneous elements into an `initializer_list` whenever the function signature requires an `initializer_list`. For more details on using `initializer_list`, see [Uniform Initialization and Delegating Constructors](#)

Constructors

CONSTRUCTOR	DESCRIPTION
initializer_list	Constructs an object of type <code>initializer_list</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>value_type</code>	The type of the elements in the <code>initializer_list</code> .
<code>reference</code>	A type that provides a reference to an element in the <code>initializer_list</code> .
<code>const_reference</code>	A type that provides a constant reference to an element in the <code>initializer_list</code> .
<code>size_type</code>	A type that represents the number of elements in the <code>initializer_list</code> .
<code>iterator</code>	A type that provides an iterator for the <code>initializer_list</code> .

TYPE NAME	DESCRIPTION
const_iterator	A type that provides a constant iterator for the <code>initializer_list</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>begin</code>	Returns a pointer to the first element in an <code>initializer_list</code> .
<code>end</code>	Returns a pointer to one past the last element in an <code>initializer_list</code> .
<code>size</code>	Returns the number of elements in the <code>initializer_list</code> .

Requirements

Header: `<initializer_list>`

Namespace: `std`

`initializer_list::begin`

Returns a pointer to the first element in an `initializer_list`.

```
constexpr const InputIterator* begin() const noexcept;
```

Return Value

A pointer to the first element of the `initializer_list`. If the list is empty, the pointer is the same for the beginning and end of the list.

Remarks

`initializer_list::end`

Returns a pointer to one past the last element in an `initializer list`.

```
constexpr const InputIterator* end() const noexcept;
```

Return Value

A pointer to one past the last element in the list. If the list is empty, this is the same as the pointer to the first element in the list.

`initializer_list::initializer_list`

Constructs an object of type `initializer_list`.

```
constexpr initializer_list() noexcept;
initializer_list(const InputIterator First, const InputIterator Last);
```

Parameters

PARAMETER	DESCRIPTION
<i>First</i>	The position of the first element in the range of elements to be copied.
<i>Last</i>	The position of the first element beyond the range of elements to be copied.

Remarks

An `initializer_list` is based on an array of objects of the specified type. Copying an `initializer_list` creates a second instance of a list pointing to the same objects; the underlying objects are not copied.

Example

```

// initializer_list_class.cpp
// compile with: /EHsc
#include <initializer_list>
#include <iostream>

int main()
{
    using namespace std;
    // Create an empty initializer_list c0
    initializer_list<int> c0;

    // Create an initializer_list c1 with 1 element
    initializer_list<int> c1{ 3 };

    // Create an initializer_list c2 with 5 elements
    initializer_list<int> c2{ 5, 4, 3, 2, 1 };

    // Create a copy, initializer_list c3, of initializer_list c2
    initializer_list<int> c3(c2);

    // Create a initializer_list c4 by copying the range c3[ first, last)
    const int* c3_ptr = c3.begin();
    c3_ptr++;
    c3_ptr++;
    initializer_list<int> c4(c3.begin(), c3_ptr);

    // Move initializer_list c4 to initializer_list c5
    initializer_list<int> c5(move(c4));

    cout << "c1 =";
    for (auto c : c1)
        cout << " " << c;
    cout << endl;

    cout << "c2 =";
    for (auto c : c2)
        cout << " " << c;
    cout << endl;

    cout << "c3 =";
    for (auto c : c3)
        cout << " " << c;
    cout << endl;

    cout << "c4 =";
    for (auto c : c4)
        cout << " " << c;
    cout << endl;

    cout << "c5 =";
    for (auto c : c5)
        cout << " " << c;
    cout << endl;
}

```

c1 = 3 c2 = 5 4 3 2 1 c3 = 5 4 3 2 1 c4 = 5 4 c5 = 5 4

initializer_list::size

Returns the number of elements in the list.

```
constexpr size_t size() const noexcept;
```

Return Value

The number of elements in the list.

Remarks

See also

[<forward_list>](#)

<iomanip>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Include the `<iostreams>` standard header `<iomanip>` to define several manipulators that each take a single argument.

Syntax

```
#include <iomanip>
```

Remarks

Each of these manipulators returns an unspecified type, called `T1` through `T10`, that overloads both `basic_istream<Elem, Tr>::operator>>` and `basic_ostream<Elem, Tr>::operator<<`.

Manipulators

<code>get_money</code>	Obtains a monetary amount, optionally in international format.
<code>get_time</code>	Obtains a time in a time structure by using a specified format.
<code>put_money</code>	Provides a monetary amount, optionally in international format.
<code>put_time</code>	Provides a time in a time structure and a format string to use.
<code>quoted</code>	Enables convenient round-tripping of strings with insertion and extraction operators.
<code>resetiosflags</code>	Clears the specified flags.
<code>setbase</code>	Set base for integers.
<code>setfill</code>	Sets the character that will be used to fill spaces in a right-justified display.
<code>setiosflags</code>	Sets the specified flags.
<code>setprecision</code>	Sets the precision for floating-point values.
<code>setw</code>	Specifies the width of the display field.

[Thread Safety in the C++ Standard Library](#)

[iostream Programming](#)

<iomanip> functions

11/9/2018 • 11 minutes to read • [Edit Online](#)

get_money	get_time	put_money
put_time	quoted	resetiosflags
setbase	setfill	setiosflags
setprecision	setw	

get_money

Extracts a monetary value from a stream using the desired format, and returns the value in a parameter.

```
template <class Money>
T7 get_money(Money& _Amount, bool _Intl);
```

Parameters

_Amount

The extracted monetary value.

_Intl

If **true**, use international format. The default value is **false**.

Remarks

The manipulator returns an object that, when extracted from the stream `str`, behaves as a `formatted input function` that calls the member function `get` for the locale facet `money_get` associated with `str`, using *_Intl* to indicate international format. If successful, the call stores in *_Amount* the extracted monetary value. The manipulator then returns `str`.

`Money` must be of type `long double` or an instantiation of `basic_string` with the same element and traits parameters as `str`.

get_time

Extracts a time value from a stream using a desired format. Returns the value in a parameter as a time structure.

```
template <class Elem>
T10 put_time(struct tm *_Tptr, const Elem *_Fmt);
```

Parameters

_Tptr

The time in the form of a time structure.

_Fmt

The desired format to use to obtain the time value.

Remarks

The manipulator returns an object that, when extracted from the stream `str`, behaves as a `formatted input function` that calls the member function `get` for the locale facet `time_get` associated with `str`, using `tptr` to indicate the time structure and `fmt` to indicate the beginning of a null-terminated format string. If successful, the call stores in the time structure the values associated with any extracted time fields. The manipulator then returns `str`.

put_money

Inserts a monetary amount using the desired format into a stream.

```
template <class Money>
T& put_money(const Money& _Amount, bool _Intl);
```

Parameters

_Amount

The monetary amount to insert into the stream.

_Intl

Set to **true** if manipulator should use international format, **false** if it should not.

Return Value

Returns `str`.

Remarks

The manipulator returns an object that, when inserted into the stream `str`, behaves as a formatted output function that calls the member function `put` for the locale facet `money_put` associated with `str`. If successful, the call inserts `amount` suitably formatted, using `*_Intl` to indicate international format and `str.fill()`, as the fill element. The manipulator then returns `str`.

`Money` must be of type `long double` or an instantiation of `basic_string` with the same element and traits parameters as `str`.

put_time

Writes a time value from a time structure to a stream by using a specified format.

```
template <class Elem>
T10 put_time(struct tm* _Tptr, const Elem* _Fmt);
```

Parameters

_Tptr

The time value to write to the stream, provided in a time structure.

_Fmt

The desired format to write the time value.

Remarks

The manipulator returns an object that, when inserted into the stream `str`, behaves as a `formatted output function`. The output function calls the member function `put` for the locale facet `time_put` associated with `str`. The output function uses `_Tptr` to indicate the time structure and `_Fmt` to indicate the beginning of a null-terminated format string. If successful, the call inserts literal text from the format string and converted values from the time structure. The manipulator then returns `str`.

quoted

(New in C++14) An iostream manipulator that enables convenient round-tripping of strings into and out of streams using the >> and << operators.

```
quoted(std::string str) // or wstring
quoted(const char* str) //or wchar_t*
quoted(std::string str, char delimiter, char escape) // or wide versions
quoted(const char* str, char delimiter, char escape) // or wide versions
```

Parameters

str

A std::string, char*, string literal or raw string literal, or a wide version of any of these (e.g. std::wstring, wchar_t*).

delimiter

A user-specified character, or wide character, to use as the delimiter for the beginning and end of the string.

escape

A user-specified character, or wide character, to use as the escape character for escape sequences within the string.

Remarks

See [Using Insertion Operators and Controlling Format](#).

Example

This example shows how to use `quoted` with the default delimiter and escape character using narrow strings. Wide strings are equally supported.

```

#include <iostream>
#include <iomanip>
#include <sstream>

using namespace std;

void show_quoted_v_nonquoted()
{
    // Results are identical regardless of input string type:
    // string inserted { R"(This is a "sentence".)" }; // raw string literal
    // string inserted { "This is a \"sentence\"," }; // regular string literal
    const char* inserted = "This is a \"sentence\","; // const char*
    stringstream ss, ss_quoted;
    string extracted, extracted_quoted;

    ss << inserted;
    ss_quoted << quoted(inserted);

    cout << "ss.str() is storing      : " << ss.str() << endl;
    cout << "ss_quoted.str() is storing: " << ss_quoted.str() << endl << endl;

    // Round-trip the strings
    ss >> extracted;
    ss_quoted >> quoted(extracted_quoted);

    cout << "After round trip: " << endl;
    cout << "Non-quoted      : " << extracted << endl;
    cout << "Quoted          : " << extracted_quoted << endl;
}

void main(int argc, char* argv[])
{
    show_quoted_v_nonquoted();

    // Keep console window open in debug mode.
    cout << endl << "Press Enter to exit" << endl;
    string input{};
    getline(cin, input);
}

/* Output:
ss.str() is storing      : This is a "sentence".
ss_quoted.str() is storing: "This is a \"sentence\","

After round trip:
Non-quoted      : This
Quoted          : This is a "sentence".

Press Enter to exit
*/

```

Example

The following example shows how to provide custom a delimiter and/or escape character:

```

#include <iostream>
#include <iomanip>
#include <sstream>

using namespace std;

void show_custom_delimiter()
{
    string inserted{ R"(This" "is" "a" "heavily-quoted" "sentence".)" };
    // string inserted{ "\"This\" \"is\" \"a\" \"heavily-quoted\" \"sentence\"" };
    // const char* inserted{ "\"This\" \"is\" \"a\" \"heavily-quoted\" \"sentence\"" };
}

```

```

stringstream ss, ss_quoted;
string extracted;

ss_quoted << quoted(inserted, '*');
ss << inserted;
cout << "ss_quoted.str() is storing: " << ss_quoted.str() << endl;
cout << "ss.str() is storing      : " << ss.str() << endl << endl;

// Use the same quoted arguments as on insertion.
ss_quoted >> quoted(extracted, '*');

cout << "After round trip: " << endl;
cout << "Quoted      : " << extracted << endl;

extracted = {};
ss >> extracted;
cout << "Non-quoted   : " << extracted << endl << endl;
}

void show_custom_escape()
{
    string inserted{ R"(\root\trunk\branch\branch\egg\yolk)" };
    // string inserted{ R"(\root\trunk\trunk\branch\branch\egg\yolk)" };
    stringstream ss, ss_quoted, ss_quoted_custom;
    string extracted;

    // Use '"' as delimiter and '~' as escape character.
    ss_quoted_custom << quoted(inserted, '"', '~');
    ss_quoted << quoted(inserted);
    ss << inserted;
    cout << "ss_quoted_custom.str(): " << ss_quoted_custom.str() << endl;
    cout << "ss_quoted.str()      : " << ss_quoted.str() << endl;
    cout << "ss.str()          : " << ss.str() << endl << endl;

    // No spaces in this string, so non-quoted behaves same as quoted
    // after round-tripping.
}

void main(int argc, char* argv[])
{
    cout << "Custom delimiter:" << endl;
    show_custom_delimiter();
    cout << "Custom escape character:" << endl;
    show_custom_escape();

    // Keep console window open in debug mode.
    cout << endl << "Press Enter to exit" << endl;
    string input{};
    getline(cin, input);
}

/* Output:
Custom delimiter:
ss_quoted.str() is storing: *This is a heavily-quoted sentence.*
ss.str() is storing      : This is a heavily-quoted sentence.

After round trip:
Quoted      : This is a heavily-quoted sentence.
Non-quoted   : This

Custom escape character:
ss_quoted_custom.str(): "\\root\\trunk\\branch\\branch\\egg\\yolk"
ss_quoted.str()      : "\\root\\trunk\\trunk\\branch\\branch\\egg\\yolk"
ss.str()          : \\root\\trunk\\branch\\branch\\egg\\yolk

Press Enter to exit
*/

```

resetiosflags

Clears the specified flags.

```
T1 resetiosflags(ios_base::fmtflags Mask);
```

Parameters

Mask

The flags to clear.

Return Value

The manipulator returns an object that, when extracted from or inserted into the stream `str`, calls **str**. `setf(ios_base:: fmtflags, _Mask)`, and then returns `str`.

Example

See [setw](#) for an example of using `resetiosflags`.

setbase

Set base for integers.

```
T3 setbase(int _Base);
```

Parameters

_Base

The number base.

Return Value

The manipulator returns an object that, when extracted from or inserted into the stream `str`, calls **str**. `setf (mask, ios_base::basefield)`, and then returns `str`. Here, `mask` is determined as follows:

- If *_Base* is 8, then `mask` is `ios_base:: oct`.
- If *_Base* is 10, then `mask` is `ios_base:: dec`.
- If *_Base* is 16, then `mask` is `ios_base:: hex`.
- If *_Base* is any other value, then `mask` is `ios_base:: fmtflags(0)`.

Example

See [setw](#) for an example of using `setbase`.

setfill

Sets the character that will be used to fill spaces in a right-justified display.

```
template <class Elem>  
T4 setfill(Elem Ch);
```

Parameters

Ch

The character that will be used to fill spaces in a right-justified display.

Return Value

The template manipulator returns an object that, when extracted from or inserted into the stream `str`, calls **str**. [fill\(ch\)](#), and then returns `str`. The type `Elem` must be the same as the element type for the stream `str`.

Example

See [setw](#) for an example of using `setfill`.

setiosflags

Sets the specified flags.

```
T2 setiosflags(ios_base::fmtflags Mask);
```

Parameters

Mask

The flags to set.

Return Value

The manipulator returns an object that, when extracted from or inserted into the stream `str`, calls **str**. [setf\(_Mask\)](#), and then returns `str`.

Example

See [setw](#) for an example of using `setiosflags`.

setprecision

Sets the precision for floating-point values.

```
T5 setprecision(streamsize Prec);
```

Parameters

Prec

The precision for floating-point values.

Return Value

The manipulator returns an object that, when extracted from or inserted into the stream `str`, calls **str**. [precision\(Prec\)](#), and then returns `str`.

Example

See [setw](#) for an example of using `setprecision`.

setw

Specifies the width of the display field for the next element in the stream.

```
T6 setw(streamsize Wide);
```

Parameters

Wide

The width of the display field.

Return Value

The manipulator returns an object that, when extracted from or inserted into the stream `str`, calls `str.width(Wide)`, then returns `str`.

Remarks

`setw` sets the width only for the next element in the stream and must be inserted before each element whose width you want to specify.

Example

```
// iomanip_setw.cpp
// compile with: /EHsc
// Defines the entry point for the console application.
//
// Sample use of the following manipulators:
//  resetiosflags
//  setiosflags
//  setbase
//  setfill
//  setprecision
//  setw

#include <iostream>
#include <iomanip>

using namespace std;

const double  d1 = 1.23456789;
const double  d2 = 12.3456789;
const double  d3 = 123.456789;
const double  d4 = 1234.56789;
const double  d5 = 12345.6789;
const long    l1 = 16;
const long    l2 = 256;

[<iomanip>](#)

<ios>

11/9/2018 • 3 minutes to read • [Edit Online](#)

Defines several types and functions basic to the operation of iostreams. This header is typically included for you by another iostream headers; you rarely include it directly.

Syntax

```
#include <ios>
```

Remarks

A large group of functions are manipulators. A manipulator declared in <ios> alters the values stored in its argument object of class [ios_base](#). Other manipulators perform actions on streams controlled by objects of a type derived from this class, such as a specialization of one of the template classes [basic_istream](#) or [basic_ostream](#). For example, [noskipws\(str\)](#) clears the format flag `ios_base::skipws` in the object `str`, which can be of one of these types.

You can also call a manipulator by inserting it into an output stream or extracting it from an input stream, because of special insertion and extraction operations supplied for the classes derived from `ios_base`. For example:

```
istr>> noskipws;
```

calls [noskipws\(istr\)](#).

Typedefs

TYPE NAME	DESCRIPTION
ios	Supports the ios class from the old iostream library.
streamoff	Supports internal operations.
streampos	Holds the current position of the buffer pointer or file pointer.
streamsize	Specifies the size of the stream.
wios	Supports the wios class from the old iostream library.
wstreampos	Holds the current position of the buffer pointer or file pointer.

Manipulators

boolalpha	Specifies that variables of type bool appear as true or false in the stream.
dec	Specifies that integer variables appear in base 10 notation.

defaultfloat	Configures the flags of an <code>ios_base</code> object to use a default display format for float values.
fixed	Specifies that a floating-point number is displayed in fixed-decimal notation.
hex	Specifies that integer variables appear in base 16 notation.
internal	Causes a number's sign to be left justified and the number to be right justified.
left	Causes text that is not as wide as the output width to appear in the stream flush with the left margin.
noboolalpha	Specifies that variables of type <code>bool</code> appear as 1 or 0 in the stream.
noshowbase	Turns off indicating the notational base in which a number is displayed.
noshowpoint	Displays only the whole-number part of floating-point numbers whose fractional part is zero.
noshowpos	Causes positive numbers to not be explicitly signed.
noskipws	Cause spaces to be read by the input stream.
nounitbuf	Causes output to be buffered and processed when the buffer is full.
nouppercase	Specifies that hexadecimal digits and the exponent in scientific notation appear in lowercase.
oct	Specifies that integer variables appear in base 8 notation.
right	Causes text that is not as wide as the output width to appear in the stream flush with the right margin.
scientific	Causes floating point numbers to be displayed using scientific notation.
showbase	Indicates the notational base in which a number is displayed.
showpoint	Displays the whole-number part of a floating-point number and digits to the right of the decimal point even when the fractional part is zero.
showpos	Causes positive numbers to be explicitly signed.
skipws	Cause spaces to not be read by the input stream.
unitbuf	Causes output to be processed when the buffer is not empty.

uppercase	Specifies that hexadecimal digits and the exponent in scientific notation appear in uppercase.

Classes

CLASS	DESCRIPTION
basic_ios	The template class describes the storage and member functions common to both input streams (of template class basic_istream) and output streams (of template class basic_ostream) that depend on the template parameters.
fpos	The template class describes an object that can store all the information needed to restore an arbitrary file-position indicator within any stream.
ios_base	The class describes the storage and member functions common to both input and output streams that do not depend on the template parameters.

<ios> functions

11/9/2018 • 12 minutes to read • [Edit Online](#)

defaultfloat	boolalpha	dec
fixed	hex	internal
left	noboolalpha	noshowbase
noshowpoint	noshowpos	noskipws
nounitbuf	nouppercase	oct
right	scientific	showbase
showpoint	showpos	skipws
unitbuf	uppercase	

boolalpha

Specifies that variables of type `bool` appear as **true** or **false** in the stream.

```
ios_base& boolalpha(ios_base& str);
```

Parameters

str

A reference to an object of type `ios_base`, or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

By default, variables of type **bool** are displayed as 1 or 0.

`boolalpha` effectively calls `str.setf(ios_base::boolalpha)`, and then returns *str*.

`noboolalpha` reverses the effect of `boolalpha`.

Example

```
// ios_boolalpha.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    bool b = true;
    cout << b << endl;
    boolalpha( cout );
    cout << b << endl;
    noboolalpha( cout );
    cout << b << endl;
    cout << boolalpha << b << endl;
}
```

```
1
true
1
true
```

dec

Specifies that integer variables appear in base 10 notation.

```
ios_base& dec(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

By default, integer variables are displayed in base 10.

`dec` effectively calls `str.setf(ios_base::dec , ios_base::basefield)`, and then returns *str*.

Example

```
// ios_dec.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    int i = 100;

    cout << i << endl;    // Default is base 10
    cout << hex << i << endl;
    dec( cout );
    cout << i << endl;
    oct( cout );
    cout << i << endl;
    cout << dec << i << endl;
}
```

```
100
64
100
144
100
```

<ios> defaultfloat

Configures the flags of an `ios_base` object to use a default display format for float values.

```
ios_base& defaultfloat(ios_base& _Iosbase);
```

Parameters

_Iosbase

An `ios_base` object.

Remarks

The manipulator effectively calls `_Iosbase.ios_base::unsetf(ios_base::floatfield)`, then returns `_Iosbase`.

fixed

Specifies that a floating-point number is displayed in fixed-decimal notation.

```
ios_base& fixed(ios_base& str);
```

Parameters

str

A reference to an object of type `ios_base`, or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

`fixed` is the default display notation for floating-point numbers. `scientific` causes floating-point numbers to be displayed using scientific notation.

The manipulator effectively calls `str.setf(ios_base::fixed, ios_base::floatfield)`, and then returns `str`.

Example

```
// ios_fixed.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    float i = 1.1F;

    cout << i << endl;    // fixed is the default
    cout << scientific << i << endl;
    cout.precision( 1 );
    cout << fixed << i << endl;
}
```

```
1.1
1.100000e+000
1.1
```

hex

Specifies that integer variables shall appear in base 16 notation.

```
ios_base& hex(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

By default, integer variables are displayed in base 10 notation. [dec](#) and [oct](#) also change the way integer variables appear.

The manipulator effectively calls `str.setf(ios_base::hex, ios_base::basefield)`, and then returns *str*.

Example

See [dec](#) for an example of how to use `hex`.

internal

Causes a number's sign to be left justified and the number to be right justified.

```
ios_base& internal(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which *str* is derived.

Remarks

[showpos](#) causes the sign to display for positive numbers.

The manipulator effectively calls `str.setf(ios_base::internal, ios_base::adjustfield)`, and then returns *str*.

Example

```
// ios_internal.cpp
// compile with: /EHsc
#include <iostream>
#include <iomanip>

int main( void )
{
    using namespace std;
    float i = -123.456F;
    cout.fill( '.' );
    cout << setw( 10 ) << i << endl;
    cout << setw( 10 ) << internal << i << endl;
}
```

```
..-123.456
-..123.456
```

left

Causes text that is not as wide as the output width to appear in the stream flush with the left margin.

```
ios_base& left(ios_base& str);
```

Parameters

str

A reference to an object of type `ios_base`, or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

The manipulator effectively calls `str.setf(ios_base::left, ios_base::adjustfield)`, and then returns *str*.

Example

```
// ios_left.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    double f1= 5.00;
    cout.width( 20 );
    cout << f1 << endl;
    cout << left << f1 << endl;
}
```

```
5
5
```

noboolalpha

Specifies that variables of type `bool` appear as 1 or 0 in the stream.

```
ios_base& noboolalpha(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

By default, `noboolalpha` is in effect.

`noboolalpha` effectively calls `str.unsetf(ios_base::boolalpha)`, and then returns *str*.

[boolalpha](#) reverses the effect of `noboolalpha`.

Example

See [boolalpha](#) for an example of using `noboolalpha`.

noshowbase

Turns off indicating the notational base in which a number is displayed.

```
ios_base& noshowbase(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

`noshowbase` is on by default. Use [showbase](#) to indicate the notational base of numbers.

The manipulator effectively calls `str.unsetf(ios_base::showbase)`, and then returns *str*.

Example

See [showbase](#) for an example of how to use `noshowbase`.

noshowpoint

Displays only the whole-number part of floating-point numbers whose fractional part is zero.

```
ios_base& noshowpoint(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

`noshowpoint` is on by default; use [showpoint](#) and [precision](#) to display zeros after the decimal point.

The manipulator effectively calls `str.unsetf(ios_base::showpoint)`, and then returns *str*.

Example

```
// ios_noshowpoint.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    double f1= 5.000;
    cout << f1 << endl;    // noshowpoint is default
    cout.precision( 4 );
    cout << showpoint << f1 << endl;
    cout << noshowpoint << f1 << endl;
}
```

```
5
5.000
5
```

noshowpos

Causes positive numbers to not be explicitly signed.

```
ios_base& noshowpos(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which *_Str* is derived.

Remarks

`noshowpos` is on by default.

The manipulator effectively calls `str.unsetf(ios_base::showps)`, then returns *str*.

Example

See [showpos](#) for an example of using `noshowpos`.

noskipws

Cause spaces to be read by the input stream.

```
ios_base& noskipws(ios_base& str);
```

Parameters

str

A reference to an object of type `ios_base`, or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

By default, `skipws` is in effect. When a space is read in the input stream, it signals the end of the buffer.

The manipulator effectively calls `str.unsetf(ios_base::skipws)`, and then returns `str`.

Example

```
// ios_noskipws.cpp
// compile with: /EHsc
#include <iostream>
#include <string>

int main() {
    using namespace std;
    string s1, s2, s3;
    cout << "Enter three strings: ";
    cin >> noskipws >> s1 >> s2 >> s3;
    cout << "." << s1 << "." << endl;
    cout << "." << s2 << "." << endl;
    cout << "." << s3 << "." << endl;
}
```

nounitbuf

Causes output to be buffered and processed on when the buffer is full.

```
ios_base& nounitbuf(ios_base& str);
```

Parameters

str

A reference to an object of type `ios_base`, or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

`unitbuf` causes the buffer to be processed when it is not empty.

The manipulator effectively calls `str.unsetf(ios_base::unitbuf)`, and then returns `str`.

nouppercase

Specifies that hexadecimal digits and the exponent in scientific notation appear in lowercase.

```
ios_base& nouppercase(ios_base& str);
```

Parameters

str

A reference to an object of type `ios_base`, or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_ Str` is derived.

Remarks

The manipulator effectively calls `str.unsetf(ios_base::uppercase)`, and then returns *str*.

Example

See [uppercase](#) for an example of using `nouppercase`.

oct

Specifies that integer variables appear in base 8 notation.

```
ios_base& oct(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which *str* is derived.

Remarks

By default, integer variables are displayed in base 10 notation. [dec](#) and [hex](#) also change the way integer variables appear.

The manipulator effectively calls `str.setf(ios_base::oct , ios_base::basefield)`, and then returns *str*.

Example

See [dec](#) for an example of how to use `oct`.

right

Causes text that is not as wide as the output width to appear in the stream flush with the right margin.

```
ios_base& right(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which *str* is derived.

Remarks

[left](#) also modifies the justification of text.

The manipulator effectively calls `str.setf(ios_base::right , ios_base::adjustfield)`, and then returns *str*.

Example

```
// ios_right.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    double f1= 5.00;
    cout << f1 << endl;
    cout.width( 20 );
    cout << f1 << endl;
    cout.width( 20 );
    cout << left << f1 << endl;
    cout.width( 20 );
    cout << f1 << endl;
    cout.width( 20 );
    cout << right << f1 << endl;
    cout.width( 20 );
    cout << f1 << endl;
}
```

```
5
           5
5
5
           5
           5
```

scientific

Causes floating-point numbers to be displayed using scientific notation.

```
ios_base& scientific(ios_base& str);
```

Parameters

str

A reference to an object of type `ios_base`, or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

By default, `fixed` notation is in effect for floating-point numbers.

The manipulator effectively calls `str.setf(ios_base::scientific, ios_base::floatfield)`, and then returns *str*.

Example

```
// ios_scientific.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    float i = 100.23F;

    cout << i << endl;
    cout << scientific << i << endl;
}
```

```
100.23
1.002300e+002
```

showbase

Indicates the notational base in which a number is displayed.

```
ios_base& showbase(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which *_Str* is derived.

Remarks

The notational base of a number can be changed with [dec](#), [oct](#), or [hex](#).

The manipulator effectively calls `str.setf(ios_base::showbase)`, and then returns *str*.

Example

```
// ios_showbase.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    int j = 100;

    cout << showbase << j << endl;    // dec is default
    cout << hex << j << showbase << endl;
    cout << oct << j << showbase << endl;

    cout << dec << j << noshowbase << endl;
    cout << hex << j << noshowbase << endl;
    cout << oct << j << noshowbase << endl;
}
```

```
100
0x64
0144
100
64
144
```

showpoint

Displays the whole-number part of a floating-point number and digits to the right of the decimal point even when the fractional part is zero.

```
ios_base& showpoint(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

By default, [noshowpoint](#) is in effect.

The manipulator effectively calls `str.setf(ios_base::showpoint)`, and then returns *str*.

Example

See [noshowpoint](#) for an example of using `showpoint`.

showpos

Causes positive numbers to be explicitly signed.

```
ios_base& showpos(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which `_Str` is derived.

Remarks

[noshowpos](#) is the default.

The manipulator effectively calls `str.setf(ios_base::showpos)`, and then returns *str*.

Example

```
// ios_showpos.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    int i = 1;

    cout << noshowpos << i << endl;    // noshowpos is default
    cout << showpos << i << endl;
}
```

```
1
+1
```

skipws

Cause spaces to not be read by the input stream.

```
ios_base& skipws(ios_base& str);
```

Parameters

str

A reference to an object of type [ios_base](#), or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which *_Str* is derived.

Remarks

By default, `skipws` is in effect. [noskipws](#) will cause spaces to be read from the input stream.

The manipulator effectively calls `str.setf(ios_base::skipws)`, and then returns *str*.

Example

```
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    char s1, s2, s3;
    cout << "Enter three characters: ";
    cin >> skipws >> s1 >> s2 >> s3;
    cout << "." << s1 << "." << endl;
    cout << "." << s2 << "." << endl;
    cout << "." << s3 << "." << endl;
}
```

```
1 2 3
```

```
Enter three characters: 1 2 3
```

```
.1.  
.2.  
.3.
```

unitbuf

Causes output to be processed when the buffer is not empty.

```
ios_base& unitbuf(ios_base& str);
```

Parameters

str

A reference to an object of type `ios_base`, or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which *str* is derived.

Remarks

Note that `endl` also flushes the buffer.

`nounitbuf` is in effect by default.

The manipulator effectively calls `str.setf(ios_base::unitbuf)`, and then returns *str*.

uppercase

Specifies that hexadecimal digits and the exponent in scientific notation appear in uppercase.

```
ios_base& uppercase(ios_base& str);
```

Parameters

str

A reference to an object of type `ios_base`, or to a type that inherits from `ios_base`.

Return Value

A reference to the object from which *str* is derived.

Remarks

By default, `nouppercase` is in effect.

The manipulator effectively calls `str.setf(ios_base::uppercase)`, and then returns *str*.

Example

```
// ios_uppercase.cpp
// compile with: /EHsc
#include <iostream>

int main( void )
{
    using namespace std;

    double i = 1.23e100;
    cout << i << endl;
    cout << uppercase << i << endl;

    int j = 10;
    cout << hex << nouppercase << j << endl;
    cout << hex << uppercase << j << endl;
}
```

```
1.23e+100
1.23E+100
a
A
```

[<ios>](#)

<ios> typedefs

10/31/2018 • 2 minutes to read • [Edit Online](#)

ios	streamoff	streampos
streamsize	wios	wstreampos

ios

Supports the ios class from the old iostream library.

```
typedef basic_ios<char, char_traits<char>> ios;
```

Remarks

The type is a synonym for template class [basic_ios](#), specialized for elements of type **char** with default character traits.

streamoff

Supports internal operations.

```
#ifdef _WIN64
    typedef __int64 streamoff;
#else
    typedef long streamoff;
#endif
```

Remarks

The type is a signed integer that describes an object that can store a byte offset involved in various stream positioning operations. Its representation has at least 32 value bits. It is not necessarily large enough to represent an arbitrary byte position within a stream. The value `streamoff(-1)` generally indicates an erroneous offset.

streampos

Holds the current position of the buffer pointer or file pointer.

```
typedef fpos<mbstate_t> streampos;
```

Remarks

The type is a synonym for `fpos<mbstate_t>`.

Example

```
// ios_streampos.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main( )
{
    using namespace std;

    ofstream x( "iostream.txt" );
    x << "testing";
    streampos y = x.tellp( );
    cout << y << endl;
}
```

7

streamsize

Denotes the size of the stream.

```
#ifndef _WIN64
    typedef __int64 streamsize;
#else
    typedef int streamsize;
#endif
```

Remarks

The type is a signed integer that describes an object that can store a count of the number of elements involved in various stream operations. Its representation has at least 16 bits. It is not necessarily large enough to represent an arbitrary byte position within a stream.

Example

After compiling and running the following program, look at the file test.txt to see the effect of setting `streamsize`.

```
// ios_streamsize.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main( )
{
    using namespace std;
    char a[16] = "any such text";
    ofstream x( "test.txt" );
    streamsize y = 6;
    x.write( a, y );
}
```

wios

Supports the wios class from the old iostream library.

```
typedef basic_ios<wchar_t, char_traits<wchar_t>> wios;
```

Remarks

The type is a synonym for template class [basic_ios](#), specialized for elements of type **wchar_t** with default character traits.

wstreampos

Holds the current position of the buffer pointer or file pointer.

```
typedef fpos<mbstate_t> wstreampos;
```

Remarks

The type is a synonym for [fpos](#)< `mbstate_t` >.

Example

```
// ios_wstreampos.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main( )
{
    using namespace std;
    wofstream xw( "wiostream.txt" );
    xw << L"testing";
    wstreampos y = xw.tellp( );
    cout << y << endl;
}
```

[<ios>](#)

basic_ios Class

11/9/2018 • 12 minutes to read • [Edit Online](#)

The template class describes the storage and member functions common to both input streams (of template class [basic_istream](#)) and output streams (of template class [basic_ostream](#)) that depend on the template parameters. (The class [ios_base](#) describes what is common and not dependent on template parameters.) An object of class **basic_ios<class Elem, class Traits>** helps control a stream with elements of type `Elem`, whose character traits are determined by the class `Traits`.

Syntax

```
template <class Elem, class Traits>
class basic_ios : public ios_base
```

Parameters

Elem

A type.

Traits

A variable of type `char_traits`.

Remarks

An object of class **basic_ios<class Elem, class Traits>** stores:

- A tie pointer to an object of type [basic_istream<Elem, Traits>](#).
- A stream buffer pointer to an object of type [basic_streambuf<Elem, Traits >](#).
- [Formatting information](#).
- [Stream state information](#) in a base object of type [ios_base](#).
- A fill character in an object of type `char_type`.

Constructors

CONSTRUCTOR	DESCRIPTION
basic_ios	Constructs the <code>basic_ios</code> class.

Typedefs

TYPE NAME	DESCRIPTION
char_type	A synonym for the template parameter <code>Elem</code> .
int_type	A synonym for <code>Traits::int_type</code> .
off_type	A synonym for <code>Traits::off_type</code> .

TYPE NAME	DESCRIPTION
<code>pos_type</code>	A synonym for <code>Traits::pos_type</code> .
<code>traits_type</code>	A synonym for the template parameter <code>Traits</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>bad</code>	Indicates a loss of integrity of the stream buffer.
<code>clear</code>	Clears all error flags.
<code>copyfmt</code>	Copies flags from one stream to another.
<code>eof</code>	Indicates if the end of a stream has been reached.
<code>exceptions</code>	Indicates which exceptions will be thrown by the stream.
<code>fail</code>	Indicates failure to extract a valid field from a stream.
<code>fill</code>	Specifies or returns the character that will be used when the text is not as wide as the stream.
<code>good</code>	Indicates the stream is in good condition.
<code>imbue</code>	Changes the locale.
<code>init</code>	Called by <code>basic_ios</code> constructors.
<code>move</code>	Moves all values, except the pointer to the stream buffer, from the parameter to the current object.
<code>narrow</code>	Finds the equivalent char to a given <code>char_type</code> .
<code>rdbuf</code>	Routes stream to specified buffer.
<code>rdstate</code>	Reads the state of bits for flags.
<code>set_rdbuf</code>	Assigns a stream buffer to be the read buffer for this stream object.
<code>setstate</code>	Sets additional flags.
<code>swap</code>	Exchanges the values in this <code>basic_ios</code> object for those of another <code>basic_ios</code> object. The pointers to the stream buffers are not swapped.
<code>tie</code>	Ensures that one stream is processed before another stream.
<code>widen</code>	Finds the equivalent <code>char_type</code> to a given char.

Operators

OPERATOR	DESCRIPTION
explicit operator bool	Allows use of a <code>basic_ios</code> object as a bool . Automatic type conversion is disabled to prevent common, unintended side effects.
operator void *	Indicates if the stream is still good.
operator!	Indicates if the stream is not bad.

Requirements

Header: `<ios>`

Namespace: `std`

`basic_ios::bad`

Indicates a loss of integrity of the stream buffer

```
bool bad() const;
```

Return Value

true if `rdstate & badbit` is nonzero; otherwise **false**.

For more information on `badbit`, see [ios_base::iostate](#).

Example

```
// basic_ios_bad.cpp
// compile with: /EHsc
#include <iostream>

int main( void )
{
    using namespace std;
    bool b = cout.bad( );
    cout << boolalpha;
    cout << b << endl;

    b = cout.good( );
    cout << b << endl;
}
```

`basic_ios::basic_ios`

Constructs the `basic_ios` class.

```
explicit basic_ios(basic_streambuf<Elem, Traits>* sb);
basic_ios();
```

Parameters

sb

Standard buffer to store input or output elements.

Remarks

The first constructor initializes its member objects by calling `init(_ Sb)`. The second (protected) constructor leaves its member objects uninitialized. A later call to `init` must initialize the object before it can be safely destroyed.

basic_ios::char_type

A synonym for the template parameter `Elem`.

```
typedef Elem char_type;
```

basic_ios::clear

Clears all error flags.

```
void clear(iostate state = goodbit, bool reraise = false);  
void clear(io_state state);
```

Parameters

state

(Optional) The flags you want to set after clearing all flags. Defaults to `goodbit`.

reraise

(Optional) Specifies whether the exception should be re-raised. Defaults to **false** (will not re-raise the exception).

Remarks

The flags are `goodbit`, `failbit`, `eofbit`, and `badbit`. Test for these flags with `good`, `bad`, `eof`, and `fail`.

The member function replaces the stored stream state information with:

```
state | ( ( rdbuf != 0 ? goodbit : badbit )
```

If `state` & `exceptions` is nonzero, it then throws an object of class `failure`.

Example

See `rdstate` and `getline` for examples using `clear`.

basic_ios::copyfmt

Copies flags from one stream to another.

```
basic_ios<Elem, Traits>& copyfmt(  
    const basic_ios<Elem, Traits>& right);
```

Parameters

right

The stream whose flags you want to copy.

Return Value

The **this** object for the stream to which you are copying the flags.

Remarks

The member function reports the callback event **erase_event**. It then copies from *right* into ***this** the fill character, the tie pointer, and the formatting information. Before altering the exception mask, it reports the callback event `copyfmt_event`. If, after the copy is complete, **state & exceptions** is nonzero, the function effectively calls `clear` with the argument `rdstate`. It returns ***this**.

Example

```
// basic_ios_copyfmt.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main( )
{
    using namespace std;
    ofstream x( "test.txt" );
    int i = 10;

    x << showpos;
    cout << i << endl;
    cout.copyfmt( x );
    cout << i << endl;
}
```

basic_ios::eof

Indicates if the end of a stream has been reached.

```
bool eof() const;
```

Return Value

true if the end of the stream has been reached, **false** otherwise.

Remarks

The member function returns **true** if `rdstate` & `eofbit` is nonzero. For more information on `eofbit`, see [ios_base::iostate](#).

Example

```
// basic_ios_eof.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

using namespace std;

int main( int argc, char* argv[] )
{
    fstream fs;
    int n = 1;
    fs.open( "basic_ios_eof.txt" ); // an empty file
    cout << boolalpha
    cout << fs.eof() << endl;
    fs >> n; // Read the char in the file
    cout << fs.eof() << endl;
}
```

basic_ios::exceptions

Indicates which exceptions will be thrown by the stream.

```
iostate exceptions() const;
void exceptions(iostate Newexcept);
void exceptions(io_state Newexcept);
```

Parameters

Newexcept

The flags that you want to throw an exception.

Return Value

The flags that are currently specified to throw an exception for the stream.

Remarks

The first member function returns the stored exception mask. The second member function stores *_Except* in the exception mask and returns its previous stored value. Note that storing a new exception mask can throw an exception just like the call [clear\(rdstate \)](#).

Example

```
// basic_ios_exceptions.cpp
// compile with: /EHsc /GR
#include <iostream>

int main( )
{
    using namespace std;

    cout << cout.exceptions( ) << endl;
    cout.exceptions( ios::eofbit );
    cout << cout.exceptions( ) << endl;
    try
    {
        cout.clear( ios::eofbit );    // Force eofbit on
    }
    catch ( exception &e )
    {
        cout.clear( );
        cout << "Caught the exception." << endl;
        cout << "Exception class: " << typeid(e).name() << endl;
        cout << "Exception description: " << e.what() << endl;
    }
}
```

```
0
1
Caught the exception.
Exception class: class std::ios_base::failure
Exception description: ios_base::eofbit set
```

basic_ios::fail

Indicates failure to extract a valid field from a stream.

```
bool fail() const;
```

Return Value

true if `rdstate` & (`badbit`|`failbit`) is nonzero, otherwise **false**.

For more information on `failbit`, see [ios_base::iostate](#).

Example

```
// basic_ios_fail.cpp
// compile with: /EHsc
#include <iostream>

int main( void )
{
    using namespace std;
    bool b = cout.fail( );
    cout << boolalpha;
    cout << b << endl;
}
```

basic_ios::fill

Specifies or returns the character that will be used when the text is not as wide as the stream.

```
char_type fill() const;
char_type fill(char_type Char);
```

Parameters

Char

The character you want as the fill character.

Return Value

The current fill character.

Remarks

The first member function returns the stored fill character. The second member function stores *Char* in the fill character and returns its previous stored value.

Example

```
// basic_ios_fill.cpp
// compile with: /EHsc
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;

    cout << setw( 5 ) << 'a' << endl;
    cout.fill( 'x' );
    cout << setw( 5 ) << 'a' << endl;
    cout << cout.fill( ) << endl;
}
```

```
a
xxxxa
x
```

basic_ios::good

Indicates the stream is in good condition.

```
bool good() const;
```

Return Value

true if `rdstate` `==` `goodbit` (no state flags are set), otherwise, **false**.

For more information on `goodbit`, see [ios_base::iostate](#).

Example

See [basic_ios::bad](#) for an example of using `good`.

basic_ios::imbue

Changes the locale.

```
locale imbue(const locale& Loc);
```

Parameters

Loc

A locale string.

Return Value

The previous locale.

Remarks

If `rdbuf` is not a null pointer, the member function calls

```
rdbuf -> pubimbue(_ Loc)
```

In any case, it returns [ios_base::imbue\(_ Loc\)](#).

Example

```
// basic_ios_imbue.cpp
// compile with: /EHsc
#include <iostream>
#include <locale>

int main( )
{
    using namespace std;

    cout.imbue( locale( "french_france" ) );
    double x = 1234567.123456;
    cout << x << endl;
}
```

basic_ios::init

Called by `basic_ios` constructors.

```
void init(basic_streambuf<Elem,Traits>* _Sb, bool _Isstd = false);
```

Parameters

_Sb

Standard buffer to store input or output elements.

_Isstd

Specifies whether this is a standard stream.

Remarks

The member function stores values in all member objects, so that:

- `rdbuf` returns *_Sb*.
- `tie` returns a null pointer.
- `rdstate` returns `goodbit` if *_Sb* is nonzero; otherwise, it returns `badbit`.
- `exceptions` returns `goodbit`.
- `flags` returns `skipws | dec`.
- `width` returns 0.
- `precision` returns 6.
- `fill` returns the space character.
- `getloc` returns `locale::classic`.
- `isword` returns zero, and `pword` returns a null pointer for all argument values.

`basic_ios::int_type`

A synonym for `traits_type::int_type`.

```
typedef typename traits_type::int_type int_type;
```

`basic_ios::move`

Moves all values, except the pointer to the stream buffer, from the parameter to the current object.

```
void move(basic_ios&& right);
```

Parameters

right

The `ios_base` object to move values from.

Remarks

The protected member function moves all the values stored in *right* to `*this` except the stored `stream buffer pointer`, which is unchanged in *right* and set to a null pointer in `*this`. The stored `tie pointer` is set to a null pointer in *right*.

`basic_ios::narrow`

Finds the equivalent char to a given `char_type`.

```
char narrow(char_type Char, char Default = '\0') const;
```

Parameters

Char

The **char** to convert.

Default

The **char** that you want returned if no equivalent is found.

Return Value

The equivalent **char** to a given `char_type`.

Remarks

The member function returns `use_facet<ctype<E>>(getloc()).narrow(Char, Default)`.

Example

```
// basic_ios_narrow.cpp
// compile with: /EHsc
#include <ios>
#include <iostream>
#include <wchar.h>

int main( )
{
    using namespace std;
    wchar_t *x = L"test";
    char y[10];
    cout << x[0] << endl;
    wcout << x << endl;
    y[0] = wcout.narrow( x[0] );
    cout << y[0] << endl;
}
```

basic_ios::off_type

A synonym for `traits_type::off_type`.

```
typedef typename traits_type::off_type off_type;
```

basic_ios::operator void *

Indicates if the stream is still good.

```
operator void *() const;
```

Return Value

The operator returns a null pointer only if [fail](#).

Example

```
// basic_ios_opgood.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    cout << (bool)(&cout != 0) << endl;    // Stream is still good
}
```

1

basic_ios::operator!

Indicates if the stream is not bad.

```
bool operator!() const;
```

Return Value

Returns [fail](#).

Example

```
// basic_ios_opbad.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    cout << !cout << endl;    // Stream is not bad
}
```

0

basic_ios::operator bool

Allows use of a `basic_ios` object as a **bool**. Automatic type conversion is disabled to prevent common, unintended side effects.

```
explicit operator bool() const;
```

Remarks

The operator returns a value convertible to **false** only if `fail()`. The return type is convertible only to **bool**, not to `void *` or other known scalar type.

basic_ios::pos_type

A synonym for `traits_type::pos_type`.

```
typedef typename traits_type::pos_type pos_type;
```

basic_ios::rdbuf

Routes stream to specified buffer.

```
basic_streambuf<Elem, Traits> *rdbuf() const;  
basic_streambuf<Elem, Traits> *rdbuf(  
    basic_streambuf<Elem, Traits>* _Sb);
```

Parameters

_Sb

A stream.

Remarks

The first member function returns the stored stream buffer pointer.

The second member function stores *_Sb* in the stored stream buffer pointer and returns the previously stored value.

Example

```
// basic_ios_rdbuf.cpp  
// compile with: /EHsc  
#include <ios>  
#include <iostream>  
#include <fstream>  
  
int main( )  
{  
    using namespace std;  
    ofstream file( "rdbuf.txt" );  
    streambuf *x = cout.rdbuf( file.rdbuf( ) );  
    cout << "test" << endl;    // Goes to file  
    cout.rdbuf(x);  
    cout << "test2" << endl;  
}
```

```
test2
```

basic_ios::rdstate

Reads the state of bits for flags.

```
iosstate rdstate() const;
```

Return Value

The stored stream state information.

Example

```
// basic_ios_rdtype.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>
using namespace std;

void TestFlags( ios& x )
{
    cout << ( x.rdstate( ) & ios::badbit ) << endl;
    cout << ( x.rdstate( ) & ios::failbit ) << endl;
    cout << ( x.rdstate( ) & ios::eofbit ) << endl;
    cout << endl;
}

int main( )
{
    fstream x( "c:\\test.txt", ios::out );
    x.clear( );
    TestFlags( x );
    x.clear( ios::badbit | ios::failbit | ios::eofbit );
    TestFlags( x );
}
```

```
0
0
0

4
2
1
```

basic_ios::setstate

Sets additional flags.

```
void setstate(iostate _State);
```

Parameters

_State

Additional flags to set.

Remarks

The member function effectively calls [clear](#)(*_State* | [rdstate](#)).

Example

```
// basic_ios_setstate.cpp
// compile with: /EHsc
#include <ios>
#include <iostream>
using namespace std;

int main( )
{
    bool b = cout.bad( );
    cout << b << endl;    // Good
    cout.clear( ios::badbit );
    b = cout.bad( );
    // cout.clear( );
    cout << b << endl;    // Is bad, good
    b = cout.fail( );
    cout << b << endl;    // Not failed
    cout.setstate( ios::failbit );
    b = cout.fail( );
    cout.clear( );
    cout << b << endl;    // Is failed, good
    return 0;
}
```

```
0
1
```

basic_ios::set_rdbuf

Assigns a stream buffer to be the read buffer for this stream object.

```
void set_rdbuf(
    basic_streambuf<Elem, Tr>* strbuf)
```

Parameters

strbuf

The stream buffer to become the read buffer.

Remarks

The protected member function stores *strbuf* in the `stream buffer pointer`. It does not call `clear`.

basic_ios::tie

Ensures that one stream is processed before another stream.

```
basic_ostream<Elem, Traits> *tie() const;
basic_ostream<Elem, Traits> *tie(
    basic_ostream<Elem, Traits>* str);
```

Parameters

str

A stream.

Return Value

The first member function returns the stored tie pointer. The second member function stores *str* in the tie pointer and returns its previous stored value.

Remarks

`tie` causes two streams to be synchronized, such that, operations on one stream occur after operations on the other stream are complete.

Example

In this example, by tying `cin` to `cout`, it is guaranteed that the "Enter a number:" string will go to the console before the number itself is extracted from `cin`. This eliminates the possibility that the "Enter a number:" string is still sitting in the buffer when the number is read, so that we are certain that the user actually has some prompt to respond to. By default, `cin` and `cout` are tied.

```
#include <ios>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    cin.tie( &cout );
    cout << "Enter a number:";
    cin >> i;
}
```

basic_ios::traits_type

A synonym for the template parameter `Traits`.

```
typedef Traits traits_type;
```

basic_ios::widen

Finds the equivalent `char_type` to a given **char**.

```
char_type widen(char Char) const;
```

Parameters

Char

The character to convert.

Return Value

Finds the equivalent `char_type` to a given **char**.

Remarks

The member function returns `use_facet< ctype< E> > (getloc). widen (Char)`.

Example

```
// basic_ios_widen.cpp
// compile with: /EHsc
#include <ios>
#include <iostream>
#include <wchar.h>

int main( )
{
    using namespace std;
    char *z = "Hello";
    wchar_t y[2] = {0,0};
    cout << z[0] << endl;
    y[0] = wcout.widen( z[0] );
    wcout << &y[0] << endl;
}
```

basic_ios::swap

Exchanges the values in this `basic_ios` object for those of another `basic_ios` object. However, the pointers to the stream buffers are not swapped.

```
void swap(basic_ios&& right);
```

Parameters

right

The `basic_ios` object that is used to exchange values.

Remarks

The protected member function exchanges all the values stored in *right* with `*this` except the stored stream buffer pointer.

fpos Class

3/28/2019 • 4 minutes to read • [Edit Online](#)

The template class describes an object that can store all the information needed to restore an arbitrary file-position indicator within any stream. An object of class `fpos< St>` effectively stores at least two member objects:

- A byte offset, of type `streamoff`.
- A conversion state, for use by an object of class `basic_filebuf`, of type `St`, typically `mbstate_t`.

It can also store an arbitrary file position, for use by an object of class `basic_filebuf`, of type `fpos_t`. For an environment with limited file size, however, `streamoff` and `fpos_t` may sometimes be used interchangeably. For an environment with no streams that have a state-dependent encoding, `mbstate_t` may actually be unused. Therefore, the number of member objects stored may vary.

Syntax

```
template <class Statetype>
class fpos
```

Parameters

Statetype

State information.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>fpos</code>	Create an object that contains information about a position (offset) in a stream.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>seekpos</code>	Used internally by the C++ Standard Library only. Do not call this method from your code.
<code>state</code>	Sets or returns the conversion state.

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests file-position indicators for inequality.
<code>operator+</code>	Increments a file-position indicator.
<code>operator+=</code>	Increments a file-position indicator.

OPERATOR	DESCRIPTION
<code>operator-</code>	Decrements a file-position indicator.
<code>operator-=</code>	Decrements a file-position indicator.
<code>operator==</code>	Tests file-position indicators for equality.
<code>operator streamoff</code>	Casts object of type <code>fpos</code> to object of type <code>streamoff</code> .

Requirements

Header: `<ios>`

Namespace: `std`

`fpos::fpos`

Create an object that contains information about a position (offset) in a stream.

```
fpos(streamoff _Off = 0);

fpos(Statetype _State, fpos_t _Filepos);
```

Parameters

_Off

The offset into the stream.

_State

The starting state of the `fpos` object.

_Filepos

The offset into the stream.

Remarks

The first constructor stores the offset *_Off*, relative to the beginning of file and in the initial conversion state (if that matters). If *_Off* is -1, the resulting object represents an invalid stream position.

The second constructor stores a zero offset and the object *_State*.

`fpos::operator!=`

Tests file-position indicators for inequality.

```
bool operator!=(const fpos<Statetype>& right) const;
```

Parameters

right

The file-position indicator against which to compare.

Return Value

true if the file-position indicators are not equal, otherwise **false**.

Remarks

The member function returns `!(*this == right)`.

Example

```
// fpos_op_neq.cpp
// compile with: /EHsc
#include <fstream>
#include <iostream>

int main( )
{
    using namespace std;

    fpos<int> pos1, pos2;
    ifstream file;
    char c;

    // Compare two fpos object
    if ( pos1 != pos2 )
        cout << "File position pos1 and pos2 are not equal" << endl;
    else
        cout << "File position pos1 and pos2 are equal" << endl;

    file.open( "fpos_op_neq.txt" );
    file.seekg( 0 ); // Goes to a zero-based position in the file
    pos1 = file.tellg( );
    file.get( c );
    cout << c << endl;

    // Increment pos1
    pos1 += 1;
    file.get( c );
    cout << c << endl;

    pos1 = file.tellg( ) - fpos<int>( 2 );
    file.seekg( pos1 );
    file.get( c );
    cout << c << endl;

    // Increment pos1
    pos1 = pos1 + fpos<int>( 1 );
    file.get(c);
    cout << c << endl;

    pos1 -= fpos<int>( 2 );
    file.seekg( pos1 );
    file.get( c );
    cout << c << endl;

    file.close( );
}
```

fpos::operator+

Increments a file-position indicator.

```
fpos<Statetype> operator+(streamoff _Off) const;
```

Parameters

_Off

The offset by which you want to increment the file-position indicator.

Return Value

The position in the file.

Remarks

The member function returns **fpos(*this) +=** `_Off` .

Example

See [operator!=](#) for a sample of using `operator+` .

fpos::operator+=

Increments a file-position indicator.

```
fpos<Statetype>& operator+=(streamoff _Off);
```

Parameters

_Off

The offset by which you want to increment the file-position indicator.

Return Value

The position in the file.

Remarks

The member function adds *_Off* to the stored offset member object and then returns ***this**. For positioning within a file, the result is generally valid only for binary streams that do not have a state-dependent encoding.

Example

See [operator!=](#) for a sample of using `operator+=` .

fpos::operator-

Decrements a file-position indicator.

```
streamoff operator-(const fpos<Statetype>& right) const;  
  
fpos<Statetype> operator-(streamoff _Off) const;
```

Parameters

right

File position.

_Off

Stream offset.

Return Value

The first member function returns `(streamoff)*this - (streamoff) right` . The second member function returns

```
fpos(*this) -= _Off .
```

Example

See [operator!=](#) for a sample of using `operator-` .

fpos::operator-=

Decrements a file-position indicator.

```
fpos<Statetype>& operator--(streamoff _Off);
```

Parameters

_Off

Stream offset.

Return Value

The member function returns `fpos(*this) -= _Off`.

Remarks

For positioning within a file, the result is generally valid only for binary streams that do not have a state-dependent encoding.

Example

See [operator!=](#) for a sample of using `operator--`.

fpos::operator==

Tests file-position indicators for equality.

```
bool operator==(const fpos<Statetype>& right) const;
```

Parameters

right

The file-position indicator against which to compare.

Return Value

true if the file-position indicators are equal; otherwise **false**.

Remarks

The member function returns `(streamoff)*this == (streamoff)right`.

Example

See [operator!=](#) for a sample of using `operator+=`.

fpos::operator streamoff

Cast object of type `fpos` to object of type `streamoff`.

```
operator streamoff() const;
```

Remarks

The member function returns the stored offset member object and any additional offset stored as part of the `fpos_t` member object.

Example

```

// fpos_op_streampos.cpp
// compile with: /EHsc
#include <ios>
#include <iostream>
#include <fstream>

int main( )
{
    using namespace std;
    streamoff s;
    ofstream file( "rdbuf.txt");

    fpos<mbstate_t> f = file.tellp( );
    // Is equivalent to ..
    // streampos f = file.tellp( );
    s = f;
    cout << s << endl;
}

```

0

fpos::seekpos

This method is used internally by the C++ Standard Library only. Do not call this method from your code.

```
fpos_t seekpos() const;
```

fpos::state

Sets or returns the conversion state.

```

Statetype state() const;

void state(Statetype _State);

```

Parameters

_State

The new conversion state.

Return Value

The conversion state.

Remarks

The first member function returns the value stored in the `st` member object. The second member function stores *_State* in the `st` member object.

Example

```
// fpos_state.cpp
// compile with: /EHsc
#include <ios>
#include <iostream>
#include <fstream>

int main() {
    using namespace std;
    streamoff s;
    ifstream file( "fpos_state.txt" );

    fpos<mbstate_t> f = file.tellg( );
    char ch;
    while ( !file.eof( ) )
        file.get( ch );
    s = f;
    cout << f.state( ) << endl;
    f.state( 9 );
    cout << f.state( ) << endl;
}
```

ios_base Class

11/8/2018 • 16 minutes to read • [Edit Online](#)

The class describes the storage and member functions common to both input and output streams that do not depend on the template parameters. (The template class [basic_ios](#) describes what is common and is dependent on template parameters.)

An object of class `ios_base` stores formatting information, which consists of:

- Format flags in an object of type [fmtflags](#).
- An exception mask in an object of type [iostate](#).
- A field width in an object of type **int**.
- A display precision in an object of type **int**.
- A locale object in an object of type `locale`.
- Two extensible arrays, with elements of type **long** and **void** pointer.

An object of class `ios_base` also stores stream state information, in an object of type [iostate](#), and a callback stack.

Constructors

CONSTRUCTOR	DESCRIPTION
ios_base	Constructs <code>ios_base</code> objects.

Typedefs

TYPE NAME	DESCRIPTION
event_callback	Describes a function passed to register_call .
fmtflags	Constants to specify the appearance of output.
iostate	Defines constants describing the state of a stream.
openmode	Describes how to interact with a stream.
seekdir	Specifies starting point for offset operations.

Enums

event	Specifies event types.
-----------------------	------------------------

Constants

--	--

<code>adjustfield</code>	A bitmask defined as <code>internal</code> <code>left</code> <code>right</code> .
<code>app</code>	Specifies seeking to the end of a stream before each insertion.
<code>ate</code>	Specifies seeking to the end of a stream when its controlling object is first created.
<code>badbit</code>	Records a loss of integrity of the stream buffer.
<code>basefield</code>	A bitmask defined as <code>dec</code> <code>hex</code> <code>oct</code> .
<code>beg</code>	Specifies seeking relative to the beginning of a sequence.
<code>binary</code>	Specifies that a file should be read as a binary stream, rather than as a text stream.
<code>boolalpha</code>	Specifies insertion or extraction of objects of type bool as names (such as true and false) rather than as numeric values.
<code>cur</code>	Specifies seeking relative to the current position within a sequence.
<code>dec</code>	Specifies insertion or extraction of integer values in decimal format.
<code>end</code>	Specifies seeking relative to the end of a sequence.
<code>eofbit</code>	Records end-of-file while extracting from a stream.
<code>failbit</code>	Records a failure to extract a valid field from a stream.
<code>fixed</code>	Specifies insertion of floating-point values in fixed-point format (with no exponent field).
<code>floatfield</code>	A bitmask defined as <code>fixed</code> <code>scientific</code>
<code>goodbit</code>	All state bits clear.
<code>hex</code>	Specifies insertion or extraction of integer values in hexadecimal format.
<code>in</code>	Specifies extraction from a stream.
<code>internal</code>	Pads to a field width by inserting fill characters at a point internal to a generated numeric field.
<code>left</code>	Specifies left justification.
<code>oct</code>	Specifies insertion or extraction of integer values in octal format.

out	Specifies insertion to a stream.
right	Specifies right justification.
scientific	Specifies insertion of floating-point values in scientific format (with an exponent field).
showbase	Specifies insertion of a prefix that reveals the base of a generated integer field.
showpoint	Specifies unconditional insertion of a decimal point in a generated floating-point field.
showpos	Specifies insertion of a plus sign in a nonnegative generated numeric field.
skipws	Specifies skipping leading white space before certain extractions.
trunc	Specifies deleting contents of an existing file when its controlling object is created.
unitbuf	Causes output to be flushed after each insertion.
uppercase	Specifies insertion of uppercase equivalents of lowercase letters in certain insertions.

Member functions

MEMBER FUNCTION	DESCRIPTION
failure	The member class serves as the base class for all exceptions thrown by the member function clear in template class basic_ios .
flags	Sets or returns the current flag settings.
getloc	Returns the stored locale object.
imbue	Changes the locale.
Init	Creates the standard iostream objects when constructed.
iword	Assigns a value to be stored as an <code>iword</code> .
precision	Specifies the number of digits to display in a floating-point number.
pword	Assigns a value to be stored as a <code>pword</code> .
register_callback	Specifies a callback function.
setf	Sets the specified flags.

MEMBER FUNCTION	DESCRIPTION
sync_with_stdio	Ensures that iostream and C run-time library operations occur in the order that they appear in source code.
unsetf	Causes the specified flags to be off.
width	Sets the length of the output stream.
xalloc	Specifies that a variable shall be part of the stream.

Operators

OPERATOR	DESCRIPTION
operator=	The assignment operator for <code>ios_base</code> objects.

Requirements

Header: `<ios>`

Namespace: `std`

`ios_base::event`

Specifies event types.

```
enum event {
    erase_event,
    imbue_event,
    copyfmt_event};
```

Remarks

The type is an enumerated type that describes an object that can store the callback event used as an argument to a function registered with [register_callback](#). The distinct event values are:

- `copyfmt_event`, to identify a callback that occurs near the end of a call to [copyfmt](#), just before the [exception mask](#) is copied.
- `erase_event`, to identify a callback that occurs at the beginning of a call to [copyfmt](#), or at the beginning of a call to the destructor for **`*this`**.
- `imbue_event`, to identify a callback that occurs at the end of a call to [imbue](#), just before the function returns.

Example

See [register_callback](#) for an example.

`ios_base::event_callback`

Describes a function passed to [register_call](#).

```
typedef void (__cdecl *event_callback)(
    event _E,
    ios_base& _Base,
    int _I);
```

Parameters

_E

The [event](#).

_Base

The stream in which the event was called.

_I

A user-defined number.

Remarks

The type describes a pointer to a function that can be registered with [register_callback](#). This type of function must not throw an exception.

Example

See [register_call](#) for an example that uses `event_callback`.

ios_base::failure

The class `failure` defines the base class for the types of all objects thrown as exceptions, by functions in the `iostreams` library, to report errors detected during stream buffer operations.

```
namespace std {
    class failure : public system_error {
    public:
        explicit failure(
            const string& _Message,
            const error_code& _Code = io_errc::stream);

        explicit failure(
            const char* str,
            const error_code& _Code = io_errc::stream);
    };
}
```

Remarks

The value returned by `what()` is a copy of `_Message`, possibly augmented with a test based on `_Code`. If `_Code` is not specified, the default value is `make_error_code(io_errc::stream)`.

Example

```
// ios_base_failure.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main ( )
{
    using namespace std;
    fstream file;
    file.exceptions(ios::failbit);
    try
    {
        file.open( "rm.txt", ios_base::in );
        // Opens nonexistent file for reading
    }
    catch( ios_base::failure f )
    {
        cout << "Caught an exception: " << f.what() << endl;
    }
}
```

```
Caught an exception: ios_base::failbit set
```

ios_base::flags

Sets or returns the current flag settings.

```
fmtflags flags() const;
fmtflags flags(fmtflags fmtfl);
```

Parameters

fmtfl

The new `fmtflags` setting.

Return Value

The previous or current `fmtflags` setting.

Remarks

See [ios_base::fmtflags](#) for a list of the flags.

The first member function returns the stored format flags. The second member function stores *fmtfl* in the format flags and returns its previous stored value.

Example

```
// ios_base_flags.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main ( )
{
    using namespace std;
    cout << cout.flags( ) << endl;
    cout.flags( ios::dec | ios::boolalpha );
    cout << cout.flags( );
}
```

ios_base::fmtflags

Constants to specify the appearance of output.

```
class ios_base {
public:
    typedef implementation-defined-bitmask-type fmtflags;
    static const fmtflags boolalpha;
    static const fmtflags dec;
    static const fmtflags fixed;
    static const fmtflags hex;
    static const fmtflags internal;
    static const fmtflags left;
    static const fmtflags oct;
    static const fmtflags right;
    static const fmtflags scientific;
    static const fmtflags showbase;
    static const fmtflags showpoint;
    static const fmtflags showpos;
    static const fmtflags skipws;
    static const fmtflags unitbuf;
    static const fmtflags uppercase;
    static const fmtflags adjustfield;
    static const fmtflags basefield;
    static const fmtflags floatfield;
    // ...
};
```

Remarks

Supports the manipulators in [ios](#).

The type is a bitmask type that describes an object that can store format flags. The distinct flag values (elements) are:

- `dec`, to insert or extract integer values in decimal format.
- `hex`, to insert or extract integer values in hexadecimal format.
- `oct`, to insert or extract integer values in octal format.
- `showbase`, to insert a prefix that reveals the base of a generated integer field.
- `internal`, to pad to a field width as needed by inserting fill characters at a point internal to a generated numeric field. (For information on setting the field width, see [setw](#)).
- `left`, to pad to a field width as needed by inserting fill characters at the end of a generated field (left justification).
- `right`, to pad to a field width as needed by inserting fill characters at the beginning of a generated field (right justification).
- `boolalpha`, to insert or extract objects of type **bool** as names (such as **true** and **false**) rather than as numeric values.
- `fixed`, to insert floating-point values in fixed-point format (with no exponent field).
- `scientific`, to insert floating-point values in scientific format (with an exponent field).

- `showpoint`, to insert a decimal point unconditionally in a generated floating-point field.
- `showpos`, to insert a plus sign in a nonnegative generated numeric field.
- `skipws`, to skip leading white space before certain extractions.
- `unitbuf`, to flush output after each insertion.
- `uppercase`, to insert uppercase equivalents of lowercase letters in certain insertions.

In addition, several useful values are:

- `adjustfield`, a bitmask defined as `internal` | `left` | `right`
- `basefield`, defined as `dec` | `hex` | `oct`
- `floatfield`, defined as `fixed` | `scientific`

For examples of functions that modify these format flags, see [<iomanip>](#).

ios_base::getloc

Returns the stored locale object.

```
locale getloc() const;
```

Return Value

The stored locale object.

Example

```
// ios_base_getlock.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    cout << cout.getloc( ).name( ).c_str( ) << endl;
}
```

C

ios_base::imbue

Changes the locale.

```
locale imbue(const locale& _Loc);
```

Parameters

_Loc

The new locale setting.

Return Value

The previous locale.

Remarks

The member function stores `_Loc` in the locale object and then reports the callback event and `imbue_event`. It returns the previous stored value.

Example

See [basic_ios::imbue](#) for a sample.

ios_base::Init

Creates the standard iostream objects when constructed.

```
class Init { };
```

Remarks

The nested class describes an object whose construction ensures that the standard iostreams objects are properly constructed, even before the execution of a constructor for an arbitrary static object.

ios_base::ios_base

Constructs `ios_base` objects.

```
ios_base();
```

Remarks

The (protected) constructor does nothing. A later call to **`basic_ios::init`** must initialize the object before it can be safely destroyed. Thus, the only safe use for class `ios_base` is as a base class for template class [basic_ios](#).

ios_base::iostate

The type of constants that describe the state of a stream.

```
class ios_base {
public:
    typedef implementation-defined-bitmask-type iostate;
    static const iostate badbit;
    static const iostate eofbit;
    static const iostate failbit;
    static const iostate goodbit;
    // ...
};
```

Remarks

The type is a bitmask type that describes an object that can store stream state information. The distinct flag values (elements) are:

- `badbit`, to record a loss of integrity of the stream buffer.
- `eofbit`, to record end-of-file while extracting from a stream.
- `failbit`, to record a failure to extract a valid field from a stream.

In addition, a useful value is `goodbit`, where none of the previously mentioned bits are set (`goodbit` is guaranteed to be zero).

ios_base::iword

Assigns a value to be stored as an `iword`.

```
long& iword(int idx);
```

Parameters

idx

The index of the value to store as an `iword`.

Remarks

The member function returns a reference to element *idx* of the extensible array with elements of type **long**. All elements are effectively present and initially store the value zero. The returned reference is invalid after the next call to `iword` for the object, after the object is altered by a call to **basic_ios::copyfmt**, or after the object is destroyed.

If *idx* is negative or if unique storage is unavailable for the element, the function calls **setstate(badbit)** and returns a reference that might not be unique.

To obtain a unique index, for use across all objects of type `ios_base`, call **xalloc**.

Example

See **xalloc** for a sample of how to use `iword`.

ios_base::openmode

Describes how to interact with a stream.

```
class ios_base {
public:
    typedef implementation-defined-bitmask-type iostate;
    static const iostate badbit;
    static const iostate eofbit;
    static const iostate failbit;
    static const iostate goodbit;
    // ...
};
```

Remarks

The type is a `bitmask type` that describes an object that can store the opening mode for several iostreams objects. The distinct flag values (elements) are:

- `app`, to seek to the end of a stream before each insertion.
- `ate`, to seek to the end of a stream when its controlling object is first created.
- `binary`, to read a file as a binary stream, rather than as a text stream.
- `in`, to permit extraction from a stream.
- `out`, to permit insertion to a stream.
- `trunc`, to delete contents of an existing file when its controlling object is created.

Example

```
// ios_base_openmode.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main ( )
{
    using namespace std;
    fstream file;
    file.open( "rm.txt", ios_base::out | ios_base::trunc );

    file << "testing";
}
```

ios_base::operator=

The assignment operator for ios_base objects.

```
ios_base& operator=(const ios_base& right);
```

Parameters

right

An object of type `ios_base`.

Return Value

The object being assigned to.

Remarks

The operator copies the stored formatting information, making a new copy of any extensible arrays. It then returns ***this**. Note that the callback stack is not copied.

This operator is only used by classes derived from `ios_base`.

ios_base::precision

Specifies the number of digits to display in a floating-point number.

```
streamsize precision() const;
streamsize precision(streamsize _Prec);
```

Parameters

_Prec

The number of significant digits to display, or the number of digits after the decimal point in fixed notation.

Return Value

The first member function returns the stored [display precision](#). The second member function stores *_Prec* in the display precision and returns its previous stored value.

Remarks

Floating-point numbers are displayed in fixed notation with [fixed](#).

Example

```
// ios_base_precision.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    float i = 31.31234F;

    cout.precision( 3 );
    cout << i << endl;          // display three significant digits
    cout << fixed << i << endl; // display three digits after decimal
                                // point
}
```

```
31.3
31.312
```

ios_base::pword

Assigns a value to be stored as a `pword`.

```
void *& pword(int _Idx);
```

Parameters

_Idx

The index of the value to store as a `pword`.

Remarks

The member function returns a reference to element *_Idx* of the extensible array with elements of type **void** pointer. All elements are effectively present and initially store the null pointer. The returned reference is invalid after the next call to `pword` for the object, after the object is altered by a call to **basic_ios::copyfmt**, or after the object is destroyed.

If *_Idx* is negative, or if unique storage is unavailable for the element, the function calls **setstate(badbit)** and returns a reference that might not be unique.

To obtain a unique index, for use across all objects of type `ios_base`, call **xalloc**.

Example

See **xalloc** for an example of using `pword`.

ios_base::register_callback

Specifies a callback function.

```
void register_callback(
    event_callback pfn, int idx);
```

Parameters

pfn

Pointer to the callback function.

idx

A user-defined number.

Remarks

The member function pushes the pair `{pfn, idx}` onto the stored callback stack [callback stack](#). When a callback event **ev** is reported, the functions are called, in reverse order of registry, by the expression

```
(*pfn)(ev, *this, idx).
```

Example

```
// ios_base_register_callback.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

using namespace std;

void callback1( ios_base::event e, ios_base& stream, int arg )
{
    cout << "in callback1" << endl;
    switch ( e )
    {
        case ios_base::erase_event:
            cout << "an erase event" << endl;
            break;
        case ios_base::imbue_event:
            cout << "an imbue event" << endl;
            break;
        case ios_base::copyfmt_event:
            cout << "an copyfmt event" << endl;
            break;
    };
}

void callback2( ios_base::event e, ios_base& stream, int arg )
{
    cout << "in callback2" << endl;
    switch ( e )
    {
        case ios_base::erase_event:
            cout << "an erase event" << endl;
            break;
        case ios_base::imbue_event:
            cout << "an imbue event" << endl;
            break;
        case ios_base::copyfmt_event:
            cout << "an copyfmt event" << endl;
            break;
    };
}

int main( )
{
    // Make sure the imbue will not throw an exception
    // assert( setlocale( LC_ALL, "german" )!=NULL );

    cout.register_callback( callback1, 0 );
    cin.register_callback( callback2, 0 );

    try
    {
        // If no exception because the locale's not found,
        // generate an imbue_event on callback1
        cout.imbue(locale("german"));
    }
    catch(...)
    {
        cout << "exception" << endl;
    }
}
```

```

    }

    // This will
    // (1) erase_event on callback1
    // (2) copyfmt_event on callback2
    cout.copyfmt(cin);

    // We get two erase events from callback2 at the end because
    // both cin and cout have callback2 registered when cin and cout
    // are destroyed at the end of program.
}

```

```

in callback1
an imbue event
in callback1
an erase event
in callback2
an copyfmt event
in callback2
an erase event
in callback2
an erase event

```

ios_base::seekdir

Specifies starting point for offset operations.

```

namespace std {
    class ios_base {
    public:
        typedef implementation-defined-enumerated-type seekdir;
        static const seekdir beg;
        static const seekdir cur;
        static const seekdir end;
        // ...
    };
}

```

Remarks

The type is an enumerated type that describes an object that can store the seek mode used as an argument to the member functions of several iostream classes. The distinct flag values are:

- `beg`, to seek (alter the current read or write position) relative to the beginning of a sequence (array, stream, or file).
- `cur`, to seek relative to the current position within a sequence.
- `end`, to seek relative to the end of a sequence.

Example

```
// ios_base_seekdir.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main ( )
{
    using namespace std;
    fstream file;
    file.open( "rm.txt", ios_base::out | ios_base::trunc );

    file << "testing";
    file.seekp( 0, ios_base::beg );
    file << "a";
    file.seekp( 0, ios_base::end );
    file << "a";
}
```

ios_base::setf

Sets the specified flags.

```
fmtflags setf(
    fmtflags _Mask
);
fmtflags setf(
    fmtflags _Mask,
    fmtflags _Unset
);
```

Parameters

_Mask

The flags to turn on.

_Unset

The flags to turn off.

Return Value

The previous format flags

Remarks

The first member function effectively calls `flags(_Mask | _Flags)` (set selected bits) and then returns the previous format flags. The second member function effectively calls `flags(_Mask & fmtfl, flags & ~_Mask)` (replace selected bits under a mask) and then returns the previous format flags.

Example

```
// ios_base_setf.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    int i = 10;
    cout << i << endl;

    cout.unsetf( ios_base::dec );
    cout.setf( ios_base::hex );
    cout << i << endl;

    cout.setf( ios_base::dec );
    cout << i << endl;
    cout.setf( ios_base::hex, ios_base::dec );
    cout << i << endl;
}
```

ios_base::sync_with_stdio

Ensures that iostream and C run-time library operations occur in the order that they appear in source code.

```
static bool sync_with_stdio(
    bool _Sync = true
);
```

Parameters

_Sync

Whether all streams are in sync with `stdio`.

Return Value

Previous setting for this function.

Remarks

The static member function stores a `stdio` sync flag, which is initially **true**. When **true**, this flag ensures that operations on the same file are properly synchronized between the [iostreams](#) functions and those defined in the C++ Standard Library. Otherwise, synchronization may or may not be guaranteed, but performance may be improved. The function stores *_Sync* in the `stdio` sync flag and returns its previous stored value. You can call it reliably only before performing any operations on the standard streams.

ios_base::unsetf

Causes the specified flags to be off.

```
void unsetf(
    fmtflags _Mask
);
```

Parameters

_Mask

The flags that you want off.

Remarks

The member function effectively calls `flags(~_Mask & flags)` (clear selected bits).

Example

See `ios_base::setf` for a sample of using `unsetf`.

ios_base::width

Sets the length of the output stream.

```
streamsize width( ) const;
streamsize width(
    streamsize _Wide
);
```

Parameters

_Wide

The desired size of the output stream.

Return Value

The current width setting.

Remarks

The first member function returns the stored field width. The second member function stores *_Wide* in the field width and returns its previous stored value.

Example

```
// ios_base_width.cpp
// compile with: /EHsc
#include <iostream>

int main( ) {
    using namespace std;

    cout.width( 20 );
    cout << cout.width( ) << endl;
    cout << cout.width( ) << endl;
}
```

```
20
0
```

ios_base::xalloc

Specifies that a variable is part of the stream.

```
static int xalloc( );
```

Return Value

The static member function returns a stored static value, which it increments on each call.

Remarks

You can use the return value as a unique index argument when calling the member functions `word` or `pword`.

Example

```
// ios_base_xalloc.cpp
// compile with: /EHsc
// Lets you store user-defined information.
// iword, jword, xalloc
#include <iostream>

int main( )
{
    using namespace std;

    static const int i = ios_base::xalloc();
    static const int j = ios_base::xalloc();
    cout.iword( i ) = 11;
    cin.iword( i ) = 13;
    cin.pword( j ) = "testing";
    cout << cout.iword( i ) << endl;
    cout << cin.iword( i ) << endl;
    cout << ( char * )cin.pword( j ) << endl;
}
```

```
11
13
testing
```

<iosfwd>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Declares forward references to several template classes used throughout iostreams. All such template classes are defined in other standard headers. You include this header explicitly only when you need one of its declarations, but not its definition.

Syntax

```
#include <iosfwd>
```

Typedefs

```
typedef T1 streamoff;
typedef T2 streamsize;
typedef fpos streampos;

// wchar_t TYPE DEFINITIONS
typedef basic_ios<char, char_traits<char>> ios;
typedef basic_streambuf<char, char_traits<char>> streambuf;
typedef basic_istream<char, char_traits<char>> istream;
typedef basic_ostream<char, char_traits<char>> ostream;
typedef basic_iostream<char, char_traits<char>> iostream;
typedef basic_stringbuf<char, char_traits<char>> stringbuf;
typedef basic_istreambuf<char, char_traits<char>> istreambuf;
typedef basic_ostreambuf<char, char_traits<char>> ostreambuf;
typedef basic_stringstream<char, char_traits<char>> stringstream;
typedef basic_filebuf<char, char_traits<char>> filebuf;
typedef basic_ifstream<char, char_traits<char>> ifstream;
typedef basic_ofstream<char, char_traits<char>> ofstream;
typedef basic_fstream<char, char_traits<char>> fstream;

// wchar_t TYPE DEFINITIONS
typedef basic_ios<wchar_t, char_traits<wchar_t>> wios;
typedef basic_streambuf<wchar_t, char_traits<wchar_t>> wstreambuf;
typedef basic_istream<wchar_t, char_traits<wchar_t>> wistream;
typedef basic_ostream<wchar_t, char_traits<wchar_t>> wostream;
typedef basic_iostream<wchar_t, char_traits<wchar_t>> wiostream;
typedef basic_stringbuf<wchar_t, char_traits<wchar_t>> wstringbuf;
typedef basic_istreambuf<wchar_t, char_traits<wchar_t>> wistreambuf;
typedef basic_ostreambuf<wchar_t, char_traits<wchar_t>> wostreambuf;
typedef basic_stringstream<wchar_t, char_traits<wchar_t>> wstringstream;
typedef basic_filebuf<wchar_t, char_traits<wchar_t>> wfilebuf;
typedef basic_ifstream<wchar_t, char_traits<wchar_t>> wifstream;
typedef basic_ofstream<wchar_t, char_traits<wchar_t>> wofstream;
typedef basic_fstream<wchar_t, char_traits<wchar_t>> wfstream;
};
```

Forward Declarations/Template Classes

[Thread Safety in the C++ Standard Library](#)

[iostream Programming](#)

<iostream>

11/9/2018 • 4 minutes to read • [Edit Online](#)

Declares objects that control reading from and writing to the standard streams. This is often the only header you need to include to perform input and output from a C++ program.

Syntax

```
#include <iostream>
```

Remarks

The objects fall into two groups:

- `cin`, `cout`, `cerr`, and `clog` are byte oriented, performing conventional byte-at-a-time transfers.
- `wcin`, `wcout`, `wcerr`, and `wclog` are wide oriented, translating to and from the wide characters that the program manipulates internally.

Once you perform certain operations on a stream, such as the standard input, you cannot perform operations of a different orientation on the same stream. Therefore, a program cannot operate interchangeably on both `cin` and `wcin`, for example.

All the objects declared in this header share a peculiar property — you can assume they are constructed before any static objects you define, in a translation unit that includes `<iostream>`. Equally, you can assume that these objects are not destroyed before the destructors for any such static objects you define. (The output streams are, however, flushed during program termination.) Therefore, you can safely read from or write to the standard streams before program startup and after program termination.

This guarantee is not universal, however. A static constructor may call a function in another translation unit. The called function cannot assume that the objects declared in this header have been constructed, given the uncertain order in which translation units participate in static construction. To use these objects in such a context, you must first construct an object of class `ios_base::Init`.

Global Stream Objects

<code>cerr</code>	Specifies the <code>cerr</code> global stream.
<code>cin</code>	Specifies the <code>cin</code> global stream.
<code>clog</code>	Specifies the <code>clog</code> global stream.
<code>cout</code>	Specifies the <code>cout</code> global stream.
<code>wcerr</code>	Specifies the <code>wcerr</code> global stream.
<code>wcin</code>	Specifies the <code>wcin</code> global stream.

<code>wclog</code>	Specifies the <code>wclog</code> global stream.
<code>wcout</code>	Specifies the <code>wcout</code> global stream.

cerr

The object `cerr` controls output to a stream buffer associated with the object `stderr`, declared in `<stdio>`.

```
extern ostream cerr;
```

Return Value

An `ostream` object.

Remarks

The object controls unbuffered insertions to the standard error output as a byte stream. Once the object is constructed, the expression `cerr.flags() & unitbuf` is nonzero, and `cerr.tie() == &cout`.

Example

```
// iostream_cerr.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

using namespace std;

void TestWide( )
{
    int i = 0;
    wcout << L"Enter a number: ";
    wcin >> i;
    wcerr << L"test for wcerr" << endl;
    wclog << L"test for wclog" << endl;
}

int main( )
{
    int i = 0;
    cout << "Enter a number: ";
    cin >> i;
    cerr << "test for cerr" << endl;
    clog << "test for clog" << endl;
    TestWide( );
}
```

cin

Specifies the `cin` global stream.

```
extern istream cin;
```

Return Value

An `istream` object.

Remarks

The object controls extractions from the standard input as a byte stream. Once the object is constructed, the call `cin.tie()` returns `&cout`.

Example

In this example, `cin` sets the fail bit on the stream when it encounters non-numeric characters. The program clears the fail bit and strips the invalid character from the stream to proceed.

```
// iostream_cin.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main()
{
    int x;
    cout << "enter choice:";
    cin >> x;
    while (x < 1 || x > 4)
    {
        cout << "Invalid choice, try again:";
        cin >> x;
        // not a numeric character, probably
        // clear the failure and pull off the non-numeric character
        if (cin.fail())
        {
            cin.clear();
            char c;
            cin >> c;
        }
    }
}
```

2

clog

Specifies the `clog` global stream.

```
extern ostream clog;
```

Return Value

An [ostream](#) object.

Remarks

The object controls buffered insertions to the standard error output as a byte stream.

Example

See [cerr](#) for an example of using `clog`.

cout

Specifies the `cout` global stream.

```
extern ostream cout;
```

Return Value

An [ostream](#) object.

Remarks

The object controls insertions to the standard output as a byte stream.

Example

See [cerr](#) for an example of using `cout`.

wcerr

Specifies the `wcerr` global stream.

```
extern wostream wcerr;
```

Return Value

A [wostream](#) object.

Remarks

The object controls unbuffered insertions to the standard error output as a wide stream. Once the object is constructed, the expression `wcerr.flags() & unitbuf` is nonzero.

Example

See [cerr](#) for an example of using `wcerr`.

wcin

Specifies the `wcin` global stream.

```
extern wistream wcin;
```

Return Value

A [wistream](#) object.

Remarks

The object controls extractions from the standard input as a wide stream. Once the object is constructed, the call `wcin.tie()` returns `&wcout`.

Example

See [cerr](#) for an example of using `wcin`.

wclog

Specifies the `wclog` global stream.

```
extern wostream wclog;
```

Return Value

A [wostream](#) object.

Remarks

The object controls buffered insertions to the standard error output as a wide stream.

Example

See [cerr](#) for an example of using `wclog`.

wcout

Specifies the `wcout` global stream.

```
extern wostream wcout;
```

Return Value

A [wostream](#) object.

Remarks

The object controls insertions to the standard output as a wide stream.

Example

See [cerr](#) for an example of using `wcout`.

`CString` instances in a `wcout` statement must be cast to `const wchar_t*`, as shown in the following example.

```
CString cs("meow");  
  
wcout <<(const wchar_t*) cs <<endl;
```

For more information, see [Basic CString Operations](#).

[Thread Safety in the C++ Standard Library](#)

[iostream Programming](#)

[iostreams Conventions](#)

<iostream>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines the template class `basic_istream`, which mediates extractions for the iostreams, and the template class `basic_iostream`, which mediates both insertions and extractions. The header also defines a related manipulator. This header file is typically included for you by another iostreams header; you rarely have to include it directly.

Syntax

```
#include <iostream>
```

Typedefs

TYPE NAME	DESCRIPTION
<code>iostream</code>	A type <code>basic_iostream</code> specialized on char .
<code>istream</code>	A type <code>basic_istream</code> specialized on char .
<code>wiostream</code>	A type <code>basic_iostream</code> specialized on wchar .
<code>wistream</code>	A type <code>basic_istream</code> specialized on wchar .

Manipulators

<code>ws</code>	Skips white space in the stream.
<code>swap</code>	Exchanges two stream objects.

Operators

OPERATOR	DESCRIPTION
<code>operator>></code>	Extracts characters and strings from the stream.

Classes

CLASS	DESCRIPTION
<code>basic_iostream</code>	A stream class that can do both input and output.
<code>basic_istream</code>	The template class describes an object that controls extraction of elements and encoded objects from a stream buffer with elements of type <code>Elem</code> , also known as <code>char_type</code> , whose character traits are determined by the class <code>Tr</code> , also known as <code>traits_type</code> .

[iostream Programming](#)

[iostreams Conventions](#)

<istream> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

swap

ws

swap

Exchanges the elements of two stream objects.

```
template <class Elem, class Tr>
void swap(
    basic_istream<Elem, Tr>& left,
    basic_istream<Elem, Tr>& right);

template <class Elem, class Tr>
void swap(
    basic_iostream<Elem, Tr>& left,
    basic_iostream<Elem, Tr>& right);
```

Parameters

left

A stream.

right

A stream.

WS

Skips white space in the stream.

```
template class<Elem, Tr> basic_istream<Elem, Tr>& ws(basic_istream<Elem, Tr>& _Istr);
```

Parameters

_Istr

A stream.

Return Value

The stream.

Remarks

The manipulator extracts and discards any elements `ch` for which `use_facet< ctype< Elem> >(_Istr).is(ctype< Elem>::space, ch)` is true.

The function calls `setstate(eofbit)` if it encounters end of file while extracting elements. It returns *_Istr*.

Example

See [operator>>](#) for an example of using `ws`.

See also

[<istream>](#)

<istream> operators

10/31/2018 • 2 minutes to read • [Edit Online](#)

operator>>

Extracts characters and strings from the stream.

```
template <class Elem, class Tr>
basic_istream<Elem, Tr>& operator>>(
    basic_istream<Elem, Tr>& Istr,
    Elem* str);

template <class Elem, class Tr>
basic_istream<Elem, Tr>& operator>>(
    basic_istream<Elem, Tr>& Istr,
    Elem& Ch);

template <class Tr>
basic_istream<char, Tr>& operator>>(
    basic_istream<char, Tr>& Istr,
    signed char* str);

template <class Tr>
basic_istream<char, Tr>& operator>>(
    basic_istream<char, Tr>& Istr,
    signed char& Ch);

template <class Tr>
basic_istream<char, Tr>& operator>>(
    basic_istream<char, Tr>& Istr,
    unsigned char* str);

template <class Tr>
basic_istream<char, Tr>& operator>>(
    basic_istream<char, Tr>& Istr,
    unsigned char& Ch);

template <class Elem, class Tr, class Type>
basic_istream<Elem, Tr>& operator>>(
    basic_istream<char, Tr>&& Istr,
    Type& val);
```

Parameters

Ch

A character.

Istr

A stream.

str

A string.

val

A type.

Return Value

The stream

Remarks

The `basic_istream` class also defines several extraction operators. For more information, see [basic_istream::operator>>](#).

The template function:

```
template <class Elem, class Tr>
basic_istream<Elem, Tr>& operator>>(
    basic_istream<Elem, Tr>& Istr, Elem* str);
```

extracts up to $N - 1$ elements and stores them in the array starting at `_Str`. If `Istr.width` is greater than zero, N is `Istr.width`; otherwise, it is the size of the largest array of `Elem` that can be declared. The function always stores the value `Elem()` after any extracted elements it stores. Extraction stops early on end of file, on a character with value `Elem(0)` (which is not extracted), or on any element (which is not extracted) that would be discarded by [ws](#). If the function extracts no elements, it calls `Istr.setstate(failbit)`. In any case, it calls `Istr.width(0)` and returns `Istr`.

Security Note The null-terminated string being extracted from the input stream must not exceed the size of the destination buffer `str`. For more information, see [Avoiding Buffer Overruns](#).

The template function:

```
template <class Elem, class Tr>
basic_istream<Elem, Tr>& operator>>(
    basic_istream<Elem, Tr>& Istr, Elem& Ch);
```

extracts an element, if it is possible, and stores it in `Ch`. Otherwise, it calls `is.setstate(failbit)`. In any case, it returns `Istr`.

The template function:

```
template <class Tr>
basic_istream<char, Tr>& operator>>(
    basic_istream<char, Tr>& Istr, signed char* str);
```

returns `Istr >> (char *) str`.

The template function:

```
template <class Tr>
basic_istream<char, Tr>& operator>>(
    basic_istream<char, Tr>& Istr, signed char& Ch);
```

returns `Istr >> (char&) Ch`.

The template function:

```
template <class Tr>
basic_istream<char, Tr>& operator>>(
    basic_istream<char, Tr>& Istr, unsigned char* str);
```

returns `Istr >> (char *) str`.

The template function:

```
template <class Tr>
basic_istream<char, Tr>& operator>>(
    basic_istream<char, Tr>& Istr, unsigned char& Ch);
```

returns `Istr >> (char&) Ch` .

The template function:

```
template <class Elem, class Tr, class Type>
basic_istream<Elem, Tr>& operator>>(
    basic_istream<char, Tr>&& Istr,
    Type& val);
```

returns `Istr >> val` (and converts an rvalue reference to `Istr` to an lvalue in the process).

Example

```
// istream_op_extract.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main( )
{
    ws( cin );
    char c[10];

    cin.width( 9 );
    cin >> c;
    cout << c << endl;
}
```

See also

[<istream>](#)

<istream> typedefs

10/31/2018 • 2 minutes to read • [Edit Online](#)

iostream	istream	wiostream
wistream		

iostream

A type `basic_iostream` specialized on **char**.

```
typedef basic_iostream<char, char_traits<char>> iostream;
```

Remarks

The type is a synonym for template class [basic_iostream](#), specialized for elements of type **char** with default character traits.

istream

A type `basic_istream` specialized on **char**.

```
typedef basic_istream<char, char_traits<char>> istream;
```

Remarks

The type is a synonym for template class [basic_istream](#), specialized for elements of type **char** with default character traits.

wiostream

A type `basic_iostream` specialized on **wchar_t**.

```
typedef basic_iostream<wchar_t, char_traits<wchar_t>> wiostream;
```

Remarks

The type is a synonym for template class [basic_iostream](#), specialized for elements of type **wchar_t** with default character traits.

wistream

A type `basic_istream` specialized on **wchar_t**.

```
typedef basic_istream<wchar_t, char_traits<wchar_t>> wistream;
```

Remarks

The type is a synonym for template class [basic_istream](#), specialized for elements of type **wchar_t** with default character traits.

See also

[<istream>](#)

basic_iostream Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

A stream class that can do both input and output.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>>
class basic_iostream : public basic_istream<Elem, Tr>,
    public basic_ostream<Elem, Tr>
{
public:
    explicit basic_iostream(basic_streambuf<Elem, Tr>* strbuf);

    virtual ~basic_iostream();

};
```

Remarks

The template class describes an object that controls insertions, through its base class `basic_ostream` < `Elem`, `Tr` >, and extractions, through its base class `basic_istream` < `Elem`, `Tr` >. The two objects share a common virtual base class `basic_ios` < `Elem`, `Tr` >. They also manage a common stream buffer, with elements of type `Elem`, whose character traits are determined by the class `Tr`. The constructor initializes its base classes through `basic_istream` (`strbuf`) and `basic_ostream` (`strbuf`).

Constructors

CONSTRUCTOR	DESCRIPTION
<code>basic_iostream</code>	Create a <code>basic_iostream</code> object.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>swap</code>	Exchanges the contents of the provided <code>basic_iostream</code> object for the contents of this object.

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Assigns the value of a specified <code>basic_iostream</code> object to this object. This is a move assignment involving an <code>rvalue</code> that does not leave a copy behind.

Requirements

Header: <istream>

Namespace: std

basic_iostream::basic_iostream

Create a `basic_iostream` object.

```
explicit basic_iostream(basic_streambuf<Elem, Tr>* strbuf);

basic_iostream(basic_iostream&& right);

basic_iostream();
```

Parameters

strbuf

An existing `basic_streambuf` object.

right

An existing `basic_iostream` object that is used to construct a new `basic_iostream`.

Remarks

The first constructor initializes the base objects by way of `basic_istream(strbuf)` and `basic_ostream(strbuf)`.

The second constructor initializes the base objects by calling `move(right)`.

basic_iostream::operator=

Assign the value of a specified `basic_iostream` object to this object. This is a move assignment involving an rvalue that does not leave a copy behind.

```
basic_iostream& operator=(basic_iostream&& right);
```

Parameters

right

An `rvalue` reference to a `basic_iostream` object to assign from.

Remarks

The member operator calls `swap(right)`.

basic_iostream::swap

Exchanges the contents of the provided `basic_iostream` object for the contents of this object.

```
void swap(basic_iostream& right);
```

Parameters

right

The `basic_iostream` object to swap.

Remarks

The member function calls `swap(right)`.

basic_istream Class

11/9/2018 • 15 minutes to read • [Edit Online](#)

Describes an object that controls extraction of elements and encoded objects from a stream buffer with elements of type `Elem`, also known as `char_type`, whose character traits are determined by the class `Tr`, also known as `traits_type`.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>>
class basic_istream : virtual public basic_ios<Elem, Tr>
```

Remarks

Most of the member functions that overload `operator>>` are formatted input functions. They follow the pattern:

```
iostate state = goodbit;
const sentry ok(*this);

if (ok)
{
    try
    {
        /*extract elements and convert
        accumulate flags in state.
        store a successful conversion*/
    }
    catch (...)
    {
        try
        {
            setstate(badbit);

        }
        catch (...)
        {
        }
        if ((exceptions() & badbit) != 0)
            throw;
    }
}
setstate(state);

return (*this);
```

Many other member functions are unformatted input functions. They follow the pattern:

```

iostate state = goodbit;
count = 0;    // the value returned by gcount
const sentry ok(*this, true);

if (ok)
{
    try
    {
        /* extract elements and deliver
           count extracted elements in count
           accumulate flags in state */
    }
    catch (...)
    {
        try
        {
            setstate(badbit);

        }
        catch (...)
        {
        }
        if ((exceptions() & badbit) != 0)
            throw;
    }
}
setstate(state);

```

Both groups of functions call `setstate(eofbit)` if they encounter end of file while extracting elements.

An object of class `basic_istream < Elem, Tr >` stores:

- A virtual public base object of class `basic_ios < Elem, Tr >`.
- An extraction count for the last unformatted input operation (called `count` in the previous code).

Example

See the example for [basic_ifstream Class](#) to learn more about input streams.

Constructors

CONSTRUCTOR	DESCRIPTION
basic_istream	Constructs an object of type <code>basic_istream</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
gcount	Returns the number of characters read during the last unformatted input.
get	Reads one or more characters from the input stream.
getline	Reads a line from the input stream.
ignore	Causes a number of elements to be skipped from the current read position.

MEMBER FUNCTION	DESCRIPTION
peek	Returns the next character to be read.
putback	Puts a specified character into the stream.
read	Reads a specified number of characters from the stream and stores them in an array.
readsome	Read from buffer only.
seekg	Moves the read position in a stream.
sentry	The nested class describes an object whose declaration structures the formatted input functions and the unformatted input functions.
swap	Exchanges this <code>basic_istream</code> object for the provided <code>basic_istream</code> object parameter.
sync	Synchronizes the input device associated with the stream with the stream's buffer.
tellg	Reports the current read position in the stream.
unget	Puts the most recently read character back into the stream.

Operators

OPERATOR	DESCRIPTION
operator>>	Calls a function on the input stream or reads formatted data from the input stream.
operator=	Assigns the <code>basic_istream</code> on the right side of the operator to this object. This is a move assignment involving an <code>rvalue</code> reference that does not leave a copy behind.

Requirements

Header: `<istream>`

Namespace: `std`

`basic_istream::basic_istream`

Constructs an object of type `basic_istream`.

```
explicit basic_istream(
    basic_streambuf<Elem, Tr>* strbuf,
    bool _Isstd = false);

basic_istream(basic_istream&& right);
```

Parameters

strbuf

An object of type [basic_streambuf](#).

_Isstd

true if this is a standard stream; otherwise, **false**.

right

A `basic_istream` object to copy.

Remarks

The first constructor initializes the base class by calling `init(_S trbuf)`. It also stores zero in the extraction count. For more information about this extraction count, see the Remarks section of the [basic_istream Class](#) overview topic.

The second constructor initializes the base class by calling `move(right)`. It also stores `_R ight.gcount()` in the extraction count and stores zero in the extraction count for `_R ight`.

Example

See the example for [basic_ifstream::basic_ifstream](#) to learn more about input streams.

basic_istream::gcount

Returns the number of characters read during the last unformatted input.

```
streamsize gcount() const;
```

Return Value

The extraction count.

Remarks

Use [basic_istream::get](#) to read unformatted characters.

Example

```
// basic_istream_gcount.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main( )
{
    cout << "Type the letter 'a': ";

    ws( cin );
    char c[10];

    cin.get( &c[0],9 );
    cout << c << endl;

    cout << cin.gcount( ) << endl;
}
```

```
a
```

Type the letter 'a': a
1

basic_istream::get

Reads one or more characters from the input stream.

```
int_type get();

basic_istream<Elem, Tr>& get(Elem& Ch);
basic_istream<Elem, Tr>& get(Elem* str, streamsize count);
basic_istream<Elem, Tr>& get(Elem* str, streamsize count, Elem Delim);

basic_istream<Elem, Tr>& get(basic_streambuf<Elem, Tr>& strbuf);
basic_istream<Elem, Tr>& get(basic_streambuf<Elem, Tr>& strbuf, Elem Delim);
```

Parameters

count

The number of characters to read from `strbuf`.

Delim

The character that should terminate the read if it is encountered before *count*.

str

A string in which to write.

Ch

A character to get.

strbuf

A buffer in which to write.

Return Value

The parameterless form of `get` returns the element read as an integer or end of file. The remaining forms return the stream (`*this`).

Remarks

The first of these unformatted input functions extracts an element, if possible, as if by returning `rddbuf` -> `sbumpc`. Otherwise, it returns **traits_type::eof**. If the function extracts no element, it calls `setstate(failbit)`.

The second function extracts the `int_type` element `meta` the same way. If `meta` compares equal to **traits_type::eof**, the function calls `setstate(failbit)`. Otherwise, it stores **traits_type::to_char_type**(`meta`) in `ch`. The function returns ***this**.

The third function returns `get(_Str, count, widen('\n'))`.

The fourth function extracts up to `count - 1` elements and stores them in the array beginning at `_Str`. It always stores `char_type` after any extracted elements it stores. In order of testing, extraction stops:

- At end of file.
- After the function extracts an element that compares equal to *Delim*, in which case the element is put back to the controlled sequence.
- After the function extracts *count* - 1 elements.

If the function extracts no elements, it calls `setstate(failbit)`. In any case, it returns ***this**.

The fifth function returns **get(*strbuf*, *widen* ('\\n'))**.

The sixth function extracts elements and inserts them in *strbuf*. Extraction stops on end-of-file or on an element that compares equal to *_ Delim*, which is not extracted. It also stops, without extracting the element in question, if an insertion fails or throws an exception (which is caught but not rethrown). If the function extracts no elements, it calls *setstate* (**failbit**). In any case, the function returns ***this**.

Example

```
// basic_istream_get.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main( )
{
    char c[10];

    c[0] = cin.get( );
    cin.get( c[1] );
    cin.get( &c[2],3 );
    cin.get( &c[4], 4, '7' );

    cout << c << endl;
}
```

1111

basic_istream::getline

Gets a line from the input stream.

```
basic_istream<Elem, Tr>& getline(
    char_type* str,
    streamsize count);

basic_istream<Elem, Tr>& getline(
    char_type* str,
    streamsize count,
    char_type Delim);
```

Parameters

count

The number of characters to read from *strbuf*.

Delim

The character that should terminate the read if it is encountered before *count*.

str

A string in which to write.

Return Value

The stream (***this**).

Remarks

The first of these unformatted input functions returns **getline(_ Str, *count*, *widen* ('\\n'))**.

The second function extracts up to *count* - 1 elements and stores them in the array beginning at *_ Str*. It always

stores the string termination character after any extracted elements it stores. In order of testing, extraction stops:

- At end of file.
- After the function extracts an element that compares equal to *Delim*, in which case the element is neither put back nor appended to the controlled sequence.
- After the function extracts *count* - 1 elements.

If the function extracts no elements or *count* - 1 elements, it calls `setstate(failbit)`. In any case, it returns ***this**.

Example

```
// basic_istream_getline.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main( )
{
    char c[10];

    cin.getline( &c[0], 5, '2' );
    cout << c << endl;
}
```

121

basic_istream::ignore

Causes a number of elements to be skipped from the current read position.

```
basic_istream<Elem, Tr>& ignore(
    streamsize count = 1,
    int_type Delim = traits_type::eof());
```

Parameters

count

The number of elements to skip from the current read position.

Delim

The element that, if encountered before *count*, causes `ignore` to return and allowing all elements after *Delim* to be read.

Return Value

The stream (***this**).

Remarks

The unformatted input function extracts up to *count* elements and discards them. If *count* equals **numeric_limits<int>::max**, however, it is taken as arbitrarily large. Extraction stops early on end of file or on an element `ch` such that `traits_type::to_int_type(ch)` compares equal to *Delim* (which is also extracted). The function returns ***this**.

Example

```
// basic_istream_ignore.cpp
// compile with: /EHsc
#include <iostream>
int main( )
{
    using namespace std;
    char chararray[10];
    cout << "Type 'abcdef': ";
    cin.ignore( 5, 'c' );
    cin >> chararray;
    cout << chararray;
}
```

```
Type 'abcdef': abcdef
def
```

basic_istream::operator>>

Calls a function on the input stream or reads formatted data from the input stream.

```
basic_istream& operator>>(basic_istream& (* Pfn)(basic_istream&));
basic_istream& operator>>(ios_base& (* Pfn)(ios_base&));
basic_istream& operator>>(basic_ios<Elem, Tr>& (* Pfn)(basic_ios<Elem, Tr>&));
basic_istream& operator>>(basic_streambuf<Elem, Tr>* strbuf);
basic_istream& operator>>(bool& val);
basic_istream& operator>>(short& val);
basic_istream& operator>>(unsigned short& val);
basic_istream& operator>>(int& val);
basic_istream& operator>>(unsigned int& val);
basic_istream& operator>>(long& val);
basic_istream& operator>>(unsigned long& val);
basic_istream& operator>>(long long& val);
basic_istream& operator>>(unsigned long long& val);
basic_istream& operator>>(void *& val);
basic_istream& operator>>(float& val);
basic_istream& operator>>(double& val);
basic_istream& operator>>(long double& val);
```

Parameters

Pfn

A function pointer.

strbuf

An object of type `stream_buf`.

val

The value to read from the stream.

Return Value

The stream (***this**).

Remarks

The `<istream>` header also defines several global extraction operators. For more information, see [operator>> \(<istream>\)](#).

The first member function ensures that an expression of the form **istr** >> `ws` calls `ws(istr)`, and then returns ***this**. The second and third functions ensure that other manipulators, such as `hex`, behave similarly. The remaining functions constitute the formatted input functions.

The function:

```
basic_istream& operator>>(
    basic_streambuf<Elem, Tr>* strbuf);
```

extracts elements, if `_Strbuf` is not a null pointer, and inserts them in `strbuf`. Extraction stops on end of file. It also stops without extracting the element in question, if an insertion fails or throws an exception (which is caught but not rethrown). If the function extracts no elements, it calls `setstate(failbit)`. In any case, the function returns ***this**.

The function:

```
basic_istream& operator>>(bool& val);
```

extracts a field and converts it to a Boolean value by calling `use_facet < num_get < Elem, InIt>(getloc). get(InIt(rdbuf), Init(0), *this, getloc, val)`. Here, `InIt` is defined as `istreambuf_iterator < Elem, Tr>`. The function returns ***this**.

The functions:

```
basic_istream& operator>>(short& val);
basic_istream& operator>>(unsigned short& val);
basic_istream& operator>>(int& val);
basic_istream& operator>>(unsigned int& val);
basic_istream& operator>>(long& val);
basic_istream& operator>>(unsigned long& val);
basic_istream& operator>>(long long& val);
basic_istream& operator>>(unsigned long long& val);
basic_istream& operator>>(void *& val);
```

each extract a field and convert it to a numeric value by calling `use_facet < num_get < Elem, InIt>(getloc). get(InIt(rdbuf), Init(0), *this, getloc, val)`. Here, `InIt` is defined as `istreambuf_iterator < Elem, Tr>`, and `val` has type **long**, **unsigned long**, or **void *** as needed.

If the converted value cannot be represented as the type of `val`, the function calls `setstate(failbit)`. In any case, the function returns ***this**.

The functions:

```
basic_istream& operator>>(float& val);
basic_istream& operator>>(double& val);
basic_istream& operator>>(long double& val);
```

each extract a field and convert it to a numeric value by calling `use_facet < num_get < Elem, InIt>(getloc). get(InIt(rdbuf), Init(0), *this, getloc, val)`. Here, `InIt` is defined as `istreambuf_iterator < Elem, Tr>`, and `val` has type **double** or **long double** as needed.

If the converted value cannot be represented as the type of `val`, the function calls `setstate(failbit)`. In any case, it returns ***this**.

Example

```

// istream_basic_istream_op_is.cpp
// compile with: /EHsc
#include <iostream>

using namespace std;

ios_base& hex2( ios_base& ib )
{
    ib.unsetf( ios_base::dec );
    ib.setf( ios_base::hex );
    return ib;
}

basic_istream<char, char_traits<char> >& somefunc(basic_istream<char, char_traits<char> > &i)
{
    if ( i == cin )
    {
        cerr << "i is cin" << endl;
    }
    return i;
}

int main( )
{
    int i = 0;
    cin >> somefunc;
    cin >> i;
    cout << i << endl;
    cin >> hex2;
    cin >> i;
    cout << i << endl;
}

```

basic_istream::operator=

Assigns the `basic_istream` on the right side of the operator to this object. This is a move assignment involving an `rvalue` reference that does not leave a copy behind.

```
basic_istream& operator=(basic_istream&& right);
```

Parameters

right

An `rvalue` reference to a `basic_ifstream` object.

Return Value

Returns `*this`.

Remarks

The member operator calls `swap (right)` .

basic_istream::peek

Returns the next character to be read.

```
int_type peek();
```

Return Value

The next character that will be read.

Remarks

The unformatted input function extracts an element, if possible, as if by returning `rdbuf` -> `sgetc`. Otherwise, it returns `traits_type::eof`.

Example

```
// basic_istream_peek.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main( )
{
    char c[10], c2;
    cout << "Type 'abcde': ";

    c2 = cin.peek( );
    cin.getline( &c[0], 9 );

    cout << c2 << " " << c << endl;
}
```

abcde

Type 'abcde': abcde
a abcde

basic_istream::putback

Puts a specified character into the stream.

```
basic_istream<Elem, Tr>& putback(
    char_type Ch);
```

Parameters

Ch

A character to put back into the stream.

Return Value

The stream (***this**).

Remarks

The [unformatted input function](#) puts back *Ch*, if possible, as if by calling `rdbuf` -> `sputbackc`. If `rdbuf` is a null pointer, or if the call to `sputbackc` returns `traits_type::eof`, the function calls `setstate(badbit)`. In any case, it returns ***this**.

Example

```
// basic_istream_putback.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main( )
{
    char c[10], c2, c3;

    c2 = cin.get( );
    c3 = cin.get( );
    cin.putback( c2 );
    cin.getline( &c[0], 9 );
    cout << c << endl;
}
```

qwq

basic_istream::read

Reads a specified number of characters from the stream and stores them in an array.

This method is potentially unsafe, as it relies on the caller to check that the passed values are correct.

```
basic_istream<Elem, Tr>& read(
    char_type* str,
    streamsize count);
```

Parameters

str

The array in which to read the characters.

count

The number of characters to read.

Return Value

The stream (`*this`).

Remarks

The unformatted input function extracts up to *count* elements and stores them in the array beginning at `_str`. Extraction stops early on end of file, in which case the function calls `setstate(failbit)`. In any case, it returns `*this`.

Example

```
// basic_istream_read.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main()
{
    char c[10];
    int count = 5;

    cout << "Type 'abcde': ";

    // Note: cin::read is potentially unsafe, consider
    // using cin::_Read_s instead.
    cin.read(&c[0], count);
    c[count] = 0;

    cout << c << endl;
}
```

```
abcde
```

```
Type 'abcde': abcde
abcde
```

basic_istream::readsome

Reads the specified number of character values.

This method is potentially unsafe, as it relies on the caller to check that the passed values are correct.

```
streamsize readsome(
    char_type* str,
    streamsize count);
```

Parameters

str

The array in which `readsome` stores the characters it reads.

count

The number of characters to read.

Return Value

The number of characters actually read, [gcount](#).

Remarks

This unformatted input function extracts up to *count* elements from the input stream and stores them in the array *str*.

This function does not wait for input. It reads whatever data is available.

Example

```

// basic_istream_readsome.cpp
// compile with: /EHsc /W3
#include <iostream>
using namespace std;

int main( )
{
    char c[10];
    int count = 5;

    cout << "Type 'abcdefgh': ";

    // cin.read blocks until user types input.
    // Note: cin::read is potentially unsafe, consider
    // using cin::_Read_s instead.
    cin.read(&c[0], 2);

    // Note: cin::readsome is potentially unsafe, consider
    // using cin::_Readsome_s instead.
    int n = cin.readsome(&c[0], count); // C4996
    c[n] = 0;
    cout << n << " characters read" << endl;
    cout << c << endl;
}

```

basic_istream::seekg

Moves the read position in a stream.

```

basic_istream<Elem, Tr>& seekg(pos_type pos);

basic_istream<Elem, Tr>& seekg(off_type off, ios_base::seekdir way);

```

Parameters

pos

The absolute position in which to move the read pointer.

off

An offset to move the read pointer relative to *way*.

way

One of the [ios_base::seekdir](#) enumerations.

Return Value

The stream (***this**).

Remarks

The first member function performs an absolute seek, the second member function performs a relative seek.

NOTE

Do not use the second member function with text files, because Standard C++ does not support relative seeks in text files.

If **fail** is false, the first member function calls **newpos** = **rdbuf** -> **pubseekpos**(**pos**), for some **pos_type** temporary object **newpos**. If **fail** is false, the second function calls **newpos** = **rdbuf** -> **pubseekoff**(**off**, **way**). In either case, if (**off_type**) **newpos** == (**off_type**)(-1) (the positioning operation fails), the function calls

`istr`. `setstate(failbit)`. Both functions return ***this**.

If `fail` is true, the member functions do nothing.

Example

```
// basic_istream_seekg.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main ( )
{
    using namespace std;
    ifstream file;
    char c, c1;

    file.open( "basic_istream_seekg.txt" );
    file.seekg(2); // seek to position 2
    file >> c;
    cout << c << endl;
}
```

basic_istream::sentry

The nested class describes an object whose declaration structures the formatted and unformatted input functions.

```
class sentry { public: explicit sentry( basic_istream<Elem, Tr>& _Istr, bool _Noskip = false); operator bool() const; };
```

Remarks

If `_Istr`. `good` is true, the constructor:

- Calls `_Istr`. `tie` -> `flush` if `_Istr`. `tie` is not a null pointer
- Effectively calls `ws(_Istr)` if `_Istr`. `flags&skipws` is nonzero

If, after any such preparation, `_Istr`. `good` is false, the constructor calls `_Istr`. `setstate(failbit)`. In any case, the constructor stores the value returned by `_Istr`. `good` in `status`. A later call to `operator bool` delivers this stored value.

basic_istream::swap

Exchanges the contents of two `basic_istream` objects.

```
void swap(basic_istream& right);
```

Parameters

right

An lvalue reference to a `basic_istream` object.

Remarks

The member function calls `basic_ios::swap(right)`. It also exchanges the extraction count with the extraction count for *right*.

basic_istream::sync

Synchronizes the input device associated with the stream with the stream's buffer.

```
int sync();
```

Return Value

If `rdbuf` is a null pointer, the function returns -1. Otherwise, it calls `rdbuf` -> `pubsync`. If that returns -1, the function calls `setstate(badbit)` and returns -1. Otherwise, the function returns zero.

basic_istream::tellg

Reports the current read position in the stream.

```
pos_type tellg();
```

Return Value

The current position in the stream.

Remarks

If `fail` is false, the member function returns `rdbuf` -> `pubseekoff(0, cur, in)`. Otherwise, it returns `pos_type` (-1).

Example

```
// basic_istream_tellg.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main()
{
    using namespace std;
    ifstream file;
    char c;
    streamoff i;

    file.open("basic_istream_tellg.txt");
    i = file.tellg();
    file >> c;
    cout << c << " " << i << endl;

    i = file.tellg();
    file >> c;
    cout << c << " " << i << endl;
}
```

basic_istream::unget

Puts the most recently read character back into the stream.

```
basic_istream<Elem, Tr>& unget();
```

Return Value

The stream (***this**).

Remarks

The [unformatted input function](#) puts back the previous element in the stream, if possible, as if by calling `rdbuf`

-> [sungetc](#). If [rdbuf](#) is a null pointer, or if the call to `sungetc` returns `traits_type::eof`, the function calls `setstate(badbit)`. In any case, it returns `*this`.

For information on how `ungetc` might fail, see [basic_streambuf::sungetc](#).

Example

```
// basic_istream_ungetc.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main( )
{
    char c[10], c2;

    cout << "Type 'abc': ";
    c2 = cin.get( );
    cin.ungetc( );
    cin.getline( &c[0], 9 );
    cout << c << endl;
}
```

abc

Type 'abc': abc
abc

[Thread Safety in the C++ Standard Library](#)

[istream Programming](#)

[istreams Conventions](#)

<iterator>

11/9/2018 • 6 minutes to read • [Edit Online](#)

Defines the iterator primitives, predefined iterators and stream iterators, as well as several supporting templates. The predefined iterators include insert and reverse adaptors. There are three classes of insert iterator adaptors: front, back, and general. They provide insert semantics rather than the overwrite semantics that the container member function iterators provide.

Syntax

```
#include <iterator>
```

Remarks

Iterators are a generalization of pointers, abstracting from their requirements in a way that allows a C++ program to work with different data structures in a uniform manner. Iterators act as intermediaries between containers and generic algorithms. Instead of operating on specific data types, algorithms are defined to operate on a range specified by a type of iterator. Any data structure that satisfies the requirements of the iterator may then be operated on by the algorithm. There are five types or categories of iterator, each with its own set of requirements and resulting functionality:

- Output: forward moving, may store but not retrieve values, provided by ostream and inserter.
- Input: forward moving, may retrieve but not store values, provided by istream.
- Forward: forward moving, may store and retrieve values.
- Bidirectional: forward and backward moving, may store and retrieve values, provided by list, set, multiset, map, and multimap.
- Random access: elements accessed in any order, may store and retrieve values, provided by vector, deque, string, and array.

Iterators that have greater requirements and so more powerful access to elements may be used in place of iterators with fewer requirements. For example, if a forward iterator is called for, then a random-access iterator may be used instead.

Visual Studio has added extensions to C++ Standard Library iterators to support a variety of debug mode situations for checked and unchecked iterators. For more information, see [Safe Libraries: C++ Standard Library](#).

Functions

FUNCTION	DESCRIPTION
advance	Increments an iterator by a specified number of positions.
back_inserter	Creates an iterator that can insert elements at the back of a specified container.
begin	Retrieves an iterator to the first element in a specified container.

FUNCTION	DESCRIPTION
<code>cbegin</code>	Retrieves a constant iterator to the first element in a specified container.
<code>cend</code>	Retrieves a constant iterator to the element that follows the last element in the specified container.
<code>distance</code>	Determines the number of increments between the positions addressed by two iterators.
<code>end</code>	Retrieves an iterator to the element that follows the last element in the specified container.
<code>front_inserter</code>	Creates an iterator that can insert elements at the front of a specified container.
<code>inserter</code>	An iterator adaptor that adds a new element to a container at a specified point of insertion.
<code>make_checked_array_iterator</code>	Creates a <code>checked_array_iterator</code> that can be used by other algorithms. Note: This function is a Microsoft extension of the C++ Standard Library. Code implemented by using this function is not portable to C++ Standard build environments that do not support this Microsoft extension.
<code>make_move_iterator</code>	Returns a move iterator containing the provided iterator as its stored base iterator.
<code>make_unchecked_array_iterator</code>	Creates an <code>unchecked_array_iterator</code> that can be used by other algorithms. Note: This function is a Microsoft extension of the C++ Standard Library. Code implemented by using this function is not portable to C++ Standard build environments that do not support this Microsoft extension.
<code>next</code>	Iterates a specified number of times and returns the new iterator position.
<code>prev</code>	Iterates in reverse a specified number of times and returns the new iterator position.

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests if the iterator object on the left side of the operator is not equal to the iterator object on the right side.
<code>operator==</code>	Tests if the iterator object on the left side of the operator is equal to the iterator object on the right side.
<code>operator<</code>	Tests if the iterator object on the left side of the operator is less than the iterator object on the right side.
<code>operator<=</code>	Tests if the iterator object on the left side of the operator is less than or equal to the iterator object on the right side.

OPERATOR	DESCRIPTION
<code>operator></code>	Tests if the iterator object on the left side of the operator is greater than the iterator object on the right side.
<code>operator>=</code>	Tests if the iterator object on the left side of the operator is greater than or equal to the iterator object on the right side.
<code>operator+</code>	Adds an offset to an iterator and returns the new <code>reverse_iterator</code> addressing the inserted element at the new offset position.
<code>operator-</code>	Subtracts one iterator from another and returns the difference.

Classes

CLASS	DESCRIPTION
<code>back_insert_iterator</code>	The template class describes an output iterator object. It inserts elements into a container of type <code>Container</code> , which it accesses through the protected <code>pointer</code> object it stores called container.
<code>bidirectional_iterator_tag</code>	A class that provides a return type for an <code>iterator_category</code> function that represents a bidirectional iterator.
<code>checked_array_iterator</code>	A class that accesses an array using a random access, checked iterator. Note: This class is a Microsoft extension of the C++ Standard Library. Code implemented by using this function is not portable to C++ Standard build environments that do not support this Microsoft extension.
<code>forward_iterator_tag</code>	A class that provides a return type for an <code>iterator_category</code> function that represents a forward iterator.
<code>front_insert_iterator</code>	The template class describes an output iterator object. It inserts elements into a container of type <code>Container</code> , which it accesses through the protected <code>pointer</code> object it stores called container.
<code>input_iterator_tag</code>	A class that provides a return type for an <code>iterator_category</code> function that represents an input iterator.
<code>insert_iterator</code>	The template class describes an output iterator object. It inserts elements into a container of type <code>Container</code> , which it accesses through the protected <code>pointer</code> object it stores called container. It also stores the protected <code>iterator</code> object, of class <code>Container::iterator</code> , called <code>iter</code> .

CLASS	DESCRIPTION
istream_iterator	The template class describes an input iterator object. It extracts objects of class <code>Ty</code> from an input stream, which it accesses through an object it stores, of type pointer to <code>basic_istream<Elem, Tr></code> .
istreambuf_iterator	The template class describes an input iterator object. It inserts elements of class <code>Elem</code> into an output stream buffer, which it accesses through an object it stores, of type pointer to <code>basic_streambuf<Elem, Tr></code> .
iterator	The template class is used as a base type for all iterators.
iterator_traits	A template helper class providing critical types that are associated with different iterator types so that they can be referred to in the same way.
move_iterator	A <code>move_iterator</code> object stores a random-access iterator of type <code>RandomIterator</code> . It behaves like a random-access iterator, except when dereferenced. The result of <code>operator*</code> is implicitly cast to <code>value_type&&</code> to make an rvalue reference.
ostream_iterator	The template class describes an output iterator object. It inserts objects of class <code>Type</code> into an output stream, which it accesses through an object it stores, of type pointer to <code>basic_ostream<Elem, Tr></code> .
ostreambuf_iterator Class	The template class describes an output iterator object. It inserts elements of class <code>Elem</code> into an output stream buffer, which it accesses through an object it stores, of type pointer to <code>basic_streambuf<Elem, Tr></code> .
output_iterator_tag	A class that provides a return type for <code>iterator_category</code> function that represents an output iterator.
random_access_iterator_tag	A class that provides a return type for <code>iterator_category</code> function that represents a random-access iterator.
reverse_iterator	The template class describes an object that behaves like a random-access iterator, only in reverse.
unchecked_array_iterator	A class that accesses an array using a random access, unchecked iterator. Note: This class is a Microsoft extension of the C++ Standard Library. Code implemented by using this function is not portable to C++ Standard build environments that do not support this Microsoft extension.

<iterator> functions

11/9/2018 • 13 minutes to read • [Edit Online](#)

advance	back_inserter	begin
cbegin	cend	distance
end	front_inserter	inserter
make_checked_array_iterator	make_move_iterator	make_unchecked_array_iterator
next	prev	

advance

Increments an iterator by a specified number of positions.

```
template <class InputIterator, class Distance>
void advance(
    InputIterator& InIt,
    Distance Off);
```

Parameters

InIt

The iterator that is to be incremented and that must satisfy the requirements for an input iterator.

Off

An integral type that is convertible to the iterator's difference type and that specifies the number of increments the position of the iterator is to be advanced.

Remarks

The range advanced through must be nonsingular, where the iterators must be dereferenceable or past the end.

If the `InputIterator` satisfies the requirements for a bidirectional iterator type, then *Off* may be negative. If

`InputIterator` is an input or forward iterator type, *Off* must be nonnegative.

The advance function has constant complexity when `InputIterator` satisfies the requirements for a random-access iterator; otherwise, it has linear complexity and so is potentially expensive.

Example

```

// iterator_advance.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    list<int> L;
    for ( i = 1 ; i < 9 ; ++i )
    {
        L.push_back ( i );
    }
    list<int>::iterator L_Iter, LPOS = L.begin ( );

    cout << "The list L is: ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++)
        cout << *L_Iter << " ";
    cout << ")." << endl;

    cout << "The iterator LPOS initially points to the first element: "
        << *LPOS << "." << endl;

    advance ( LPOS , 4 );
    cout << "LPOS is advanced 4 steps forward to point"
        << " to the fifth element: "
        << *LPOS << "." << endl;

    advance ( LPOS , -3 );
    cout << "LPOS is moved 3 steps back to point to the "
        << "2nd element: " << *LPOS << "." << endl;
}

```

```

The list L is: ( 1 2 3 4 5 6 7 8 ).
The iterator LPOS initially points to the first element: 1.
LPOS is advanced 4 steps forward to point to the fifth element: 5.
LPOS is moved 3 steps back to point to the 2nd element: 2.

```

back_inserter

Creates an iterator that can insert elements at the back of a specified container.

```

template <class Container>
back_insert_iterator<Container> back_inserter(Container& _Cont);

```

Parameters

_Cont

The container into which the back insertion is to be executed.

Return Value

A `back_insert_iterator` associated with the container object *_Cont*.

Remarks

Within the C++ Standard Library, the argument must refer to one of the three sequence containers that have the member function `push_back`: [deque Class](#), [list Class](#), or [vector Class](#).

Example

```
// iterator_back_inserter.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 0 ; i < 3 ; ++i )
    {
        vec.push_back ( i );
    }

    vector<int>::iterator vIter;
    cout << "The initial vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    // Insertions can be done with template function
    back_insert_iterator<vector<int> > backiter ( vec );
    *backiter = 30;
    backiter++;
    *backiter = 40;

    // Alternatively, insertions can be done with the
    // back_inserter_iterator member function
    back_inserter ( vec ) = 500;
    back_inserter ( vec ) = 600;

    cout << "After the insertions, the vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ); vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;
}
```

The initial vector vec is: (0 1 2).
After the insertions, the vector vec is: (0 1 2 30 40 500 600).

begin

Retrieves an iterator to the first element in a specified container.

```
template <class Container>
auto begin(Container& cont) \
    -> decltype(cont.begin());

template <class Container>
auto begin(const Container& cont) \
    -> decltype(cont.begin());

template <class Ty, class Size>
Ty *begin(Ty (& array)[Size]);
```

Parameters

cont

A container.

array

An array of objects of type `Ty`.

Return Value

The first two template functions return `cont.begin()`. The first function is non-constant; the second one is constant.

The third template function returns *array*.

Example

We recommend that you use this template function in place of container member `begin()` when more generic behavior is required.

```
// cl.exe /EHsc /nologo /W4 /MTd
#include <algorithm>
#include <functional>
#include <iostream>
#include <iterator>
#include <vector>

template <typename C> void reverse_sort(C& c) {
    using std::begin;
    using std::end;

    std::sort(begin(c), end(c), std::greater<>());
}

template <typename C> void print(const C& c) {
    for (const auto& e : c) {
        std::cout << e << " ";
    }

    std::cout << "\n";
}

int main() {
    std::vector<int> v = { 11, 34, 17, 52, 26, 13, 40, 20, 10, 5, 16, 8, 4, 2, 1 };

    print(v);
    reverse_sort(v);
    print(v);

    std::cout << "--\n";

    int arr[] = { 23, 70, 35, 106, 53, 160, 80, 40, 20, 10, 5, 16, 8, 4, 2, 1 };

    print(arr);
    reverse_sort(arr);
    print(arr);
}
```

```
11 34 17 52 26 13 40 20 10 5 16 8 4 2 1
52 40 34 26 20 17 16 13 11 10 8 5 4 2 1
--
23 70 35 106 53 160 80 40 20 10 5 16 8 4 2 1
160 106 80 70 53 40 35 23 20 16 10 8 5 4 2 1
```

The function `reverse_sort` supports containers of any kind, in addition to regular arrays, because it calls the non-member version of `begin()`. If `reverse_sort` were coded to use the container member `begin()`:

```
template <typename C>
void reverse_sort(C& c) {
    using std::begin;
    using std::end;

    std::sort(c.begin(), c.end(), std::greater<>());
}
```

Then sending an array to it would cause this compiler error:

```
error C2228: left of '.begin' must have class/struct/union
```

cbegin

Retrieves a const iterator to the first element in a specified container.

```
template <class Container>
auto cbegin(const Container& cont)
    -> decltype(cont.begin());
```

Parameters

cont

A container or `initializer_list`.

Return Value

A constant `cont.begin()` .

Remarks

This function works with all C++ Standard Library containers and with [initializer_list](#).

You can use this member function in place of the `begin()` template function to guarantee that the return value is `const_iterator` . Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non-**const**) container or `initializer_list` of any kind that supports `begin()` and `cbegin()` .

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

cend

Retrieves a const iterator to the element that follows the last element in the specified container.

```
template <class Container>
auto cend(const Container& cont)
    -> decltype(cont.end());
```

Parameters

cont

A container or `initializer_list`.

Return Value

A constant `cont.end()` .

Remarks

This function works with all C++ Standard Library containers and with [initializer_list](#).

You can use this member function in place of the [end\(\)](#) template function to guarantee that the return value is `const_iterator` . Typically, it's used in conjunction with the [auto](#) type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container or `initializer_list` of any kind that supports `end()` and `cend()` .

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

distance

Determines the number of increments between the positions addressed by two iterators.

```
template <class InputIterator>
typename iterator_traits<InputIterator>::difference_type distance(InputIterator first, InputIterator last);
```

Parameters

first

The first iterator whose distance from the second is to be determined.

last

The second iterator whose distance from the first is to be determined.

Return Value

The number of times that *first* must be incremented until it equal *last*.

Remarks

The distance function has constant complexity when `InputIterator` satisfies the requirements for a random-access iterator; otherwise, it has linear complexity and so is potentially expensive.

Example

```

// iterator_distance.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    list<int> L;
    for ( i = -1 ; i < 9 ; ++i )
    {
        L.push_back ( 2 * i );
    }
    list<int>::iterator L_Iter, LPOS = L.begin ( );

    cout << "The list L is: ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ) ; L_Iter++ )
        cout << *L_Iter << " ";
    cout << ")." << endl;

    cout << "The iterator LPOS initially points to the first element: "
        << *LPOS << "." << endl;

    advance ( LPOS , 7 );
    cout << "LPOS is advanced 7 steps forward to point "
        << " to the eighth element: "
        << *LPOS << "." << endl;

    list<int>::difference_type Ldiff ;
    Ldiff = distance ( L.begin ( ) , LPOS );
    cout << "The distance from L.begin( ) to LPOS is: "
        << Ldiff << "." << endl;
}

```

The list L is: (-2 0 2 4 6 8 10 12 14 16).
 The iterator LPOS initially points to the first element: -2.
 LPOS is advanced 7 steps forward to point to the eighth element: 12.
 The distance from L.begin() to LPOS is: 7.

end

Retrieves an iterator to the element that follows the last element in the specified container.

```

template <class Container>
auto end(Container& cont)
    -> decltype(cont.end());

template <class Container>
auto end(const Container& cont)
    -> decltype(cont.end());

template <class Ty, class Size>
Ty *end(Ty (& array)[Size]);

```

Parameters

cont

A container.

array

An array of objects of type `Ty`.

Return Value

The first two template functions return `cont.end()` (the first is non-constant and the second is constant).

The third template function returns `array + Size`.

Remarks

For a code example, see [begin](#).

front_inserter

Creates an iterator that can insert elements at the front of a specified container.

```
template <class Container>
front_insert_iterator<Container> front_inserter(Container& _Cont);
```

Parameters

_Cont

The container object whose front is having an element inserted.

Return Value

A `front_insert_iterator` associated with the container object *_Cont*.

Remarks

The member function [front_insert_iterator](#) of the `front_insert_iterator` class may also be used.

Within the C++ Standard Library, the argument must refer to one of the two sequence containers that have the member function `push_back`: [deque Class](#) or "list Class".

Example

```

// iterator_front_inserter.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    list<int>::iterator L_Iter;

    list<int> L;
    for ( i = -1 ; i < 9 ; ++i )
    {
        L.push_back ( i );
    }

    cout << "The list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++)
        cout << *L_Iter << " ";
    cout << ")." << endl;

    // Using the template function to insert an element
    front_insert_iterator< list< int> > Iter(L);
    *Iter = 100;

    // Alternatively, you may use the front_insert member function
    front_inserter ( L ) = 200;

    cout << "After the front insertions, the list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++)
        cout << *L_Iter << " ";
    cout << ")." << endl;
}

```

```

The list L is:
( -1 0 1 2 3 4 5 6 7 8 ).
After the front insertions, the list L is:
( 200 100 -1 0 1 2 3 4 5 6 7 8 ).

```

inserter

A helper template function that lets you use `inserter(_Cont, _Where)` instead of

`insert_iterator<Container>(_Cont, _Where)`.

```

template <class Container>
insert_iterator<Container>
inserter(
    Container& _Cont,
    typename Container::iterator _Where);

```

Parameters

_Cont

The container to which new elements are to be added.

_Where

An iterator locating the point of insertion.

Remarks

The template function returns `insert_iterator<Container>(_Cont, _Where)` .

Example

```
// iterator_inserter.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    list<int>::iterator L_Iter;

    list<int> L;
    for (i = 2 ; i < 5 ; ++i )
    {
        L.push_back ( 10 * i );
    }

    cout << "The list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ) ; L_Iter++ )
        cout << *L_Iter << " ";
    cout << ")." << endl;

    // Using the template version to insert an element
    insert_iterator<list<int> > Iter( L, L.begin ( ) );
    *Iter = 1;

    // Alternatively, using the member function to insert an element
    inserter ( L, L.end ( ) ) = 500;

    cout << "After the insertions, the list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ) ; L_Iter++)
        cout << *L_Iter << " ";
    cout << ")." << endl;
}
```

```
The list L is:
( 20 30 40 ).
After the insertions, the list L is:
( 1 20 30 40 500 ).
```

make_checked_array_iterator

Creates a `checked_array_iterator` that can be used by other algorithms.

NOTE

This function is a Microsoft extension of the C++ Standard Library. Code implemented by using this function is not portable to C++ Standard build environments that do not support this Microsoft extension.

```
template <class Iter>
checked_array_iterator<Iter>
    make_checked_array_iterator(
Iter Ptr,
    size_t Size,
    size_t Index = 0);
```

Parameters

Ptr

A pointer to the destination array.

Size

The size of the destination array.

Index

Optional index into the array.

Return Value

An instance of `checked_array_iterator`.

Remarks

The `make_checked_array_iterator` function is defined in the `stdext` namespace.

This function takes a raw pointer—which would ordinarily cause concern about bounds overrun—and wraps it in a [checked_array_iterator](#) class that does checking. Because that class is marked as checked, the C++ Standard Library doesn't warn about it. For more information and code examples, see [Checked Iterators](#).

Example

In the following example, a [vector](#) is created and populated with 10 items. The contents of the vector are copied into an array by using the copy algorithm, and then `make_checked_array_iterator` is used to specify the destination. This is followed by an intentional violation of the bounds checking so that a debug assertion failure is triggered.

```

// make_checked_array_iterator.cpp
// compile with: /EHsc /W4 /MTd

#include <algorithm>
#include <iterator> // stdext::make_checked_array_iterator
#include <memory> // std::make_unique
#include <iostream>
#include <vector>
#include <string>

using namespace std;

template <typename C> void print(const string& s, const C& c) {
    cout << s;

    for (const auto& e : c) {
        cout << e << " ";
    }

    cout << endl;
}

int main()
{
    const size_t dest_size = 10;
    // Old-school but not exception safe, favor make_unique<int[]>
    // int* dest = new int[dest_size];
    unique_ptr<int[]> updest = make_unique<int[]>(dest_size);
    int* dest = updest.get(); // get a raw pointer for the demo

    vector<int> v;

    for (int i = 0; i < dest_size; ++i) {
        v.push_back(i);
    }
    print("vector v: ", v);

    copy(v.begin(), v.end(), stdext::make_checked_array_iterator(dest, dest_size));

    cout << "int array dest: ";
    for (int i = 0; i < dest_size; ++i) {
        cout << dest[i] << " ";
    }
    cout << endl;

    // Add another element to the vector to force an overrun.
    v.push_back(10);
    // The next line causes a debug assertion when it executes.
    copy(v.begin(), v.end(), stdext::make_checked_array_iterator(dest, dest_size));
}

```

make_move_iterator

Creates a `move iterator` that contains the provided iterator as the `stored` iterator.

```

template <class Iterator>
move_iterator<Iterator>
make_move_iterator(const Iterator& _It);

```

Parameters

`_It`

The iterator stored in the new move iterator.

Remarks

The template function returns `move_iterator` `<Iterator>(_It)`.

make_unchecked_array_iterator

Creates an [unchecked_array_iterator](#) that can be used by other algorithms.

NOTE

This function is a Microsoft extension of the C++ Standard Library. Code implemented by using this function is not portable to C++ Standard build environments that do not support this Microsoft extension.

```
template <class Iter>
unchecked_array_iterator<Iter>
    make_unchecked_array_iterator(Iter Ptr);
```

Parameters

Ptr

A pointer to the destination array.

Return Value

An instance of `unchecked_array_iterator`.

Remarks

The `make_unchecked_array_iterator` function is defined in the `stdext` namespace.

This function takes a raw pointer and wraps it in a class that performs no checking and therefore optimizes away to nothing, but it also silences compiler warnings such as [C4996](#). Therefore, this is a targeted way to deal with unchecked-pointer warnings without globally silencing them or incurring the cost of checking. For more information and code examples, see [Checked Iterators](#).

Example

In the following example, a [vector](#) is created and populated with 10 items. The contents of the vector are copied into an array by using the copy algorithm, and then `make_unchecked_array_iterator` is used to specify the destination.

```

// make_unchecked_array_iterator.cpp
// compile with: /EHsc /W4 /MTd

#include <algorithm>
#include <iterator> // stdext::make_unchecked_array_iterator
#include <iostream>
#include <vector>
#include <string>

using namespace std;

template <typename C> void print(const string& s, const C& c) {
    cout << s;

    for (const auto& e : c) {
        cout << e << " ";
    }

    cout << endl;
}

int main()
{
    const size_t dest_size = 10;
    int *dest = new int[dest_size];
    vector<int> v;

    for (int i = 0; i < dest_size; ++i) {
        v.push_back(i);
    }
    print("vector v: ", v);

    // COMPILER WARNING SILENCED: stdext::unchecked_array_iterator is marked as checked in debug mode
    // (it performs no checking, so an overrun will trigger undefined behavior)
    copy(v.begin(), v.end(), stdext::make_unchecked_array_iterator(dest));

    cout << "int array dest: ";
    for (int i = 0; i < dest_size; ++i) {
        cout << dest[i] << " ";
    }
    cout << endl;

    delete[] dest;
}

```

next

Iterates a specified number of times and returns the new iterator position.

```

template <class InputIterator>
InputIterator next(
    InputIterator first,
    typename iterator_traits<InputIterator>::difference_type _Off = 1);

```

Parameters

first

The current position.

_Off

The number of times to iterate.

Return Value

Returns the new iterator position after iterating *_Off* times.

Remarks

The template function returns `next` incremented *_Off* times

prev

Iterates in reverse a specified number of times and returns the new iterator position.

```
template <class BidirectionalIterator>
BidirectionalIterator prev(
    BidirectionalIterator first,
    typename iterator_traits<BidirectionalIterator>::difference_type _Off = 1);
```

Parameters

first

The current position.

_Off

The number of times to iterate.

Remarks

The template function returns `next` decremented `off` times.

[<iterator>](#)

<iterator> operators

10/31/2018 • 15 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<=</code>	<code>operator+</code>
<code>operator-</code>	<code>operator==</code>	

operator!=

Tests if the iterator object on the left side of the operator is not equal to the iterator object on the right side.

```
template <class RandomIterator>
bool operator!=(const reverse_iterator<RandomIterator>& left, const reverse_iterator<RandomIterator>& right);

template <class Type, class CharType, class Traits, class Distance>
bool operator!=(const istream_iterator<Type, CharType, Traits, Distance>& left, const istream_iterator<Type,
CharType, Traits, Distance>& right);

template <class CharType, class Tr>
bool operator!=(const istreambuf_iterator<CharType, Traits>& left, const istreambuf_iterator<CharType, Traits>&
right);
```

Parameters

left

An object of type `iterator`.

right

An object of type `iterator`.

Return Value

true if the iterator objects are not equal; **false** if the iterator objects are equal.

Remarks

One iterator object is equal to another if they address the same elements in a container. If two iterators point to different elements in a container, then they are not equal.

Example

```

// iterator_op_ne.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 1 ; i < 9 ; ++i )
    {
        vec.push_back ( i );
    }

    vector<int>::iterator vIter;

    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;

    // Initializing reverse_iterators to the last element
    vector<int>::reverse_iterator rVPOS1 = vec.rbegin ( ),
        rVPOS2 = vec.rbegin ( );

    cout << "The iterator rVPOS1 initially points to the first "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    if ( rVPOS1 != rVPOS2 )
        cout << "The iterators are not equal." << endl;
    else
        cout << "The iterators are equal." << endl;

    rVPOS1++;
    cout << "The iterator rVPOS1 now points to the second "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    if ( rVPOS1 != rVPOS2 )
        cout << "The iterators are not equal." << endl;
    else
        cout << "The iterators are equal." << endl;
}

```

```

The vector vec is: ( 1 2 3 4 5 6 7 8 ).
The iterator rVPOS1 initially points to the first element
in the reversed sequence: 8.
The iterators are equal.
The iterator rVPOS1 now points to the second element
in the reversed sequence: 7.
The iterators are not equal.

```

operator==

Tests if the iterator object on the left side of the operator is equal to the iterator object on the right side.

```

template <class RandomIterator1, class RandomIterator2>
bool operator==(
    const move_iterator<RandomIterator1>& left,
    const move_iterator<RandomIterator2>& right);

template <class RandomIterator1, class RandomIterator2>
bool operator==(
    const reverse_iterator<RandomIterator1>& left,
    const reverse_iterator<RandomIterator2>& right);

template <class Type, class CharType, class Traits, class Distance>
bool operator==(
    const istream_iterator<Type, CharType, Traits, Distance>& left,
    const istream_iterator<Type, CharType, Traits, Distance>& right);

template <class CharType, class Tr>
bool operator==(
    const istreambuf_iterator<CharType, Traits>& left,
    const istreambuf_iterator<CharType, Traits>& right);

```

Parameters

left

An object of type iterator.

right

An object of type iterator.

Return Value

true if the iterator objects are equal; **false** if the iterator objects are not equal.

Remarks

One iterator object is equal to another if they address the same elements in a container. If two iterators point to different elements in a container, then they are not equal.

The first two template operators return true only if both *left* and *right* store the same iterator. The third template operator returns true only if both *left* and *right* store the same stream pointer. The fourth template operator returns

`left.equal (right) .`

Example

```

// iterator_op_eq.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( 2 * i );
    }

    vector<int>::iterator vIter;

    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    // Initializing reverse_iterators to the last element
    vector<int>::reverse_iterator rVPOS1 = vec.rbegin ( ),
        rVPOS2 = vec.rbegin ( );

    cout << "The iterator rVPOS1 initially points to the first "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    if ( rVPOS1 == rVPOS2 )
        cout << "The iterators are equal." << endl;
    else
        cout << "The iterators are not equal." << endl;

    rVPOS1++;
    cout << "The iterator rVPOS1 now points to the second "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    if ( rVPOS1 == rVPOS2 )
        cout << "The iterators are equal." << endl;
    else
        cout << "The iterators are not equal." << endl;
}

```

```

The vector vec is: ( 2 4 6 8 10 ).
The iterator rVPOS1 initially points to the first element
in the reversed sequence: 10.
The iterators are equal.
The iterator rVPOS1 now points to the second element
in the reversed sequence: 8.
The iterators are not equal.

```

operator<

Tests if the iterator object on the left side of the operator is less than the iterator object on the right side.

```

template <class RandomIterator>
bool operator<(const reverse_iterator<RandomIterator>& left, const reverse_iterator<RandomIterator>& right);

```

Parameters

left

An object of type `iterator` .

right

An object of type `iterator` .

Return Value

true if the iterator on the left side of the expression is less than the iterator on the right side of the expression; **false** if it is greater than or equal to the iterator on the right.

Remarks

One iterator object is less than another if it addresses an element that occurs earlier in the container than the element addressed by the other iterator object. One iterator object is not less than another if it addresses either the same element as the other iterator object or an element that occurs later in the container than the element addressed by the other iterator object.

Example

```

// iterator_op_lt.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 0 ; i < 6 ; ++i )
    {
        vec.push_back ( 2 * i );
    }

    vector<int>::iterator vIter;

    cout << "The initial vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    // Initializing reverse_iterators to the last element
    vector<int>::reverse_iterator rVPOS1 = vec.rbegin ( ),
        rVPOS2 = vec.rbegin ( );

    cout << "The iterators rVPOS1& rVPOS2 initially point to the "
        << "first element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    if ( rVPOS1 < rVPOS2 )
        cout << "The iterator rVPOS1 is less than"
            << " the iterator rVPOS2." << endl;
    else
        cout << "The iterator rVPOS1 is not less than"
            << " the iterator rVPOS2." << endl;

    rVPOS2++;
    cout << "The iterator rVPOS2 now points to the second "
        << "element\n in the reversed sequence: "
        << *rVPOS2 << "." << endl;

    if ( rVPOS1 < rVPOS2 )
        cout << "The iterator rVPOS1 is less than"
            << " the iterator rVPOS2." << endl;
    else
        cout << "The iterator rVPOS1 is not less than"
            << " the iterator rVPOS2." << endl;
}

```

The initial vector vec is: (0 2 4 6 8 10).
 The iterators rVPOS1& rVPOS2 initially point to the first element
 in the reversed sequence: 10.
 The iterator rVPOS1 is not less than the iterator rVPOS2.
 The iterator rVPOS2 now points to the second element
 in the reversed sequence: 8.
 The iterator rVPOS1 is less than the iterator rVPOS2.

operator<=

Tests if the iterator object on the left side of the operator is less than or equal to the iterator object on the right side.

```
template <class RandomIterator>
bool operator<=(const reverse_iterator<RandomIterator>& left, const reverse_iterator<RandomIterator>& right);
```

Parameters

left

An object of type iterator.

right

An object of type iterator.

Return Value

true if the iterator on the left side of the expression is less than or equal to the iterator on the right side of the expression; **false** if it is greater than the iterator on the right.

Remarks

One iterator object is less than or equal to another if it addresses the same element or an element that occurs earlier in the container than the element addressed by the other iterator object. One iterator object is greater than another if it addresses an element that occurs later in the container than the element addressed by the other iterator object.

Example

```

// iterator_op_le.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 0 ; i < 6 ; ++i ) {
        vec.push_back ( 2 * i );
    }

    vector <int>::iterator vIter;

    cout << "The initial vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rVPOS1 = vec.rbegin ( ) + 1,
        rVPOS2 = vec.rbegin ( );

    cout << "The iterator rVPOS1 initially points to the "
        << "second element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    cout << "The iterator rVPOS2 initially points to the "
        << "first element\n in the reversed sequence: "
        << *rVPOS2 << "." << endl;

    if ( rVPOS1 <= rVPOS2 )
        cout << "The iterator rVPOS1 is less than or "
            << "equal to the iterator rVPOS2." << endl;
    else
        cout << "The iterator rVPOS1 is greater than "
            << "the iterator rVPOS2." << endl;

    rVPOS2++;
    cout << "The iterator rVPOS2 now points to the second "
        << "element\n in the reversed sequence: "
        << *rVPOS2 << "." << endl;

    if ( rVPOS1 <= rVPOS2 )
        cout << "The iterator rVPOS1 is less than or "
            << "equal to the iterator rVPOS2." << endl;
    else
        cout << "The iterator rVPOS1 is greater than "
            << "the iterator rVPOS2." << endl;
}

```

The initial vector vec is: (0 2 4 6 8 10).
 The iterator rVPOS1 initially points to the second element
 in the reversed sequence: 8.
 The iterator rVPOS2 initially points to the first element
 in the reversed sequence: 10.
 The iterator rVPOS1 is greater than the iterator rVPOS2.
 The iterator rVPOS2 now points to the second element
 in the reversed sequence: 8.
 The iterator rVPOS1 is less than or equal to the iterator rVPOS2.

operator>

Tests if the iterator object on the left side of the operator is greater than the iterator object on the right side.

```
template <class RandomIterator>
bool operator>(const reverse_iterator<RandomIterator>& left, const reverse_iterator<RandomIterator>& right);
```

Parameters

left

An object of type iterator.

right

An object of type iterator.

Return Value

true if the iterator on the left side of the expression is greater than the iterator on the right side of the expression;

false if it is less than or equal to the iterator on the right.

Remarks

One iterator object is greater than another if it addresses an element that occurs later in the container than the element addressed by the other iterator object. One iterator object is not greater than another if it addresses either the same element as the other iterator object or an element that occurs earlier in the container than the element addressed by the other iterator object.

Example

```

// iterator_op_gt.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 0 ; i < 6 ; ++i ) {
        vec.push_back ( 2 * i );
    }

    vector<int>::iterator vIter;

    cout << "The initial vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector<int>::reverse_iterator rVPOS1 = vec.rbegin ( ),
        rVPOS2 = vec.rbegin ( );

    cout << "The iterators rVPOS1 & rVPOS2 initially point to "
        << "the first element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    if ( rVPOS1 > rVPOS2 )
        cout << "The iterator rVPOS1 is greater than "
            << "the iterator rVPOS2." << endl;
    else
        cout << "The iterator rVPOS1 is less than or "
            << "equal to the iterator rVPOS2." << endl;

    rVPOS1++;
    cout << "The iterator rVPOS1 now points to the second "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    if ( rVPOS1 > rVPOS2 )
        cout << "The iterator rVPOS1 is greater than "
            << "the iterator rVPOS2." << endl;
    else
        cout << "The iterator rVPOS1 is less than or "
            << "equal to the iterator rVPOS2." << endl;
}

```

```

The initial vector vec is: ( 0 2 4 6 8 10 ).
The iterators rVPOS1 & rVPOS2 initially point to the first element
in the reversed sequence: 10.
The iterator rVPOS1 is less than or equal to the iterator rVPOS2.
The iterator rVPOS1 now points to the second element
in the reversed sequence: 8.
The iterator rVPOS1 is greater than the iterator rVPOS2.

```

operator>=

Tests if the iterator object on the left side of the operator is greater than or equal to the iterator object on the right side.

```
template <class RandomIterator>
bool operator>=(const reverse_iterator<RandomIterator>& left, const reverse_iterator<RandomIterator>& right);
```

Parameters

left

An object of type iterator.

right

An object of type iterator.

Return Value

true if the iterator on the left side of the expression is greater than or equal to the iterator on the right side of the expression; **false** if it is less than the iterator on the right.

Remarks

One iterator object is greater than or equal to another if it addresses the same element or an element that occurs later in the container than the element addressed by the other iterator object. One iterator object is less than another if it addresses an element that occurs earlier in the container than the element addressed by the other iterator object.

Example

```

// iterator_op_ge.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 0 ; i < 6 ; ++i ) {
        vec.push_back ( 2 * i );
    }

    vector<int>::iterator vIter;

    cout << "The initial vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector<int>::reverse_iterator rVPOS1 = vec.rbegin ( ),
        rVPOS2 = vec.rbegin ( ) + 1;

    cout << "The iterator rVPOS1 initially points to the "
        << "first element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    cout << "The iterator rVPOS2 initially points to the "
        << "second element\n in the reversed sequence: "
        << *rVPOS2 << "." << endl;

    if ( rVPOS1 >= rVPOS2 )
        cout << "The iterator rVPOS1 is greater than or "
            << "equal to the iterator rVPOS2." << endl;
    else
        cout << "The iterator rVPOS1 is less than "
            << "the iterator rVPOS2." << endl;

    rVPOS1++;
    cout << "The iterator rVPOS1 now points to the second "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    if ( rVPOS1 >= rVPOS2 )
        cout << "The iterator rVPOS1 is greater than or "
            << "equal to the iterator rVPOS2." << endl;
    else
        cout << "The iterator rVPOS1 is less than "
            << "the iterator rVPOS2." << endl;
}

```

The initial vector vec is: (0 2 4 6 8 10).
 The iterator rVPOS1 initially points to the first element
 in the reversed sequence: 10.
 The iterator rVPOS2 initially points to the second element
 in the reversed sequence: 8.
 The iterator rVPOS1 is less than the iterator rVPOS2.
 The iterator rVPOS1 now points to the second element
 in the reversed sequence: 8.
 The iterator rVPOS1 is greater than or equal to the iterator rVPOS2.

operator+

Adds an offset to an iterator and returns a `move_iterator` or a `reverse_iterator` addressing the inserted element at the new offset position.

```
template <class RandomIterator, class Diff>
move_iterator<RandomIterator>
operator+(
    Diff _Off,
    const move_iterator<RandomIterator>& right);

template <class RandomIterator>
reverse_iterator<RandomIterator>
operator+(
    Diff _Off,
    const reverse_iterator<RandomIterator>& right);
```

Parameters

_Off

The number of positions the const `move_iterator` or const `reverse_iterator` is to be offset.

right

The iterator to be offset.

Return Value

Returns the sum *right* + *_Off*.

Example

```

// iterator_op_insert.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 0 ; i < 6 ; ++i ) {
        vec.push_back ( 2 * i );
    }

    vector <int>::iterator vIter;

    cout << "The initial vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rVPOS1 = vec.rbegin ( );

    cout << "The iterator rVPOS1 initially points to "
        << "the first element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    vector<int>::difference_type diff = 4;
    rVPOS1 = diff +rVPOS1;

    cout << "The iterator rVPOS1 now points to the fifth "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;
}

```

```

The initial vector vec is: ( 0 2 4 6 8 10 ).
The iterator rVPOS1 initially points to the first element
in the reversed sequence: 10.
The iterator rVPOS1 now points to the fifth element
in the reversed sequence: 2.

```

operator-

Subtracts one iterator from another and returns the difference.

```

template <class RandomIterator1, class RandomIterator2>
Tdiff operator-(
    const move_iterator<RandomIterator1>& left,
    const move_iterator<RandomIterator2>& right);

template <class RandomIterator1, class RandomIterator2>
Tdiff operator-(
    const reverse_iterator<RandomIterator1>& left,
    const reverse_iterator<RandomIterator2>& right);

```

Parameters

left

An iterator.

right

An iterator.

Return Value

The difference between two iterators .

Remarks

The first template operator returns `left.base() - right.base()` .

The second template operator returns `right.current - left.current` .

`Tdiff` is determined by the type of the returned expression. Otherwise, it is `RandomIterator1::difference_type` .

Example

```
// iterator_op_sub.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 0 ; i < 6 ; ++i )
    {
        vec.push_back ( 2 * i );
    }

    vector <int>::iterator vIter;

    cout << "The initial vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rVPOS1 = vec.rbegin ( ),
        rVPOS2 = vec.rbegin ( );

    cout << "The iterators rVPOS1 & rVPOS2 initially point to "
        << "the first element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    for (i = 1; i < 5; ++i)
    {
        rVPOS2++;
    }
    cout << "The iterator rVPOS2 now points to the fifth "
        << "element\n in the reversed sequence: "
        << *rVPOS2 << "." << endl;

    vector<int>::difference_type diff = rVPOS2 - rVPOS1;
    cout << "The difference: rVPOS2 - rVPOS1= "
        << diff << "." << endl;
}
```

The initial vector vec is: (0 2 4 6 8 10).
The iterators rVPOS1 & rVPOS2 initially point to the first element
in the reversed sequence: 10.
The iterator rVPOS2 now points to the fifth element
in the reversed sequence: 2.
The difference: rVPOS2 - rVPOS1= 4.

[<iterator>](#)

back_insert_iterator Class

10/31/2018 • 6 minutes to read • [Edit Online](#)

Describes an iterator adaptor that satisfies the requirements of an output iterator. It inserts, rather than overwrites, elements into the back end of a sequence and thus provides semantics that are different from the overwrite semantics provided by the iterators of the C++ sequence containers. The `back_insert_iterator` class is templated on the type of container.

Syntax

```
template <class Container>
class back_insert_iterator;
```

Parameters

Container

The type of container into the back of which elements are to be inserted by a `back_insert_iterator`.

Remarks

The container must satisfy the requirements for a back insertion sequence where it is possible to insert elements at the end of the sequence in amortized constant time. C++ Standard Library sequence containers defined by the [deque Class](#), [list Class](#) and [vector Class](#) provide the needed `push_back` member function and satisfy these requirements. These three containers as well as strings may each be adapted to use with `back_insert_iterator`s. A `back_insert_iterator` must always be initialized with its container.

Constructors

CONSTRUCTOR	DESCRIPTION
back_insert_iterator	Constructs a <code>back_insert_iterator</code> that inserts elements after the last element in a container.

Typedefs

TYPE NAME	DESCRIPTION
container_type	A type that provides a container for the <code>back_insert_iterator</code> .
reference	A type that provides a reference for the <code>back_insert_iterator</code> .

Operators

OPERATOR	DESCRIPTION
operator*	Dereferencing operator used to implement the output iterator expression <code>*i = x</code> for a back insertion.

OPERATOR	DESCRIPTION
<code>operator++</code>	Increments the <code>back_insert_iterator</code> to the next location into which a value may be stored.
<code>operator=</code>	Assignment operator used to implement the output iterator expression <code>* i = x</code> for a back insertion.

Requirements

Header: `<iterator>`

Namespace: `std`

`back_insert_iterator::back_insert_iterator`

Constructs a `back_insert_iterator` that inserts elements after the last element in a container.

```
explicit back_insert_iterator(Container& _Cont);
```

Parameters

_Cont

The container that the `back_insert_iterator` is to insert an element into.

Return Value

A `back_insert_iterator` for the parameter container.

Example

```

// back_insert_iterator_back_insert_iterator.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 1 ; i < 4 ; ++i )
    {
        vec.push_back ( i );
    }

    vector<int>::iterator vIter;
    cout << "The initial vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    // Insertions with member function
    back_inserter ( vec ) = 40;
    back_inserter ( vec ) = 50;

    // Alternatively, insertions can be done with template function
    back_insert_iterator<vector<int> > backiter ( vec );
    *backiter = 600;
    backiter++;
    *backiter = 700;

    cout << "After the insertions, the vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;
}

```

The initial vector vec is: (1 2 3).
 After the insertions, the vector vec is: (1 2 3 40 50 600 700).

back_insert_iterator::container_type

A type that provides a container for the `back_insert_iterator`.

```

typedef Container
container_type;

```

Remarks

The type is a synonym for the template parameter **Container**.

Example

```

// back_insert_iterator_container_type.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 4 ; ++i )
    {
        vec.push_back ( i );
    }

    vector<int>::iterator vIter;
    cout << "The original vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    back_insert_iterator<vector<int> >::container_type> vec1 = vec;
    back_inserter ( vec1 ) = 40;

    cout << "After the insertion, the vector is: ( ";
    for ( vIter = vec1.begin ( ) ; vIter != vec1.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;
}

```

The original vector vec is: (1 2 3).
 After the insertion, the vector is: (1 2 3 40).

back_insert_iterator::operator*

Dereferencing operator used to implement the output iterator expression $*i = x$.

```
back_insert_iterator<Container>& operator*();
```

Return Value

A reference to the element inserted at the back of the container.

Remarks

Used to implement the output iterator expression ***Iter = value**. If **Iter** is an iterator that addresses an element in a sequence, then ***Iter = value** replaces that element with value and does not change the total number of elements in the sequence.

Example

```

// back_insert_iterator_back_insert.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 4 ; ++i )
    {
        vec.push_back ( i );
    }

    vector<int>::iterator vIter;
    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    back_insert_iterator<vector<int> > backiter ( vec );
    *backiter = 10;
    backiter++;      // Increment to the next element
    *backiter = 20;
    backiter++;

    cout << "After the insertions, the vector vec becomes: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;
}

```

The vector vec is: (1 2 3).
 After the insertions, the vector vec becomes: (1 2 3 10 20).

back_insert_iterator::operator++

Increments the `back_insert_iterator` to the next location into which a value may be stored.

```

back_insert_iterator<Container>& operator++();
back_insert_iterator<Container> operator++(int);

```

Return Value

A `back_insert_iterator` addressing the next location into which a value may be stored.

Remarks

Both preincrementation and postincrementation operators return the same result.

Example

```

// back_insert_iterator_op_incre.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 3 ; ++i )
    {
        vec.push_back ( 10 * i );
    }

    vector<int>::iterator vIter;
    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    back_insert_iterator<vector<int> > backiter ( vec );
    *backiter = 30;
    backiter++;      // Increment to the next element
    *backiter = 40;
    backiter++;

    cout << "After the insertions, the vector vec becomes: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;
}

```

The vector vec is: (10 20).
 After the insertions, the vector vec becomes: (10 20 30 40).

back_insert_iterator::operator=

Appends or pushes a value onto the back end of a container.

```

back_insert_iterator<Container>& operator=(typename Container::const_reference val);
back_insert_iterator<Container>& operator=(typename Container::value_type&& val);

```

Parameters

val

The value to be inserted into the container.

Return Value

A reference to the last element inserted at the back of the container.

Remarks

The first member operator evaluates `Container.push_back(val)`,

then returns `*this`. The second member operator evaluates

```

container->push_back((typename Container::value_type&&)val) ,

```

then returns `*this`.

Example

```
// back_insert_iterator_op_assign.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 4 ; ++i )
    {
        vec.push_back ( i );
    }

    vector<int>::iterator vIter;
    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    back_insert_iterator<vector<int> > backiter ( vec );
    *backiter = 10;
    backiter++;      // Increment to the next element
    *backiter = 20;
    backiter++;

    cout << "After the insertions, the vector vec becomes: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;
}
```

back_insert_iterator::reference

A type that provides a reference for the `back_insert_iterator`.

```
typedef typename Container::reference reference;
```

Remarks

The type describes a reference to an element of the sequence controlled by the associated container.

Example

```

// back_insert_iterator_reference.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 4 ; ++i )
    {
        vec.push_back ( i );
    }

    vector<int>::iterator vIter;
    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    back_insert_iterator<vector<int> >::reference
        RefLast = *(vec.end ( ) - 1 );
    cout << "The last element in the vector vec is: "
        << RefLast << "." << endl;
}

```

```

The vector vec is: ( 1 2 3 ).
The last element in the vector vec is: 3.

```

[C++ Standard Library Reference](#)

bidirectional_iterator_tag Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

A class that provides a return type for `iterator_category` function that represents a bidirectional iterator.

Syntax

```
struct bidirectional_iterator_tag : public forward_iterator_tag {};
```

Remarks

The category tag classes are used as compile tags for algorithm selection. The template function needs to find the most specific category of its iterator argument, so that it can use the most efficient algorithm at compile time. For every iterator of type `Iterator`, `iterator_traits < Iterator >::iterator_category` must be defined to be the most specific category tag that describes the iterator's behavior.

The type is the same as `iterator < Iter >::iterator_category` when `Iter` describes an object that can serve as a bidirectional iterator.

Example

See [random_access_iterator_tag](#) for an example of how to use `bidirectional_iterator_tag`.

Requirements

Header: `<iterator>`

Namespace: `std`

checked_array_iterator Class

3/28/2019 • 13 minutes to read • [Edit Online](#)

The `checked_array_iterator` class allows you to transform an array or pointer into a checked iterator. Use this class as a wrapper (using the [make_checked_array_iterator](#) function) for raw pointers or arrays as a targeted way to provide checking and to manage unchecked pointer warnings instead of globally silencing these warnings. If necessary, you can use the unchecked version of this class, [unchecked_array_iterator](#).

NOTE

This class is a Microsoft extension of the C++ Standard Library. Code implemented by using this function is not portable to C++ Standard build environments that do not support this Microsoft extension. For an example demonstrating how to write code that does not require the use of this class, see the second example below.

Syntax

```
template <class _Iterator>
class checked_array_iterator;
```

Remarks

This class is defined in the [stdext](#) namespace.

For more information and example code on the checked iterator feature, see [Checked Iterators](#).

Example

The following sample shows how to define and use a checked array iterator.

If the destination is not large enough to hold all the elements being copied, such as would be the case if you changed the line:

```
copy(a, a + 5, checked_array_iterator<int*>(b, 5));
```

to

```
copy(a, a + 5, checked_array_iterator<int*>(b, 4));
```

A runtime error will occur.

```

// compile with: /EHsc /W4 /MTd
#include <algorithm>
#include <iostream>

using namespace std;
using namespace stdext;

int main() {
    int a[]={0, 1, 2, 3, 4};
    int b[5];
    copy(a, a + 5, checked_array_iterator<int*>(b, 5));

    cout << "(";
    for (int i = 0 ; i < 5 ; i++)
        cout << " " << b[i];
    cout << " )" << endl;

    // constructor example
    checked_array_iterator<int*> checked_out_iter(b, 5);
    copy(a, a + 5, checked_out_iter);

    cout << "(";
    for (int i = 0 ; i < 5 ; i++)
        cout << " " << b[i];
    cout << " )" << endl;
}
/* Output:
( 0 1 2 3 4 )
( 0 1 2 3 4 )
*/

```

Example

To avoid the need for the `checked_array_iterator` class when using C++ Standard Library algorithms, consider using a `vector` instead of a dynamically allocated array. The following example demonstrates how to do this.

```
// compile with: /EHsc /W4 /MTd

#include <algorithm>
#include <iostream>
#include <vector>

using namespace std;

int main()
{
    std::vector<int> v(10);
    int *arr = new int[10];
    for (int i = 0; i < 10; ++i)
    {
        v[i] = i;
        arr[i] = i;
    }

    // std::copy(v.begin(), v.end(), arr); will result in
    // warning C4996. To avoid this warning while using int *,
    // use the Microsoft extension checked_array_iterator.
    std::copy(v.begin(), v.end(),
              stdext::checked_array_iterator<int *>(arr, 10));

    // Instead of using stdext::checked_array_iterator and int *,
    // consider using std::vector to encapsulate the array. This will
    // result in no warnings, and the code will be portable.
    std::vector<int> arr2(10);    // Similar to int *arr = new int[10];
    std::copy(v.begin(), v.end(), arr2.begin());

    for (int j = 0; j < arr2.size(); ++j)
    {
        cout << " " << arr2[j];
    }
    cout << endl;

    return 0;
}
/* Output:
0 1 2 3 4 5 6 7 8 9
*/
```

Constructors

CONSTRUCTOR	DESCRIPTION
checked_array_iterator	Constructs a default <code>checked_array_iterator</code> or a <code>checked_array_iterator</code> from an underlying iterator.

Typedefs

TYPE NAME	DESCRIPTION
difference_type	A type that provides the difference between two <code>checked_array_iterator</code> s referring to elements within the same container.
pointer	A type that provides a pointer to an element addressed by a <code>checked_array_iterator</code> .

TYPE NAME	DESCRIPTION
<code>reference</code>	A type that provides a reference to an element addressed by a <code>checked_array_iterator</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>base</code>	Recovers the underlying iterator from its <code>checked_array_iterator</code> .

Operators

OPERATOR	DESCRIPTION
<code>operator==</code>	Tests two <code>checked_array_iterator</code> s for equality.
<code>operator!=</code>	Tests two <code>checked_array_iterator</code> s for inequality.
<code>operator<</code>	Tests if the <code>checked_array_iterator</code> on the left side of the operator is less than the <code>checked_array_iterator</code> on the right side.
<code>operator></code>	Tests if the <code>checked_array_iterator</code> on the left side of the operator is greater than the <code>checked_array_iterator</code> on the right side.
<code>operator<=</code>	Tests if the <code>checked_array_iterator</code> on the left side of the operator is less than or equal to the <code>checked_array_iterator</code> on the right side.
<code>operator>=</code>	Tests if the <code>checked_array_iterator</code> on the left side of the operator is greater than or equal to the <code>checked_array_iterator</code> on the right side.
<code>operator*</code>	Returns the element that a <code>checked_array_iterator</code> addresses.
<code>operator-></code>	Returns a pointer to the element addressed by the <code>checked_array_iterator</code> .
<code>operator++</code>	Increments the <code>checked_array_iterator</code> to the next element.
<code>operator--</code>	Decrements the <code>checked_array_iterator</code> to the previous element.
<code>operator+=</code>	Adds a specified offset to a <code>checked_array_iterator</code> .
<code>operator+</code>	Adds an offset to an iterator and returns the new <code>checked_array_iterator</code> addressing the inserted element at the new offset position.

OPERATOR	DESCRIPTION
<code>operator-=</code>	Decrements a specified offset from a <code>checked_array_iterator</code> .
<code>operator-</code>	Decrements an offset from an iterator and returns the new <code>checked_array_iterator</code> addressing the inserted element at the new offset position.
<code>operator[]</code>	Returns a reference to an element offset from the element addressed by a <code>checked_array_iterator</code> by a specified number of positions.

Requirements

Header: `<iterator>`

Namespace: `stdext`

`checked_array_iterator::base`

Recovers the underlying iterator from its `checked_array_iterator`.

```
_Iterator base() const;
```

Remarks

For more information, see [Checked Iterators](#).

Example

```
// checked_array_iterators_base.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main() {
    using namespace std;

    int V1[10];

    for (int i = 0; i < 10 ; i++)
        V1[i] = i;

    int* bpos;

    stdext::checked_array_iterator<int*> rpos(V1, 10);
    rpos++;

    bpos = rpos.base ( );
    cout << "The iterator underlying rpos is bpos & it points to: "
         << *bpos << "." << endl;
}
/* Output:
The iterator underlying rpos is bpos & it points to: 1.
*/
```

checked_array_iterator::checked_array_iterator

Constructs a default `checked_array_iterator` or a `checked_array_iterator` from an underlying iterator.

```
checked_array_iterator();

checked_array_iterator(
    IIterator ptr,
    size_t size,
    size_t index = 0);
```

Parameters

ptr

A pointer to the array.

size

The size of the array.

index

(Optional) An element in the array, to initialize the iterator. By default, the iterator is initialized to the first element in the array.

Remarks

For more information, see [Checked Iterators](#).

Example

```
// checked_array_iterators_ctor.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>

using namespace std;
using namespace stdext;

int main() {
    int a[] = {0, 1, 2, 3, 4};
    int b[5];
    copy(a, a + 5, checked_array_iterator<int*>(b,5));

    for (int i = 0 ; i < 5 ; i++)
        cout << b[i] << " ";
    cout << endl;

    checked_array_iterator<int*> checked_output_iterator(b,5);
    copy (a, a + 5, checked_output_iterator);
    for (int i = 0 ; i < 5 ; i++)
        cout << b[i] << " ";
    cout << endl;

    checked_array_iterator<int*> checked_output_iterator2(b,5,3);
    cout << *checked_output_iterator2 << endl;
}
/* Output:
0 1 2 3 4
0 1 2 3 4
3
*/
```

checked_array_iterator::difference_type

A type that provides the difference between two `checked_array_iterator`s referring to elements within the same container.

```
typedef typename iterator_traits<_Iterator>::difference_type difference_type;
```

Remarks

The `checked_array_iterator` difference type is the same as the iterator difference type.

See [checked_array_iterator::operator\[\]](#) for a code sample.

For more information, see [Checked Iterators](#).

checked_array_iterator::operator==

Tests two `checked_array_iterator`s for equality.

```
bool operator==(const checked_array_iterator<_Iterator>& right) const;
```

Parameters

right

The `checked_array_iterator` against which to check for equality.

Remarks

For more information, see [Checked Iterators](#).

Example

```

// checked_array_iterators_opeq.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>

using namespace std;
using namespace stdext;

int main() {
    int a[] = {0, 1, 2, 3, 4};
    int b[5];
    copy(a, a + 5, checked_array_iterator<int*>(b,5));
    copy(a, a + 5, checked_array_iterator<int*>(b,5));

    checked_array_iterator<int*> checked_output_iterator(b,5);
    checked_array_iterator<int*> checked_output_iterator2(b,5);

    if (checked_output_iterator2 == checked_output_iterator)
        cout << "checked_array_iterators are equal" << endl;
    else
        cout << "checked_array_iterators are not equal" << endl;

    copy (a, a + 5, checked_output_iterator);
    checked_output_iterator++;

    if (checked_output_iterator2 == checked_output_iterator)
        cout << "checked_array_iterators are equal" << endl;
    else
        cout << "checked_array_iterators are not equal" << endl;
}
/* Output:
checked_array_iterators are equal
checked_array_iterators are not equal
*/

```

checked_array_iterator::operator!=

Tests two `checked_array_iterator`s for inequality.

```
bool operator!=(const checked_array_iterator<Iterator>& right) const;
```

Parameters

right

The `checked_array_iterator` against which to check for inequality.

Remarks

For more information, see [Checked Iterators](#).

Example

```

// checked_array_iterators_opneq.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>

using namespace std;
using namespace stdext;

int main() {
    int a[] = {0, 1, 2, 3, 4};
    int b[5];
    copy(a, a + 5, checked_array_iterator<int*>(b,5));
    copy(a, a + 5, checked_array_iterator<int*>(b,5));

    checked_array_iterator<int*> checked_output_iterator(b,5);
    checked_array_iterator<int*> checked_output_iterator2(b,5);

    if (checked_output_iterator2 != checked_output_iterator)
        cout << "checked_array_iterators are not equal" << endl;
    else
        cout << "checked_array_iterators are equal" << endl;

    copy (a, a + 5, checked_output_iterator);
    checked_output_iterator++;

    if (checked_output_iterator2 != checked_output_iterator)
        cout << "checked_array_iterators are not equal" << endl;
    else
        cout << "checked_array_iterators are equal" << endl;
}
/* Output:
checked_array_iterators are equal
checked_array_iterators are not equal
*/

```

checked_array_iterator::operator<

Tests if the `checked_array_iterator` on the left side of the operator is less than the `checked_array_iterator` on the right side.

```
bool operator<(const checked_array_iterator<_Iterator>& right) const;
```

Parameters

right

The `checked_array_iterator` against which to check for inequality.

Remarks

For more information, see [Checked Iterators](#).

Example

```

// checked_array_iterators_oplt.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>

using namespace std;
using namespace stdext;

int main() {
    int a[] = {0, 1, 2, 3, 4};
    int b[5];
    copy(a, a + 5, checked_array_iterator<int*>(b,5));
    copy(a, a + 5, checked_array_iterator<int*>(b,5));

    checked_array_iterator<int*> checked_output_iterator(b,5);
    checked_array_iterator<int*> checked_output_iterator2(b,5);

    if (checked_output_iterator2 < checked_output_iterator)
        cout << "checked_output_iterator2 is less than checked_output_iterator" << endl;
    else
        cout << "checked_output_iterator2 is not less than checked_output_iterator" << endl;

    copy (a, a + 5, checked_output_iterator);
    checked_output_iterator++;

    if (checked_output_iterator2 < checked_output_iterator)
        cout << "checked_output_iterator2 is less than checked_output_iterator" << endl;
    else
        cout << "checked_output_iterator2 is not less than checked_output_iterator" << endl;
}
/* Output:
checked_output_iterator2 is not less than checked_output_iterator
checked_output_iterator2 is less than checked_output_iterator
*/

```

checked_array_iterator::operator>

Tests if the `checked_array_iterator` on the left side of the operator is greater than the `checked_array_iterator` on the right side.

```
bool operator>(const checked_array_iterator<_Iterator>& right) const;
```

Parameters

right

The `checked_array_iterator` to compare against.

Remarks

See [checked_array_iterator::operator<](#) for a code sample.

For more information, see [Checked Iterators](#).

checked_array_iterator::operator<=

Tests if the `checked_array_iterator` on the left side of the operator is less than or equal to the `checked_array_iterator` on the right side.

```
bool operator<=(const checked_array_iterator<_Iterator>& right) const;
```

Parameters

right

The `checked_array_iterator` to compare against.

Remarks

See `checked_array_iterator::operator>=` for a code sample.

For more information, see [Checked Iterators](#).

checked_array_iterator::operator>=

Tests if the `checked_array_iterator` on the left side of the operator is greater than or equal to the `checked_array_iterator` on the right side.

```
bool operator>=(const checked_array_iterator<_Iterator>& right) const;
```

Parameters

right

The `checked_array_iterator` to compare against.

Remarks

For more information, see [Checked Iterators](#).

Example

```
// checked_array_iterators_opgteq.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>

using namespace std;
using namespace stdext;

int main() {
    int a[] = {0, 1, 2, 3, 4};
    int b[5];
    copy(a, a + 5, checked_array_iterator<int*>(b,5));
    copy(a, a + 5, checked_array_iterator<int*>(b,5));

    checked_array_iterator<int*> checked_output_iterator(b,5);
    checked_array_iterator<int*> checked_output_iterator2(b,5);

    if (checked_output_iterator2 >= checked_output_iterator)
        cout << "checked_output_iterator2 is greater than or equal to checked_output_iterator" << endl;
    else
        cout << "checked_output_iterator2 is less than checked_output_iterator" << endl;

    copy (a, a + 5, checked_output_iterator);
    checked_output_iterator++;

    if (checked_output_iterator2 >= checked_output_iterator)
        cout << "checked_output_iterator2 is greater than or equal to checked_output_iterator" << endl;
    else
        cout << "checked_output_iterator2 is less than checked_output_iterator" << endl;
}
/* Output:
checked_output_iterator2 is greater than or equal to checked_output_iterator
checked_output_iterator2 is less than checked_output_iterator
*/
```

checked_array_iterator::operator*

Returns the element that a `checked_array_iterator` addresses.

```
reference operator*() const;
```

Return Value

The value of the element addressed by the `checked_array_iterator`.

Remarks

For more information, see [Checked Iterators](#).

Example

```
// checked_array_iterator_pointer.cpp
// compile with: /EHsc
#include <iterator>
#include <algorithm>
#include <vector>
#include <utility>
#include <iostream>

using namespace std;
using namespace stdext;

int main() {
    int a[] = {0, 1, 2, 3, 4};
    int b[5];
    pair<int, int> c[1];
    copy(a, a + 5, checked_array_iterator<int*>(b,5));

    for (int i = 0 ; i < 5 ; i++)
        cout << b[i] << endl;

    c[0].first = 10;
    c[0].second = 20;

    checked_array_iterator<int*> checked_output_iterator(b,5);
    checked_array_iterator<int*>::pointer p = &(*checked_output_iterator);
    checked_array_iterator<pair<int, int>*> chk_c(c, 1);
    checked_array_iterator<pair<int, int>*>::pointer p_c = &(*chk_c);

    cout << "b[0] = " << *p << endl;
    cout << "c[0].first = " << p_c->first << endl;
}
/* Output:
0
1
2
3
4
b[0] = 0
c[0].first = 10
*/
```

checked_array_iterator::operator->

Returns a pointer to the element addressed by the `checked_array_iterator`.

```
pointer operator->() const;
```

Return Value

A pointer to the element addressed by the `checked_array_iterator` .

Remarks

See [checked_array_iterator::pointer](#) for a code sample.

For more information, see [Checked Iterators](#).

checked_array_iterator::operator++

Increments the `checked_array_iterator` to the next element.

```
checked_array_iterator& operator++();  
  
checked_array_iterator<_Iterator> operator++(int);
```

Return Value

The first operator returns the preincremented `checked_array_iterator` and the second, the postincrement operator, returns a copy of the incremented `checked_array_iterator` .

Remarks

For more information, see [Checked Iterators](#).

Example

```
// checked_array_iterators_op_plus_plus.cpp  
// compile with: /EHsc  
#include <vector>  
#include <iostream>  
  
int main() {  
    using namespace stdext;  
    using namespace std;  
    int a[] = {6, 3, 77, 199, 222};  
    int b[5];  
    copy(a, a + 5, checked_array_iterator<int*>(b,5));  
  
    checked_array_iterator<int*> checked_output_iterator(b,5);  
  
    cout << *checked_output_iterator << endl;  
    ++checked_output_iterator;  
    cout << *checked_output_iterator << endl;  
    checked_output_iterator++;  
    cout << *checked_output_iterator << endl;  
}  
/* Output:  
6  
3  
77  
*/
```

checked_array_iterator::operator--

Decrements the `checked_array_iterator` to the previous element.

```
checked_array_iterator<_Iterator>& operator--();  
  
checked_array_iterator<_Iterator> operator--(int);
```

Return Value

The first operator returns the predecremented `checked_array_iterator` and the second, the postdecrement operator, returns a copy of the decremented `checked_array_iterator`.

Remarks

For more information, see [Checked Iterators](#).

Example

```
// checked_array_iterators_op_minus_minus.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main() {
    using namespace stdext;
    using namespace std;
    int a[] = {6, 3, 77, 199, 222};
    int b[5];
    copy(a, a + 5, checked_array_iterator<int*>(b,5));

    checked_array_iterator<int*> checked_output_iterator(b,5);

    cout << *checked_output_iterator << endl;
    checked_output_iterator++;
    cout << *checked_output_iterator << endl;
    checked_output_iterator--;
    cout << *checked_output_iterator << endl;
}
/* Output:
6
3
6
*/
```

checked_array_iterator::operator+=

Adds a specified offset to a `checked_array_iterator`.

```
checked_array_iterator<_Iterator>& operator+=(difference_type _Off);
```

Parameters

_Off

The offset by which to increment the iterator.

Return Value

A reference to the element addressed by the `checked_array_iterator`.

Remarks

For more information, see [Checked Iterators](#).

Example

```

// checked_array_iterators_op_plus_eq.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main() {
    using namespace stdext;
    using namespace std;
    int a[] = {6, 3, 77, 199, 222};
    int b[5];
    copy(a, a + 5, checked_array_iterator<int*>(b,5));

    checked_array_iterator<int*> checked_output_iterator(b,5);

    cout << *checked_output_iterator << endl;
    checked_output_iterator += 3;
    cout << *checked_output_iterator << endl;
}
/* Output:
6
199
*/

```

checked_array_iterator::operator+

Adds an offset to an iterator and returns the new `checked_array_iterator` addressing the inserted element at the new offset position.

```
checked_array_iterator<_Iterator> operator+(difference_type _Off) const;
```

Parameters

_Off

The offset to be added to the `checked_array_iterator`.

Return Value

A `checked_array_iterator` addressing the offset element.

Remarks

For more information, see [Checked Iterators](#).

Example

```

// checked_array_iterators_op_plus.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main() {
    using namespace stdext;
    using namespace std;
    int a[] = {6, 3, 77, 199, 222};
    int b[5];
    copy(a, a + 5, checked_array_iterator<int*>(b,5));

    checked_array_iterator<int*> checked_output_iterator(b,5);

    cout << *checked_output_iterator << endl;
    checked_output_iterator = checked_output_iterator + 3;
    cout << *checked_output_iterator << endl;
}
/* Output:
6
199
*/

```

checked_array_iterator::operator-=

Decrements a specified offset from a `checked_array_iterator`.

```
checked_array_iterator<_Iterator>& operator-=(difference_type _Off);
```

Parameters

_Off

The offset by which to increment the iterator.

Return Value

A reference to the element addressed by the `checked_array_iterator`.

Remarks

For more information, see [Checked Iterators](#).

Example

```
// checked_array_iterators_op_minus_eq.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main() {
    using namespace stdext;
    using namespace std;
    int a[] = {6, 3, 77, 199, 222};
    int b[5];
    copy(a, a + 5, checked_array_iterator<int*>(b,5));

    checked_array_iterator<int*> checked_output_iterator(b,5);

    checked_output_iterator += 3;
    cout << *checked_output_iterator << endl;
    checked_output_iterator -= 2;
    cout << *checked_output_iterator << endl;
}
/* Output:
199
3
*/
```

checked_array_iterator::operator-

Decrements an offset from an iterator and returns the new `checked_array_iterator` addressing the inserted element at the new offset position.

```
checked_array_iterator<_Iterator> operator-(difference_type _Off) const;

difference_type operator-(const checked_array_iterator& right) const;
```

Parameters

_Off

The offset to be decremented from the `checked_array_iterator`.

Return Value

A `checked_array_iterator` addressing the offset element.

Remarks

For more information, see [Checked Iterators](#).

checked_array_iterator::operator[]

Returns a reference to an element offset from the element addressed by a `checked_array_iterator` by a specified number of positions.

```
reference operator[](difference_type _Off) const;
```

Parameters

_Off

The offset from the `checked_array_iterator` address.

Return Value

The reference to the element offset.

Remarks

For more information, see [Checked Iterators](#).

Example

```
// checked_array_iterators_op_diff.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main() {
    using namespace std;
    int V1[10];

    for (int i = 0; i < 10 ; i++)
        V1[i] = i;

    // Declare a difference type for a parameter
    stdext::checked_array_iterator<int*>::difference_type diff = 2;

    stdext::checked_array_iterator<int*> VChkIter(V1, 10);

    stdext::checked_array_iterator<int*>::reference refrpos = VChkIter [diff];

    cout << refrpos + 1 << endl;
}
/* Output:
3
*/
```

checked_array_iterator::pointer

A type that provides a pointer to an element addressed by a `checked_array_iterator`.

```
typedef typename iterator_traits<_Iterator>::pointer pointer;
```

Remarks

See [checked_array_iterator::operator*](#) for a code sample.

For more information, see [Checked Iterators](#).

checked_array_iterator::reference

A type that provides a reference to an element addressed by a `checked_array_iterator`.

```
typedef typename iterator_traits<_Iterator>::reference reference;
```

Remarks

See [checked_array_iterator::operator\[\]](#) for a code sample.

For more information, see [Checked Iterators](#).

[<iterator>](#)

[C++ Standard Library Reference](#)

forward_iterator_tag Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

A class that provides a return type for **iterator_category** function that represents a forward iterator.

Syntax

```
struct forward_iterator_tag      : public input_iterator_tag {};
```

Remarks

The category tag classes are used as compile tags for algorithm selection. The template function needs to find out what is the most specific category of its iterator argument so that it can use the most efficient algorithm at compile time. For every iterator of type `Iterator`, `iterator_traits < Iterator > ::iterator_category` must be defined to be the most specific category tag that describes the iterator's behavior.

The type is the same as `iterator< Iter> ::iterator_category` when `Iter` describes an object that can serve as a forward iterator.

Example

See [iterator_traits](#) or [random_access_iterator_tag](#) for an example of how to use the **iterator_tags**.

Requirements

Header: `<iterator>`

Namespace: `std`

[input_iterator_tag Struct](#)

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

front_insert_iterator Class

10/31/2018 • 6 minutes to read • [Edit Online](#)

Describes an iterator adaptor that satisfies the requirements of an output iterator. It inserts, rather than overwrites, elements into the front of a sequence and thus provides semantics that are different from the overwrite semantics provided by the iterators of the C++ sequence containers. The `front_insert_iterator` class is templated on the type of container.

Syntax

```
template <class Container>
class front_insert_iterator;
```

Parameters

Container

The type of container into the front of which elements are to be inserted by a `front_insert_iterator`.

Remarks

The container must satisfy the requirements for a front insertion sequence where it is possible to insert elements at the beginning of the sequence in amortized constant time. The C++ Standard Library sequence containers defined by the [deque Class](#) and [list Class](#) provide the needed `push_front` member function and satisfy these requirements. By contrast, sequence containers defined by the [vector Class](#) do not satisfy these requirements and cannot be adapted to use with `front_insert_iterator`s. A `front_insert_iterator` must always be initialized with its container.

Constructors

CONSTRUCTOR	DESCRIPTION
front_insert_iterator	Creates an iterator that can insert elements at the front of a specified container object.

Typedefs

TYPE NAME	DESCRIPTION
container_type	A type that represents the container into which a front insertion is to be made.
reference	A type that provides a reference to an element in a sequence controlled by the associated container.

Operators

OPERATOR	DESCRIPTION
operator*	Dereferencing operator used to implement the output iterator expression <code>* i = x</code> for a front insertion.

OPERATOR	DESCRIPTION
<code>operator++</code>	Increments the <code>front_insert_iterator</code> to the next location into which a value may be stored.
<code>operator=</code>	Assignment operator used to implement the output iterator expression <code>* i = x</code> for a front insertion.

Requirements

Header: `<iterator>`

Namespace: `std`

`front_insert_iterator::container_type`

A type that represents the container into which a front insertion is to be made.

```
typedef Container container_type;
```

Remarks

The type is a synonym for the template parameter *Container*.

Example

```
// front_insert_iterator_container_type.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    list<int> L1;
    front_insert_iterator<list<int> >::container_type L2 = L1;
    front_inserter ( L2 ) = 20;
    front_inserter ( L2 ) = 10;
    front_inserter ( L2 ) = 40;

    list<int>::iterator vIter;
    cout << "The list L2 is: ( ";
    for ( vIter = L2.begin ( ) ; vIter != L2.end ( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;
}
/* Output:
The list L2 is: ( 40 10 20 ).
*/
```

`front_insert_iterator::front_insert_iterator`

Creates an iterator that can insert elements at the front of a specified container object.

```
explicit front_insert_iterator(Container& _Cont);
```

Parameters

`_Cont`

The container object into which the `front_insert_iterator` is to insert elements.

Return Value

A `front_insert_iterator` for the parameter container object.

Example

```
// front_insert_iterator_front_insert_iterator.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    list<int>::iterator L_Iter;

    list<int> L;
    for (i = -1 ; i < 9 ; ++i )
    {
        L.push_back ( 2 * i );
    }

    cout << "The list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++)
        cout << *L_Iter << " ";
    cout << ")." << endl;

    // Using the member function to insert an element
    front_inserter ( L ) = 20;

    // Alternatively, one may use the template function
    front_insert_iterator< list < int> > Iter(L);
    *Iter = 30;

    cout << "After the front insertions, the list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++)
        cout << *L_Iter << " ";
    cout << ")." << endl;
}
/* Output:
The list L is:
( -2 0 2 4 6 8 10 12 14 16 ).
After the front insertions, the list L is:
( 30 20 -2 0 2 4 6 8 10 12 14 16 ).
*/
```

`front_insert_iterator::operator*`

Dereferences the insert iterator returning the element it addresses.

```
front_insert_iterator<Container>& operator*();
```

Return Value

The member function returns the value of the element addressed.

Remarks

Used to implement the output iterator expression ***Iter = value**. If `Iter` is an iterator that addresses an element in a sequence, then ***Iter = value** replaces that element with value and does not change the total number of elements in the sequence.

Example

```
// front_insert_iterator_deref.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    list<int>::iterator L_Iter;

    list<int> L;
    for ( i = -1 ; i < 9 ; ++i )
    {
        L.push_back ( 2 * i );
    }

    cout << "The list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++)
        cout << *L_Iter << " ";
    cout << ")." << endl;

    front_insert_iterator< list< int> > Iter(L);
    *Iter = 20;

    // Alternatively, you may use
    front_inserter ( L ) = 30;

    cout << "After the front insertions, the list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++)
        cout << *L_Iter << " ";
    cout << ")." << endl;
}
/* Output:
The list L is:
( -2 0 2 4 6 8 10 12 14 16 ).
After the front insertions, the list L is:
( 30 20 -2 0 2 4 6 8 10 12 14 16 ).
*/
```

front_insert_iterator::operator++

Increments the `back_insert_iterator` to the next location into which a value may be stored.

```
front_insert_iterator<Container>& operator++();

front_insert_iterator<Container> operator++(int);
```

Return Value

A `front_insert_iterator` addressing the next location into which a value may be stored.

Remarks

Both preincrementation and postincrementation operators return the same result.

Example

```

// front_insert_iterator_op_incre.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    list<int> L1;
    front_insert_iterator<list<int> > iter ( L1 );
    *iter = 10;
    iter++;
    *iter = 20;
    iter++;
    *iter = 30;
    iter++;

    list<int>::iterator vIter;
    cout << "The list L1 is: ( ";
    for ( vIter = L1.begin ( ) ; vIter != L1.end ( ); vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;
}
/* Output:
The list L1 is: ( 30 20 10 ).
*/

```

front_insert_iterator::operator=

Appends (pushes) a value onto the front of the container.

```

front_insert_iterator<Container>& operator=(typename Container::const_reference val);

front_insert_iterator<Container>& operator=(typename Container::value_type&& val);

```

Parameters

val

The value to be assigned to the container.

Return Value

A reference to the last element inserted at the front of the container.

Remarks

The first member operator evaluates `container.push_front(val)`, then returns `*this`.

The second member operator evaluates

```
container->push_front((typename Container::value_type&& val) ,
```

then returns `*this`.

Example

```

// front_insert_iterator_op_assign.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    list<int> L1;
    front_insert_iterator<list<int> > iter ( L1 );
    *iter = 10;
    iter++;
    *iter = 20;
    iter++;
    *iter = 30;
    iter++;

    list<int>::iterator vIter;
    cout << "The list L1 is: ( ";
    for ( vIter = L1.begin ( ) ; vIter != L1.end ( ); vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;
}
/* Output:
The list L1 is: ( 30 20 10 ).
*/

```

front_insert_iterator::reference

A type that provides a reference to an element in a sequence controlled by the associated container.

```

typedef typename Container::reference reference;

```

Example

```

// front_insert_iterator_reference.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    list<int> L;
    front_insert_iterator<list<int> > fiivIter( L );
    *fiivIter = 10;
    *fiivIter = 20;
    *fiivIter = 30;

    list<int>::iterator LIter;
    cout << "The list L is: ( ";
    for ( LIter = L.begin ( ) ; LIter != L.end ( ); LIter++)
        cout << *LIter << " ";
    cout << ")." << endl;

    front_insert_iterator<list<int> >::reference
        RefFirst = *(L.begin ( ));
    cout << "The first element in the list L is: "
        << RefFirst << "." << endl;
}
/* Output:
The list L is: ( 30 20 10 ).
The first element in the list L is: 30.
*/

```

input_iterator_tag Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

A class that provides a return type for `iterator_category` function that represents an input iterator.

Syntax

```
struct input_iterator_tag {};
```

Remarks

The category tag classes are used as compile tags for algorithm selection. The template function needs to find the most specific category of its iterator argument so that it can use the most efficient algorithm at compile time. For every iterator of type `Iterator`, `iterator_traits < Iterator > ::iterator_category` must be defined to be the most specific category tag that describes the iterator's behavior.

The type is the same as `iterator< Iter> ::iterator_category` when `Iter` describes an object that can serve as an input iterator.

Example

See [iterator_traits](#) or [random_access_iterator_tag](#) for an example of how to use `iterator_tag` S.

Requirements

Header: `<iterator>`

Namespace: `std`

insert_iterator Class

10/31/2018 • 6 minutes to read • [Edit Online](#)

Describes an iterator adaptor that satisfies the requirements of an output iterator. It inserts, rather than overwrites, elements into a sequence and thus provides semantics that are different from the overwrite semantics provided by the iterators of the C++ sequence and associative containers. The `insert_iterator` class is templated on the type of container being adapted.

Syntax

```
template <class Container>
class insert_iterator;
```

Parameters

Container

The type of container into which elements are to be inserted by an `insert_iterator`.

Remarks

The container of type `Container` must satisfy the requirements for a variable-sized container and have a two-argument insert member function where the parameters are of type `Container::iterator` and `Container::value_type` and that returns a type `Container::iterator`. C++ Standard Library sequence and sorted associative containers satisfy these requirements and can be adapted to use with `insert_iterator`s. For associative containers, the position argument is treated as a hint, which has the potential to improve or degrade performance depending on how good the hint is. An `insert_iterator` must always be initialized with its container.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>insert_iterator</code>	Constructs an <code>insert_iterator</code> that inserts an element into a specified position in a container.

Typedefs

TYPE NAME	DESCRIPTION
<code>container_type</code>	A type that represents the container into which a general insertion is to be made.
<code>reference</code>	A type that provides a reference to an element in a sequence controlled by the associated container.

Operators

OPERATOR	DESCRIPTION
<code>operator*</code>	Dereferencing operator used to implement the output iterator expression <code>*i = x</code> for a general insertion.

OPERATOR	DESCRIPTION
<code>operator++</code>	Increments the <code>insert_iterator</code> to the next location into which a value may be stored.
<code>operator=</code>	Assignment operator used to implement the output iterator expression <code>* i = x</code> for a general insertion.

Requirements

Header: `<iterator>`

Namespace: `std`

`insert_iterator::container_type`

A type that represents the container into which a general insertion is to be made.

```
typedef Container container_type;
```

Remarks

The type is a synonym for the template parameter *Container*.

Example

```
// insert_iterator_container_type.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    list<int> L1;
    insert_iterator<list<int> >::container_type L2 = L1;
    inserter ( L2, L2.end ( ) ) = 20;
    inserter ( L2, L2.end ( ) ) = 10;
    inserter ( L2, L2.begin ( ) ) = 40;

    list<int>::iterator vIter;
    cout << "The list L2 is: ( ";
    for ( vIter = L2.begin ( ) ; vIter != L2.end ( ) ; vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;
}
/* Output:
The list L2 is: ( 40 20 10 ).
*/
```

`insert_iterator::insert_iterator`

Constructs an `insert_iterator` that inserts an element into a specified position in a container.

```
insert_iterator(Container& _Cont, typename Container::iterator _It);
```

Parameters

_Cont

The container into which the `insert_iterator` is to insert elements.

_It

The position for the insertion.

Remarks

All containers have the `insert` member function called by the `insert_iterator`. For associative containers the position parameter is merely a suggestion. The `inserter` function provides a convenient way to insert to values.

Example

```
// insert_iterator_insert_iterator.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    list<int>::iterator L_Iter;

    list<int> L;
    for (i = 1 ; i < 4 ; ++i )
    {
        L.push_back ( 10 * i );
    }

    cout << "The list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++)
        cout << *L_Iter << " ";
    cout << ")." << endl;

    // Using the member function to insert an element
    inserter ( L, L.begin( ) ) = 2;

    // Alternatively, you may use the template version
    insert_iterator< list< int> > Iter(L, L.end( ) );
    *Iter = 300;

    cout << "After the insertions, the list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++ )
        cout << *L_Iter << " ";
    cout << ")." << endl;
}
/* Output:
The list L is:
( 10 20 30 ).
After the insertions, the list L is:
( 2 10 20 30 300 ).
*/
```

`insert_iterator::operator*`

Dereferences the insert iterator returning the element it addresses.

```
insert_iterator<Container>& operator*();
```

Return Value

The member function returns the value of the element addressed.

Remarks

Used to implement the output iterator expression ***Iter = value**. If `Iter` is an iterator that addresses an element in a sequence, then ***Iter = value** replaces that element with value and does not change the total number of elements in the sequence.

Example

```
// insert_iterator_op_deref.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    list<int>::iterator L_Iter;

    list<int> L;
    for (i = 0 ; i < 4 ; ++i )
    {
        L.push_back ( 2 * i );
    }

    cout << "The original list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++ )
        cout << *L_Iter << " ";
    cout << ")." << endl;

    insert_iterator< list< int> > Iter(L, L.begin ( ) );
    *Iter = 10;
    *Iter = 20;
    *Iter = 30;

    cout << "After the insertions, the list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ); L_Iter++ )
        cout << *L_Iter << " ";
    cout << ")." << endl;
}
/* Output:
The original list L is:
( 0 2 4 6 ).
After the insertions, the list L is:
( 10 20 30 0 2 4 6 ).
*/
```

insert_iterator::operator++

Increments the `insert_iterator` to the next location into which a value may be stored.

```
insert_iterator<Container>& operator++();

insert_iterator<Container> operator++(int);
```

Parameters

A `insert_iterator` addressing the next location into which a value may be stored.

Remarks

Both preincrementation and postincrementation operators return the same result.

Example

```
// insert_iterator_op_incr.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 5 ; ++i )
    {
        vec.push_back ( i );
    }

    vector <int>::iterator vIter;
    cout << "The vector vec is:\n ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;

    insert_iterator<vector<int> > ii ( vec, vec.begin ( ) );
    *ii = 30;
    ii++;
    *ii = 40;
    ii++;
    *ii = 50;

    cout << "After the insertions, the vector vec becomes:\n ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;
}
/* Output:
The vector vec is:
( 1 2 3 4 ).
After the insertions, the vector vec becomes:
( 30 40 50 1 2 3 4 ).
*/
```

insert_iterator::operator=

Inserts a value into the container and returns the iterator updated to point to the new element.

```
insert_iterator<Container>& operator=(
    typename Container::const_reference val,);

insert_iterator<Container>& operator=(
    typename Container::value_type&& val);
```

Parameters

val

The value to be assigned to the container.

Return Value

A reference to the element inserted into the container.

Remarks

The first member operator evaluates

```
Iter = container->insert(Iter, val);
```

```
++Iter;
```

then returns `*this`.

The second member operator evaluates

```
Iter = container->insert(Iter, std::move(val));
```

```
++Iter;
```

then returns `*this`.

Example

```
// insert_iterator_op_assign.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    list<int>::iterator L_Iter;

    list<int> L;
    for (i = 0 ; i < 4 ; ++i )
    {
        L.push_back ( 2 * i );
    }

    cout << "The original list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ) ; L_Iter++ )
        cout << *L_Iter << " ";
    cout << ")." << endl;

    insert_iterator< list<int> > Iter(L, L.begin( ) );
    *Iter = 10;
    *Iter = 20;
    *Iter = 30;

    cout << "After the insertions, the list L is:\n ( ";
    for ( L_Iter = L.begin( ) ; L_Iter != L.end( ) ; L_Iter++ )
        cout << *L_Iter << " ";
    cout << ")." << endl;
}
/* Output:
The original list L is:
( 0 2 4 6 ).
After the insertions, the list L is:
( 10 20 30 0 2 4 6 ).
*/
```

insert_iterator::reference

A type that provides a reference to an element in a sequence controlled by the associated container.

```
typedef typename Container::reference reference;
```

Remarks

The type describes a reference to an element of the sequence controlled by the associated container.

Example

```
// insert_iterator_container_reference.cpp
// compile with: /EHsc
#include <iterator>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    list<int> L;
    insert_iterator<list<int> > iivIter( L , L.begin ( ) );
    *iivIter = 10;
    *iivIter = 20;
    *iivIter = 30;

    list<int>::iterator LIter;
    cout << "The list L is: ( ";
    for ( LIter = L.begin ( ) ; LIter != L.end ( ); LIter++ )
        cout << *LIter << " ";
    cout << ")." << endl;

    insert_iterator<list<int> >::reference
        RefFirst = *(L.begin ( ));
    cout << "The first element in the list L is: "
        << RefFirst << "." << endl;
}
/* Output:
The list L is: ( 10 20 30 ).
The first element in the list L is: 10.
*/
```

istream_iterator Class

10/31/2018 • 5 minutes to read • [Edit Online](#)

Describes an input iterator object. It extracts objects of class `Type` from an input stream, which it accesses through an object it stores, of type `pointer` to `basic_istream` < `CharType`, `Traits` >.

Syntax

```
template <class Type, class CharType = char, class Traits = char_traits<CharType>, class Distance = ptrdiff_t,>
class istream_iterator
: public iterator<
    input_iterator_tag, Type, Distance,
    const Type *,
    const Type&>;
```

Parameters

Type

The type of object to be extracted from the input stream.

CharType

The type that represents the character type for the `istream_iterator`. This argument is optional and the default value is **char**.

Traits

The type that represents the character type for the `istream_iterator`. This argument is optional and the default value is `char_traits` < `CharType` >.

Distance

A signed integral type that represents the difference type for the `istream_iterator`. This argument is optional and the default value is `ptrdiff_t`.

After constructing or incrementing an object of class `istream_iterator` with a nonnull stored pointer, the object attempts to extract and store an object of type `Type` from the associated input stream. If the extraction fails, the object effectively replaces the stored pointer with a null pointer, thus making an end-of-sequence indicator.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>istream_iterator</code>	Constructs either an end-of-stream iterator as the default <code>istream_iterator</code> or a <code>istream_iterator</code> initialized to the iterator's stream type from which it reads.

Typedefs

TYPE NAME	DESCRIPTION
<code>char_type</code>	A type that provides for the character type of the <code>istream_iterator</code> .

TYPE NAME	DESCRIPTION
<code>istream_type</code>	A type that provides for the stream type of the <code>istream_iterator</code> .
<code>traits_type</code>	A type that provides for the character traits type of the <code>istream_iterator</code> .

Operators

OPERATOR	DESCRIPTION
<code>operator*</code>	The dereferencing operator returns the stored object of type <code>Type</code> addressed by the <code>istream_iterator</code> .
<code>operator-></code>	Returns the value of a member, if any.
<code>operator++</code>	Either extracts an incremented object from the input stream or copies the object before incrementing it and returns the copy.

Requirements

Header: `<iterator>`

Namespace: `std`

`istream_iterator::char_type`

A type that provides for the character type of the `istream_iterator`.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter `CharType`.

Example

```

// istream_iterator_char_type.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    typedef istream_iterator<int>::char_type CHT1;
    typedef istream_iterator<int>::traits_type CHTR1;

    // Standard iterator interface for reading
    // elements from the input stream:
    cout << "Enter integers separated by spaces & then\n"
         << " any character ( try example: '2 4 f' ): ";

    // istream_iterator for reading int stream
    istream_iterator<int, CHT1, CHTR1> intRead ( cin );

    // End-of-stream iterator
    istream_iterator<int, CHT1, CHTR1> EOFintRead;

    while ( intRead != EOFintRead )
    {
        cout << "Reading:  " << *intRead << endl;
        ++intRead;
    }
    cout << endl;
}

```

istream_iterator::istream_iterator

Constructs either an end-of-stream iterator as the default `istream_iterator` or a `istream_iterator` initialized to the iterator's stream type from which it reads.

```

istream_iterator();

istream_iterator(istream_type& _Istr);

```

Parameters

_Istr

The input stream to be read use to initialize the `istream_iterator`.

Remarks

The First constructor initializes the input stream pointer with a null pointer and creates an end-of-stream iterator. The second constructor initializes the input stream pointer with `&_Istr`, then attempts to extract and store an object of type `Type`.

The end-of-stream iterator can be use to test whether an `istream_iterator` has reached the end of a stream.

Example

```

// istream_iterator_istream_iterator.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <algorithm>
#include <iostream>

int main( )
{
    using namespace std;

    // Used in conjunction with copy algorithm
    // to put elements into a vector read from cin
    vector<int> vec ( 4 );
    vector<int>::iterator Iter;

    cout << "Enter 4 integers separated by spaces & then\n"
        << " a character ( try example: '2 4 6 8 a' ): ";
    istream_iterator<int> intvecRead ( cin );

    // Default constructor will test equal to end of stream
    // for delimiting source range of vecor
    copy ( intvecRead , istream_iterator<int>( ) , vec.begin ( ) );
    cin.clear ( );

    cout << "vec = ";
    for ( Iter = vec.begin( ) ; Iter != vec.end( ) ; Iter++ )
        cout << *Iter << " "; cout << endl;
}

```

istream_iterator::istream_type

A type that provides for the stream type of the `istream_iterator`.

```
typedef basic_istream<CharType, Traits> istream_type;
```

Remarks

The type is a synonym for `basic_istream<CharType, Traits>`.

Example

See [istream_iterator](#) for an example of how to declare and use `istream_type`.

istream_iterator::operator*

The dereferencing operator returns the stored object of type `Type` addressed by the `istream_iterator`.

```
const Type& operator*() const;
```

Return Value

The stored object of type `Type`.

Example

```

// istream_iterator_operator.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <algorithm>
#include <iostream>

int main( )
{
    using namespace std;

    cout << "Enter integers separated by spaces & then\n"
         << " a character ( try example: '2 4 6 8 a' ): ";

    // istream_iterator from stream cin
    istream_iterator<int> intRead ( cin );

    // End-of-stream iterator
    istream_iterator<int> EOFintRead;

    while ( intRead != EOFintRead )
    {
        cout << "Reading:  " << *intRead << endl;
        ++intRead;
    }
    cout << endl;
}

```

istream_iterator::operator->

Returns the value of a member, if any.

```
const Type* operator->() const;
```

Return Value

The value of a member, if any.

Remarks

`i->m` is equivalent to `(*i).m`

The operator returns `&*this` .

Example

```

// istream_iterator_operator_vm.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>
#include <complex>

using namespace std;

int main( )
{
    cout << "Enter complex numbers separated by spaces & then\n"
        << " a character pair ( try example: '(1,2) (3,4) (a,b)' ): ";

    // istream_iterator from stream cin
    istream_iterator< complex<double> > intRead ( cin );

    // End-of-stream iterator
    istream_iterator<complex<double> > EOFintRead;

    while ( intRead != EOFintRead )
    {
        cout << "Reading the real part: " << intRead ->real( ) << endl;
        cout << "Reading the imaginary part: " << intRead ->imag( ) << endl;
        ++intRead;
    }
    cout << endl;
}

```

istream_iterator::operator++

Either extracts an incremented object from the input stream or copies the object before incrementing it and returns the copy.

```

istream_iterator<Type, CharType, Traits, Distance>& operator++();

istream_iterator<Type, CharType, Traits, Distance> operator++(int);

```

Return Value

The first member operator returns a reference to the incremented object of type `Type` extracted from the input stream and the second member function returns a copy of the object.

Example

```

// istream_iterator_operator_incr.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <algorithm>
#include <iostream>

int main( )
{
    using namespace std;

    cout << "Enter integers separated by spaces & then\n"
         << " a character ( try example: '2 4 6 8 a' ): ";

    // istream_iterator from stream cin
    istream_iterator<int> intRead ( cin );

    // End-of-stream iterator
    istream_iterator<int> EOFintRead;

    while ( intRead != EOFintRead )
    {
        cout << "Reading:  " << *intRead << endl;
        ++intRead;
    }
    cout << endl;
}

```

istream_iterator::traits_type

A type that provides for the character traits type of the `istream_iterator`.

```
typedef Traits traits_type;
```

Remarks

The type is a synonym for the template parameter *Traits*.

Example

```

// istream_iterator_traits_type.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>

int main( )
{
    using namespace std;

    typedef istream_iterator<int>::char_type CHT1;
    typedef istream_iterator<int>::traits_type CHTR1;

    // Standard iterator interface for reading
    // elements from the input stream:
    cout << "Enter integers separated by spaces & then\n"
         << " any character ( try example: '10 20 a' ): ";

    // istream_iterator for reading int stream
    istream_iterator<int, CHT1, CHTR1> intRead ( cin );

    // End-of-stream iterator
    istream_iterator<int, CHT1, CHTR1> EOFintRead;

    while ( intRead != EOFintRead )
    {
        cout << "Reading:  " << *intRead << endl;
        ++intRead;
    }
    cout << endl;
}

```

[C++ Standard Library Reference](#)

istreambuf_iterator Class

10/31/2018 • 6 minutes to read • [Edit Online](#)

The template class `istreambuf_iterator` describes an input iterator object that extracts character elements from an input stream buffer, which it accesses through an object it stores, of type pointer to `basic_streambuf` < **CharType**, **Traits**>.

Syntax

```
template <class CharType class Traits = char_traits <CharType>>
class istreambuf_iterator
: public iterator<input_iterator_tag, CharType, typename Traits ::off_type, CharType*, CharType&>
```

Parameters

CharType

The type that represents the character type for the `istreambuf_iterator`.

Traits

The type that represents the character type for the `istreambuf_iterator`. This argument is optional and the default value is `char_traits` < *CharType*>.

Remarks

The `istreambuf_iterator` class must satisfy the requirements for an input iterator.

After constructing or incrementing an object of class `istreambuf_iterator` with a non-null stored pointer, the object effectively attempts to extract and store an object of type *CharType* from the associated input stream. The extraction may be delayed, however, until the object is actually dereferenced or copied. If the extraction fails, the object effectively replaces the stored pointer with a null pointer, thus making an end-of-sequence indicator.

Constructors

CONSTRUCTOR	DESCRIPTION
istreambuf_iterator	Constructs an <code>istreambuf_iterator</code> that is initialized to read characters from the input stream.

Typedefs

TYPE NAME	DESCRIPTION
char_type	A type that provides for the character type of the <code>ostreambuf_iterator</code> .
int_type	A type that provides an integer type for an <code>istreambuf_iterator</code> .
istream_type	A type that provides for the stream type of the <code>istream_iterator</code> .

TYPE NAME	DESCRIPTION
<code>streambuf_type</code>	A type that provides for the stream type of the <code>istreambuf_iterator</code> .
<code>traits_type</code>	A type that provides for the character traits type of the <code>istream_iterator</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>equal</code>	Tests for equality between two input stream buffer iterators.

Operators

OPERATOR	DESCRIPTION
<code>operator*</code>	The dereferencing operator returns the next character in the stream.
<code>operator++</code>	Either returns the next character from the input stream or copies the object before incrementing it and returns the copy.
<code>operator-></code>	Returns the value of a member, if any.

Requirements

Header: `<iterator>`

Namespace: `std`

`istreambuf_iterator::char_type`

A type that provides for the character type of the `ostreambuf_iterator`.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter *CharType*.

Example

```

// istreambuf_iterator_char_type.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>
#include <algorithm>

int main( )
{
    using namespace std;

    typedef istreambuf_iterator<char>::char_type CHT1;
    typedef istreambuf_iterator<char>::traits_type CHTR1;

    cout << "(Try the example: 'So many dots to be done'\n"
        << " then an Enter key to insert into the output,\n"
        << " & use a ctrl-Z Enter key combination to exit): ";

    // istreambuf_iterator for input stream
    istreambuf_iterator< CHT1, CHTR1> charInBuf ( cin );
    ostreambuf_iterator<char> charOut ( cout );

    // Used in conjunction with replace_copy algorithm
    // to insert into output stream and replace spaces
    // with dot-separators
    replace_copy ( charInBuf , istreambuf_iterator<char>( ),
        charOut , ' ' , '.' );
}

```

istreambuf_iterator::equal

Tests for equivalence between two input stream buffer iterators.

```
bool equal(const istreambuf_iterator<CharType, Traits>& right) const;
```

Parameters

right

The iterator for which to check for equality.

Return Value

true if both `istreambuf_iterator`s are end-of-stream iterators or if neither is an end-of-stream iterator; otherwise **false**.

Remarks

A range is defined by the `istreambuf_iterator` to the current position and the end-of-stream iterator, but since all non-end-of stream iterators are equivalent under the `equal` member function, it is not possible to define any subranges using `istreambuf_iterator`s. The `==` and `!=` operators have the same semantics.

Example

```
// istreambuf_iterator_equal.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>

int main( )
{
    using namespace std;

    cout << "(Try the example: 'Hello world!'\n"
        << " then an Enter key to insert into the output,\n"
        << " & use a ctrl-Z Enter key combination to exit): ";

    istreambuf_iterator<char> charReadIn1 ( cin );
    istreambuf_iterator<char> charReadIn2 ( cin );

    bool b1 = charReadIn1.equal ( charReadIn2 );

    if (b1)
        cout << "The iterators are equal." << endl;
    else
        cout << "The iterators are not equal." << endl;
}
```

istreambuf_iterator::int_type

A type that provides an integer type for an `istreambuf_iterator`.

```
typedef typename traits_type::int_type int_type;
```

Remarks

The type is a synonym for `Traits::int_type`.

Example

```
// istreambuf_iterator_int_type.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>

int main( )
{
    using namespace std;
    istreambuf_iterator<char>::int_type inttype1 = 100;
    cout << "The inttype1 = " << inttype1 << "." << endl;
}
/* Output:
The inttype1 = 100.
*/
```

istreambuf_iterator::istream_type

A type that provides for the stream type of the `istreambuf_iterator`.

```
typedef basic_istream<CharType, Traits> istream_type;
```

Remarks

The type is a synonym for `basic_istream < CharType, Traits >`.

Example

See [istreambuf_iterator](#) for an example of how to declare and use `istream_type`.

istreambuf_iterator::istreambuf_iterator

Constructs an `istreambuf_iterator` that is initialized to read characters from the input stream.

```
istreambuf_iterator(istreambuf_type* strbuf = 0) throw();
istreambuf_iterator(istream_type& _Istr) throw();
```

Parameters

strbuf

The input stream buffer to which the `istreambuf_iterator` is being attached.

_Istr

The input stream to which the `istreambuf_iterator` is being attached.

Remarks

The first constructor initializes the input stream-buffer pointer with *strbuf*. The second constructor initializes the input stream-buffer pointer with *_Istr*. `rdbuf`, and then eventually attempts to extract and store an object of type `CharType`.

Example

```
// istreambuf_iterator_istreambuf_iterator.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <algorithm>
#include <iostream>

int main( )
{
    using namespace std;

    // Following declarations will not compile:
    istreambuf_iterator<char>::istream_type &istrm = cin;
    istreambuf_iterator<char>::istreambuf_type *strmbf = cin.rdbuf( );

    cout << "(Try the example: 'Oh what a world!'\n"
         << " then an Enter key to insert into the output,\n"
         << " & use a ctrl-Z Enter key combination to exit): ";
    istreambuf_iterator<char> charReadIn ( cin );
    ostreambuf_iterator<char> charOut ( cout );

    // Used in conjunction with replace_copy algorithm
    // to insert into output stream and replace spaces
    // with hyphen-separators
    replace_copy ( charReadIn , istreambuf_iterator<char>( ),
                  charOut , ' ' , '-' );
}
```

istreambuf_iterator::operator*

The dereferencing operator returns the next character in the stream.

```
CharType operator*() const;
```

Return Value

The next character in the stream.

Example

```
// istreambuf_iterator_operator_deref.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>

int main( )
{
    using namespace std;

    cout << "Type string of characters & enter to output it,\n"
        << " with stream buffer iterators,(try: 'I'll be back.')
```

istreambuf_iterator::operator++

Either returns the next character from the input stream or copies the object before incrementing it and returns the copy.

```
istreambuf_iterator<CharType, Traits>& operator++();
istreambuf_iterator<CharType, Traits> operator++(int);
```

Return Value

An `istreambuf_iterator` or a reference to an `istreambuf_iterator`.

Remarks

The first operator eventually attempts to extract and store an object of type `CharType` from the associated input stream. The second operator makes a copy of the object, increments the object, and then returns the copy.

Example

```
// istreambuf_iterator_operator_incr.cpp
// compile with: /EHsc
#include <iterator>
#include <iostream>

int main( )
{
    using namespace std;

    cout << "Type string of characters & enter to output it,\n"
        << " with stream buffer iterators,(try: 'I'll be back.')

```

istreambuf_iterator::operator->

Returns the value of a member, if any.

```
const Elem* operator->() const;
```

Return Value

The operator returns **&***this**.

istreambuf_iterator::streambuf_type

A type that provides for the stream type of the istreambuf_iterator.

```
typedef basic_streambuf<CharType, Traits> streambuf_type;
```

Remarks

The type is a synonym for `basic_streambuf` < **CharType, Traits**>.

Example

See [istreambuf_iterator](#) for an example of how to declare and use `istreambuf_type`.

istreambuf_iterator::traits_type

A type that provides for the character traits type of the `istream_iterator`.

```
typedef Traits traits_type;
```

Remarks

The type is a synonym for the template parameter *Traits*.

Example

```

// istreambuf_iterator_traits_type.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>
#include <algorithm>

int main( )
{
    using namespace std;

    typedef istreambuf_iterator<char>::char_type CHT1;
    typedef istreambuf_iterator<char>::traits_type CHTR1;

    cout << "(Try the example: 'So many dots to be done'\n"
        << " then an Enter key to insert into the output,\n"
        << " & use a ctrl-Z Enter key combination to exit): ";

    // istreambuf_iterator for input stream
    istreambuf_iterator< CHT1, CHTR1> charInBuf ( cin );
    ostreambuf_iterator<char> charOut ( cout );

    // Used in conjunction with replace_copy algorithm
    // to insert into output stream and replace spaces
    // with dot-separators
    replace_copy ( charInBuf , istreambuf_iterator<char>( ),
        charOut , ' ' , '.' );
}

```

[<iterator>](#)

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

iterator Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

An empty base struct used to ensure that a user-defined iterator class works properly with `iterator_traits`.

Syntax

```
struct iterator {  
    typedef Category iterator_category;  
    typedef Type value_type;  
    typedef Distance difference_type;  
    typedef Distance distance_type;  
    typedef Pointer pointer;  
    typedef Reference reference;  
};
```

Remarks

The template struct serves as a base type for all iterators. It defines the member types

- `iterator_category` (a synonym for the template parameter `Category`).
- `value_type` (a synonym for the template parameter `Type`).
- `difference_type` (a synonym for the template parameter `Distance`).
- `distance_type` (a synonym for the template parameter `Distance`).
- `pointer` (a synonym for the template parameter `Pointer`).
- `reference` (a synonym for the template parameter `Reference`).

Note that `value_type` should not be a constant type even if `pointer` points at an object of **const** `Type` and `reference` designates an object of **const** `Type`.

Example

See [iterator_traits](#) for an example of how to declare and use the types in the iterator base class.

Requirements

Header: `<iterator>`

Namespace: `std`

See also

[<iterator>](#)

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

iterator_traits Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

A template helper struct used to specify all the critical type definitions that an iterator should have.

Syntax

```
struct iterator_traits {  
    typedef typename Iterator::iterator_category iterator_category;  
    typedef typename Iterator::value_type value_type;  
    typedef typename Iterator::difference_type difference_type;  
    typedef difference_type distance_type;  
    typedef typename Iterator::pointer pointer;  
    typedef typename Iterator::reference reference;  
};
```

Remarks

The template struct defines the member types

- `iterator_category` : a synonym for `Iterator::iterator_category` .
- `value_type` : a synonym for `Iterator::value_type` .
- `difference_type` : a synonym for `Iterator::difference_type` .
- `distance_type` : a synonym for `Iterator::difference_type` .
- `pointer` : a synonym for `Iterator::pointer` .
- `reference` : a synonym for `Iterator::reference` .

The partial specializations determine the critical types associated with an object pointer of type **Type *** or **const Type ***.

In this implementation you can also use several template functions that do not make use of partial specialization:

```
template <class Category, class Type, class Diff>  
C _Iter_cat(const iterator<Category, Ty, Diff>&);  
  
template <class Ty>  
random_access_iterator_tag _Iter_cat(const Ty *);  
  
template <class Category, class Ty, class Diff>  
Ty *val_type(const iterator<Category, Ty, Diff>&);  
  
template <class Ty>  
Ty *val_type(const Ty *);  
  
template <class Category, class Ty, class Diff>  
Diff *_Dist_type(const iterator<Category, Ty, Diff>&);  
  
template <class Ty>  
ptrdiff_t *_Dist_type(const Ty *);
```

which determine several of the same types more indirectly. You use these functions as arguments on a function

call. Their sole purpose is to supply a useful template class parameter to the called function.

Example

```
// iterator_traits.cpp
// compile with: /EHsc
#include <iostream>
#include <iterator>
#include <vector>
#include <list>

using namespace std;

template< class it >
void
function( it i1, it i2 )
{
    iterator_traits<it>::iterator_category cat;
    cout << typeid( cat ).name( ) << endl;
    while ( i1 != i2 )
    {
        iterator_traits<it>::value_type x;
        x = *i1;
        cout << x << " ";
        i1++;
    };
    cout << endl;
};

int main( )
{
    vector<char> vc( 10, 'a' );
    list<int> li( 10 );
    function( vc.begin( ), vc.end( ) );
    function( li.begin( ), li.end( ) );
}
/* Output:
struct std::random_access_iterator_tag
a a a a a a a a a a
struct std::bidirectional_iterator_tag
0 0 0 0 0 0 0 0 0 0
*/
```

Requirements

Header: <iterator>

Namespace: std

[<iterator>](#)

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

move_iterator Class

3/28/2019 • 5 minutes to read • [Edit Online](#)

Class template `move_iterator` is a wrapper for an iterator. The `move_iterator` provides the same behavior as the iterator it wraps (stores), except it turns the stored iterator's dereference operator into an rvalue reference, turning a copy into a move. For more information about rvalues, see [Rvalue Reference Declarator: &&](#).

Syntax

```
class move_iterator;
```

Remarks

The template class describes an object that behaves like an iterator except when dereferenced. It stores a random-access iterator of type `Iterator`, accessed by way of the member function `base()`. All operations on a `move_iterator` are performed directly on the stored iterator, except that the result of `operator*` is implicitly cast to `value_type&&` to make an rvalue reference.

A `move_iterator` might be capable of operations that are not defined by the wrapped iterator. These operations should not be used.

Constructors

CONSTRUCTOR	DESCRIPTION
move_iterator	The constructor for objects of type <code>move_iterator</code> .

Typedefs

TYPE NAME	DESCRIPTION
iterator_type	A synonym for the template parameter <code>RandomIterator</code> .
iterator_category	A synonym for a longer typename expression of the same name, <code>iterator_category</code> identifies the general abilities of the iterator.
value_type	A synonym for a longer typename expression of the same name, <code>value_type</code> describes what type the iterator elements are.
difference_type	A synonym for a longer typename expression of the same name, <code>difference_type</code> describes the integral type required to express difference values between elements.
pointer	A synonym for template parameter <code>RandomIterator</code> .
reference	A synonym for the <code>rvalue</code> reference <code>value_type&&</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>base</code>	The member function returns the stored iterator wrapped by this <code>move_iterator</code> .

Operators

OPERATOR	DESCRIPTION
<code>move_iterator::operator*</code>	Returns <code>(reference)*base()</code> .
<code>move_iterator::operator++</code>	Increments the stored iterator. Exact behavior depends on whether it is a preincrement or a postincrement operation.
<code>move_iterator::operator--</code>	Decrements the stored iterator. Exact behavior depends on whether it is a predecrement or a postdecrement operation.
<code>move_iterator::operator-></code>	Returns <code>&***this</code> .
<code>move_iterator::operator-</code>	Returns <code>move_iterator(*this) -=</code> by first subtracting the right-hand value from the current position.
<code>move_iterator::operator[]</code>	Returns <code>(reference)*(*this + off)</code> . Allows you to specify an offset from the current base to obtain the value at that location.
<code>move_iterator::operator+</code>	Returns <code>move_iterator(*this) +=</code> the value. Allows you to add an offset to the base to obtain the value at that location.
<code>move_iterator::operator+=</code>	Adds the right-hand value to the stored iterator, and returns <code>*this</code> .
<code>move_iterator::operator-=</code>	Subtracts the right-hand value from the stored iterator, and returns <code>*this</code> .

Requirements

Header: `<iterator>`

Namespace: `std`

`move_iterator::base`

Returns the stored iterator for this `move_iterator`.

```
RandomIterator base() const;
```

Remarks

The member function returns the stored iterator.

`move_iterator::difference_type`

The type `difference_type` is a `move_iterator` `typedef` based on the iterator trait `difference_type`, and can be

used interchangeably with it.

```
typedef typename iterator_traits<RandomIterator>::difference_type difference_type;
```

Remarks

The type is a synonym for the iterator trait `typename iterator_traits<RandomIterator>::pointer`.

move_iterator::iterator_category

The type `iterator_category` is a `move_iterator` `typedef` based on the iterator trait `iterator_category`, and can be used interchangeably with it.

```
typedef typename iterator_traits<RandomIterator>::iterator_category iterator_category;
```

Remarks

The type is a synonym for the iterator trait `typename iterator_traits<RandomIterator>::iterator_category`.

move_iterator::iterator_type

The type `iterator_type` is based on the template parameter `RandomIterator` for the class template `move_iterator`, and can be used interchangeably in its place.

```
typedef RandomIterator iterator_type;
```

Remarks

The type is a synonym for the template parameter `RandomIterator`.

move_iterator::move_iterator

Constructs a move iterator. Uses the parameter as the stored iterator.

```
move_iterator();  
explicit move_iterator(RandomIterator right);  
template <class Type>  
move_iterator(const move_iterator<Type>& right);
```

Parameters

right

The iterator to use as the stored iterator.

Remarks

The first constructor initializes the stored iterator with its default constructor. The remaining constructors initialize the stored iterator with `base.base()`.

move_iterator::operator+=

Adds an offset to the stored iterator, so that the stored iterator points to the element at the new current location. The operator then moves the new current element.

```
move_iterator& operator+=(difference_type _Off);
```

Parameters

_Off

An offset to add to the current position to determine the new current position.

Return Value

Returns the new current element.

Remarks

The operator adds *_Off* to the stored iterator. Then returns `*this`.

move_iterator::operator-=

Moves across a specified number of previous elements. This operator subtracts an offset from the stored iterator.

```
move_iterator& operator-=(difference_type _Off);
```

Parameters

Remarks

The operator evaluates `*this += -_Off`. Then returns `*this`.

move_iterator::operator++

Increments the stored iterator that belongs to this `move_iterator`. The current element is accessed by the postincrement operator. The next element is accessed by the preincrement operator.

```
move_iterator& operator++();  
move_iterator operator++(int);
```

Parameters

Remarks

The first (preincrement) operator increments the stored iterator. Then returns `*this`.

The second (postincrement) operator makes a copy of `*this`, evaluates `++*this`. Then returns the copy.

move_iterator::operator+

Returns the iterator position advanced by any number of elements.

```
move_iterator operator+(difference_type _Off) const;
```

Parameters

Remarks

The operator returns `move_iterator(*this) += _Off`.

move_iterator::operator[]

Allows array index access to elements across the range of the `move iterator`.

```
reference operator[](difference_type _Off) const;
```

Parameters

Remarks

The operator returns `(reference)*(*this + _Off)`.

move_iterator::operator--

Pre- and postdecrement member operators perform a decrement on the stored iterator.

```
move_iterator& operator--();  
move_iterator operator--();
```

Parameters

Remarks

The first member operator (predecrement) decrements the stored iterator. Then returns `*this`.

The second (postdecrement) operator makes a copy of `*this`, evaluates `--*this`. Then returns the copy.

move_iterator::operator-

Decrements the stored iterator and returns the indicated value.

```
move_iterator operator-(difference_type _Off) const;
```

Parameters

Remarks

The operator returns `move_iterator(*this) -= _Off`.

move_iterator::operator*

Dereferences the stored iterator and returns the value. This behaves like an `rvalue reference` and performs a move assignment. The operator transfers the current element out of the base iterator. The element that follows becomes the new current element.

```
reference operator*() const;
```

Remarks

The operator returns `(reference)*base()`.

move_iterator::operator->

Like a normal `RandomIterator` `operator->`, it provides access to the fields that belong to the current element.

```
pointer operator->() const;
```

Remarks

The operator returns `&***this`.

move_iterator::pointer

The type `pointer` is a **typedef** based on the random iterator `RandomIterator` for `move_iterator`, and can be used interchangeably.

```
typedef RandomIterator pointer;
```

Remarks

The type is a synonym for `RandomIterator`.

move_iterator::reference

The type `reference` is a **typedef** based on `value_type&&` for `move_iterator`, and can be used interchangeably with `value_type&&`.

```
typedef value_type&& reference;
```

Remarks

The type is a synonym for `value_type&&`, which is an rvalue reference.

move_iterator::value_type

The type `value_type` is a `move_iterator` **typedef** based on the iterator trait `value_type`, and can be used interchangeably with it.

```
typedef typename iterator_traits<RandomIterator>::value_type value_type;
```

Remarks

The type is a synonym for the iterator trait `typename iterator_traits<RandomIterator>::value_type`.

[Move Constructors and Move Assignment Operators \(C++\)](#)

[C++ Standard Library Reference](#)

ostream_iterator Class

10/31/2018 • 6 minutes to read • [Edit Online](#)

The template class `ostream_iterator` describes an output iterator object that writes successive elements onto the output stream with the extraction `operator <<`.

Syntax

```
template <class Type class CharType = char class Traits = char_traits <CharType>>
class ostream_iterator
```

Parameters

Type

The type of object to be inserted into the output stream.

CharType

The type that represents the character type for the `ostream_iterator`. This argument is optional and the default value is **char**.

Traits

The type that represents the character type for the `ostream_iterator`. This argument is optional and the default value is `char_traits < CharType >`.

The `ostream_iterator` class must satisfy the requirements for an output iterator. Algorithms can be written directly to output streams using an `ostream_iterator`.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>ostream_iterator</code>	Constructs an <code>ostream_iterator</code> that is initialized and delimited to write to the output stream.

Typedefs

TYPE NAME	DESCRIPTION
<code>char_type</code>	A type that provides for the character type of the <code>ostream_iterator</code> .
<code>ostream_type</code>	A type that provides for the stream type of the <code>ostream_iterator</code> .
<code>traits_type</code>	A type that provides for the character traits type of the <code>ostream_iterator</code> .

Operators

OPERATOR	DESCRIPTION
<code>operator*</code>	Dereferencing operator used to implement the output iterator expression <code>* i = x</code> .
<code>operator++</code>	A nonfunctional increment operator that returns an <code>ostream_iterator</code> to the same object it addressed before the operation was called.
<code>operator=</code>	Assignment operator used to implement the output iterator expression <code>* i = x</code> for writing to an output stream.

Requirements

Header: `<iterator>`

Namespace: `std`

`ostream_iterator::char_type`

A type that provides for the character type of the iterator.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter `CharType`.

Example

```

// ostream_iterator_char_type.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    typedef ostream_iterator<int>::char_type CHT1;
    typedef ostream_iterator<int>::traits_type CHTR1;

    // ostream_iterator for stream cout
    // with new line delimiter:
    ostream_iterator<int, CHT1, CHTR1> intOut ( cout , "\n" );

    // Standard iterator interface for writing
    // elements to the output stream:
    cout << "The integers written to the output stream\n"
        << "by intOut are:" << endl;
    *intOut = 10;
    *intOut = 20;
    *intOut = 30;
}
/* Output:
The integers written to the output stream
by intOut are:
10
20
30
*/

```

ostream_iterator::operator*

Dereferencing operator used to implement the output iterator expression $*\tilde{i} = x$.

```
ostream_iterator<Type, CharType, Traits>& operator*();
```

Return Value

A reference to the `ostream_iterator`.

Remarks

The requirements for an output iterator that the `ostream_iterator` must satisfy require only the expression $*\tilde{i} = t$ be valid and says nothing about the **operator** or the `operator=` on their own. The member operator in this implementation returns ***this**.

Example

```

// ostream_iterator_op_deref.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // ostream_iterator for stream cout
    // with new line delimiter
    ostream_iterator<int> intOut ( cout , "\n" );

    // Standard iterator interface for writing
    // elements to the output stream
    cout << "Elements written to output stream:" << endl;
    *intOut = 10;
    intOut++;           // No effect on iterator position
    *intOut = 20;
    *intOut = 30;
}
/* Output:
Elements written to output stream:
10
20
30
*/

```

ostream_iterator::operator++

A nonfunctional increment operator that returns an `ostream_iterator` to the same object it addressed before the operation was called.

```

ostream_iterator<Type, CharType, Traits>& operator++();
ostream_iterator<Type, CharType, Traits> operator++(int);

```

Return Value

A reference to the `ostream_iterator`.

Remarks

These member operators both return ***this**.

Example

```

// ostream_iterator_op_incr.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // ostream_iterator for stream cout
    // with new line delimiter
    ostream_iterator<int> intOut ( cout , "\n" );

    // standard iterator interface for writing
    // elements to the output stream
    cout << "Elements written to output stream:" << endl;
    *intOut = 10;
    intOut++; // No effect on iterator position
    *intOut = 20;
    *intOut = 30;
}
/* Output:
Elements written to output stream:
10
20
30
*/

```

ostream_iterator::operator=

Assignment operator used to implement the output_iterator expression * `i` = `x` for writing to an output stream.

```
ostream_iterator<Type, CharType, Traits>& operator=(const Type& val);
```

Parameters

val

The value of the object of type `Type` to be inserted into the output stream.

Return Value

The operator inserts *val* into the output stream associated with the object, followed by the delimiter specified in the [ostream_iterator constructor](#) (if any), and then returns a reference to the `ostream_iterator`.

Remarks

The requirements for an output iterator that the `ostream_iterator` must satisfy require only the expression * `ii` = `t` be valid and says nothing about the operator or the operator= on their own. This member operator returns `*this`.

Example

```

// ostream_iterator_op_assign.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // ostream_iterator for stream cout
    // with new line delimiter
    ostream_iterator<int> intOut ( cout , "\n" );

    // Standard iterator interface for writing
    // elements to the output stream
    cout << "Elements written to output stream:" << endl;
    *intOut = 10;
    intOut++;      // No effect on iterator position
    *intOut = 20;
    *intOut = 30;
}
/* Output:
Elements written to output stream:
10
20
30
*/

```

ostream_iterator::ostream_iterator

Constructs an `ostream_iterator` that is initialized and delimited to write to the output stream.

```

ostream_iterator(
    ostream_type& _Ostr);

ostream_iterator(
    ostream_type& _Ostr,
    const CharType* _Delimiter);

```

Parameters

_Ostr

The output stream of type `ostream_iterator::ostream_type` to be iterated over.

_Delimiter

The delimiter that is inserted into the output stream between values.

Remarks

The first constructor initializes the output stream pointer with `&_ostr`. The delimiter string pointer designates an empty string.

The second constructor initializes the output stream pointer with `&_ostr` and the delimiter string pointer with *_Delimiter*.

Example

```

// ostream_iterator_ostream_iterator.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // ostream_iterator for stream cout
    ostream_iterator<int> intOut ( cout , "\n" );
    *intOut = 10;
    intOut++;
    *intOut = 20;
    intOut++;

    int i;
    vector<int> vec;
    for ( i = 1 ; i < 7 ; ++i )
    {
        vec.push_back ( i );
    }

    // Write elements to standard output stream
    cout << "Elements output without delimiter: ";
    copy ( vec.begin ( ), vec.end ( ),
           ostream_iterator<int> ( cout ) );
    cout << endl;

    // Write elements with delimiter " : " to output stream
    cout << "Elements output with delimiter: ";
    copy ( vec.begin ( ), vec.end ( ),
           ostream_iterator<int> ( cout, " : " ) );
    cout << endl;
}
/* Output:
10
20
Elements output without delimiter: 123456
Elements output with delimiter: 1 : 2 : 3 : 4 : 5 : 6 :
*/

```

ostream_iterator::ostream_type

A type that provides for the stream type of the iterator.

```
typedef basic_ostream<CharType, Traits> ostream_type;
```

Remarks

The type is a synonym for `basic_ostream< CharType , Traits >`, a stream class of the iostream hierarchy that defines objects that can be used for writing.

Example

See [ostream_iterator](#) for an example of how to declare and use `ostream_type`.

ostream_iterator::traits_type

A type that provides for the character traits type of the iterator.

```
typedef Traits traits_type;
```

Remarks

The type is a synonym for the template parameter `Traits`.

Example

```
// ostream_iterator_traits_type.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // The following not OK, but are just the default values:
    typedef ostream_iterator<int>::char_type CHT1;
    typedef ostream_iterator<int>::traits_type CHTR1;

    // ostream_iterator for stream cout
    // with new line delimiter:
    ostream_iterator<int, CHT1, CHTR1> intOut ( cout , "\n" );

    // Standard iterator interface for writing
    // elements to the output stream:
    cout << "The integers written to output stream\n"
        << "by intOut are:" << endl;
    *intOut = 1;
    *intOut = 10;
    *intOut = 100;
}
/* Output:
The integers written to output stream
by intOut are:
1
10
100
*/
```

ostreambuf_iterator Class

10/31/2018 • 6 minutes to read • [Edit Online](#)

The template class `ostreambuf_iterator` describes an output iterator object that writes successive character elements onto the output stream with the extraction **operator**`>>`. The `ostreambuf_iterator`s differ from those of the [ostream_iterator Class](#) in having characters instead of a generic type at the type of object being inserted into the output stream.

Syntax

```
template <class CharType = char class Traits = char_traits <CharType>>
```

Parameters

CharType

The type that represents the character type for the `ostreambuf_iterator`. This argument is optional and the default value is **char**.

Traits

The type that represents the character type for the `ostreambuf_iterator`. This argument is optional and the default value is `char_traits < CharType>`.

Remarks

The `ostreambuf_iterator` class must satisfy the requirements for an output iterator. Algorithms can be written directly to output streams using an `ostreambuf_iterator`. The class provides a low-level stream iterator that allows access to the raw (unformatted) I/O stream in the form of characters and the ability to bypass the buffering and character translations associated with the high-level stream iterators.

Constructors

CONSTRUCTOR	DESCRIPTION
ostreambuf_iterator	Constructs an <code>ostreambuf_iterator</code> that is initialized to write characters to the output stream.

Typedefs

TYPE NAME	DESCRIPTION
char_type	A type that provides for the character type of the <code>ostreambuf_iterator</code> .
ostream_type	A type that provides for the stream type of the <code>ostream_iterator</code> .
streambuf_type	A type that provides for the stream type of the <code>ostreambuf_iterator</code> .

TYPE NAME	DESCRIPTION
<code>traits_type</code>	A type that provides for the character traits type of the <code>ostream_iterator</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>failed</code>	Tests for failure of an insertion into the output stream buffer.

Operators

OPERATOR	DESCRIPTION
<code>operator*</code>	Dereferencing operator used to implement the output iterator expression <code>*i = x</code> .
<code>operator++</code>	A nonfunctional increment operator that returns an <code>ostreambuf_iterator</code> to the same object it addressed before the operation was called.
<code>operator=</code>	The operator inserts a character into the associated stream buffer.

Requirements

Header: `<iterator>`

Namespace: `std`

ostreambuf_iterator::char_type

A type that provides for the character type of the `ostreambuf_iterator`.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter `CharType`.

Example

```

// ostreambuf_iterator_char_type.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    typedef ostreambuf_iterator<char>::char_type CHT1;
    typedef ostreambuf_iterator<char>::traits_type CHTR1;

    // ostreambuf_iterator for stream cout
    // with new line delimiter:
    ostreambuf_iterator< CHT1, CHTR1> charOutBuf ( cout );

    // Standard iterator interface for writing
    // elements to the output streambuf:
    cout << "The characters written to the output stream\n"
         << " by charOutBuf are: ";
    *charOutBuf = 'O';
    charOutBuf++;
    *charOutBuf = 'U';
    charOutBuf++;
    *charOutBuf = 'T';
    charOutBuf++;
    cout << "." << endl;
}
/* Output:
The characters written to the output stream
by charOutBuf are: OUT.
*/

```

ostreambuf_iterator::failed

Tests for failure of an insertion into the output stream buffer.

```
bool failed() const throw();
```

Return Value

true if no insertion into the output stream buffer has failed earlier; otherwise **false**.

Remarks

The member function returns **true** if, in any prior use of member `operator=`, the call to **subf_->** `sputc` returned **eof**.

Example

```

// ostreambuf_iterator_failed.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // ostreambuf_iterator for stream cout
    ostreambuf_iterator<char> charOut ( cout );

    *charOut = 'a';
    charOut ++;
    *charOut = 'b';
    charOut ++;
    *charOut = 'c';
    cout << " are characters output individually." << endl;

    bool b1 = charOut.failed ( );
    if (b1)
        cout << "At least one insertion failed." << endl;
    else
        cout << "No insertions failed." << endl;
}
/* Output:
abc are characters output individually.
No insertions failed.
*/

```

ostreambuf_iterator::operator*

A nonfunctional dereferencing operator used to implement the output iterator expression $*i = x$.

```
ostreambuf_iterator<CharType, Traits>& operator*();
```

Return Value

The ostreambuf iterator object.

Remarks

This operator functions only in the output iterator expression $*i = x$ to output characters to stream buffer. Applied to an ostreambuf iterator, it returns the iterator; ***iter** returns **iter**,

Example

```

// ostreambuf_iterator_op_deref.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // ostreambuf_iterator for stream cout
    // with new line delimiter
    ostreambuf_iterator<char> charOutBuf ( cout );

    // Standard iterator interface for writing
    // elements to the output stream
    cout << "Elements written to output stream:" << endl;
    *charOutBuf = 'O';
    charOutBuf++; // no effect on iterator position
    *charOutBuf = 'U';
    *charOutBuf = 'T';
}
/* Output:
Elements written to output stream:
OUT
*/

```

ostreambuf_iterator::operator++

A nonfunctional increment operator that returns an ostream iterator to the same character it addressed before the operation was called.

```

ostreambuf_iterator<CharType, Traits>& operator++();
ostreambuf_iterator<CharType, Traits>& operator++(int);

```

Return Value

A reference to the character originally addressed or to an implementation-defined object that is convertible to

`ostreambuf_iterator` < **CharType**, **Traits**>.

Remarks

The operator is used to implement the output iterator expression $*i = x$.

Example

```

// ostreambuf_iterator_op_incr.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // ostreambuf_iterator for stream cout
    // with new line delimiter
    ostreambuf_iterator<char> charOutBuf ( cout );

    // Standard iterator interface for writing
    // elements to the output stream
    cout << "Elements written to output stream:" << endl;
    *charOutBuf = 'O';
    charOutBuf++; // No effect on iterator position
    *charOutBuf = 'U';
    *charOutBuf = 'T';
}
/* Output:
Elements written to output stream:
OUT
*/

```

ostreambuf_iterator::operator=

The operator inserts a character into the associated stream buffer.

```
ostreambuf_iterator<CharType, Traits>& operator=(CharType _Char);
```

Parameters

_Char

The character to be inserted into the stream buffer.

Return Value

A reference to the character inserted into the stream buffer.

Remarks

Assignment operator used to implement the output iterator expression $*i = x$ for writing to an output stream.

Example

```

// ostreambuf_iterator_op_assign.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // ostreambuf_iterator for stream cout
    // with new line delimiter
    ostreambuf_iterator<char> charOutBuf ( cout );

    // Standard iterator interface for writing
    // elements to the output stream
    cout << "Elements written to output stream:" << endl;
    *charOutBuf = 'O';
    charOutBuf++; // No effect on iterator position
    *charOutBuf = 'U';
    *charOutBuf = 'T';
}
/* Output:
Elements written to output stream:
OUT
*/

```

ostreambuf_iterator::ostreambuf_iterator

Constructs an `ostreambuf_iterator` that is initialized to write characters to the output stream.

```

ostreambuf_iterator(streambuf_type* strbuf) throw();
ostreambuf_iterator(ostream_type& ostr) throw();

```

Parameters

strbuf

The output streambuf object used to initialize the output stream-buffer pointer.

Ostr

The output stream object used to initialize the output stream-buffer pointer.

Remarks

The first constructor initializes the output stream-buffer pointer with *strbuf*.

The second constructor initializes the output stream-buffer pointer with `ostr`. `rdbuf`. The stored pointer must not be a null pointer.

Example

```

// ostreambuf_iteratorOstreambuf_iterator.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // ostreambuf_iterator for stream cout
    ostreambuf_iterator<char> charOut ( cout );

    *charOut = 'O';
    charOut ++;
    *charOut = 'U';
    charOut ++;
    *charOut = 'T';
    cout << " are characters output individually." << endl;

    ostreambuf_iterator<char> strOut ( cout );
    string str = "These characters are being written to the output stream.\n ";
    copy ( str.begin ( ), str.end ( ), strOut );
}
/* Output:
OUT are characters output individually.
These characters are being written to the output stream.
*/

```

ostreambuf_iterator::ostream_type

A type that provides for the stream type of the `ostream_iterator`.

```
typedef basicOstream<CharType, Traits> ostream_type;
```

Remarks

The type is a synonym for `basicOstream<CharType, Traits>`.

Example

See [ostreambuf_iterator](#) for an example of how to declare and use `ostream_type`.

ostreambuf_iterator::streambuf_type

A type that provides for the stream type of the `ostreambuf_iterator`.

```
typedef basic_streambuf<CharType, Traits> streambuf_type;
```

Remarks

The type is a synonym for `basic_streambuf<CharType, Traits>`, a stream class for I/O buffers that becomes `streambuf` when specialized to character type `char`.

Example

See [ostreambuf_iterator](#) for an example of how to declare and use `streambuf_type`.

ostreambuf_iterator::traits_type

A type that provides for the character traits type of the `ostream_iterator`.

```
typedef Traits traits_type;
```

Remarks

The type is a synonym for the template parameter `Traits`.

Example

```
// ostreambuf_iterator_traits_type.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    typedef ostreambuf_iterator<char>::char_type CHT1;
    typedef ostreambuf_iterator<char>::traits_type CHTR1;

    // ostreambuf_iterator for stream cout
    // with new line delimiter:
    ostreambuf_iterator< CHT1, CHTR1> charOutBuf ( cout );

    // Standard iterator interface for writing
    // elements to the output streambuf:
    cout << "The characters written to the output stream\n"
         << " by charOutBuf are: ";
    *charOutBuf = 'O';
    charOutBuf++;
    *charOutBuf = 'U';
    charOutBuf++;
    *charOutBuf = 'T';
    charOutBuf++;
    cout << "." << endl;
}
/* Output:
The characters written to the output stream
by charOutBuf are: OUT.
*/
```

output_iterator_tag Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

A class that provides a return type for `iterator_category` function that represents an output iterator.

Syntax

```
struct output_iterator_tag {};
```

Remarks

The category tag classes are used as compile tags for algorithm selection. The template function needs to find the most specific category of its iterator argument so that it can use the most efficient algorithm at compile time. For every iterator of type `Iterator`, `iterator_traits < Iterator > ::iterator_category` must be defined to be the most specific category tag that describes the iterator's behavior.

The type is the same as `iterator < Iter > ::iterator_category` when `Iter` describes an object that can serve as a output iterator.

This tag is not parameterized on the `value_type` or `difference_type` for the iterator, as with the other iterator tags, because output iterators do not have either a `value_type` or a `difference_type`.

Example

See [iterator_traits](#) or [random_access_iterator_tag](#) for an example of how to use `iterator_tag`s.

Requirements

Header: `<iterator>`

Namespace: `std`

See also

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

random_access_iterator_tag Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

A class that provides a return type for `iterator_category` function that represents a random-access iterator.

Syntax

```
struct random_access_iterator_tag : public bidirectional_iterator_tag {};
```

Remarks

The category tag classes are used as compile tags for algorithm selection. The template function needs to find the most specific category of its iterator argument so that it can use the most efficient algorithm at compile time. For every iterator of type `Iterator`, `iterator_traits < Iterator > ::iterator_category` must be defined to be the most specific category tag that describes the iterator's behavior.

The type is the same as `iterator < Iter > ::iterator_category` when `Iter` describes an object that can serve as a random-access iterator.

Example

```

// iterator_rait.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>
#include <list>

using namespace std;

int main( )
{
    vector<int> vi;
    vector<char> vc;
    list<char> lc;
    iterator_traits<vector<int>:: iterator>::iterator_category cati;
    iterator_traits<vector<char>:: iterator>::iterator_category catc;
    iterator_traits<list<char>:: iterator>::iterator_category catlc;

    // These are both random-access iterators
    cout << "The type of iterator for vector<int> is "
        << "identified by the tag:\n "
        << typeid ( cati ).name( ) << endl;
    cout << "The type of iterator for vector<char> is "
        << "identified by the tag:\n "
        << typeid ( catc ).name( ) << endl;
    if ( typeid ( cati ) == typeid( catc ) )
        cout << "The iterators are the same." << endl << endl;
    else
        cout << "The iterators are not the same." << endl << endl;

    // But the list iterator is bidirectinal, not random access
    cout << "The type of iterator for list<char> is "
        << "identified by the tag:\n "
        << typeid ( catlc ).name( ) << endl;

    // cout << ( typeid ( vi.begin( ) ) == typeid( vc.begin( ) ) ) << endl;
    if ( typeid ( vi.begin( ) ) == typeid( vc.begin( ) ) )
        cout << "The iterators are the same." << endl;
    else
        cout << "The iterators are not the same." << endl;
    // A random-access iterator is a bidirectional iterator.
    cout << ( void* ) dynamic_cast< iterator_traits<list<char>:: iterator>
        ::iterator_category* > ( &catc ) << endl;
}

```

Sample Output

The following output is for x86.

```

The type of iterator for vector<int> is identified by the tag:
    struct std::random_access_iterator_tag
The type of iterator for vector<char> is identified by the tag:
    struct std::random_access_iterator_tag
The iterators are the same.

The type of iterator for list<char> is identified by the tag:
    struct std::bidirectional_iterator_tag
The iterators are not the same.
0012FF3B

```

Requirements

Header: <iterator>

Namespace: `std`

reverse_iterator Class

3/28/2019 • 18 minutes to read • [Edit Online](#)

The template class is an iterator adaptor that describes a reverse iterator object that behaves like a random-access or bidirectional iterator, only in reverse. It enables the backward traversal of a range.

Syntax

```
template <class RandomIterator>
class reverse_iterator
```

Parameters

RandomIterator The type that represents the iterator to be adapted to operate in reverse.

Remarks

Existing C++ Standard Library containers also define `reverse_iterator` and `const_reverse_iterator` types and have member functions `rbegin` and `rend` that return reverse iterators. These iterators have overwrite semantics. The `reverse_iterator` adaptor supplements this functionality as it offers insert semantics and can also be used with streams.

The `reverse_iterator` that requires a bidirectional iterator must not call any of the member functions `operator++`, `operator+`, `operator--`, `operator-`, or `operator[]`, which may only be used with random-access iterators.

The range of an iterator is $[first, last)$, where the square bracket on the left indicates the inclusion of *first* and the parenthesis on the right indicates the inclusion of elements up to but excluding *last* itself. The same elements are included in the reversed sequence $[\text{rev} - first, \text{rev} - last)$ so that if *last* is the one-past-the-end element in a sequence, then the first element $\text{rev} - first$ in the reversed sequence points to $*(last - 1)$. The identity which relates all reverse iterators to their underlying iterators is:

$$\&*(\text{reverse_iterator}(i)) == \&*(i - 1).$$

In practice, this means that in the reversed sequence the `reverse_iterator` will refer to the element one position beyond (to the right of) the element that the iterator had referred to in the original sequence. So if an iterator addressed the element 6 in the sequence (2, 4, 6, 8), then the `reverse_iterator` will address the element 4 in the reversed sequence (8, 6, 4, 2).

Constructors

CONSTRUCTOR	DESCRIPTION
<code>reverse_iterator</code>	Constructs a default <code>reverse_iterator</code> or a <code>reverse_iterator</code> from an underlying iterator.

Typedefs

TYPE NAME	DESCRIPTION
-----------	-------------

TYPE NAME	DESCRIPTION
difference_type	A type that provides the difference between two <code>reverse_iterator</code> s referring to elements within the same container.
iterator_type	A type that provides the underlying iterator for a <code>reverse_iterator</code> .
pointer	A type that provides a pointer to an element addressed by a <code>reverse_iterator</code> .
reference	A type that provides a reference to an element addressed by a <code>reverse_iterator</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
base	Recovers the underlying iterator from its <code>reverse_iterator</code> .

Operators

OPERATOR	DESCRIPTION
operator_star	Returns the element that a <code>reverse_iterator</code> addresses.
operator+	Adds an offset to an iterator and returns the new <code>reverse_iterator</code> addressing the inserted element at the new offset position.
operator++	Increments the <code>reverse_iterator</code> to the next element.
operator+=	Adds a specified offset from a <code>reverse_iterator</code> .
operator-	Subtracts an offset from a <code>reverse_iterator</code> and returns a <code>reverse_iterator</code> addressing the element at the offset position.
operator--	Decrements the <code>reverse_iterator</code> to the previous element.
operator-=	Subtracts a specified offset from a <code>reverse_iterator</code> .
operator->	Returns a pointer to the element addressed by the <code>reverse_iterator</code> .
operator[]	Returns a reference to an element offset from the element addressed by a <code>reverse_iterator</code> by a specified number of positions.

Requirements

Header: `<iterator>`

Namespace: std

reverse_iterator::base

Recovers the underlying iterator from its `reverse_iterator`.

```
RandomIterator base() const;
```

Return Value

The iterator underlying the `reverse_iterator`.

Remarks

The identity that relates all reverse iterators to their underlying iterators is:

$$\&*(\text{reverse_iterator}(i)) == \&(i - 1).$$

In practice, this means that in the reversed sequence the `reverse_iterator` will refer to the element one position beyond (to the right of) the element that the iterator had referred to in the original sequence. So if an iterator addressed the element 6 in the sequence (2, 4, 6, 8), then the `reverse_iterator` will address the element 4 in the reversed sequence (8, 6, 4, 2).

Example

```

// reverse_iterator_base.cpp
// compile with: /EHsc
#include <iterator>
#include <algorithm>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( 2 * i );
    }

    vector<int>::iterator vIter;
    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;

    vector<int>::reverse_iterator rvIter;
    cout << "The vector vec reversed is: ( ";
    for ( rvIter = vec.rbegin( ) ; rvIter != vec.rend( ) ; rvIter++ )
        cout << *rvIter << " ";
    cout << ")." << endl;

    vector<int>::iterator pos, bpos;
    pos = find ( vec.begin ( ), vec.end ( ), 6 );
    cout << "The iterator pos points to: " << *pos << "." << endl;

    typedef reverse_iterator<vector<int>::iterator>::iterator_type it_vec_int_type;

    reverse_iterator<it_vec_int_type> rpos ( pos );
    cout << "The reverse_iterator rpos points to: " << *rpos
        << "." << endl;

    bpos = rpos.base ( );
    cout << "The iterator underlying rpos is bpos & it points to: "
        << *bpos << "." << endl;
}

```

reverse_iterator::difference_type

A type that provides the difference between two `reverse_iterator`s referring to elements within the same container.

```
typedef typename iterator_traits<RandomIterator>::difference_type difference_type;
```

Remarks

The `reverse_iterator` difference type is the same as the iterator difference type.

The type is a synonym for the iterator trait typename `iterator_traits < RandomIterator > ::pointer`.

Example

See [reverse_iterator::operator\[\]](#) for an example of how to declare and use `difference_type`.

reverse_iterator::iterator_type

A type that provides the underlying iterator for a `reverse_iterator`.

```
typedef RandomIterator iterator_type;
```

Remarks

The type is a synonym for the template parameter `Iterator`.

Example

See [reverse_iterator::base](#) for an example of how to declare and use `iterator_type`.

reverse_iterator::operator*

Returns the element that a `reverse_iterator` addresses.

```
reference operator*() const;
```

Return Value

The value of the elements addressed by the `reverse_iterator`.

Remarks

The operator returns `*(current - 1)`.

Example

```

// reverse_iterator_op_ref.cpp
// compile with: /EHsc
#include <iterator>
#include <algorithm>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( 2 * i );
    }

    vector <int>::iterator vIter;
    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ); vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rvIter;
    cout << "The vector vec reversed is: ( ";
    for ( rvIter = vec.rbegin( ) ; rvIter != vec.rend( ); rvIter++ )
        cout << *rvIter << " ";
    cout << ")." << endl;

    vector <int>::iterator pos, bpos;
    pos = find ( vec.begin ( ), vec.end ( ), 6 );

    // Declare a difference type for a parameter
    // declare a reference return type
    reverse_iterator<vector<int>::iterator>::reference refpos = *pos;
    cout << "The iterator pos points to: " << refpos << "." << endl;
}

```

reverse_iterator::operator+

Adds an offset to an iterator and returns the new `reverse_iterator` addressing the inserted element at the new offset position.

```
reverse_iterator<RandomIterator> operator+(difference_type Off) const;
```

Parameters

Off

The offset to be added to the reverse iterator.

Return Value

A `reverse_iterator` addressing the offset element.

Remarks

This member function may only be used if the `reverse_iterator` satisfies the requirements for a random-access iterator.

Example

```

// reverse_iterator_op_add.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( 2 * i );
    }

    vector <int>::iterator vIter;
    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rvIter;
    cout << "The vector vec reversed is: ( ";
    for ( rvIter = vec.rbegin( ) ; rvIter != vec.rend( ); rvIter++)
        cout << *rvIter << " ";
    cout << ")." << endl;

    // Initializing reverse_iterators to the first element
    vector <int>::reverse_iterator rVPOS1 = vec.rbegin ( );

    cout << "The iterator rVPOS1 initially points to the first "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    vector <int>::reverse_iterator rVPOS2 =rVPOS1 + 2; // offset added
    cout << "After the +2 offset, the iterator rVPOS2 points\n"
        << " to the 3rd element in the reversed sequence: "
        << *rVPOS2 << "." << endl;
}

```

The vector vec is: (2 4 6 8 10).
 The vector vec reversed is: (10 8 6 4 2).
 The iterator rVPOS1 initially points to the first element
 in the reversed sequence: 10.
 After the +2 offset, the iterator rVPOS2 points
 to the 3rd element in the reversed sequence: 6.

reverse_iterator::operator++

Increments the reverse_iterator to the previous element.

```

reverse_iterator<RandomIterator>& operator++();
reverse_iterator<RandomIterator> operator++(int);

```

Return Value

The first operator returns the preincremented `reverse_iterator` and the second, the postincrement operator, returns a copy of the incremented `reverse_iterator`.

Remarks

This member function may only be used if the `reverse_iterator` satisfies the requirements for a bidirectional iterator.

Example

```
// reverse_iterator_op_incr.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( 2 * i - 1 );
    }

    vector<int>::iterator vIter;
    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector<int>::reverse_iterator rvIter;
    cout << "The vector vec reversed is: ( ";
    for ( rvIter = vec.rbegin( ) ; rvIter != vec.rend( ); rvIter++)
        cout << *rvIter << " ";
    cout << ")." << endl;

    // Initializing reverse_iterators to the last element
    vector<int>::reverse_iterator rVPOS1 = vec.rbegin( );

    cout << "The iterator rVPOS1 initially points to the first "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    rVPOS1++; // postincrement, preincrement: ++rVPOS1

    cout << "After incrementing, the iterator rVPOS1 points\n"
        << " to the second element in the reversed sequence: "
        << *rVPOS1 << "." << endl;
}
```

```
The vector vec is: ( 1 3 5 7 9 ).
The vector vec reversed is: ( 9 7 5 3 1 ).
The iterator rVPOS1 initially points to the first element
in the reversed sequence: 9.
After incrementing, the iterator rVPOS1 points
to the second element in the reversed sequence: 7.
```

reverse_iterator::operator+=

Adds a specified offset from a reverse_iterator.

```
reverse_iterator<RandomIterator>& operator+=(difference_type Off);
```

Parameters

Off

The offset by which to increment the iterator.

Return Value

A reference to the element addressed by the `reverse_iterator`.

Example

```
// reverse_iterator_op_addoff.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( 2 * i );
    }

    vector <int>::iterator vIter;

    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rvIter;
    cout << "The vector vec reversed is: ( ";
    for ( rvIter = vec.rbegin( ) ; rvIter != vec.rend( ); rvIter++)
        cout << *rvIter << " ";
    cout << ")." << endl;

    // Initializing reverse_iterators to the last element
    vector <int>::reverse_iterator rVPOS1 = vec.rbegin ( );

    cout << "The iterator rVPOS1 initially points to the first "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    rVPOS1+=2; // addition of an offset
    cout << "After the +2 offset, the iterator rVPOS1 now points\n"
        << " to the third element in the reversed sequence: "
        << *rVPOS1 << "." << endl;
}
```

The vector vec is: (2 4 6 8 10).
The vector vec reversed is: (10 8 6 4 2).
The iterator rVPOS1 initially points to the first element
in the reversed sequence: 10.
After the +2 offset, the iterator rVPOS1 now points
to the third element in the reversed sequence: 6.

reverse_iterator::operator-

Subtracts an offset from a `reverse_iterator` and returns a `reverse_iterator` addressing the element at the offset position.

```
reverse_iterator<RandomIterator> operator-(difference_type Off) const;
```

Parameters

Off

The offset to be subtracted from the reverse_iterator.

Return Value

A `reverse_iterator` addressing the offset element.

Remarks

This member function may only be used if the `reverse_iterator` satisfies the requirements for a random-access iterator.

Example

```
// reverse_iterator_op_sub.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( 3 * i );
    }

    vector <int>::iterator vIter;

    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ) ; vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rvIter;
    cout << "The vector vec reversed is: ( ";
    for ( rvIter = vec.rbegin( ) ; rvIter != vec.rend( ) ; rvIter++)
        cout << *rvIter << " ";
    cout << ")." << endl;

    // Initializing reverse_iterators to the first element
    vector <int>::reverse_iterator rVPOS1 = vec.rend ( ) - 1;

    cout << "The iterator rVPOS1 initially points to the last "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    vector <int>::reverse_iterator rVPOS2 =rVPOS1 - 2; // offset subtracted
    cout << "After the -2 offset, the iterator rVPOS2 points\n"
        << " to the 2nd element from the last in the reversed sequence: "
        << *rVPOS2 << "." << endl;
}
```

The vector `vec` is: (3 6 9 12 15).
The vector `vec` reversed is: (15 12 9 6 3).
The iterator `rVPOS1` initially points to the last element
in the reversed sequence: 3.
After the -2 offset, the iterator `rVPOS2` points
to the 2nd element from the last in the reversed sequence: 9.

`reverse_iterator::operator--`

Decrements the `reverse_iterator` to the previous element.

```
reverse_iterator<RandomIterator>& operator--();  
reverse_iterator<RandomIterator> operator--(int);
```

Return Value

The first operator returns the predecremented `reverse_iterator` and the second, the postdecrement operator, returns a copy of the decremented `reverse_iterator`.

Remarks

This member function may only be used if the `reverse_iterator` satisfies the requirements for a bidirectional iterator.

Example

```

// reverse_iterator_op_decr.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( 2 * i - 1 );
    }

    vector <int>::iterator vIter;

    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rvIter;
    cout << "The vector vec reversed is: ( ";
    for ( rvIter = vec.rbegin( ) ; rvIter != vec.rend( ); rvIter++)
        cout << *rvIter << " ";
    cout << ")." << endl;

    // Initializing reverse_iterators to the first element
    vector <int>::reverse_iterator rVPOS1 = vec.rend ( ) - 1;

    cout << "The iterator rVPOS1 initially points to the last "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;
    rVPOS1--; // postdecrement, predecrement: --rVPOS1

    cout << "After the decrement, the iterator rVPOS1 points\n"
        << " to the next-to-last element in the reversed sequence: "
        << *rVPOS1 << "." << endl;
}

```

The vector vec is: (1 3 5 7 9).
 The vector vec reversed is: (9 7 5 3 1).
 The iterator rVPOS1 initially points to the last element
 in the reversed sequence: 1.
 After the decrement, the iterator rVPOS1 points
 to the next-to-last element in the reversed sequence: 3.

reverse_iterator::operator-=

Subtracts a specified offset from a `reverse_iterator`.

```
reverse_iterator<RandomIterator>& operator-=(difference_type Off);
```

Parameters

Off

The offset to be subtracted from the `reverse_iterator`.

Remarks

This member function may only be used if the `reverse_iterator` satisfies the requirements for a random-access iterator.

The operator evaluates **current** + *_ Off*. then returns ***this**.

Example

```
// reverse_iterator_op_suboff.cpp
// compile with: /EHsc
#include <iterator>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( 3 * i );
    }

    vector <int>::iterator vIter;

    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin( ) ; vIter != vec.end( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rvIter;
    cout << "The vector vec reversed is: ( ";
    for ( rvIter = vec.rbegin( ) ; rvIter != vec.rend( ); rvIter++)
        cout << *rvIter << " ";
    cout << ")." << endl;

    // Initializing reverse_iterators to the first element
    vector <int>::reverse_iterator rVPOS1 = vec.rend ( ) - 1;

    cout << "The iterator rVPOS1 initially points to the last "
        << "element\n in the reversed sequence: "
        << *rVPOS1 << "." << endl;

    rVPOS1-=2;      // Subtraction of an offset
    cout << "After the -2 offset, the iterator rVPOS1 now points\n"
        << " to the 2nd element from the last in the reversed sequence: "
        << *rVPOS1 << "." << endl;
}
```

```
The vector vec is: ( 3 6 9 12 15 ).
The vector vec reversed is: ( 15 12 9 6 3 ).
The iterator rVPOS1 initially points to the last element
in the reversed sequence: 3.
After the -2 offset, the iterator rVPOS1 now points
to the 2nd element from the last in the reversed sequence: 9.
```

reverse_iterator::operator->

Returns a pointer to the element addressed by the `reverse_iterator` .

```
pointer operator->() const;
```

Return Value

A pointer to the element addressed by the `reverse_iterator`.

Remarks

The operator returns **&*&this**.

Example

```
// reverse_iterator_ptrto.cpp
// compile with: /EHsc
#include <iterator>
#include <algorithm>
#include <vector>
#include <utility>
#include <iostream>

int main( )
{
    using namespace std;

    typedef vector<pair<int,int> > pVector;
    pVector vec;
    vec.push_back(pVector::value_type(1,2));
    vec.push_back(pVector::value_type(3,4));
    vec.push_back(pVector::value_type(5,6));

    pVector::iterator pvIter;
    cout << "The vector vec of integer pairs is:\n( ";
    for ( pvIter = vec.begin ( ) ; pvIter != vec.end ( ); pvIter++)
        cout << "( " << pvIter -> first << ", " << pvIter -> second << " ) ";
    cout << ")" << endl << endl;

    pVector::reverse_iterator rpvIter;
    cout << "The vector vec reversed is:\n( ";
    for ( rpvIter = vec.rbegin( ) ; rpvIter != vec.rend( ); rpvIter++ )
        cout << "( " << rpvIter -> first << ", " << rpvIter -> second << " ) ";
    cout << ")" << endl << endl;

    pVector::iterator pos = vec.begin ( );
    pos++;
    cout << "The iterator pos points to:\n( " << pos -> first << ", "
    << pos -> second << " )" << endl << endl;

    pVector::reverse_iterator rpos (pos);

    // Use operator -> with return type: why type int and not int*
    int fint = rpos -> first;
    int sint = rpos -> second;

    cout << "The reverse_iterator rpos points to:\n( " << fint << ", "
    << sint << " )" << endl;
}
```

```
The vector vec of integer pairs is:  
( ( 1, 2) ( 3, 4) ( 5, 6) )
```

```
The vector vec reversed is:  
( ( 5, 6) ( 3, 4) ( 1, 2) )
```

```
The iterator pos points to:  
( 3, 4 )
```

```
The reverse_iterator rpos points to:  
( 1, 2 )
```

reverse_iterator::operator[]

Returns a reference to an element offset from the element addressed by a `reverse_iterator` by a specified number of positions.

```
reference operator[](difference_type Off) const;
```

Parameters

Off

The offset from the `reverse_iterator` address.

Return Value

The reference to the element offset.

Remarks

The operator returns `*(*this + off)`.

Example

```

// reverse_iterator_ret_ref.cpp
// compile with: /EHsc
#include <iterator>
#include <algorithm>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for (i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( 2 * i );
    }

    vector <int>::iterator vIter;
    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ) ; vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rvIter;
    cout << "The vector vec reversed is: ( ";
    for ( rvIter = vec.rbegin( ) ; rvIter != vec.rend( ) ; rvIter++ )
        cout << *rvIter << " ";
    cout << ")." << endl;

    vector <int>::iterator pos;
    pos = find ( vec.begin ( ), vec.end ( ), 8 );
    reverse_iterator<vector<int>::iterator> rpos ( pos );

    // Declare a difference type for a parameter
    reverse_iterator<vector<int>::iterator>::difference_type diff = 2;

    cout << "The iterator pos points to: " << *pos << "." << endl;
    cout << "The iterator rpos points to: " << *rpos << "." << endl;

    // Declare a reference return type & use operator[]
    reverse_iterator<vector<int>::iterator>::reference refrpos = rpos [diff];
    cout << "The iterator rpos now points to: " << refrpos << "." << endl;
}

```

```

The vector vec is: ( 2 4 6 8 10 ).
The vector vec reversed is: ( 10 8 6 4 2 ).
The iterator pos points to: 8.
The iterator rpos points to: 6.
The iterator rpos now points to: 2.

```

reverse_iterator::pointer

A type that provides a pointer to an element addressed by a `reverse_iterator`.

```

typedef typename iterator_traits<RandomIterator>::pointer pointer;

```

Remarks

The type is a synonym for the iterator trait typename `iterator_traits < RandomIterator > ::pointer`.

Example

```

// reverse_iterator_pointer.cpp
// compile with: /EHsc
#include <iterator>
#include <algorithm>
#include <vector>
#include <utility>
#include <iostream>

int main( )
{
    using namespace std;

    typedef vector<pair<int,int> > pVector;
    pVector vec;
    vec.push_back( pVector::value_type( 1,2 ) );
    vec.push_back( pVector::value_type( 3,4 ) );
    vec.push_back( pVector::value_type( 5,6 ) );

    pVector::iterator pvIter;
    cout << "The vector vec of integer pairs is:\n" << "( ";
    for ( pvIter = vec.begin ( ) ; pvIter != vec.end ( ); pvIter++)
        cout << "( " << pvIter -> first << ", " << pvIter -> second << " ) ";
    cout << ")" << endl;

    pVector::reverse_iterator rpvIter;
    cout << "\nThe vector vec reversed is:\n" << "( ";
    for ( rpvIter = vec.rbegin( ) ; rpvIter != vec.rend( ); rpvIter++)
        cout << "( " << rpvIter -> first << ", " << rpvIter -> second << " ) ";
    cout << ")" << endl;

    pVector::iterator pos = vec.begin ( );
    pos++;
    cout << "\nThe iterator pos points to:\n"
        << "( " << pos -> first << ", "
        << pos -> second << " )" << endl;

    pVector::reverse_iterator rpos (pos);
    cout << "\nThe iterator rpos points to:\n"
        << "( " << rpos -> first << ", "
        << rpos -> second << " )" << endl;
}

```

The vector vec of integer pairs is:
 ((1, 2) (3, 4) (5, 6))

The vector vec reversed is:
 ((5, 6) (3, 4) (1, 2))

The iterator pos points to:
 (3, 4)

The iterator rpos points to:
 (1, 2)

reverse_iterator::reference

A type that provides a reference to an element addressed by a reverse_iterator.

```

typedef typename iterator_traits<RandomIterator>::reference reference;

```

Remarks

The type is a synonym for the iterator trait typename `iterator_traits< RandomIterator>::reference`.

Example

See `reverse_iterator::operator[]` or `reverse_iterator::operator*` for examples of how to declare and use `reference`.

reverse_iterator::reverse_iterator

Constructs a default `reverse_iterator` or a `reverse_iterator` from an underlying iterator.

```
reverse_iterator();
explicit reverse_iterator(RandomIterator right);

template <class Type>
reverse_iterator(const reverse_iterator<Type>& right);
```

Parameters

right

The iterator that is to be adapted to a `reverse_iterator`.

Return Value

A default `reverse_iterator` or a `reverse_iterator` adapting an underlying iterator.

Remarks

The identity which relates all reverse iterators to their underlying iterators is:

$$\&*(\text{reverse_iterator}(i)) == \&(i - 1).$$

In practice, this means that in the reversed sequence the `reverse_iterator` will refer to the element one position beyond (to the right of) the element that the iterator had referred to in the original sequence. So if an iterator addressed the element 6 in the sequence (2, 4, 6, 8), then the `reverse_iterator` will address the element 4 in the reversed sequence (8, 6, 4, 2).

Example

```

// reverse_iterator_reverse_iterator.cpp
// compile with: /EHsc
#include <iterator>
#include <algorithm>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    vector<int> vec;
    for ( i = 1 ; i < 6 ; ++i )
    {
        vec.push_back ( i );
    }

    vector <int>::iterator vIter;
    cout << "The vector vec is: ( ";
    for ( vIter = vec.begin ( ) ; vIter != vec.end ( ); vIter++)
        cout << *vIter << " ";
    cout << ")." << endl;

    vector <int>::reverse_iterator rvIter;
    cout << "The vector vec reversed is: ( ";
    for ( rvIter = vec.rbegin( ) ; rvIter != vec.rend( ); rvIter++)
        cout << *rvIter << " ";
    cout << ")." << endl;

    vector <int>::iterator pos;
    pos = find ( vec.begin ( ), vec.end ( ), 4 );
    cout << "The iterator pos = " << *pos << "." << endl;

    vector <int>::reverse_iterator rpos ( pos );
    cout << "The reverse_iterator rpos = " << *rpos
        << "." << endl;
}

```

[C++ Standard Library Reference](#)

unchecked_array_iterator Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The `unchecked_array_iterator` class allows you to wrap an array or pointer into an unchecked iterator. Use this class as a wrapper (using the [make_unchecked_array_iterator](#) function) for raw pointers or arrays as a targeted way to manage unchecked pointer warnings instead of globally silencing these warnings. If possible, prefer the checked version of this class, [checked_array_iterator](#).

NOTE

This class is a Microsoft extension of the C++ Standard Library. Code implemented by using this function is not portable to C++ Standard build environments that do not support this Microsoft extension.

Syntax

```
template <class Iterator>
class unchecked_array_iterator;
```

Remarks

This class is defined in the [stdext](#) namespace.

This is the unchecked version of the [checked_array_iterator Class](#) and supports all the same overloads and members. For more information on the checked iterator feature with code examples, see [Checked Iterators](#).

Requirements

Header: <iterator>

Namespace: stdext

<limits>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines the template class `numeric_limits` and two enumerations concerning floating-point representations and rounding.

Syntax

```
#include <limits>
```

Remarks

Explicit specializations of the `numeric_limits` class describe many properties of the fundamental types, including the character, integer, and floating-point types and **bool** that are implementation defined rather than fixed by the rules of the C++ language. Properties described in <limits> include accuracy, minimum and maximum sized representations, rounding, and signaling type errors.

Enumerations

<code>float_denorm_style</code>	The enumeration describes the various methods that an implementation can choose for representing a denormalized floating-point value — one too small to represent as a normalized value:
<code>float_round_style</code>	The enumeration describes the various methods that an implementation can choose for rounding a floating-point value to an integer value.

Classes

CLASS	DESCRIPTION
<code>numeric_limits</code> Class	The template class describes arithmetic properties of built-in numerical types.

<limits> enums

10/31/2018 • 2 minutes to read • [Edit Online](#)

[float_denorm_style](#)

[float_round_style](#)

float_denorm_style Enumeration

The enumeration describes the various methods that an implementation can choose for representing a denormalized floating-point value — one too small to represent as a normalized value:

```
enum float_denorm_style {
    denorm_indeterminate = -1,
    denorm_absent = 0,
    denorm_present = 1    };
```

Return Value

The enumeration returns:

- `denorm_indeterminate` if the presence or absence of denormalized forms cannot be determined at translation time.
- `denorm_absent` if denormalized forms are absent.
- `denorm_present` if denormalized forms are present.

Example

See [numeric_limits::has_denorm](#) for an example in which the values of this enumeration may be accessed.

float_round_style Enumeration

The enumeration describes the various methods that an implementation can choose for rounding a floating-point value to an integer value.

```
enum float_round_style {
    round_indeterminate = -1,
    round_toward_zero = 0,
    round_to_nearest = 1,
    round_toward_infinity = 2,
    round_toward_neg_infinity = 3    };
```

Return Value

The enumeration returns:

- `round_indeterminate` if the rounding method cannot be determined.
- `round_toward_zero` if the round toward zero.
- `round_to_nearest` if the round to nearest integer.
- `round_toward_infinity` if the round away from zero.

- `round_toward_neg_infinity` if the round to more negative integer.

Example

See [numeric_limits::round_style](#) for an example in which the values of this enumeration may be accessed.

See also

[<limits>](#)

numeric_limits Class

10/31/2018 • 27 minutes to read • [Edit Online](#)

The template class describes arithmetic properties of built-in numerical types.

Syntax

```
template <class Type>
class numeric_limits
```

Parameters

Type

The fundamental element data type whose properties are being tested or queried or set.

Remarks

The header defines explicit specializations for the types **wchar_t**, **bool**, **char**, **signed char**, **unsigned char**, **short**, **unsigned short**, **int**, **unsigned int**, **long**, **unsigned long**, **float**, **double**, **long double**, **long long**, **unsigned long long**, **char16_t**, and **char32_t**. For these explicit specializations, the member `numeric_limits::is_specialized` is **true**, and all relevant members have meaningful values. The program can supply additional explicit specializations. Most member functions of the class describe or test possible implementations of **float**.

For an arbitrary specialization, no members have meaningful values. A member object that does not have a meaningful value stores zero (or **false**) and a member function that does not return a meaningful value returns

`Type(0)`.

Static Functions and Constants

<code>denorm_min</code>	Returns the smallest nonzero denormalized value.
<code>digits</code>	Returns the number of radix digits that the type can represent without loss of precision.
<code>digits10</code>	Returns the number of decimal digits that the type can represent without loss of precision.
<code>epsilon</code>	Returns the difference between 1 and the smallest value greater than 1 that the data type can represent.
<code>has_denorm</code>	Tests whether a type allows denormalized values.
<code>has_denorm_loss</code>	Tests whether loss of accuracy is detected as a denormalization loss rather than as an inexact result.
<code>has_infinity</code>	Tests whether a type has a representation for positive infinity.
<code>has_quiet_NaN</code>	Tests whether a type has a representation for a quiet not a number (NaN), which is nonsignaling.

<code>has_signaling_NaN</code>	Tests whether a type has a representation for signaling not a number (NaN).
<code>infinity</code>	The representation for positive infinity for a type, if available.
<code>is_bounded</code>	Tests if the set of values that a type may represent is finite.
<code>is_exact</code>	Tests if the calculations done on a type are free of rounding errors.
<code>is_iec559</code>	Tests if a type conforms to IEC 559 standards.
<code>is_integer</code>	Tests if a type has an integer representation.
<code>is_modulo</code>	Tests if a type has a modulo representation.
<code>is_signed</code>	Tests if a type has a signed representation.
<code>is_specialized</code>	Tests if a type has an explicit specialization defined in the template class <code>numeric_limits</code> .
<code>lowest</code>	Returns the most negative finite value.
<code>max</code>	Returns the maximum finite value for a type.
<code>max_digits10</code>	Returns the number of decimal digits required to ensure that two distinct values of the type have distinct decimal representations.
<code>max_exponent</code>	Returns the maximum positive integral exponent that the floating-point type can represent as a finite value when a base of radix is raised to that power.
<code>max_exponent10</code>	Returns the maximum positive integral exponent that the floating-point type can represent as a finite value when a base of ten is raised to that power.
<code>min</code>	Returns the minimum normalized value for a type.
<code>min_exponent</code>	Returns the maximum negative integral exponent that the floating-point type can represent as a finite value when a base of radix is raised to that power.
<code>min_exponent10</code>	Returns the maximum negative integral exponent that the floating-point type can represent as a finite value when a base of ten is raised to that power.
<code>quiet_NaN</code>	Returns the representation of a quiet not a number (NaN) for the type.
<code>radix</code>	Returns the integral base, referred to as radix, used for the representation of a type.

round_error	Returns the maximum rounding error for the type.
round_style	Returns a value that describes the various methods that an implementation can choose for rounding a floating-point value to an integer value.
signaling_NaN	Returns the representation of a signaling not a number (NaN) for the type.
tinyness_before	Tests whether a type can determine that a value is too small to represent as a normalized value before rounding it.
traps	Tests whether trapping that reports on arithmetic exceptions is implemented for a type.

Requirements

Header: <limits>

Namespace: std

numeric_limits::denorm_min

Returns the smallest nonzero denormalized value.

```
static constexpr Type denorm_min() throw();
```

Return Value

The smallest nonzero denormalized value.

Remarks

long double is the same as **double** for the C++ compiler.

The function returns the minimum value for the type, which is the same as [min](#) if [has_denorm](#) is not equal to

`denorm_present` .

Example

```

// numeric_limits_denorm_min.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The smallest nonzero denormalized value" << endl
         << "for float objects is: "
         << numeric_limits<float>::denorm_min( ) << endl;
    cout << "The smallest nonzero denormalized value" << endl
         << "for double objects is: "
         << numeric_limits<double>::denorm_min( ) << endl;
    cout << "The smallest nonzero denormalized value" << endl
         << "for long double objects is: "
         << numeric_limits<long double>::denorm_min( ) << endl;

    // A smaller value will round to zero
    cout << numeric_limits<float>::denorm_min( )/2 <<endl;
    cout << numeric_limits<double>::denorm_min( )/2 <<endl;
    cout << numeric_limits<long double>::denorm_min( )/2 <<endl;
}

```

```

The smallest nonzero denormalized value
for float objects is: 1.4013e-045
The smallest nonzero denormalized value
for double objects is: 4.94066e-324
The smallest nonzero denormalized value
for long double objects is: 4.94066e-324
0
0
0

```

numeric_limits::digits

Returns the number of radix digits that the type can represent without loss of precision.

```
static constexpr int digits = 0;
```

Return Value

The number of radix digits that the type can represent without loss of precision.

Remarks

The member stores the number of radix digits that the type can represent without change, which is the number of bits other than any sign bit for a predefined integer type, or the number of mantissa digits for a predefined floating-point type.

Example

```
// numeric_limits_digits_min.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << numeric_limits<float>::digits <<endl;
    cout << numeric_limits<double>::digits <<endl;
    cout << numeric_limits<long double>::digits <<endl;
    cout << numeric_limits<int>::digits <<endl;
    cout << numeric_limits<__int64>::digits <<endl;
}
```

```
24
53
53
31
63
```

numeric_limits::digits10

Returns the number of decimal digits that the type can represent without loss of precision.

```
static constexpr int digits10 = 0;
```

Return Value

The number of decimal digits that the type can represent without loss of precision.

Example

```
// numeric_limits_digits10.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << numeric_limits<float>::digits10 <<endl;
    cout << numeric_limits<double>::digits10 <<endl;
    cout << numeric_limits<long double>::digits10 <<endl;
    cout << numeric_limits<int>::digits10 <<endl;
    cout << numeric_limits<__int64>::digits10 <<endl;
    float f = (float)99999999;
    cout.precision ( 10 );
    cout << "The float is; " << f << endl;
}
```

```
6
15
15
9
18
The float is; 100000000
```

numeric_limits::epsilon

The function returns the difference between 1 and the smallest value greater than 1 that is representable for the data type.

```
static constexpr Type epsilon() throw();
```

Return Value

The difference between 1 and the smallest value greater than 1 that is representable for the data type.

Remarks

The value is FLT_EPSILON for type **float**. `epsilon` for a type is the smallest positive floating-point number N such that $N + \text{epsilon} + N$ is representable.

Example

```
// numeric_limits_epsilon.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The difference between 1 and the smallest "
        << "value greater than 1" << endl
        << "for float objects is: "
        << numeric_limits<float>::epsilon( ) << endl;
    cout << "The difference between 1 and the smallest "
        << "value greater than 1" << endl
        << "for double objects is: "
        << numeric_limits<double>::epsilon( ) << endl;
    cout << "The difference between 1 and the smallest "
        << "value greater than 1" << endl
        << "for long double objects is: "
        << numeric_limits<long double>::epsilon( ) << endl;
}
```

```
The difference between 1 and the smallest value greater than 1
for float objects is: 1.19209e-007
The difference between 1 and the smallest value greater than 1
for double objects is: 2.22045e-016
The difference between 1 and the smallest value greater than 1
for long double objects is: 2.22045e-016
```

numeric_limits::has_denorm

Tests whether a type allows denormalized values.

```
static constexpr float_denorm_style has_denorm = denorm_absent;
```

Return Value

An enumeration value of type **const** `float_denorm_style`, indicating whether the type allows denormalized values.

Remarks

The member stores `denorm_present` for a floating-point type that has denormalized values, effectively a variable number of exponent bits.

Example

```
// numeric_limits_has_denorm.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects allow denormalized values: "
          << numeric_limits<float>::has_denorm
          << endl;
    cout << "Whether double objects allow denormalized values: "
          << numeric_limits<double>::has_denorm
          << endl;
    cout << "Whether long int objects allow denormalized values: "
          << numeric_limits<long int>::has_denorm
          << endl;
}
```

```
Whether float objects allow denormalized values: 1
Whether double objects allow denormalized values: 1
Whether long int objects allow denormalized values: 0
```

numeric_limits::has_denorm_loss

Tests whether loss of accuracy is detected as a denormalization loss rather than as an inexact result.

```
static constexpr bool has_denorm_loss = false;
```

Return Value

true if the loss of accuracy is detected as a denormalization loss; **false** if not.

Remarks

The member stores true for a type that determines whether a value has lost accuracy because it is delivered as a denormalized result (too small to represent as a normalized value) or because it is inexact (not the same as a result not subject to limitations of exponent range and precision), an option with IEC 559 floating-point representations that can affect some results.

Example

```
// numeric_limits_has_denorm_loss.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects can detect denormalized loss: "
          << numeric_limits<float>::has_denorm_loss
          << endl;
    cout << "Whether double objects can detect denormalized loss: "
          << numeric_limits<double>::has_denorm_loss
          << endl;
    cout << "Whether long int objects can detect denormalized loss: "
          << numeric_limits<long int>::has_denorm_loss
          << endl;
}
```

```
Whether float objects can detect denormalized loss: 1
Whether double objects can detect denormalized loss: 1
Whether long int objects can detect denormalized loss: 0
```

numeric_limits::has_infinity

Tests whether a type has a representation for positive infinity.

```
static constexpr bool has_infinity = false;
```

Return Value

true if the type has a representation for positive infinity; **false** if not.

Remarks

The member returns **true** if [is_iec559](#) is **true**.

Example

```
// numeric_limits_has_infinity.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects have infinity: "
          << numeric_limits<float>::has_infinity
          << endl;
    cout << "Whether double objects have infinity: "
          << numeric_limits<double>::has_infinity
          << endl;
    cout << "Whether long int objects have infinity: "
          << numeric_limits<long int>::has_infinity
          << endl;
}
```

```
Whether float objects have infinity: 1
Whether double objects have infinity: 1
Whether long int objects have infinity: 0
```

numeric_limits::has_quiet_NaN

Tests whether a type has a representation for a quiet not a number (NaN), which is nonsignaling.

```
static constexpr bool has_quiet_NaN = false;
```

Return Value

true if the **type** has a representation for a quiet NaN; **false** if not.

Remarks

A quiet NaN is an encoding for not a number, which does not signal its presence in an expression. The return value is **true** if [is_iec559](#) is true.

Example

```
// numeric_limits_has_quiet_nan.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects have quiet_NaN: "
          << numeric_limits<float>::has_quiet_NaN
          << endl;
    cout << "Whether double objects have quiet_NaN: "
          << numeric_limits<double>::has_quiet_NaN
          << endl;
    cout << "Whether long int objects have quiet_NaN: "
          << numeric_limits<long int>::has_quiet_NaN
          << endl;
}
```

```
Whether float objects have quiet_NaN: 1
Whether double objects have quiet_NaN: 1
Whether long int objects have quiet_NaN: 0
```

numeric_limits::has_signaling_NaN

Tests whether a type has a representation for signaling not a number (NaN).

```
static constexpr bool has_signaling_NaN = false;
```

Return Value

true if the type has a representation for a signaling NaN; **false** if not.

Remarks

A signaling NaN is an encoding for not a number, which signals its presence in an expression. The return value is

true if [is_iec559](#) is true.

Example

```
// numeric_limits_has_signaling_nan.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects have a signaling_NaN: "
          << numeric_limits<float>::has_signaling_NaN
          << endl;
    cout << "Whether double objects have a signaling_NaN: "
          << numeric_limits<double>::has_signaling_NaN
          << endl;
    cout << "Whether long int objects have a signaling_NaN: "
          << numeric_limits<long int>::has_signaling_NaN
          << endl;
}
```

```
Whether float objects have a signaling_NaN: 1
Whether double objects have a signaling_NaN: 1
Whether long int objects have a signaling_NaN: 0
```

numeric_limits::infinity

The representation of positive infinity for a type, if available.

```
static constexpr Type infinity() throw();
```

Return Value

The representation of positive infinity for a type, if available.

Remarks

The return value is meaningful only if [has_infinity](#) is **true**.

Example

```

// numeric_limits_infinity.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << numeric_limits<float>::has_infinity <<endl;
    cout << numeric_limits<double>::has_infinity<<endl;
    cout << numeric_limits<long double>::has_infinity <<endl;
    cout << numeric_limits<int>::has_infinity <<endl;
    cout << numeric_limits<__int64>::has_infinity <<endl;

    cout << "The representation of infinity for type float is: "
         << numeric_limits<float>::infinity( ) <<endl;
    cout << "The representation of infinity for type double is: "
         << numeric_limits<double>::infinity( ) <<endl;
    cout << "The representation of infinity for type long double is: "
         << numeric_limits<long double>::infinity( ) <<endl;
}

```

```

1
1
1
0
0
The representation of infinity for type float is: inf
The representation of infinity for type double is: inf
The representation of infinity for type long double is: inf

```

numeric_limits::is_bounded

Tests if the set of values that a type may represent is finite.

```
static constexpr bool is_bounded = false;
```

Return Value

true if the type has a bounded set of representable values; **false** if not.

Remarks

All predefined types have a bounded set of representable values and return **true**.

Example

```

// numeric_limits_is_bounded.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects have bounded set "
          << "of representable values: "
          << numeric_limits<float>::is_bounded
          << endl;
    cout << "Whether double objects have bounded set "
          << "of representable values: "
          << numeric_limits<double>::is_bounded
          << endl;
    cout << "Whether long int objects have bounded set "
          << "of representable values: "
          << numeric_limits<long int>::is_bounded
          << endl;
    cout << "Whether unsigned char objects have bounded set "
          << "of representable values: "
          << numeric_limits<unsigned char>::is_bounded
          << endl;
}

```

```

Whether float objects have bounded set of representable values: 1
Whether double objects have bounded set of representable values: 1
Whether long int objects have bounded set of representable values: 1
Whether unsigned char objects have bounded set of representable values: 1

```

numeric_limits::is_exact

Tests if the calculations done on a type are free of rounding errors.

```
static constexpr bool is_exact = false;
```

Return Value

true if the calculations are free of rounding errors; **false** if not.

Remarks

All predefined integer types have exact representations for their values and return **false**. A fixed-point or rational representation is also considered exact, but a floating-point representation is not.

Example

```

// numeric_limits_is_exact.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects have calculations "
          << "free of rounding errors: "
          << numeric_limits<float>::is_exact
          << endl;
    cout << "Whether double objects have calculations "
          << "free of rounding errors: "
          << numeric_limits<double>::is_exact
          << endl;
    cout << "Whether long int objects have calculations "
          << "free of rounding errors: "
          << numeric_limits<long int>::is_exact
          << endl;
    cout << "Whether unsigned char objects have calculations "
          << "free of rounding errors: "
          << numeric_limits<unsigned char>::is_exact
          << endl;
}

```

```

Whether float objects have calculations free of rounding errors: 0
Whether double objects have calculations free of rounding errors: 0
Whether long int objects have calculations free of rounding errors: 1
Whether unsigned char objects have calculations free of rounding errors: 1

```

numeric_limits::is_iec559

Tests if a type conforms to IEC 559 standards.

```
static constexpr bool is_iec559 = false;
```

Return Value

true if the type conforms to the IEC 559 standards; **false** if not.

Remarks

The IEC 559 is an international standard for representing floating-point values and is also known as IEEE 754 in the USA.

Example

```
// numeric_limits_is_iec559.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects conform to iec559 standards: "
          << numeric_limits<float>::is_iec559
          << endl;
    cout << "Whether double objects conform to iec559 standards: "
          << numeric_limits<double>::is_iec559
          << endl;
    cout << "Whether int objects conform to iec559 standards: "
          << numeric_limits<int>::is_iec559
          << endl;
    cout << "Whether unsigned char objects conform to iec559 standards: "
          << numeric_limits<unsigned char>::is_iec559
          << endl;
}
```

```
Whether float objects conform to iec559 standards: 1
Whether double objects conform to iec559 standards: 1
Whether int objects conform to iec559 standards: 0
Whether unsigned char objects conform to iec559 standards: 0
```

numeric_limits::is_integer

Tests if a type has an integer representation.

```
static constexpr bool is_integer = false;
```

Return Value

true if the type has an integer representation; **false** if not.

Remarks

All predefined integer types have an integer representation.

Example

```

// numeric_limits_is_integer.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects have an integral representation: "
          << numeric_limits<float>::is_integer
          << endl;
    cout << "Whether double objects have an integral representation: "
          << numeric_limits<double>::is_integer
          << endl;
    cout << "Whether int objects have an integral representation: "
          << numeric_limits<int>::is_integer
          << endl;
    cout << "Whether unsigned char objects have an integral representation: "
          << numeric_limits<unsigned char>::is_integer
          << endl;
}

```

```

Whether float objects have an integral representation: 0
Whether double objects have an integral representation: 0
Whether int objects have an integral representation: 1
Whether unsigned char objects have an integral representation: 1

```

numeric_limits::is_modulo

Tests if a **type** has a modulo representation.

```
static constexpr bool is_modulo = false;
```

Return Value

true if the type has a modulo representation; **false** if not.

Remarks

A modulo representation is a representation where all results are reduced modulo some value. All predefined unsigned integer types have a modulo representation.

Example

```

// numeric_limits_is_modulo.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects have a modulo representation: "
          << numeric_limits<float>::is_modulo
          << endl;
    cout << "Whether double objects have a modulo representation: "
          << numeric_limits<double>::is_modulo
          << endl;
    cout << "Whether signed char objects have a modulo representation: "
          << numeric_limits<signed char>::is_modulo
          << endl;
    cout << "Whether unsigned char objects have a modulo representation: "
          << numeric_limits<unsigned char>::is_modulo
          << endl;
}

```

```

Whether float objects have a modulo representation: 0
Whether double objects have a modulo representation: 0
Whether signed char objects have a modulo representation: 1
Whether unsigned char objects have a modulo representation: 1

```

numeric_limits::is_signed

Tests if a type has a signed representation.

```
static constexpr bool is_signed = false;
```

Return Value

true if the type has a signed representation; **false** if not.

Remarks

The member stores true for a type that has a signed representation, which is the case for all predefined floating-point and signed integer types.

Example

```
// numeric_limits_is_signaled.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects have a signed representation: "
          << numeric_limits<float>::is_signed
          << endl;
    cout << "Whether double objects have a signed representation: "
          << numeric_limits<double>::is_signed
          << endl;
    cout << "Whether signed char objects have a signed representation: "
          << numeric_limits<signed char>::is_signed
          << endl;
    cout << "Whether unsigned char objects have a signed representation: "
          << numeric_limits<unsigned char>::is_signed
          << endl;
}
```

```
Whether float objects have a signed representation: 1
Whether double objects have a signed representation: 1
Whether signed char objects have a signed representation: 1
Whether unsigned char objects have a signed representation: 0
```

numeric_limits::is_specialized

Tests if a type has an explicit specialization defined in the template class `numeric_limits`.

```
static constexpr bool is_specialized = false;
```

Return Value

true if the type has an explicit specialization defined in the template class; **false** if not.

Remarks

All scalar types other than pointers have an explicit specialization defined for template class `numeric_limits`.

Example

```
// numeric_limits_is_specialized.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float objects have an explicit "
          << "specialization in the class: "
          << numeric_limits<float>::is_specialized
          << endl;
    cout << "Whether float* objects have an explicit "
          << "specialization in the class: "
          << numeric_limits<float*>::is_specialized
          << endl;
    cout << "Whether int objects have an explicit "
          << "specialization in the class: "
          << numeric_limits<int>::is_specialized
          << endl;
    cout << "Whether int* objects have an explicit "
          << "specialization in the class: "
          << numeric_limits<int*>::is_specialized
          << endl;
}
```

```
Whether float objects have an explicit specialization in the class: 1
Whether float* objects have an explicit specialization in the class: 0
Whether int objects have an explicit specialization in the class: 1
Whether int* objects have an explicit specialization in the class: 0
```

numeric_limits::lowest

Returns the most negative finite value.

```
static constexpr Type lowest() throw();
```

Return Value

Returns the most negative finite value.

Remarks

Returns the most negative finite value for the type (which is typically `min()` for integer types and `-max()` for floating-point types). The return value is meaningful if `is_bounded` is **true**.

numeric_limits::max

Returns the maximum finite value for a type.

```
static constexpr Type max() throw();
```

Return Value

The maximum finite value for a type.

Remarks

The maximum finite value is `INT_MAX` for type **int** and `FLT_MAX` for type **float**. The return value is meaningful if

`is_bounded` is **true**.

Example

```
// numeric_limits_max.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main() {
    cout << "The maximum value for type float is: "
          << numeric_limits<float>::max( )
          << endl;
    cout << "The maximum value for type double is: "
          << numeric_limits<double>::max( )
          << endl;
    cout << "The maximum value for type int is: "
          << numeric_limits<int>::max( )
          << endl;
    cout << "The maximum value for type short int is: "
          << numeric_limits<short int>::max( )
          << endl;
}
```

numeric_limits::max_digits10

Returns the number of decimal digits required to make sure that two distinct values of the type have distinct decimal representations.

```
static constexpr int max_digits10 = 0;
```

Return Value

Returns the number of decimal digits that are required to make sure that two distinct values of the type have distinct decimal representations.

Remarks

The member stores the number of decimal digits required to make sure that two distinct values of the type have distinct decimal representations.

numeric_limits::max_exponent

Returns the maximum positive integral exponent that the floating-point type can represent as a finite value when a base of radix is raised to that power.

```
static constexpr int max_exponent = 0;
```

Return Value

The maximum integral radix-based exponent representable by the type.

Remarks

The member function return is meaningful only for floating-point types. The `max_exponent` is the value `FLT_MAX_EXP` for type **float**.

Example

```

// numeric_limits_max_exponent.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The maximum radix-based exponent for type float is: "
          << numeric_limits<float>::max_exponent
          << endl;
    cout << "The maximum radix-based exponent for type double is: "
          << numeric_limits<double>::max_exponent
          << endl;
    cout << "The maximum radix-based exponent for type long double is: "
          << numeric_limits<long double>::max_exponent
          << endl;
}

```

```

The maximum radix-based exponent for type float is: 128
The maximum radix-based exponent for type double is: 1024
The maximum radix-based exponent for type long double is: 1024

```

numeric_limits::max_exponent10

Returns the maximum positive integral exponent that the floating-point type can represent as a finite value when a base of ten is raised to that power.

```
static constexpr int max_exponent10 = 0;
```

Return Value

The maximum integral base 10 exponent representable by the type.

Remarks

The member function return is meaningful only for floating-point types. The `max_exponent` is the value `FLT_MAX_10` for type **float**.

Example

```
// numeric_limits_max_exponent10.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The maximum base 10 exponent for type float is: "
          << numeric_limits<float>::max_exponent10
          << endl;
    cout << "The maximum base 10 exponent for type double is: "
          << numeric_limits<double>::max_exponent10
          << endl;
    cout << "The maximum base 10 exponent for type long double is: "
          << numeric_limits<long double>::max_exponent10
          << endl;
}
```

```
The maximum base 10 exponent for type float is: 38
The maximum base 10 exponent for type double is: 308
The maximum base 10 exponent for type long double is: 308
```

numeric_limits::min

Returns the minimum normalized value for a type.

```
static constexpr Type min() throw();
```

Return Value

The minimum normalized value for the type.

Remarks

The minimum normalized value is INT_MIN for type **int** and FLT_MIN for type **float**. The return value is meaningful if [is_bounded](#) is **true** or if [is_signed](#) is **false**.

Example

```

// numeric_limits_min.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The minimum value for type float is: "
          << numeric_limits<float>::min( )
          << endl;
    cout << "The minimum value for type double is: "
          << numeric_limits<double>::min( )
          << endl;
    cout << "The minimum value for type int is: "
          << numeric_limits<int>::min( )
          << endl;
    cout << "The minimum value for type short int is: "
          << numeric_limits<short int>::min( )
          << endl;
}

```

```

The minimum value for type float is:  1.17549e-038
The minimum value for type double is:  2.22507e-308
The minimum value for type int is:    -2147483648
The minimum value for type short int is: -32768

```

numeric_limits::min_exponent

Returns the maximum negative integral exponent that the floating-point type can represent as a finite value when a base of radix is raised to that power.

```
static constexpr int min_exponent = 0;
```

Return Value

The minimum integral radix-based exponent representable by the type.

Remarks

The member function is meaningful only for floating-point types. The `min_exponent` is the value `FLT_MIN_EXP` for type **float**.

Example

```

// numeric_limits_min_exponent.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The minimum radix-based exponent for type float is:  "
          << numeric_limits<float>::min_exponent
          << endl;
    cout << "The minimum radix-based exponent for type double is:  "
          << numeric_limits<double>::min_exponent
          << endl;
    cout << "The minimum radix-based exponent for type long double is:  "
          << numeric_limits<long double>::min_exponent
          << endl;
}

```

```

The minimum radix-based exponent for type float is:  -125
The minimum radix-based exponent for type double is:  -1021
The minimum radix-based exponent for type long double is:  -1021

```

numeric_limits::min_exponent10

Returns the maximum negative integral exponent that the floating-point type can represent as a finite value when a base of ten is raised to that power.

```
static constexpr int min_exponent10 = 0;
```

Return Value

The minimum integral base 10 exponent representable by the type.

Remarks

The member function is meaningful only for floating-point types. The `min_exponent10` is the value `FLT_MIN_10_EXP` for type **float**.

Example

```

// numeric_limits_min_exponent10.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The minimum base 10 exponent for type float is: "
          << numeric_limits<float>::min_exponent10
          << endl;
    cout << "The minimum base 10 exponent for type double is: "
          << numeric_limits<double>::min_exponent10
          << endl;
    cout << "The minimum base 10 exponent for type long double is: "
          << numeric_limits<long double>::min_exponent10
          << endl;
}

```

```

The minimum base 10 exponent for type float is: -37
The minimum base 10 exponent for type double is: -307
The minimum base 10 exponent for type long double is: -307

```

numeric_limits::quiet_NaN

Returns the representation of a quiet not a number (NaN) for the type.

```
static constexpr Type quiet_NaN() throw();
```

Return Value

The representation of a quiet NaN for the type.

Remarks

The return value is meaningful only if [has_quiet_NaN](#) is **true**.

Example

```

// numeric_limits_quiet_nan.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The quiet NaN for type float is: "
          << numeric_limits<float>::quiet_NaN( )
          << endl;
    cout << "The quiet NaN for type int is: "
          << numeric_limits<int>::quiet_NaN( )
          << endl;
    cout << "The quiet NaN for type long double is: "
          << numeric_limits<long double>::quiet_NaN( )
          << endl;
}

```

```
The quiet NaN for type float is:  1.#QNAN
The quiet NaN for type int  is:   0
The quiet NaN for type long double is: 1.#QNAN
```

numeric_limits::radix

Returns the integral base, referred to as radix, used for the representation of a type.

```
static constexpr int radix = 0;
```

Return Value

The integral base for the representation of the type.

Remarks

The base is 2 for the predefined integer types, and the base to which the exponent is raised, or FLT_RADIX, for the predefined floating-point types.

Example

```
// numeric_limits_radix.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The base for type float is:  "
          << numeric_limits<float>::radix
          << endl;
    cout << "The base for type int is:  "
          << numeric_limits<int>::radix
          << endl;
    cout << "The base for type long double is:  "
          << numeric_limits<long double>::radix
          << endl;
}
```

```
The base for type float is:  2
The base for type int  is:   2
The base for type long double is:  2
```

numeric_limits::round_error

Returns the maximum rounding error for the type.

```
static constexpr Type round_error() throw();
```

Return Value

The maximum rounding error for the type.

Example

```
// numeric_limits_round_error.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The maximum rounding error for type float is: "
          << numeric_limits<float>::round_error( )
          << endl;
    cout << "The maximum rounding error for type int is: "
          << numeric_limits<int>::round_error( )
          << endl;
    cout << "The maximum rounding error for type long double is: "
          << numeric_limits<long double>::round_error( )
          << endl;
}
```

```
The maximum rounding error for type float is: 0.5
The maximum rounding error for type int is: 0
The maximum rounding error for type long double is: 0.5
```

numeric_limits::round_style

Returns a value that describes the various methods that an implementation can choose for rounding a floating-point value to an integer value.

```
static constexpr float_round_style round_style = round_toward_zero;
```

Return Value

A value from the `float_round_style` enumeration that describes the rounding style.

Remarks

The member stores a value that describes the various methods that an implementation can choose for rounding a floating-point value to an integer value.

The round style is hard coded in this implementation, so even if the program starts up with a different rounding mode, that value will not change.

Example

```
// numeric_limits_round_style.cpp
// compile with: /EHsc
#include <iostream>
#include <float.h>
#include <limits>

using namespace std;

int main( )
{
    cout << "The rounding style for a double type is: "
          << numeric_limits<double>::round_style << endl;
    _controlfp_s(NULL, _RC_DOWN, _MCW_RC );
    cout << "The rounding style for a double type is now: "
          << numeric_limits<double>::round_style << endl;
    cout << "The rounding style for an int type is: "
          << numeric_limits<int>::round_style << endl;
}
```

```
The rounding style for a double type is: 1
The rounding style for a double type is now: 1
The rounding style for an int type is: 0
```

numeric_limits::signaling_NaN

Returns the representation of a signaling not a number (NaN) for the type.

```
static constexpr Type signaling_NaN() throw();
```

Return Value

The representation of a signaling NaN for the type.

Remarks

The return value is meaningful only if [has_signaling_NaN](#) is **true**.

Example

```
// numeric_limits_signaling_nan.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "The signaling NaN for type float is: "
          << numeric_limits<float>::signaling_NaN( )
          << endl;
    cout << "The signaling NaN for type int is: "
          << numeric_limits<int>::signaling_NaN( )
          << endl;
    cout << "The signaling NaN for type long double is: "
          << numeric_limits<long double>::signaling_NaN( )
          << endl;
}
```

numeric_limits::tinyness_before

Tests whether a type can determine that a value is too small to represent as a normalized value before rounding it.

```
static constexpr bool tinyness_before = false;
```

Return Value

true if the type can detect tiny values before rounding; **false** if it cannot.

Remarks

Types that can detect tinyness were included as an option with IEC 559 floating-point representations and its implementation can affect some results.

Example

```
// numeric_limits_tinyness_before.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float types can detect tinyness before rounding: "
          << numeric_limits<float>::tinyness_before
          << endl;
    cout << "Whether double types can detect tinyness before rounding: "
          << numeric_limits<double>::tinyness_before
          << endl;
    cout << "Whether long int types can detect tinyness before rounding: "
          << numeric_limits<long int>::tinyness_before
          << endl;
    cout << "Whether unsigned char types can detect tinyness before rounding: "
          << numeric_limits<unsigned char>::tinyness_before
          << endl;
}
```

```
Whether float types can detect tinyness before rounding: 1
Whether double types can detect tinyness before rounding: 1
Whether long int types can detect tinyness before rounding: 0
Whether unsigned char types can detect tinyness before rounding: 0
```

numeric_limits::traps

Tests whether trapping that reports on arithmetic exceptions is implemented for a type.

```
static constexpr bool traps = false;
```

Return Value

true if trapping is implemented for the type; **false** if it is not.

Example

```
// numeric_limits_traps.cpp
// compile with: /EHsc
#include <iostream>
#include <limits>

using namespace std;

int main( )
{
    cout << "Whether float types have implemented trapping: "
          << numeric_limits<float>::traps
          << endl;
    cout << "Whether double types have implemented trapping: "
          << numeric_limits<double>::traps
          << endl;
    cout << "Whether long int types have implemented trapping: "
          << numeric_limits<long int>::traps
          << endl;
    cout << "Whether unsigned char types have implemented trapping: "
          << numeric_limits<unsigned char>::traps
          << endl;
}
```

```
Whether float types have implemented trapping: 1
Whether double types have implemented trapping: 1
Whether long int types have implemented trapping: 0
Whether unsigned char types have implemented trapping: 0
```

<list>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template class list and several supporting templates.

Syntax

```
#include <list>
```

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests if the list object on the left side of the operator is not equal to the list object on the right side.
<code>operator<</code>	Tests if the list object on the left side of the operator is less than the list object on the right side.
<code>operator<=</code>	Tests if the list object on the left side of the operator is less than or equal to the list object on the right side.
<code>operator==</code>	Tests if the list object on the left side of the operator is equal to the list object on the right side.
<code>operator></code>	Tests if the list object on the left side of the operator is greater than the list object on the right side.
<code>operator>=</code>	Tests if the list object on the left side of the operator is greater than or equal to the list object on the right side.

Classes

CLASS	DESCRIPTION
<code>list Class</code>	A template class of sequence containers that maintain their elements in a linear arrangement and allow efficient insertions and deletions at any location within the sequence.

<list> operators

10/31/2018 • 5 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<=</code>	<code>operator==</code>

operator!=

Tests if the list object on the left side of the operator is not equal to the list object on the right side.

```
bool operator!=(  
    const list<Type, Allocator>& left,  
    const list<Type, Allocator>& right);
```

Parameters

left

An object of type `list`.

right

An object of type `list`.

Return Value

true if the lists are not equal; **false** if the lists are equal.

Remarks

The comparison between list objects is based on a pairwise comparison of their elements. Two lists are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```

// list_op_ne.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1, c2;
    c1.push_back( 1 );
    c2.push_back( 2 );

    if ( c1 != c2 )
        cout << "Lists not equal." << endl;
    else
        cout << "Lists equal." << endl;
}
/* Output:
Lists not equal.
*/

```

operator<

Tests if the list object on the left side of the operator is less than the list object on the right side.

```

bool operator<(
    const list<Type, Allocator>& left,
    const list<Type, Allocator>& right);

```

Parameters

left

An object of type `list`.

right

An object of type `list`.

Return Value

true if the list on the left side of the operator is less than but not equal to the list on the right side of the operator; otherwise **false**.

Remarks

The comparison between list objects is based on a pairwise comparison of their elements. The less-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// list_op_lt.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1, c2;
    c1.push_back( 1 );
    c1.push_back( 2 );
    c1.push_back( 4 );

    c2.push_back( 1 );
    c2.push_back( 3 );

    if ( c1 < c2 )
        cout << "List c1 is less than list c2." << endl;
    else
        cout << "List c1 is not less than list c2." << endl;
}
/* Output:
List c1 is less than list c2.
*/

```

operator<=

Tests if the list object on the left side of the operator is less than or equal to the list object on the right side.

```

bool operator<=(
    const list<Type, Allocator>& left,
    const list<Type, Allocator>& right);

```

Parameters

left

An object of type `list`.

right

An object of type `list`.

Return Value

true if the list on the left side of the operator is less than or equal to the list on the right side of the operator; otherwise **false**.

Remarks

The comparison between list objects is based on a pairwise comparison of their elements. The less than or equal to relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// list_op_le.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1, c2;
    c1.push_back( 1 );
    c1.push_back( 2 );
    c1.push_back( 4 );

    c2.push_back( 1 );
    c2.push_back( 3 );

    if ( c1 <= c2 )
        cout << "List c1 is less than or equal to list c2." << endl;
    else
        cout << "List c1 is greater than list c2." << endl;
}
/* Output:
List c1 is less than or equal to list c2.
*/

```

operator==

Tests if the list object on the left side of the operator is equal to the list object on the right side.

```

bool operator==(
    const list<Type, Allocator>& left,
    const list<Type, Allocator>& right);

```

Parameters

left

An object of type `list`.

right

An object of type `list`.

Return Value

true if the list on the left side of the operator is equal to the list on the right side of the operator; otherwise **false**.

Remarks

The comparison between list objects is based on a pairwise comparison of their elements. Two lists are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```

// list_op_eq.cpp
// compile with: /EHsc
#include <list>
#include <iostream>
int main( )
{
    using namespace std;

    list<int> c1, c2;
    c1.push_back( 1 );
    c2.push_back( 1 );

    if ( c1 == c2 )
        cout << "The lists are equal." << endl;
    else
        cout << "The lists are not equal." << endl;
}
/* Output:
The lists are equal.
*/

```

operator>

Tests if the list object on the left side of the operator is greater than the list object on the right side.

```

bool operator>(
    const list<Type, Allocator>& left,
    const list<Type, Allocator>& right);

```

Parameters

left

An object of type `list`.

right

An object of type `list`.

Return Value

true if the list on the left side of the operator is greater than the list on the right side of the operator; otherwise **false**.

Remarks

The comparison between list objects is based on a pairwise comparison of their elements. The greater-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// list_op_gt.cpp
// compile with: /EHsc
#include <list>
#include <iostream>
int main( )
{
    using namespace std;
    list<int> c1, c2;
    c1.push_back( 1 );
    c1.push_back( 3 );
    c1.push_back( 1 );

    c2.push_back( 1 );
    c2.push_back( 2 );
    c2.push_back( 2 );

    if ( c1 > c2 )
        cout << "List c1 is greater than list c2." << endl;
    else
        cout << "List c1 is not greater than list c2." << endl;
}
/* Output:
List c1 is greater than list c2.
*/

```

operator>=

Tests if the list object on the left side of the operator is greater than or equal to the list object on the right side.

```

bool operator>=(
    const list<Type, Allocator>& left,
    const list<Type, Allocator>& right);

```

Parameters

left

An object of type `list`.

right

An object of type `list`.

Return Value

true if the list on the left side of the operator is greater than or equal to the list on the right side of the operator; otherwise **false**.

Remarks

The comparison between list objects is based on a pairwise comparison of their elements. The greater than or equal to relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// list_op_ge.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1, c2;
    c1.push_back( 1 );
    c1.push_back( 3 );
    c1.push_back( 1 );

    c2.push_back( 1 );
    c2.push_back( 2 );
    c2.push_back( 2 );

    if ( c1 >= c2 )
        cout << "List c1 is greater than or equal to list c2." << endl;
    else
        cout << "List c1 is less than list c2." << endl;
}
/* Output:
List c1 is greater than or equal to list c2.
*/

```

[<list>](#)

list Class

11/9/2018 • 45 minutes to read • [Edit Online](#)

The C++ Standard Library list class is a template class of sequence containers that maintain their elements in a linear arrangement and allow efficient insertions and deletions at any location within the sequence. The sequence is stored as a bidirectional linked list of elements, each containing a member of some type *Type*.

Syntax

```
template <class Type, class Allocator= allocator<Type>>
class list
```

Parameters

Type

The element data type to be stored in the list.

Allocator

The type that represents the stored allocator object that encapsulates details about the list's allocation and deallocation of memory. This argument is optional, and the default value is **allocator<Type>**.

Remarks

The choice of container type should be based in general on the type of searching and inserting required by the application. Vectors should be the preferred container for managing a sequence when random access to any element is at a premium and insertions or deletions of elements are only required at the end of a sequence. The performance of the class deque container is superior when random access is needed and insertions and deletions at both the beginning and the end of a sequence are at a premium.

The list member functions [merge](#), [reverse](#), [unique](#), [remove](#), and [remove_if](#) have been optimized for operation on list objects and offer a high-performance alternative to their generic counterparts.

List reallocation occurs when a member function must insert or erase elements of the list. In all such cases, only iterators or references that point at erased portions of the controlled sequence become invalid.

Include the C++ Standard Library standard header `<list>` to define the [container](#) template class list and several supporting templates.

Constructors

CONSTRUCTOR	DESCRIPTION
list	Constructs a list of a specific size or with elements of a specific value or with a specific <code>allocator</code> or as a copy of some other list.

Typedefs

TYPE NAME	DESCRIPTION
allocator_type	A type that represents the <code>allocator</code> class for a list object.

TYPE NAME	DESCRIPTION
<code>const_iterator</code>	A type that provides a bidirectional iterator that can read a const element in a list.
<code>const_pointer</code>	A type that provides a pointer to a const element in a list.
<code>const_reference</code>	A type that provides a reference to a const element stored in a list for reading and performing const operations.
<code>const_reverse_iterator</code>	A type that provides a bidirectional iterator that can read any const element in a list.
<code>difference_type</code>	A type that provides the difference between two iterators that refer to elements within the same list.
<code>iterator</code>	A type that provides a bidirectional iterator that can read or modify any element in a list.
<code>pointer</code>	A type that provides a pointer to an element in a list.
<code>reference</code>	A type that provides a reference to a const element stored in a list for reading and performing const operations.
<code>reverse_iterator</code>	A type that provides a bidirectional iterator that can read or modify an element in a reversed list.
<code>size_type</code>	A type that counts the number of elements in a list.
<code>value_type</code>	A type that represents the data type stored in a list.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>assign</code>	Erases elements from a list and copies a new set of elements to the target list.
<code>back</code>	Returns a reference to the last element of a list.
<code>begin</code>	Returns an iterator addressing the first element in a list.
<code>cbegin</code>	Returns a const iterator addressing the first element in a list.
<code>cend</code>	Returns a const iterator that addresses the location succeeding the last element in a list.
<code>clear</code>	Erases all the elements of a list.
<code>crbegin</code>	Returns a const iterator addressing the first element in a reversed list.
<code>crend</code>	Returns a const iterator that addresses the location succeeding the last element in a reversed list.

MEMBER FUNCTION	DESCRIPTION
<code>emplace</code>	Inserts an element constructed in place into a list at a specified position.
<code>emplace_back</code>	Adds an element constructed in place to the end of a list.
<code>emplace_front</code>	Adds an element constructed in place to the beginning of a list.
<code>empty</code>	Tests if a list is empty.
<code>end</code>	Returns an iterator that addresses the location succeeding the last element in a list.
<code>erase</code>	Removes an element or a range of elements in a list from specified positions.
<code>front</code>	Returns a reference to the first element in a list.
<code>get_allocator</code>	Returns a copy of the <code>allocator</code> object used to construct a list.
<code>insert</code>	Inserts an element or a number of elements or a range of elements into a list at a specified position.
<code>max_size</code>	Returns the maximum length of a list.
<code>merge</code>	Removes the elements from the argument list, inserts them into the target list, and orders the new, combined set of elements in ascending order or in some other specified order.
<code>pop_back</code>	Deletes the element at the end of a list.
<code>pop_front</code>	Deletes the element at the beginning of a list.
<code>push_back</code>	Adds an element to the end of a list.
<code>push_front</code>	Adds an element to the beginning of a list.
<code>rbegin</code>	Returns an iterator addressing the first element in a reversed list.
<code>remove</code>	Erases elements in a list that match a specified value.
<code>remove_if</code>	Erases elements from the list for which a specified predicate is satisfied.
<code>rend</code>	Returns an iterator that addresses the location succeeding the last element in a reversed list.
<code>resize</code>	Specifies a new size for a list.
<code>reverse</code>	Reverses the order in which the elements occur in a list.

MEMBER FUNCTION	DESCRIPTION
size	Returns the number of elements in a list.
sort	Arranges the elements of a list in ascending order or with respect to some other order relation.
splice	Removes elements from the argument list and inserts them into the target list.
swap	Exchanges the elements of two lists.
unique	Removes adjacent duplicate elements or adjacent elements that satisfy some other binary predicate from the list.

Operators

OPERATOR	DESCRIPTION
list::operator=	Replaces the elements of the list with a copy of another list.

Requirements

Header: <list>

list::allocator_type

A type that represents the allocator class for a list object.

```
typedef Allocator allocator_type;
```

Remarks

`allocator_type` is a synonym for the template parameter *Allocator*.

Example

See the example for [get_allocator](#).

list::assign

Erases elements from a list and copies a new set of elements to a target list.

```
void assign(
    size_type Count,
    const Type& Val);

void assign
    initializer_list<Type> IList);

template <class InputIterator>
void assign(
    InputIterator First,
    InputIterator Last);
```

Parameters

First

Position of the first element in the range of elements to be copied from the argument list.

Last

Position of the first element just beyond the range of elements to be copied from the argument list.

Count

The number of copies of an element being inserted into the list.

Val

The value of the element being inserted into the list.

lList

The initializer_list that contains the elements to be inserted.

Remarks

After erasing any existing elements in the target list, assign either inserts a specified range of elements from the original list or from some other list into the target list or inserts copies of a new element of a specified value into the target list

Example

```
// list_assign.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main()
{
    using namespace std;
    list<int> c1, c2;
    list<int>::const_iterator cIter;

    c1.push_back(10);
    c1.push_back(20);
    c1.push_back(30);
    c2.push_back(40);
    c2.push_back(50);
    c2.push_back(60);

    cout << "c1 =";
    for (auto c : c1)
        cout << " " << c;
    cout << endl;

    c1.assign(++c2.begin(), c2.end());
    cout << "c1 =";
    for (auto c : c1)
        cout << " " << c;
    cout << endl;

    c1.assign(7, 4);
    cout << "c1 =";
    for (auto c : c1)
        cout << " " << c;
    cout << endl;

    c1.assign({ 10, 20, 30, 40 });
    cout << "c1 =";
    for (auto c : c1)
        cout << " " << c;
    cout << endl;
}
```

```
c1 = 10 20 30 c1 = 50 60 c1 = 4 4 4 4 4 4 c1 = 10 20 30 40
```

list::back

Returns a reference to the last element of a list.

```
reference back();

const_reference back() const;
```

Return Value

The last element of the list. If the list is empty, the return value is undefined.

Remarks

If the return value of `back` is assigned to a `const_reference`, the list object cannot be modified. If the return value of `back` is assigned to a `reference`, the list object can be modified.

When compiled by using `_ITERATOR_DEBUG_LEVEL` defined as 1 or 2, a runtime error will occur if you attempt to access an element in an empty list. See [Checked Iterators](#) for more information.

Example

```
// list_back.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;

    c1.push_back( 10 );
    c1.push_back( 11 );

    int& i = c1.back( );
    const int& ii = c1.front( );

    cout << "The last integer of c1 is " << i << endl;
    i--;
    cout << "The next-to-last integer of c1 is " << ii << endl;
}
```

```
The last integer of c1 is 11
The next-to-last integer of c1 is 10
```

list::begin

Returns an iterator addressing the first element in a list.

```
const_iterator begin() const;

iterator begin();
```

Return Value

A bidirectional iterator addressing the first element in the list or to the location succeeding an empty list.

Remarks

If the return value of `begin` is assigned to a `const_iterator`, the elements in the list object cannot be modified.

If the return value of `begin` is assigned to an `iterator`, the elements in the list object can be modified.

Example

```
// list_begin.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::iterator c1_Iter;
    list<int>::const_iterator c1_cIter;

    c1.push_back( 1 );
    c1.push_back( 2 );

    c1_Iter = c1.begin( );
    cout << "The first element of c1 is " << *c1_Iter << endl;

    *c1_Iter = 20;
    c1_Iter = c1.begin( );
    cout << "The first element of c1 is now " << *c1_Iter << endl;

    // The following line would be an error because iterator is const
    // *c1_cIter = 200;
}
```

```
The first element of c1 is 1
The first element of c1 is now 20
```

list::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** bidirectional-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin`, the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

list::cend

Returns a `const` iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A `const` bidirectional-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

list::clear

Erases all the elements of a list.

```
void clear();
```

Example

```
// list_clear.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main() {
    using namespace std;
    list<int> c1;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );

    cout << "The size of the list is initially " << c1.size( ) << endl;
    c1.clear( );
    cout << "The size of list after clearing is " << c1.size( ) << endl;
}
```

```
The size of the list is initially 3
The size of list after clearing is 0
```

list::const_iterator

A type that provides a bidirectional iterator that can read a **const** element in a list.

```
typedef implementation-defined const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

Example

See the example for [back](#).

list::const_pointer

Provides a pointer to a **const** element in a list.

```
typedef typename Allocator::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a list object.

list::const_reference

A type that provides a reference to a **const** element stored in a list for reading and performing **const** operations.

```
typedef typename Allocator::const_reference const_reference;
```

Remarks

A type `const_reference` cannot be used to modify the value of an element.

Example

```
// list_const_ref.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;

    c1.push_back( 10 );
    c1.push_back( 20 );

    const list<int> c2 = c1;
    const int &i = c2.front( );
    const int &j = c2.back( );
    cout << "The first element is " << i << endl;
    cout << "The second element is " << j << endl;

    // The following line would cause an error because c2 is const
    // c2.push_back( 30 );
}
```

```
The first element is 10
The second element is 20
```

list::const_reverse_iterator

A type that provides a bidirectional iterator that can read any **const** element in a list.

```
typedef std::reverse_iterator<const_iterator> const_reverse_iterator;
```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is used to iterate through the list in reverse.

Example

See the example for [rbegin](#).

list::crbegin

Returns a const iterator addressing the first element in a reversed list.

```
const_reverse_iterator rbegin() const;
```

Return Value

A const reverse bidirectional iterator addressing the first element in a reversed list (or addressing what had been the last element in the unreversed `list`).

Remarks

`crbegin` is used with a reversed list just as [list::begin](#) is used with a `list`.

With the return value of `crbegin`, the list object cannot be modified. [list::rbegin](#) can be used to iterate through a list backwards.

Example

```
// list_crbegin.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::const_reverse_iterator c1_crIter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );
    c1_crIter = c1.crbegin( );
    cout << "The last element in the list is " << *c1_crIter << "." << endl;
}
```

The last element in the list is 30.

list::crend

Returns a const iterator that addresses the location succeeding the last element in a reversed list.

```
const_reverse_iterator rend() const;
```

Return Value

A const reverse bidirectional iterator that addresses the location succeeding the last element in a reversed [list](#) (the location that had preceded the first element in the unreversed `list`).

Remarks

`crend` is used with a reversed list just as [list::end](#) is used with a `list`.

With the return value of `crend`, the `list` object cannot be modified.

`crend` can be used to test to whether a reverse iterator has reached the end of its `list`.

The value returned by `crend` should not be dereferenced.

Example

```

// list_crend.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::const_reverse_iterator c1_crIter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );

    c1_crIter = c1.crend( );
    c1_crIter --; // Decrementing a reverse iterator moves it forward in
                  // the list (to point to the first element here)
    cout << "The first element in the list is: " << *c1_crIter << endl;
}

```

```
The first element in the list is: 10
```

list::difference_type

A signed integer type that can be used to represent the number of elements of a list in a range between elements pointed to by iterators.

```
typedef typename Allocator::difference_type difference_type;
```

Remarks

The `difference_type` is the type returned when subtracting or incrementing through iterators of the container.

The `difference_type` is typically used to represent the number of elements in the range [`first`, `last`) between the iterators `first` and `last`, includes the element pointed to by `first` and the range of elements up to, but not including, the element pointed to by `last`.

Note that although `difference_type` is available for all iterators that satisfy the requirements of an input iterator, which includes the class of bidirectional iterators supported by reversible containers like `set`, subtraction between iterators is only supported by random-access iterators provided by a random-access container, such as [vector Class](#).

Example

```

// list_diff_type.cpp
// compile with: /EHsc
#include <iostream>
#include <list>
#include <algorithm>

int main( )
{
    using namespace std;

    list<int> c1;
    list<int>::iterator c1_Iter, c2_Iter;

    c1.push_back( 30 );
    c1.push_back( 20 );
    c1.push_back( 30 );
    c1.push_back( 10 );
    c1.push_back( 30 );
    c1.push_back( 20 );

    c1_Iter = c1.begin( );
    c2_Iter = c1.end( );

    list<int>::difference_type df_typ1, df_typ2, df_typ3;

    df_typ1 = count( c1_Iter, c2_Iter, 10 );
    df_typ2 = count( c1_Iter, c2_Iter, 20 );
    df_typ3 = count( c1_Iter, c2_Iter, 30 );
    cout << "The number '10' is in c1 collection " << df_typ1 << " times.\n";
    cout << "The number '20' is in c1 collection " << df_typ2 << " times.\n";
    cout << "The number '30' is in c1 collection " << df_typ3 << " times.\n";
}

```

```

The number '10' is in c1 collection 1 times.
The number '20' is in c1 collection 2 times.
The number '30' is in c1 collection 3 times.

```

list::emplace

Inserts an element constructed in place into a list at a specified position.

```
void emplace(iterator Where, Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>Where</i>	The position in the target list where the first element is inserted.
<i>val</i>	The element added to the end of the <code>list</code> .

Remarks

If an exception is thrown, the `list` is left unaltered and the exception is rethrown.

Example

```
// list_emplace.cpp
// compile with: /EHsc
#include <list>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    list<string> c2;
    string str("a");

    c2.emplace(c2.begin(), move( str ) );
    cout << "Moved first element: " << c2.back( ) << endl;
}
```

Moved first element: a

list::emplace_back

Adds an element constructed in place to the end of a list.

```
void emplace_back(Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The element added to the end of the list .

Remarks

If an exception is thrown, the `list` is left unaltered and the exception is rethrown.

Example

```
// list_emplace_back.cpp
// compile with: /EHsc
#include <list>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    list<string> c2;
    string str("a");

    c2.emplace_back( move( str ) );
    cout << "Moved first element: " << c2.back( ) << endl;
}
```

Moved first element: a

list::emplace_front

Adds an element constructed in place to the beginning of a list.

```
void emplace_front(Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The element added to the beginning of the list .

Remarks

If an exception is thrown, the `list` is left unaltered and the exception is rethrown.

Example

```
// list_emplace_front.cpp
// compile with: /EHsc
#include <list>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    list <string> c2;
    string str("a");

    c2.emplace_front( move( str ) );
    cout << "Moved first element: " << c2.front( ) << endl;
}
```

```
Moved first element: a
```

list::empty

Tests if a list is empty.

```
bool empty() const;
```

Return Value

true if the list is empty; **false** if the list is not empty.

Example

```

// list_empty.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;

    c1.push_back( 10 );
    if ( c1.empty( ) )
        cout << "The list is empty." << endl;
    else
        cout << "The list is not empty." << endl;
}

```

The list is not empty.

list::end

Returns an iterator that addresses the location succeeding the last element in a list.

```

const_iterator end() const;
iterator end();

```

Return Value

A bidirectional iterator that addresses the location succeeding the last element in a list. If the list is empty, then

```
list::end == list::begin .
```

Remarks

`end` is used to test whether an iterator has reached the end of its list.

Example

```

// list_end.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::iterator c1_Iter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );

    c1_Iter = c1.end( );
    c1_Iter--;
    cout << "The last integer of c1 is " << *c1_Iter << endl;

    c1_Iter--;
    *c1_Iter = 400;
    cout << "The new next-to-last integer of c1 is "
        << *c1_Iter << endl;

    // If a const iterator had been declared instead with the line:
    // list<int>::const_iterator c1_Iter;
    // an error would have resulted when inserting the 400

    cout << "The list is now:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
}

```

```

The last integer of c1 is 30
The new next-to-last integer of c1 is 400
The list is now: 10 400 30

```

list::erase

Removes an element or a range of elements in a list from specified positions.

```

iterator erase(iterator Where);
iterator erase(iterator first, iterator last);

```

Parameters

Where

Position of the element to be removed from the list.

first

Position of the first element removed from the list.

last

Position just beyond the last element removed from the list.

Return Value

A bidirectional iterator that designates the first element remaining beyond any elements removed, or a pointer to the end of the list if no such element exists.

Remarks

No reallocation occurs, so iterators and references become invalid only for the erased elements.

`erase` never throws an exception.

Example

```
// list_erase.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::iterator Iter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );
    c1.push_back( 40 );
    c1.push_back( 50 );
    cout << "The initial list is:";
    for ( Iter = c1.begin( ); Iter != c1.end( ); Iter++ )
        cout << " " << *Iter;
    cout << endl;

    c1.erase( c1.begin( ) );
    cout << "After erasing the first element, the list becomes:";
    for ( Iter = c1.begin( ); Iter != c1.end( ); Iter++ )
        cout << " " << *Iter;
    cout << endl;
    Iter = c1.begin( );
    Iter++;
    c1.erase( Iter, c1.end( ) );
    cout << "After erasing all elements but the first, the list becomes: ";
    for (Iter = c1.begin( ); Iter != c1.end( ); Iter++ )
        cout << " " << *Iter;
    cout << endl;
}
```

```
The initial list is: 10 20 30 40 50
After erasing the first element, the list becomes: 20 30 40 50
After erasing all elements but the first, the list becomes:  20
```

list::front

Returns a reference to the first element in a list.

```
reference front();
const_reference front() const;
```

Return Value

If the list is empty, the return is undefined.

Remarks

If the return value of `front` is assigned to a `const_reference`, the list object cannot be modified. If the return value of `front` is assigned to a `reference`, the list object can be modified.

When compiled by using `_ITERATOR_DEBUG_LEVEL` defined as 1 or 2, a runtime error will occur if you

attempt to access an element in an empty list. See [Checked Iterators](#) for more information.

Example

```
// list_front.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main() {
    using namespace std;
    list<int> c1;

    c1.push_back( 10 );

    int& i = c1.front();
    const int& ii = c1.front();

    cout << "The first integer of c1 is " << i << endl;
    i++;
    cout << "The first integer of c1 is " << ii << endl;
}
```

```
The first integer of c1 is 10
The first integer of c1 is 11
```

list::get_allocator

Returns a copy of the allocator object used to construct a list.

```
Allocator get_allocator() const;
```

Return Value

The allocator used by the list.

Remarks

Allocators for the list class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```

// list_get_allocator.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    // The following lines declare objects
    // that use the default allocator.
    list<int> c1;
    list<int, allocator<int> > c2 = list<int, allocator<int> >( allocator<int>( ) );

    // c3 will use the same allocator class as c1
    list<int> c3( c1.get_allocator( ) );

    list<int>::allocator_type xlst = c1.get_allocator( );
    // You can now call functions on the allocator class used by c1
}

```

list::insert

Inserts an element or a number of elements or a range of elements into a list at a specified position.

```

iterator insert(iterator Where, const Type& Val);
iterator insert(iterator Where, Type&& Val);

void insert(iterator Where, size_type Count, const Type& Val);
iterator insert(iterator Where, initializer_list<Type> Ilist);

template <class InputIterator>
void insert(iterator Where, InputIterator First, InputIterator Last);

```

Parameters

PARAMETER	DESCRIPTION
<i>Where</i>	The position in the target list where the first element is inserted.
<i>Val</i>	The value of the element being inserted into the list.
<i>Count</i>	The number of elements being inserted into the list.
<i>First</i>	The position of the first element in the range of elements in the argument list to be copied.
<i>Last</i>	The position of the first element beyond the range of elements in the argument list to be copied.

Return Value

The first two insert functions return an iterator that points to the position where the new element was inserted into the list.

Example

```

// list_class_insert.cpp
// compile with: /EHsc
#include <list>
#include <iostream>
#include <string>

int main()
{
    using namespace std;
    list<int> c1, c2;
    list<int>::iterator Iter;

    c1.push_back(10);
    c1.push_back(20);
    c1.push_back(30);
    c2.push_back(40);
    c2.push_back(50);
    c2.push_back(60);

    cout << "c1 =";
    for (auto c : c1)
        cout << " " << c;
    cout << endl;

    Iter = c1.begin();
    Iter++;
    c1.insert(Iter, 100);
    cout << "c1 =";
    for (auto c : c1)
        cout << " " << c;
    cout << endl;

    Iter = c1.begin();
    Iter++;
    Iter++;
    c1.insert(Iter, 2, 200);

    cout << "c1 =";
    for(auto c : c1)
        cout << " " << c;
    cout << endl;

    c1.insert(++c1.begin(), c2.begin(), --c2.end());

    cout << "c1 =";
    for (auto c : c1)
        cout << " " << c;
    cout << endl;

    // initialize a list of strings by moving
    list< string > c3;
    string str("a");

    c3.insert(c3.begin(), move(str));
    cout << "Moved first element: " << c3.front() << endl;

    // Assign with an initializer_list
    list<int> c4{ {1, 2, 3, 4} };
    c4.insert(c4.begin(), { 5, 6, 7, 8 });

    cout << "c4 =";
    for (auto c : c4)
        cout << " " << c;
    cout << endl;
}

```

list::iterator

A type that provides a bidirectional iterator that can read or modify any element in a list.

```
typedef implementation-defined iterator;
```

Remarks

A type `iterator` can be used to modify the value of an element.

Example

See the example for [begin](#).

list::list

Constructs a list of a specific size or with elements of a specific value or with a specific allocator or as a copy of all or part of some other list.

```
list();
explicit list(const Allocator& Al);
explicit list(size_type Count);
list(size_type Count, const Type& Val);
list(size_type Count, const Type& Val, const Allocator& Al);

list(const list& Right);
list(list&& Right);
list(initializer_list<Type> IList, const Allocator& Al);

template <class InputIterator>
list(InputIterator First, InputIterator Last);

template <class InputIterator>
list(InputIterator First, InputIterator Last, const Allocator& Al);
```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The allocator class to use with this object.
<i>Count</i>	The number of elements in the list constructed.
<i>Val</i>	The value of the elements in the list.
<i>Right</i>	The list of which the constructed list is to be a copy.
<i>First</i>	The position of the first element in the range of elements to be copied.
<i>Last</i>	The position of the first element beyond the range of elements to be copied.
<i>IList</i>	The initializer_list that contains the elements to be copied.

Remarks

All constructors store an allocator object (*Al*) and initialize the list.

`get_allocator` returns a copy of the allocator object used to construct a list.

The first two constructors specify an empty initial list, the second specifying the allocator type (*Al*) to be used.

The third constructor specifies a repetition of a specified number (*Count*) of elements of the default value for class `Type`.

The fourth and fifth constructors specify a repetition of (*Count*) elements of value *Val*.

The sixth constructor specifies a copy of the list *Right*.

The seventh constructor moves the list *Right*.

The eighth constructor uses an `initializer_list` to specify the elements.

The next two constructors copy the range `[First, Last)` of a list.

None of the constructors perform any interim reallocations.

Example

```
// list_class_list.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main()
{
    using namespace std;
    // Create an empty list c0
    list<int> c0;

    // Create a list c1 with 3 elements of default value 0
    list<int> c1(3);

    // Create a list c2 with 5 elements of value 2
    list<int> c2(5, 2);

    // Create a list c3 with 3 elements of value 1 and with the
    // allocator of list c2
    list<int> c3(3, 1, c2.get_allocator());

    // Create a copy, list c4, of list c2
    list<int> c4(c2);

    // Create a list c5 by copying the range c4[ first, last)
    list<int>::iterator c4_Iter = c4.begin();
    c4_Iter++;
    c4_Iter++;
    list<int> c5(c4.begin(), c4_Iter);

    // Create a list c6 by copying the range c4[ first, last) and with
    // the allocator of list c2
    c4_Iter = c4.begin();
    c4_Iter++;
    c4_Iter++;
    c4_Iter++;
    list<int> c6(c4.begin(), c4_Iter, c2.get_allocator());

    cout << "c1 =";
    for (auto c : c1)
        cout << " " << c;
    cout << endl;

    cout << "c2 =";
    for (auto c : c2)
        cout << " " << c;
```

```

    cout << endl;

    cout << "c3 =";
    for (auto c : c3)
        cout << " " << c;
    cout << endl;

    cout << "c4 =";
    for (auto c : c4)
        cout << " " << c;
    cout << endl;

    cout << "c5 =";
    for (auto c : c5)
        cout << " " << c;
    cout << endl;

    cout << "c6 =";
    for (auto c : c6)
        cout << " " << c;
    cout << endl;

    // Move list c6 to list c7
    list<int> c7(move(c6));
    cout << "c7 =";
    for (auto c : c7)
        cout << " " << c;
    cout << endl;

    // Construct with initializer_list
    list<int> c8({ 1, 2, 3, 4 });
    cout << "c8 =";
    for (auto c : c8)
        cout << " " << c;
    cout << endl;
}

```

c1 = 0 0 0 c2 = 2 2 2 2 2 c3 = 1 1 1 c4 = 2 2 2 2 2 c5 = 2 2 c6 = 2 2 2 c7 = 2 2 2 c8 = 1 2 3 4

list::max_size

Returns the maximum length of a list.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the list.

Example

```
// list_max_size.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::size_type i;

    i = c1.max_size( );
    cout << "Maximum possible length of the list is " << i << "." << endl;
}
```

list::merge

Removes the elements from the argument list, inserts them into the target list, and orders the new, combined set of elements in ascending order or in some other specified order.

```
void merge(list<Type, Allocator>& right);

template <class Traits>
void merge(list<Type, Allocator>& right, Traits comp);
```

Parameters

right

The argument list to be merged with the target list.

comp

The comparison operator used to order the elements of the target list.

Remarks

The argument list *right* is merged with the target list.

Both argument and target lists must be ordered with the same comparison relation by which the resulting sequence is to be ordered. The default order for the first member function is ascending order. The second member function imposes the user-specified comparison operation *comp* of class `Traits`.

Example

```

// list_merge.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1, c2, c3;
    list<int>::iterator c1_Iter, c2_Iter, c3_Iter;

    c1.push_back( 3 );
    c1.push_back( 6 );
    c2.push_back( 2 );
    c2.push_back( 4 );
    c3.push_back( 5 );
    c3.push_back( 1 );

    cout << "c1 =";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    cout << "c2 =";
    for ( c2_Iter = c2.begin( ); c2_Iter != c2.end( ); c2_Iter++ )
        cout << " " << *c2_Iter;
    cout << endl;

    c2.merge( c1 ); // Merge c1 into c2 in (default) ascending order
    c2.sort( greater<int>( ) );
    cout << "After merging c1 with c2 and sorting with >: c2 =";
    for ( c2_Iter = c2.begin( ); c2_Iter != c2.end( ); c2_Iter++ )
        cout << " " << *c2_Iter;
    cout << endl;

    cout << "c3 =";
    for ( c3_Iter = c3.begin( ); c3_Iter != c3.end( ); c3_Iter++ )
        cout << " " << *c3_Iter;
    cout << endl;

    c2.merge( c3, greater<int>( ) );
    cout << "After merging c3 with c2 according to the '>' comparison relation: c2 =";
    for ( c2_Iter = c2.begin( ); c2_Iter != c2.end( ); c2_Iter++ )
        cout << " " << *c2_Iter;
    cout << endl;
}

```

```

c1 = 3 6
c2 = 2 4
After merging c1 with c2 and sorting with >: c2 = 6 4 3 2
c3 = 5 1
After merging c3 with c2 according to the '>' comparison relation: c2 = 6 5 4 3 2 1

```

list::operator=

Replaces the elements of the list with a copy of another list.

```

list& operator=(const list& right);
list& operator=(list&& right);

```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The list being copied into the <code>list</code> .

Remarks

After erasing any existing elements in a `list`, the operator either copies or moves the contents of *right* into the `list`.

Example

```
// list_operator_as.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> v1, v2, v3;
    list<int>::iterator iter;

    v1.push_back(10);
    v1.push_back(20);
    v1.push_back(30);
    v1.push_back(40);
    v1.push_back(50);

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = forward< list<int> >(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;
}
```

list::pointer

Provides a pointer to an element in a list.

```
typedef typename Allocator::pointer pointer;
```

Remarks

A type `pointer` can be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a list object.

list::pop_back

Deletes the element at the end of a list.

```
void pop_back();
```

Remarks

The last element must not be empty. `pop_back` never throws an exception.

Example

```
// list_pop_back.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;

    c1.push_back( 1 );
    c1.push_back( 2 );
    cout << "The first element is: " << c1.front( ) << endl;
    cout << "The last element is: " << c1.back( ) << endl;

    c1.pop_back( );
    cout << "After deleting the element at the end of the list, "
         << "the last element is: " << c1.back( ) << endl;
}
```

```
The first element is: 1
The last element is: 2
After deleting the element at the end of the list, the last element is: 1
```

list::pop_front

Deletes the element at the beginning of a list.

```
void pop_front();
```

Remarks

The first element must not be empty. `pop_front` never throws an exception.

Example

```
// list_pop_front.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;

    c1.push_back( 1 );
    c1.push_back( 2 );
    cout << "The first element is: " << c1.front( ) << endl;
    cout << "The second element is: " << c1.back( ) << endl;

    c1.pop_front( );
    cout << "After deleting the element at the beginning of the list, "
         << "the first element is: " << c1.front( ) << endl;
}
```

```
The first element is: 1
The second element is: 2
After deleting the element at the beginning of the list, the first element is: 2
```

list::push_back

Adds an element to the end of a list.

```
void push_back(const Type&& val);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The element added to the end of the list.

Remarks

If an exception is thrown, the list is left unaltered and the exception is rethrown.

Example

```

// list_push_back.cpp
// compile with: /EHsc
#include <list>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    list<int> c1;

    c1.push_back( 1 );
    if ( c1.size( ) != 0 )
        cout << "Last element: " << c1.back( ) << endl;

    c1.push_back( 2 );
    if ( c1.size( ) != 0 )
        cout << "New last element: " << c1.back( ) << endl;

    // move initialize a list of strings
    list<string> c2;
    string str("a");

    c2.push_back( move( str ) );
    cout << "Moved first element: " << c2.back( ) << endl;
}

```

```

Last element: 1
New last element: 2
Moved first element: a

```

list::push_front

Adds an element to the beginning of a list.

```

void push_front(const Type& val);
void push_front(Type&& val);

```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The element added to the beginning of the list.

Remarks

If an exception is thrown, the list is left unaltered and the exception is rethrown.

Example

```

// list_push_front.cpp
// compile with: /EHsc
#include <list>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    list<int> c1;

    c1.push_front( 1 );
    if ( c1.size( ) != 0 )
        cout << "First element: " << c1.front( ) << endl;

    c1.push_front( 2 );
    if ( c1.size( ) != 0 )
        cout << "New first element: " << c1.front( ) << endl;

    // move initialize a list of strings
    list<string> c2;
    string str("a");

    c2.push_front( move( str ) );
    cout << "Moved first element: " << c2.front( ) << endl;
}

```

```

First element: 1
New first element: 2
Moved first element: a

```

list::rbegin

Returns an iterator that addresses the first element in a reversed list.

```

const_reverse_iterator rbegin() const;
reverse_iterator rbegin();

```

Return Value

A reverse bidirectional iterator addressing the first element in a reversed list (or addressing what had been the last element in the unreversed list).

Remarks

`rbegin` is used with a reversed list just as `begin` is used with a list.

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, the list object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, the list object can be modified.

`rbegin` can be used to iterate through a list backwards.

Example

```

// list_rbegin.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::iterator c1_Iter;
    list<int>::reverse_iterator c1_rIter;

    // If the following line replaced the line above, *c1_rIter = 40;
    // (below) would be an error
    //list<int>::const_reverse_iterator c1_rIter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );
    c1_rIter = c1.rbegin( );
    cout << "The last element in the list is " << *c1_rIter << "." << endl;

    cout << "The list is:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    // rbegin can be used to start an iteration through a list in
    // reverse order
    cout << "The reversed list is:";
    for ( c1_rIter = c1.rbegin( ); c1_rIter != c1.rend( ); c1_rIter++ )
        cout << " " << *c1_rIter;
    cout << endl;

    c1_rIter = c1.rbegin( );
    *c1_rIter = 40;
    cout << "The last element in the list is now " << *c1_rIter << "." << endl;
}

```

```

The last element in the list is 30.
The list is: 10 20 30
The reversed list is: 30 20 10
The last element in the list is now 40.

```

list::reference

A type that provides a reference to an element stored in a list.

```

typedef typename Allocator::reference reference;

```

Example

```
// list_ref.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;

    c1.push_back( 10 );
    c1.push_back( 20 );

    int &i = c1.front( );
    int &j = c1.back( );
    cout << "The first element is " << i << endl;
    cout << "The second element is " << j << endl;
}
```

```
The first element is 10
The second element is 20
```

list::remove

Erases elements in a list that match a specified value.

```
void remove(const Type& val);
```

Parameters

val

The value which, if held by an element, will result in that element's removal from the list.

Remarks

The order of the elements remaining is not affected.

Example

```

// list_remove.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::iterator c1_Iter, c2_Iter;

    c1.push_back( 5 );
    c1.push_back( 100 );
    c1.push_back( 5 );
    c1.push_back( 200 );
    c1.push_back( 5 );
    c1.push_back( 300 );

    cout << "The initial list is c1 =";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    list<int> c2 = c1;
    c2.remove( 5 );
    cout << "After removing elements with value 5, the list becomes c2 =";
    for ( c2_Iter = c2.begin( ); c2_Iter != c2.end( ); c2_Iter++ )
        cout << " " << *c2_Iter;
    cout << endl;
}

```

The initial list is c1 = 5 100 5 200 5 300
 After removing elements with value 5, the list becomes c2 = 100 200 300

list::remove_if

Erases elements from a list for which a specified predicate is satisfied.

```

template <class Predicate>
void remove_if(Predicate pred)

```

Parameters

pred

The unary predicate which, if satisfied by an element, results in the deletion of that element from the list.

Example

```

// list_remove_if.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

template <class T> class is_odd : public std::unary_function<T, bool>
{
public:
    bool operator( ) ( T& val )
    {
        return ( val % 2 ) == 1;
    }
};

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::iterator c1_Iter, c2_Iter;

    c1.push_back( 3 );
    c1.push_back( 4 );
    c1.push_back( 5 );
    c1.push_back( 6 );
    c1.push_back( 7 );
    c1.push_back( 8 );

    cout << "The initial list is c1 =";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    list<int> c2 = c1;
    c2.remove_if( is_odd<int>( ) );

    cout << "After removing the odd elements, "
        << "the list becomes c2 =";
    for ( c2_Iter = c2.begin( ); c2_Iter != c2.end( ); c2_Iter++ )
        cout << " " << *c2_Iter;
    cout << endl;
}

```

```

The initial list is c1 = 3 4 5 6 7 8
After removing the odd elements, the list becomes c2 = 4 6 8

```

list::rend

Returns an iterator that addresses the location that follows the last element in a reversed list.

```

const_reverse_iterator rend() const;
reverse_iterator rend();

```

Return Value

A reverse bidirectional iterator that addresses the location succeeding the last element in a reversed list (the location that had preceded the first element in the unreversed list).

Remarks

`rend` is used with a reversed list just as `end` is used with a list.

If the return value of `rend` is assigned to a `const_reverse_iterator`, the list object cannot be modified. If the

return value of `rend` is assigned to a `reverse_iterator`, the list object can be modified.

`rend` can be used to test to whether a reverse iterator has reached the end of its list.

The value returned by `rend` should not be dereferenced.

Example

```
// list_rend.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::iterator c1_Iter;
    list<int>::reverse_iterator c1_rIter;

    // If the following line had replaced the line above, an error would
    // have resulted in the line modifying an element (commented below)
    // because the iterator would have been const
    // list<int>::const_reverse_iterator c1_rIter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );

    c1_rIter = c1.rend( );
    c1_rIter --; // Decrementing a reverse iterator moves it forward in
                // the list (to point to the first element here)
    cout << "The first element in the list is: " << *c1_rIter << endl;

    cout << "The list is:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    // rend can be used to test if an iteration is through all of the
    // elements of a reversed list
    cout << "The reversed list is:";
    for ( c1_rIter = c1.rbegin( ); c1_rIter != c1.rend( ); c1_rIter++ )
        cout << " " << *c1_rIter;
    cout << endl;

    c1_rIter = c1.rend( );
    c1_rIter--; // Decrementing the reverse iterator moves it backward
               // in the reversed list (to the last element here)

    *c1_rIter = 40; // This modification of the last element would have
                   // caused an error if a const_reverse iterator had
                   // been declared (as noted above)

    cout << "The modified reversed list is:";
    for ( c1_rIter = c1.rbegin( ); c1_rIter != c1.rend( ); c1_rIter++ )
        cout << " " << *c1_rIter;
    cout << endl;
}
```

```
The first element in the list is: 10
The list is: 10 20 30
The reversed list is: 30 20 10
The modified reversed list is: 30 20 40
```

list::resize

Specifies a new size for a list.

```
void resize(size_type _Nsize);  
void resize(size_type _Nsize, Type val);
```

Parameters

_Nsize

The new size of the list.

val

The value of the new elements to be added to the list if the new size is larger than the original size. If the value is omitted, the new elements are assigned the default value for the class.

Remarks

If the list's size is less than the requested size, *_Nsize*, elements are added to the list until it reaches the requested size.

If the list's size is larger than the requested size, the elements closest to the end of the list are deleted until the list reaches the size *_Nsize*.

If the present size of the list is the same as the requested size, no action is taken.

[size](#) reflects the current size of the list.

Example

```
// list_resize.cpp  
// compile with: /EHsc  
#include <list>  
#include <iostream>  
  
int main( )  
{  
    using namespace std;  
    list<int> c1;  
  
    c1.push_back( 10 );  
    c1.push_back( 20 );  
    c1.push_back( 30 );  
  
    c1.resize( 4,40 );  
    cout << "The size of c1 is " << c1.size( ) << endl;  
    cout << "The value of the last element is " << c1.back( ) << endl;  
  
    c1.resize( 5 );  
    cout << "The size of c1 is now " << c1.size( ) << endl;  
    cout << "The value of the last element is now " << c1.back( ) << endl;  
  
    c1.resize( 2 );  
    cout << "The reduced size of c1 is: " << c1.size( ) << endl;  
    cout << "The value of the last element is now " << c1.back( ) << endl;  
}
```

```
The size of c1 is 4
The value of the last element is 40
The size of c1 is now 5
The value of the last element is now 0
The reduced size of c1 is: 2
The value of the last element is now 20
```

list::reverse

Reverses the order in which the elements occur in a list.

```
void reverse();
```

Example

```
// list_reverse.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::iterator c1_Iter;

    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 30 );

    cout << "c1 =";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    c1.reverse( );
    cout << "Reversed c1 =";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;
}
```

```
c1 = 10 20 30
Reversed c1 = 30 20 10
```

list::reverse_iterator

A type that provides a bidirectional iterator that can read or modify an element in a reversed list.

```
typedef std::reverse_iterator<iterator> reverse_iterator;
```

Remarks

A type `reverse_iterator` is used to iterate through the list in reverse.

Example

See the example for [rbegin](#).

list::size

Returns the number of elements in a list.

```
size_type size() const;
```

Return Value

The current length of the list.

Example

```
// list_size.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::size_type i;

    c1.push_back( 5 );
    i = c1.size( );
    cout << "List length is " << i << "." << endl;

    c1.push_back( 7 );
    i = c1.size( );
    cout << "List length is now " << i << "." << endl;
}
```

```
List length is 1.
List length is now 2.
```

list::size_type

A type that counts the number of elements in a list.

```
typedef typename Allocator::size_type size_type;
```

Example

See the example for [size](#).

list::sort

Arranges the elements of a list in ascending order or with respect to some other user-specified order.

```
void sort();

template <class Traits>
void sort(Traits comp);
```

Parameters

comp

The comparison operator used to order successive elements.

Remarks

The first member function puts the elements in ascending order by default.

The member template function orders the elements according to the user-specified comparison operation *comp* of class `Traits`.

Example

```
// list_sort.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::iterator c1_Iter;

    c1.push_back( 20 );
    c1.push_back( 10 );
    c1.push_back( 30 );

    cout << "Before sorting: c1 =";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    c1.sort( );
    cout << "After sorting c1 =";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    c1.sort( greater<int>( ) );
    cout << "After sorting with 'greater than' operation, c1 =";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;
}
```

```
Before sorting: c1 = 20 10 30
After sorting c1 = 10 20 30
After sorting with 'greater than' operation, c1 = 30 20 10
```

list::splice

Removes elements from a source list and inserts them into a destination list.

```
// insert the entire source list
void splice(const_iterator Where, list<Type, Allocator>& Source);
void splice(const_iterator Where, list<Type, Allocator>&& Source);

// insert one element of the source list
void splice(const_iterator Where, list<Type, Allocator>& Source, const_iterator Iter);
void splice(const_iterator Where, list<Type, Allocator>&& Source, const_iterator Iter);

// insert a range of elements from the source list
void splice(const_iterator Where, list<Type, Allocator>& Source, const_iterator First, const_iterator Last);
void splice(const_iterator Where, list<Type, Allocator>&& Source, const_iterator First, const_iterator Last);
```

Parameters

Where

The position in the destination list before which to insert.

Source

The source list that is to be inserted into the destination list.

Iter

The element to be inserted from the source list.

First

The first element in the range to be inserted from the source list.

Last

The first position beyond the last element in the range to be inserted from the source list.

Remarks

The first pair of member functions inserts all elements in the source list into the destination list before the position referred to by *Where* and removes all elements from the source list. (`&Source` must not equal `this`.)

The second pair of member functions inserts the element referred to by *Iter* before the position in the destination list referred to by *Where* and removes *Iter* from the source list. (If `Where == Iter || Where == ++Iter`, no change occurs.)

The third pair of member functions inserts the range designated by [`First`, `Last`) before the element in the destination list referred to by *Where* and removes that range of elements from the source list. (If `&Source == this`, the range [`First`, `Last`) must not include the element pointed to by *Where*.)

If the ranged splice inserts `N` elements, and `&Source != this`, an object of class [iterator](#) is incremented `N` times.

In all cases iterators, pointers, or references that refer to spliced elements remain valid and are transferred to the destination container.

Example

```
// list_splice.cpp
// compile with: /EHsc /W4
#include <list>
#include <iostream>

using namespace std;

template <typename S> void print(const S& s) {
    cout << s.size() << " elements: ";

    for (const auto& p : s) {
        cout << "(" << p << ") ";
    }

    cout << endl;
}

int main()
{
    list<int> c1{10,11};
    list<int> c2{20,21,22};
    list<int> c3{30,31};
    list<int> c4{40,41,42,43};

    list<int>::iterator where_iter;
    list<int>::iterator first_iter;
```

```

list<int>::iterator last_iter;

cout << "Beginning state of lists:" << endl;
cout << "c1 = ";
print(c1);
cout << "c2 = ";
print(c2);
cout << "c3 = ";
print(c3);
cout << "c4 = ";
print(c4);

where_iter = c2.begin();
++where_iter; // start at second element
c2.splice(where_iter, c1);
cout << "After splicing c1 into c2:" << endl;
cout << "c1 = ";
print(c1);
cout << "c2 = ";
print(c2);

first_iter = c3.begin();
c2.splice(where_iter, c3, first_iter);
cout << "After splicing the first element of c3 into c2:" << endl;
cout << "c3 = ";
print(c3);
cout << "c2 = ";
print(c2);

first_iter = c4.begin();
last_iter = c4.end();
// set up to get the middle elements
++first_iter;
--last_iter;
c2.splice(where_iter, c4, first_iter, last_iter);
cout << "After splicing a range of c4 into c2:" << endl;
cout << "c4 = ";
print(c4);
cout << "c2 = ";
print(c2);
}

```

```

Beginning state of lists:c1 = 2 elements: (10) (11)c2 = 3 elements: (20) (21) (22)c3 = 2 elements: (30)
(31)c4 = 4 elements: (40) (41) (42) (43)After splicing c1 into c2:c1 = 0 elements:c2 = 5 elements: (20) (10)
(11) (21) (22)After splicing the first element of c3 into c2:c3 = 1 elements: (31)c2 = 6 elements: (20) (10)
(11) (30) (21) (22)After splicing a range of c4 into c2:c4 = 2 elements: (40) (43)c2 = 8 elements: (20) (10)
(11) (30) (41) (42) (21) (22)

```

list::swap

Exchanges the elements of two lists.

```

void swap(list<Type, Allocator>& right);
friend void swap(list<Type, Allocator>& left, list<Type, Allocator>& right)

```

Parameters

right

The list providing the elements to be swapped, or the list whose elements are to be exchanged with those of the list *left*.

left

A list whose elements are to be exchanged with those of the list *right*.

Example

```
// list_swap.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1, c2, c3;
    list<int>::iterator c1_Iter;

    c1.push_back( 1 );
    c1.push_back( 2 );
    c1.push_back( 3 );
    c2.push_back( 10 );
    c2.push_back( 20 );
    c3.push_back( 100 );

    cout << "The original list c1 is:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    c1.swap( c2 );

    cout << "After swapping with c2, list c1 is:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    swap( c1, c3 );

    cout << "After swapping with c3, list c1 is:";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;
}
```

```
The original list c1 is: 1 2 3
After swapping with c2, list c1 is: 10 20
After swapping with c3, list c1 is: 100
```

list::unique

Removes adjacent duplicate elements or adjacent elements that satisfy some other binary predicate from a list.

```
void unique();

template <class BinaryPredicate>
void unique(BinaryPredicate pred);
```

Parameters

pred

The binary predicate used to compare successive elements.

Remarks

This function assumes that the list is sorted, so that all duplicate elements are adjacent. Duplicates that are not

adjacent will not be deleted.

The first member function removes every element that compares equal to its preceding element.

The second member function removes every element that satisfies the predicate function *pred* when compared with its preceding element. You can use any of the binary function objects declared in the <functional> header for the argument *pred* or you can create your own.

Example

```
// list_unique.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int> c1;
    list<int>::iterator c1_Iter, c2_Iter, c3_Iter;
    not_equal_to<int> mypred;

    c1.push_back( -10 );
    c1.push_back( 10 );
    c1.push_back( 10 );
    c1.push_back( 20 );
    c1.push_back( 20 );
    c1.push_back( -10 );

    cout << "The initial list is c1 =";
    for ( c1_Iter = c1.begin( ); c1_Iter != c1.end( ); c1_Iter++ )
        cout << " " << *c1_Iter;
    cout << endl;

    list<int> c2 = c1;
    c2.unique( );
    cout << "After removing successive duplicate elements, c2 =";
    for ( c2_Iter = c2.begin( ); c2_Iter != c2.end( ); c2_Iter++ )
        cout << " " << *c2_Iter;
    cout << endl;

    list<int> c3 = c2;
    c3.unique( mypred );
    cout << "After removing successive unequal elements, c3 =";
    for ( c3_Iter = c3.begin( ); c3_Iter != c3.end( ); c3_Iter++ )
        cout << " " << *c3_Iter;
    cout << endl;
}
```

```
The initial list is c1 = -10 10 10 20 20 -10
After removing successive duplicate elements, c2 = -10 10 20 -10
After removing successive unequal elements, c3 = -10 -10
```

list::value_type

A type that represents the data type stored in a list.

```
typedef typename Allocator::value_type value_type;
```

Remarks

`value_type` is a synonym for the template parameter *Type*.

Example

```
// list_value_type.cpp
// compile with: /EHsc
#include <list>
#include <iostream>

int main( )
{
    using namespace std;
    list<int>::value_type AnInt;
    AnInt = 44;
    cout << AnInt << endl;
}
```

44

<locale>

11/9/2018 • 5 minutes to read • [Edit Online](#)

Defines template classes and functions that C++ programs can use to encapsulate and manipulate different cultural conventions regarding the representation and formatting of numeric, monetary, and calendric data, including internationalization support for character classification and string collation.

Syntax

```
#include <locale>
```

Functions

FUNCTION	DESCRIPTION
has_facet	Tests if a particular facet is stored in a specified locale.
isalnum	Tests whether an element in a locale is an alphabetic or a numeric character.
isalpha	Tests whether an element in a locale is alphabetic character.
isctrl	Tests whether an element in a locale is a control character.
isdigit	Tests whether an element in a locale is a numeric character.
isgraph	Tests whether an element in a locale is an alphanumeric or punctuation character.
islower	Tests whether an element in a locale is lower case.
isprint	Tests whether an element in a locale is a printable character.
ispunct	Tests whether an element in a locale is a punctuation character.
isspace	Tests whether an element in a locale is a whitespace character.
isupper	Tests whether an element in a locale is upper case.
isxdigit	Tests whether an element in a locale is a character used to represent a hexadecimal number.
tolower	Converts a character to lower case.
toupper	Converts a character to upper case.

FUNCTION	DESCRIPTION
use_facet	Returns a reference to a facet of a specified type stored in a locale.

Classes

CLASS	DESCRIPTION
codecvt	A template class that provides a facet used to convert between internal and external character encodings.
codecvt_base	A base class for the codecvt class that is used to define an enumeration type referred to as <code>result</code> , used as the return type for the facet member functions to indicate the result of a conversion.
codecvt_byname	A derived template class that describes an object that can serve as a collate facet of a given locale, enabling the retrieval of information specific to a cultural area concerning conversions.
collate	A collate template class that provides a facet that handles string sorting conventions.
collate_byname	A derived template class that describes an object that can serve as a collate facet of a given locale, enabling the retrieval of information specific to a cultural area concerning string sorting conventions.
ctype	A template class that provides a facet that is used to classify characters, convert from upper- and lowercase and between the native character set and that set used by the locale.
ctype<char>	A class that is an explicit specialization of template class <code>ctype<CharType></code> to type char , describing an object that can serve as a locale facet to characterize various properties of a character of type char .
ctype_base	A base class for the ctype class that is used to define enumeration types used to classify or test characters either individually or within entire ranges.
ctype_byname	A derived template class that describes an object that can serve as a ctype facet of a given locale, enabling the classification of characters and conversion of characters between case and native and locale specified character sets.
locale	A class that describes a locale object that encapsulates culture-specific information as a set of facets that collectively define a specific localized environment.
messages	A template class that describes an object that can serve as a locale facet to retrieve localized messages from a catalog of internationalized messages for a given locale.

CLASS	DESCRIPTION
messages_base	A base class that describes an int type for the catalog of messages.
messages_byname	A derived template class that describes an object that can serve as a message facet of a given locale, enabling the retrieval of localized messages.
money_base	A base class for the ctype class that is used to define enumeration types used to classify or test characters either individually or within entire ranges.
money_get	A template class that describes an object that can serve as a locale facet to control conversions of sequences of type CharType to monetary values.
money_put	A template class that describes an object that can serve as a locale facet to control conversions of monetary values to sequences of type CharType .
moneypunct	A template class that describes an object that can serve as a locale facet to describe the sequences of type CharType used to represent a monetary input field or a monetary output field.
moneypunct_byname	A derived template class that describes an object that can serve as a moneypunct facet of a given locale enabling the formatting monetary input or output fields.
num_get	A template class that describes an object that can serve as a locale facet to control conversions of sequences of type CharType to numeric values.
num_put	A template class that describes an object that can serve as a locale facet to control conversions of numeric values to sequences of type CharType .
numpunct	A template class that describes an object that can serve as a local facet to describe the sequences of type CharType used to represent information about the formatting and punctuation of numeric and Boolean expressions.
numpunct_byname	A derived template class that describes an object that can serve as a moneypunct facet of a given locale enabling the formatting and punctuation of numeric and Boolean expressions.
time_base	A class that serves as a base class for facets of template class time_get , defining just the enumerated type dateorder and several constants of this type.
time_get	A template class that describes an object that can serve as a locale facet to control conversions of sequences of type CharType to time values.

CLASS	DESCRIPTION
time_get_byname	A derived template class that describes an object that can serve as a locale facet of type <code>time_get<CharType, InputIterator></code> .
time_put	A template class that describes an object that can serve as a locale facet to control conversions of time values to sequences of type CharType .
time_put_byname	A derived template class that describes an object that can serve as a locale facet of type <code>time_put<CharType, OutputIterator></code> .
wbuffer_convert Class	Describes a stream buffer that controls the transmission of elements to and from a byte stream buffer.
wstring_convert Class	A template class that performs conversions between a wide string and a byte string.

<locale> functions

10/31/2018 • 15 minutes to read • [Edit Online](#)

has_facet	isalnum	isalpha
iscntrl	isdigit	isgraph
islower	isprint	ispunct
isspace	isupper	isxdigit
tolower	toupper	use_facet

has_facet

Tests if a particular facet is stored in a specified locale.

```
template <class Facet>
bool has_facet(const locale& Loc);
```

Parameters

Loc

The locale to be tested for the presence of a facet.

Return Value

true if the locale has the facet tested for; **false** if it does not.

Remarks

The template function is useful for checking whether nonmandatory facets are listed in a locale before `use_facet` is called to avoid the exception that would be thrown if it were not present.

Example

```
// locale_has_facet.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result = has_facet <ctype<char> > ( loc );
    cout << result << endl;
}
```

isalnum

Tests whether an element in a locale is an alphabetic or a numeric character.

```
template <class CharType>
bool isalnum(CharType Ch, const locale& Loc)
```

Parameters

Ch

The alphanumeric element to be tested.

Loc

The locale containing the alphanumeric element to be tested.

Return Value

true if the element tested is alphanumeric; **false** if it is not.

Example

```
// locale_isalnum.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>

using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = isalnum ( 'L', loc);
    bool result2 = isalnum ( '@', loc);
    bool result3 = isalnum ( '3', loc);

    if ( result1 )
        cout << "The character 'L' in the locale is "
              << "alphanumeric." << endl;
    else
        cout << "The character 'L' in the locale is "
              << " not alphanumeric." << endl;

    if ( result2 )
        cout << "The character '@' in the locale is "
              << "alphanumeric." << endl;
    else
        cout << "The character '@' in the locale is "
              << " not alphanumeric." << endl;

    if ( result3 )
        cout << "The character '3' in the locale is "
              << "alphanumeric." << endl;
    else
        cout << "The character '3' in the locale is "
              << " not alphanumeric." << endl;
}
```

```
The character 'L' in the locale is alphanumeric.
The character '@' in the locale is not alphanumeric.
The character '3' in the locale is alphanumeric.
```

isalpha

Tests whether an element in a locale is an alphabetic character.

```
template <class CharType>
bool isalpha(CharType Ch, const locale& Loc)
```

Parameters

Ch

The element to be tested.

Loc

The locale containing the alphabetic element to be tested.

Return Value

true if the element tested is alphabetic; **false** if it is not.

Remarks

The template function returns `use_facet< ctype< CharType> >(Loc).is(ctype< CharType>:: alpha, Ch)`.

Example

```
// locale_isalpha.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>

using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = isalpha ( 'L', loc);
    bool result2 = isalpha ( '@', loc);
    bool result3 = isalpha ( '3', loc);

    if ( result1 )
        cout << "The character 'L' in the locale is "
              << "alphabetic." << endl;
    else
        cout << "The character 'L' in the locale is "
              << " not alphabetic." << endl;

    if ( result2 )
        cout << "The character '@' in the locale is "
              << "alphabetic." << endl;
    else
        cout << "The character '@' in the locale is "
              << " not alphabetic." << endl;

    if ( result3 )
        cout << "The character '3' in the locale is "
              << "alphabetic." << endl;
    else
        cout << "The character '3' in the locale is "
              << " not alphabetic." << endl;
}
```

isctrl

Tests whether an element in a locale is a control character.

```
template <class CharType>
bool iscntrl(CharType Ch, const locale& Loc)
```

Parameters

Ch

The element to be tested.

Loc

The locale containing the element to be tested.

Return Value

true if the element tested is a control character; **false** if it is not.

Remarks

The template function returns `use_facet<ctype< CharType>> (&Loc).is(ctype< CharType>::cntrl, Ch)`.

Example

```
// locale_iscntrl.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>

using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = iscntrl ( 'L', loc );
    bool result2 = iscntrl ( '\n', loc );
    bool result3 = iscntrl ( '\t', loc );

    if ( result1 )
        cout << "The character 'L' in the locale is "
              << "a control character." << endl;
    else
        cout << "The character 'L' in the locale is "
              << " not a control character." << endl;

    if ( result2 )
        cout << "The character-set 'backslash-n' in the locale\n is "
              << "a control character." << endl;
    else
        cout << "The character-set 'backslash-n' in the locale\n is "
              << " not a control character." << endl;

    if ( result3 )
        cout << "The character-set 'backslash-t' in the locale\n is "
              << "a control character." << endl;
    else
        cout << "The character-set 'backslash-n' in the locale \n is "
              << " not a control character." << endl;
}
```

isdigit

Tests whether an element in a locale is a numeric character.

```
template <class CharType>
bool isdigit(CharType Ch, const locale& Loc)
```

Parameters

Ch

The element to be tested.

Loc

The locale containing the element to be tested.

Return Value

true if the element tested is a numeric character; **false** if it is not.

Remarks

The template function returns `use_facet<ctype< CharType>> (&Loc).is(ctype< CharType>::digit, Ch)`.

Example

```
// locale_is_digit.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>

using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = isdigit ( 'L', loc );
    bool result2 = isdigit ( '@', loc );
    bool result3 = isdigit ( '3', loc );

    if ( result1 )
        cout << "The character 'L' in the locale is "
              << "a numeric character." << endl;
    else
        cout << "The character 'L' in the locale is "
              << " not a numeric character." << endl;

    if ( result2 )
        cout << "The character '@' in the locale is "
              << "a numeric character." << endl;
    else
        cout << "The character '@' in the locale is "
              << " not a numeric character." << endl;

    if ( result3 )
        cout << "The character '3' in the locale is "
              << "a numeric character." << endl;
    else
        cout << "The character '3' in the locale is "
              << " not a numeric character." << endl;
}
```

isgraph

Tests whether an element in a locale is an alphanumeric or punctuation character.

```
template <class CharType>
bool isgraph(CharType Ch, const locale& Loc)
```

Parameters

Ch

The element to be tested.

Loc

The locale containing the element to be tested.

Return Value

true if the element tested is an alphanumeric or a punctuation character; **false** if it is not.

Remarks

The template function returns `use_facet< ctype< CharType> > (Loc). is(ctype< CharType>:: graph, Ch)`.

Example

```
// locale_is_graph.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>

using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = isgraph ( 'L', loc );
    bool result2 = isgraph ( '\\t', loc );
    bool result3 = isgraph ( '.', loc );

    if ( result1 )
        cout << "The character 'L' in the locale is\\n "
              << "an alphanumeric or punctuation character." << endl;
    else
        cout << "The character 'L' in the locale is\\n "
              << " not an alphanumeric or punctuation character." << endl;

    if ( result2 )
        cout << "The character 'backslash-t' in the locale is\\n "
              << "an alphanumeric or punctuation character." << endl;
    else
        cout << "The character 'backslash-t' in the locale is\\n "
              << "not an alphanumeric or punctuation character." << endl;

    if ( result3 )
        cout << "The character '.' in the locale is\\n "
              << "an alphanumeric or punctuation character." << endl;
    else
        cout << "The character '.' in the locale is\\n "
              << " not an alphanumeric or punctuation character." << endl;
}
```

islower

Tests whether an element in a locale is lower case.

```
template <class CharType>
bool islower(CharType Ch, const locale& Loc)
```

Parameters

Ch

The element to be tested.

Loc

The locale containing the element to be tested.

Return Value

true if the element tested is a lowercase character; **false** if it is not.

Remarks

The template function returns `use_facet<ctype< CharType>> (&Loc).is(ctype< CharType>::lower, Ch)`.

Example

```
// locale_islower.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>

using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = islower ( 'L', loc );
    bool result2 = islower ( 'n', loc );
    bool result3 = islower ( '3', loc );

    if ( result1 )
        cout << "The character 'L' in the locale is "
              << "a lowercase character." << endl;
    else
        cout << "The character 'L' in the locale is "
              << " not a lowercase character." << endl;

    if ( result2 )
        cout << "The character 'n' in the locale is "
              << "a lowercase character." << endl;
    else
        cout << "The character 'n' in the locale is "
              << " not a lowercase character." << endl;

    if ( result3 )
        cout << "The character '3' in the locale is "
              << "a lowercase character." << endl;
    else
        cout << "The character '3' in the locale is "
              << " not a lowercase character." << endl;
}
```

isprint

Tests whether an element in a locale is a printable character.

```
template <class CharType>
bool isprint(CharType Ch, const locale& Loc)
```

Parameters

Ch

The element to be tested.

Loc

The locale containing the element to be tested.

Return Value

true if the element tested is a printable; **false** if it is not.

Remarks

The template function returns `use_facet< ctype< CharType> > (Loc). is(ctype< CharType>:: print, Ch)`.

Example

```
// locale_isprint.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc ( "German_Germany" );

    bool result1 = isprint ( 'L', loc );
    if ( result1 )
        cout << "The character 'L' in the locale is "
              << "a printable character." << endl;
    else
        cout << "The character 'L' in the locale is "
              << " not a printable character." << endl;

    bool result2 = isprint( '\\t', loc );
    if ( result2 )
        cout << "The character 'backslash-t' in the locale is "
              << "a printable character." << endl;
    else
        cout << "The character 'backslash-t' in the locale is "
              << " not a printable character." << endl;

    bool result3 = isprint( '\\n', loc );
    if ( result3 )
        cout << "The character 'backslash-n' in the locale is "
              << "a printable character." << endl;
    else
        cout << "The character 'backslash-n' in the locale is "
              << " not a printable character." << endl;
}
```

ispunct

Tests whether an element in a locale is a punctuation character.

```
template <class CharType>
bool ispunct(CharType Ch, const locale& Loc)
```

Parameters

Ch

The element to be tested.

Loc

The locale containing the element to be tested.

Return Value

true if the element tested is a punctuation character; **false** if it is not.

Remarks

The template function returns `use_facet<ctype< CharType>> (&Loc).is(ctype< CharType>::punct, Ch)`.

Example

```
// locale_ispunct.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>

using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = ispunct ( 'L', loc );
    bool result2 = ispunct ( ';', loc );
    bool result3 = ispunct ( '*', loc );

    if ( result1 )
        cout << "The character 'L' in the locale is "
              << "a punctuation character." << endl;
    else
        cout << "The character 'L' in the locale is "
              << " not a punctuation character." << endl;

    if ( result2 )
        cout << "The character ';' in the locale is "
              << "a punctuation character." << endl;
    else
        cout << "The character ';' in the locale is "
              << " not a punctuation character." << endl;

    if ( result3 )
        cout << "The character '*' in the locale is "
              << "a punctuation character." << endl;
    else
        cout << "The character '*' in the locale is "
              << " not a punctuation character." << endl;
}
```

isspace

Tests whether an element in a locale is a whitespace character.

```
template <class CharType>
bool isspace(CharType Ch, const locale& Loc)
```

Parameters

Ch

The element to be tested.

Loc

The locale containing the element to be tested.

Return Value

true if the element tested is a whitespace character; **false** if it is not.

Remarks

The template function returns `use_facet< ctype< CharType> >(Loc).is(ctype< CharType>::space, Ch)`.

Example

```
// locale_isspace.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>

using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = isspace ( 'L', loc );
    bool result2 = isspace ( '\n', loc );
    bool result3 = isspace ( ' ', loc );

    if ( result1 )
        cout << "The character 'L' in the locale is "
              << "a whitespace character." << endl;
    else
        cout << "The character 'L' in the locale is "
              << " not a whitespace character." << endl;

    if ( result2 )
        cout << "The character 'backslash-n' in the locale is "
              << "a whitespace character." << endl;
    else
        cout << "The character 'backslash-n' in the locale is "
              << " not a whitespace character." << endl;

    if ( result3 )
        cout << "The character ' ' in the locale is "
              << "a whitespace character." << endl;
    else
        cout << "The character ' ' in the locale is "
              << " not a whitespace character." << endl;
}
```

isupper

Tests whether an element in a locale is in upper case.

```
template <class CharType>
bool isupper(CharType Ch, const locale& Loc)
```

Parameters

Ch

The element to be tested.

Loc

The locale containing the element to be tested.

Return Value

true if the element tested is an uppercase character; **false** if it is not.

Remarks

The template function returns `use_facet< ctype< CharType> >(Loc).is(ctype< CharType>::upper, Ch)`.

Example

```
// locale_isupper.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>

using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = isupper ( 'L', loc );
    bool result2 = isupper ( 'n', loc );
    bool result3 = isupper ( '3', loc );

    if ( result1 )
        cout << "The character 'L' in the locale is "
              << "a uppercase character." << endl;
    else
        cout << "The character 'L' in the locale is "
              << " not a uppercase character." << endl;

    if ( result2 )
        cout << "The character 'n' in the locale is "
              << "a uppercase character." << endl;
    else
        cout << "The character 'n' in the locale is "
              << " not a uppercase character." << endl;

    if ( result3 )
        cout << "The character '3' in the locale is "
              << "a uppercase character." << endl;
    else
        cout << "The character '3' in the locale is "
              << " not a uppercase character." << endl;
}
```

isxdigit

Tests whether an element in a locale is a character used to represent a hexadecimal number.

```
template <class CharType>
bool isxdigit(CharType Ch, const locale& Loc)
```

Parameters

Ch

The element to be tested.

Loc

The locale containing the element to be tested.

Return Value

true if the element tested is a character used to represent a hexadecimal number; **false** if it is not.

Remarks

The template function returns `use_facet< ctype< CharType> >(Loc).is(ctype< CharType>::xdigit, Ch)`.

Hexadecimal digits use base 16 to represent numbers, using the numbers 0 through 9 plus case-insensitive letters A through F to represent the decimal numbers 0 through 15.

Example

```
// locale_isxdigit.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>

using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = isxdigit ( '5', loc );
    bool result2 = isxdigit ( 'd', loc );
    bool result3 = isxdigit ( 'q', loc );

    if ( result1 )
        cout << "The character '5' in the locale is "
              << "a hexadecimal digit-character." << endl;
    else
        cout << "The character '5' in the locale is "
              << " not a hexadecimal digit-character." << endl;

    if ( result2 )
        cout << "The character 'd' in the locale is "
              << "a hexadecimal digit-character." << endl;
    else
        cout << "The character 'd' in the locale is "
              << " not a hexadecimal digit-character." << endl;

    if ( result3 )
        cout << "The character 'q' in the locale is "
              << "a hexadecimal digit-character." << endl;
    else
        cout << "The character 'q' in the locale is "
              << " not a hexadecimal digit-character." << endl;
}
```

tolower

Converts a character to lower case.

```
template <class CharType>
CharType tolower(CharType Ch, const locale& Loc)
```

Parameters

Ch

The character to be converted to lower case.

Loc

The locale containing the character to be converted.

Return Value

The character converted to lower case.

Remarks

The template function returns `use_facet< ctype< CharType> >(Loc). tolower(Ch)`.

Example

```
// locale_tolower.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    char result1 = tolower ( 'H', loc );
    cout << "The lower case of 'H' in the locale is: "
         << result1 << "." << endl;
    char result2 = tolower ( 'h', loc );
    cout << "The lower case of 'h' in the locale is: "
         << result2 << "." << endl;
    char result3 = tolower ( '$', loc );
    cout << "The lower case of '$' in the locale is: "
         << result3 << "." << endl;
}
```

toupper

Converts a character to upper case.

```
template <class CharType>
CharType toupper(CharType Ch, const locale& Loc)
```

Parameters

Ch

The character to be converted to upper case.

Loc

The locale containing the character to be converted.

Return Value

The character converted to upper case.

Remarks

The template function returns `use_facet< ctype< CharType> >(Loc). toupper(Ch)`.

Example

```
// locale_toupper.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    char result1 = toupper ( 'h', loc );
    cout << "The upper case of 'h' in the locale is: "
         << result1 << "." << endl;
    char result2 = toupper ( 'H', loc );
    cout << "The upper case of 'H' in the locale is: "
         << result2 << "." << endl;
    char result3 = toupper ( '$', loc );
    cout << "The upper case of '$' in the locale is: "
         << result3 << "." << endl;
}
```

use_facet

Returns a reference to a facet of a specified type stored in a locale.

```
template <class Facet>
const Facet& use_facet(const locale& Loc);
```

Parameters

Loc

The const locale containing the type of facet being referenced.

Return Value

A reference to the facet of class `Facet` contained within the argument locale.

Remarks

The reference to the facet returned by the template function remains valid as long as any copy of the containing locale exists. If no such facet object of class `Facet` is listed in the argument locale, the function throws a `bad_cast` exception.

Example

```

// locale_use_facet.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc1 ( "German_Germany" ), loc2 ( "English_Australia" );
    bool result1 = use_facet<ctype<char> > ( loc1 ).is(
        ctype_base::alpha, 'a'
    );
    bool result2 = use_facet<ctype<char> > ( loc2 ).is( ctype_base::alpha, '!'
    );

    if ( result1 )
        cout << "The character 'a' in locale loc1 is alphabetic."
            << endl;
    else
        cout << "The character 'a' in locale loc1 is not alphabetic."
            << endl;

    if ( result2 )
        cout << "The character '!' in locale loc2 is alphabetic."
            << endl;
    else
        cout << "The character '!' in locale loc2 is not alphabetic."
            << endl;
}

```

```

The character 'a' in locale loc1 is alphabetic.
The character '!' in locale loc2 is not alphabetic.

```

[<locale>](#)

codecvt Class

10/31/2018 • 16 minutes to read • [Edit Online](#)

A template class that describes an object that can serve as a locale facet. It is able to control conversions between a sequence of values used to encode characters within the program and a sequence of values used to encode characters outside the program.

Syntax

```
template <class CharType, class Byte, class StateType>
class codecvt : public locale::facet, codecvt_base;
```

Parameters

CharType

The type used within a program to encode characters.

Byte

A type used to encode characters outside a program.

StateType

A type that can be used to represent intermediate states of a conversion between internal and external types of character representations.

Remarks

The template class describes an object that can serve as a [locale facet](#), to control conversions between a sequence of values of type *CharType* and a sequence of values of type *Byte*. The class *StateType* characterizes the transformation -- and an object of class *StateType* stores any necessary state information during a conversion.

The internal encoding uses a representation with a fixed number of bytes per character, usually either type **char** or type **wchar_t**.

As with any locale facet, the static object `id` has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in `id`.

The template versions of [do_in](#) and [do_out](#) always return `codecvt_base::noconv`.

The C++ Standard Library defines several explicit specializations:

```
template<>
codecvt<wchar_t, char, mbstate_t>
```

converts between **wchar_t** and **char** sequences.

```
template<>
codecvt<char16_t, char, mbstate_t>
```

converts between `char16_t` sequences encoded as UTF-16 and **char** sequences encoded as UTF-8.

```
template<>
codecv<char32_t, char, mbstate_t>
```

converts between `char32_t` sequences encoded as UTF-32 (UCS-4) and **char** sequences encoded as UTF-8.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>codecvt</code>	The constructor for objects of class <code>codecvt</code> that serves as a locale facet to handle conversions.

Typedefs

TYPE NAME	DESCRIPTION
<code>extern_type</code>	A character type that is used for external representations.
<code>intern_type</code>	A character type that is used for internal representations.
<code>state_type</code>	A character type that is used to represent intermediate states during conversions between internal and external representations.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>always_noconv</code>	Tests whether no conversions need be done.
<code>do_always_noconv</code>	A virtual function called to test whether no conversions need be done.
<code>do_encoding</code>	A virtual function that tests if the encoding of the <code>Byte</code> stream is state dependent, whether the ratio between the <code>Byte</code> s used and the <code>CharType</code> s produced is constant, and, if so, determines the value of that ratio.
<code>do_in</code>	A virtual function called to convert a sequence of internal <code>Byte</code> s to a sequence of external <code>CharType</code> s.
<code>do_length</code>	A virtual function that determines how many <code>Byte</code> s from a given sequence of external <code>Byte</code> s produce not more than a given number of internal <code>CharType</code> s and returns that number of <code>Byte</code> s.
<code>do_max_length</code>	A virtual function that returns the maximum number of external Bytes necessary to produce one internal <code>CharType</code> .
<code>do_out</code>	A virtual function called to convert a sequence of internal <code>CharType</code> s to a sequence of external Bytes.
<code>do_unshift</code>	A virtual function called to provide the <code>Byte</code> s needed in a state-dependent conversion to complete the last character in a sequence of <code>Byte</code> s.

MEMBER FUNCTION	DESCRIPTION
encoding	Tests if the encoding of the <code>Byte</code> stream is state dependent, whether the ratio between the <code>Byte</code> s used and the <code>CharType</code> s produced is constant, and, if so, determines the value of that ratio.
in	Converts an external representation of a sequence of <code>Byte</code> s to an internal representation of a sequence of <code>CharType</code> s.
length	Determines how many <code>Byte</code> s from a given sequence of external <code>Byte</code> s produce not more than a given number of internal <code>CharType</code> s and returns that number of <code>Byte</code> s.
max_length	Returns the maximum number of external <code>Byte</code> s necessary to produce one internal <code>CharType</code> .
out	Converts a sequence of internal <code>CharType</code> s to a sequence of external <code>Byte</code> s.
unshift	Provides the external <code>Byte</code> s needed in a state-dependent conversion to complete the last character in the sequence of <code>Byte</code> s.

Requirements

Header: <locale>

Namespace: std

codecvt::always_noconv

Tests whether no conversions need be done.

```
bool always_noconv() const throw();
```

Return Value

A Boolean value that is **true** if no conversions need be done; **false** is at least one needs to be done.

Remarks

The member function returns [do_always_noconv](#).

Example

```
// codecvt_always_noconv.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    bool result1 = use_facet<codecvt<char, char, mbstate_t> >
        ( loc ).always_noconv( );

    if ( result1 )
        cout << "No conversion is needed." << endl;
    else
        cout << "At least one conversion is required." << endl;

    bool result2 = use_facet<codecvt<wchar_t, char, mbstate_t> >
        ( loc ).always_noconv( );

    if ( result2 )
        cout << "No conversion is needed." << endl;
    else
        cout << "At least one conversion is required." << endl;
}
```

```
No conversion is needed.
At least one conversion is required.
```

codecvt::codecvt

The constructor for objects of class `codecvt` that serves as a locale facet to handle conversions.

```
explicit codecvt(size_t _Refs = 0);
```

Parameters

_Refs

Integer value used to specify the type of memory management for the object.

Remarks

The possible values for the *_Refs* parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.
- 2: These values are not defined.

The constructor initializes its `locale::facet` base object with **locale::facet**(`_Refs`).

codecvt::do_always_noconv

A virtual function called to test whether no conversions need be done.

```
virtual bool do_always_noconv() const throw();
```

Return Value

The protected virtual member function returns **true** only if every call to `do_in` or `do_out` returns `noconv`.

The template version always returns **true**.

Example

See the example for `always_noconv`, which calls `do_always_noconv`.

codecvt::do_encoding

A virtual function that tests if the encoding of the `Byte` stream is state dependent, whether the ratio between the `Byte`s used and the `CharType`s produced is constant and, if so, determines the value of that ratio.

```
virtual int do_encoding() const throw();
```

Return Value

The protected virtual member function returns:

- -1, if the encoding of sequences of type `extern_type` is state dependent.
- 0, if the encoding involves sequences of varying lengths.
- N , if the encoding involves only sequences of length N

Example

See the example for `encoding`, which calls `do_encoding`.

codecvt::do_in

A virtual function called to convert a sequence of external `Byte`s to a sequence of internal `CharType`s.

```
virtual result do_in(  
    StateType& _State,  
    const Byte* first1,  
    const Byte* last1,  
    const Byte*& next1,  
    CharType* first2,  
    CharType* last2,  
    CharType*& next2,) const;
```

Parameters

_State

The conversion state that is maintained between calls to the member function.

first1

Pointer to the beginning of the sequence to be converted.

last1

Pointer to the end of the sequence to be converted.

next1

Pointer beyond the end of the converted sequence, to the first unconverted character.

first2

Pointer to the beginning of the converted sequence.

last2

Pointer to the end of the converted sequence.

next2

Pointer to the `CharType` that comes after the last converted `CharType`, to the first unaltered character in the destination sequence.

Return Value

A return that indicates the success, partial success, or failure of the operation. The function returns:

- `codecvt_base::error` if the source sequence is ill formed.
- `codecvt_base::noconv` if the function performs no conversion.
- `codecvt_base::ok` if the conversion succeeds.
- `codecvt_base::partial` if the source is insufficient or if the destination is not large enough, for the conversion to succeed.

Remarks

_State must represent the initial conversion state at the beginning of a new source sequence. The function alters its stored value as needed to reflect the current state of a successful conversion. Its stored value is otherwise unspecified.

Example

See the example for [in](#), which calls `do_in`.

codecvt::do_length

A virtual function that determines how many `Byte`s from a given sequence of external `Byte`s produce not more than a given number of internal `CharType`s and returns that number of `Byte`s.

```
virtual int do_length(  
    const StateType& _State,  
    const Byte* first1,  
    const Byte* last1,  
    size_t _Len2) const;
```

Parameters

_State

The conversion state that is maintained between calls to the member function.

first1

Pointer to the beginning of the external sequence.

last1

Pointer to the end of the external sequence.

_Len2

The maximum number of `Byte`s that can be returned by the member function.

Return Value

An integer that represents a count of the maximum number of conversions, not greater than *_Len2*, defined by the external source sequence at [`first1`, `last1`).

Remarks

The protected virtual member function effectively calls `do_in` (`_State`, `first1`, `last1`, `next1`, `_Buf`, `_Buf` + `_Len2`, `next2`) for *_State* (a copy of state), some buffer `_Buf`, and pointers `next1` and `next2`.

It then returns `next2` - `buf`. Thus, it counts the maximum number of conversions, not greater than *_Len2*, defined

by the source sequence at [`first1` , `last1`).

The template version always returns the lesser of *last1 - first1* and *_Len2*.

Example

See the example for [length](#), which calls `do_length` .

codecvt::do_max_length

A virtual function that returns the maximum number of external `Byte` s necessary to produce one internal `CharType` .

```
virtual int do_max_length() const throw();
```

Return Value

The maximum number of `Byte` s necessary to produce one `CharType` .

Remarks

The protected virtual member function returns the largest permissible value that can be returned by [do_length](#)(`first1` , `last1` , 1) for arbitrary valid values of *first1* and *last1*.

Example

See the example for [max_length](#), which calls `do_max_length` .

codecvt::do_out

A virtual function called to convert a sequence of internal `CharType` s to a sequence of external `Byte` s.

```
virtual result do_out(  
    StateType& _State,  
    const CharType* first1,  
    const CharType* last1,  
    const CharType*& next1,  
    Byte* first2,  
    Byte* last2,  
    Byte*& next2) const;
```

Parameters

_State

The conversion state that is maintained between calls to the member function.

first1

Pointer to the beginning of the sequence to be converted.

last1

Pointer to the end of the sequence to be converted.

next1

Reference to a pointer to the first unconverted `CharType` , after the last `CharType` converted.

first2

Pointer to the beginning of the converted sequence.

last2

Pointer to the end of the converted sequence.

next2

Reference to a pointer to the first unconverted `Byte`, after the last `Byte` converted.

Return Value

The function returns:

- `codecvt_base::error` if the source sequence is ill formed.
- `codecvt_base::noconv` if the function performs no conversion.
- `codecvt_base::ok` if the conversion succeeds.
- `codecvt_base::partial` if the source is insufficient or if the destination is not large enough for the conversion to succeed.

Remarks

`_State` must represent the initial conversion state at the beginning of a new source sequence. The function alters its stored value as needed to reflect the current state of a successful conversion. Its stored value is otherwise unspecified.

Example

See the example for `out`, which calls `do_out`.

codecvt::do_unshift

A virtual function called to provide the `Byte`s needed in a state-dependent conversion to complete the last character in a sequence of `Byte`s.

```
virtual result do_unshift(
    StateType& _State,
    Byte* first2,
    Byte* last2,
    Byte*& next2) const;
```

Parameters

_State

The conversion state that is maintained between calls to the member function.

first2

Pointer to the first position in the destination range.

last2

Pointer to the last position in the destination range.

next2

Pointer to the first unaltered element in the destination sequence.

Return Value

The function returns:

- `codecvt_base::error` if `_State` represents an invalid state
- `codecvt_base::noconv` if the function performs no conversion
- `codecvt_base::ok` if the conversion succeeds
- `codecvt_base::partial` if the destination is not large enough for the conversion to succeed

Remarks

The protected virtual member function tries to convert the source element `CharType` (0) to a destination sequence that it stores within [`first2`, `last2`), except for the terminating element `Byte` (0). It always stores in `next2` a pointer to the first unaltered element in the destination sequence.

`_State` must represent the initial conversion state at the beginning of a new source sequence. The function alters its stored value as needed to reflect the current state of a successful conversion. Typically, converting the source element `CharType` (0) leaves the current state in the initial conversion state.

Example

See the example for [unshift](#), which calls `do_unshift`.

codecvt::encoding

Tests if the encoding of the `Byte` stream is state dependent, whether the ratio between the `Byte`s used and the `CharType`s produced is constant, and, if so, determines the value of that ratio.

```
int encoding() const throw();
```

Return Value

If the return value is positive then that value is the constant number of `Byte` characters required to produce the `CharType` character.

The protected virtual member function returns:

- -1, if the encoding of sequences of type `extern_type` is state dependent.
- 0, if the encoding involves sequences of varying lengths.
- *N*, if the encoding involves only sequences of length *N*.

Remarks

The member function returns [do_encoding](#).

Example

```
// codecvt_encoding.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    int result1 = use_facet<codecvt<char, char, mbstate_t> > ( loc ).encoding ( );
    cout << result1 << endl;
    result1 = use_facet<codecvt<wchar_t, char, mbstate_t> > ( loc ).encoding( );
    cout << result1 << endl;
    result1 = use_facet<codecvt<char, wchar_t, mbstate_t> > ( loc ).encoding( );
    cout << result1 << endl;
}
```

```
1
1
1
```

codecvt::extern_type

A character type that is used for external representations.

```
typedef Byte extern_type;
```

Remarks

The type is a synonym for the template parameter `Byte`.

codecvt::in

Converts an external representation of a sequence of `Byte`s to an internal representation of a sequence of `CharType` S.

```
result in(  
    StateType& _State,  
    const Byte* first1,  
    const Byte* last1,  
    const Byte*& next1,  
    CharType* first2,  
    CharType* last2,  
    CharType*& next2,) const;
```

Parameters

_State

The conversion state that is maintained between calls to the member function.

first1

Pointer to the beginning of the sequence to be converted.

last1

Pointer to the end of the sequence to be converted.

next1

Pointer beyond the end of the converted sequence to the first unconverted character.

first2

Pointer to the beginning of the converted sequence.

last2

Pointer to the end of the converted sequence.

next2

Pointer to the `CharType` that comes after the last converted `CharType` to the first unaltered character in the destination sequence.

Return Value

A return that indicates the success, partial success or failure of the operation. The function returns:

- `codecvt_base::error` if the source sequence is ill formed.
- `codecvt_base::noconv` if the function performs no conversion.
- `codecvt_base::ok` if the conversion succeeds.
- `codecvt_base::partial` if the source is insufficient or if the destination is not large enough for the conversion to succeed.

Remarks

`_State` must represent the initial conversion state at the beginning of a new source sequence. The function alters its stored value, as needed, to reflect the current state of a successful conversion. After a partial conversion, `_State` must be set so as to allow the conversion to resume when new characters arrive.

The member function returns `do_in(_State, _First1, last1, next1, First2, _Llast2, next2)`.

Example

```
// codecvt_in.cpp
// compile with: /EHsc
#define _INTL
#include <locale>
#include <iostream>
using namespace std;
#define LEN 90
int main( )
{
    char* pszExt = "This is the string to be converted!";
    wchar_t pwszInt [LEN+1];
    memset(&pwszInt[0], 0, (sizeof(wchar_t))*(LEN+1));
    const char* pszNext;
    wchar_t* pwszNext;
    mbstate_t state = {0};
    locale loc("C");//English_Britain");//German_Germany
    int res = use_facet<codecvt<wchar_t, char, mbstate_t> >
        ( loc ).in( state,
            pszExt, &pszExt[strlen(pszExt)], pszNext,
            pwszInt, &pwszInt[strlen(pszExt)], pwszNext );
    pwszInt[strlen(pszExt)] = 0;
    wcout << ( (res!=codecvt_base::error) ? L"It worked! " : L"It didn't work! " )
    << L"The converted string is:\n ["
    << &pwszInt[0]
    << L"]" << endl;
    exit(-1);
}
```

```
It worked! The converted string is:
[This is the string to be converted!]
```

codecvt::intern_type

A character type that is used for internal representations.

```
typedef CharType intern_type;
```

Remarks

The type is a synonym for the template parameter `CharType`.

codecvt::length

Determines how many `Byte`s from a given sequence of external `Byte`s produce not more than a given number of internal `CharType`s and returns that number of `Byte`s.

```
int length(
    const StateType& _State,
    const Byte* first1,
    const Byte* last1,
    size_t _Len2) const;
```

Parameters

_State

The conversion state that is maintained between calls to the member function.

first1

Pointer to the beginning of the external sequence.

last1

Pointer to the end of the external sequence.

_Len2

The maximum number of Bytes that can be returned by the member function.

Return Value

An integer that represents a count of the maximum number of conversions, not greater than *_Len2*, defined by the external source sequence at [*first1* , *last1*).

Remarks

The member function returns `do_length(_State, first1, last1, _Len2)`.

Example

```
// codecvt_length.cpp
// compile with: /EHsc
#define _INTL
#include <locale>
#include <iostream>
using namespace std;
#define LEN 90
int main( )
{
    char* pszExt = "This is the string whose length is to be measured!";
    mbstate_t state = {0};
    locale loc("C");//English_Britain");//German_Germany
    int res = use_facet<codecvt<wchar_t, char, mbstate_t> >
        ( loc ).length( state,
            pszExt, &pszExt[strlen(pszExt)], LEN );
    cout << "The length of the string is: ";
    wcout << res;
    cout << "." << endl;
    exit(-1);
}
```

The length of the string is: 50.

codecvt::max_length

Returns the maximum number of external `Byte`s necessary to produce one internal `CharType`.

```
int max_length() const throw();
```

Return Value

The maximum number of `Byte`s necessary to produce one `CharType`.

Remarks

The member function returns `do_max_length`.

Example

```
// codecvt_max_length.cpp
// compile with: /EHsc
#define _INTL
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc( "C");//English_Britain" );//German_Germany
    int res = use_facet<codecvt<char, char, mbstate_t> >
        ( loc ).max_length( );
    wcout << res << endl;
}
```

1

codecvt::out

Converts a sequence of internal `CharType`s to a sequence of external `Byte`s.

```
result out(
    StateType& _State,
    const CharType* first1,
    const CharType* last1,
    const CharType*& next1,
    Byte* first2,
    Byte* last2,
    Byte*& next2) const;
```

Parameters

_State

The conversion state that is maintained between calls to the member function.

first1

Pointer to the beginning of the sequence to be converted.

last1

Pointer to the end of the sequence to be converted.

next1

Reference to a pointer to the first unconverted `CharType` after the last `CharType` converted.

first2

Pointer to the beginning of the converted sequence.

last2

Pointer to the end of the converted sequence.

next2

Reference to a pointer to the first unconverted `Byte` after the last converted `Byte` .

Return Value

The member function returns `do_out(_State , first1 , last1 , next1 , first2 , last2 , next2)`.

Remarks

For more information, see [codecvt::do_out](#).

Example

```
// codecvt_out.cpp
// compile with: /EHsc
#define _INTL
#include <locale>
#include <iostream>
#include <wchar.h>
using namespace std;
#define LEN 90
int main( )
{
    char pszExt[LEN+1];
    wchar_t *pwszInt = L"This is the wchar_t string to be converted.";
    memset( &pszExt[0], 0, ( sizeof( char ) )*( LEN+1 ) );
    char* pszNext;
    const wchar_t* pwszNext;
    mbstate_t state;
    locale loc("C");//English_Britain");//German_Germany
    int res = use_facet<codecvt<wchar_t, char, mbstate_t> >
        ( loc ).out( state,
        pwszInt, &pwszInt[wcslen( pwszInt )], pwszNext ,
        pszExt, &pszExt[wcslen( pwszInt )], pszNext );
    pszExt[wcslen( pwszInt )] = 0;
    cout << ( ( res!=codecvt_base::error ) "It worked: " : "It didn't work: " )
    << "The converted string is:\n ["
    << &pszExt[0]
    << "]" << endl;
}
```

```
It worked: The converted string is:
[This is the wchar_t string to be converted.]
```

codecvt::state_type

A character type that is used to represent intermediate states during conversions between internal and external representations.

```
typedef StateType state_type;
```

Remarks

The type is a synonym for the template parameter `StateType` .

codecvt::unshift

Provides the `Byte` s needed in a state-dependent conversion to complete the last character in a sequence of `Byte` s.

```
result unshift(
    StateType& _State,
    Byte* first2,
    Byte* last2,
    Byte*& next2) const;
```

Parameters

_State

The conversion state that is maintained between calls to the member function.

first2

Pointer to the first position in the destination range.

last2

Pointer to the last position in the destination range.

next2

Pointer to the first unaltered element in the destination sequence.

Return Value

The function returns:

- `codecvt_base::error` if state represents an invalid state.
- `codecvt_base::noconv` if the function performs no conversion.
- `codecvt_base::ok` if the conversion succeeds.
- `codecvt_base::partial` if the destination is not large enough for the conversion to succeed.

Remarks

The protected virtual member function tries to convert the source element `CharType` (0) to a destination sequence that it stores within [`first2`, `last2`), except for the terminating element `Byte` (0). It always stores in *next2* a pointer to the first unaltered element in the destination sequence.

_State must represent the initial conversion state at the beginning of a new source sequence. The function alters its stored value, as needed, to reflect the current state of a successful conversion. Typically, converting the source element `CharType` (0) leaves the current state in the initial conversion state.

The member function returns `do_unshift(_State, first2, last2, next2)`.

[Locale Names, Languages, and Country/Region Strings](#)

[Thread Safety in the C++ Standard Library](#)

codecvt_base Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

A base class for the `codecvt` class that is used to define an enumeration type referred to as `result`, used as the return type for the facet member functions to indicate the result of a conversion.

Syntax

```
class codecvt_base : public locale::facet {
public:
    enum result {ok, partial, error, noconv};
    codecvt_base( size_t _Refs = 0);
    bool always_noconv() const;
    int max_length() const;
    int encoding() const;
    ~codecvt_base()

protected:
    virtual bool do_always_noconv() const;
    virtual int do_max_length() const;
    virtual int do_encoding() const;
};
```

Remarks

The class describes an enumeration common to all specializations of template class `codecvt`. The enumeration `result` describes the possible return values from `do_in` or `do_out`:

- `ok` if the conversion between internal and external character encodings succeeds.
- `partial` if the destination is not large enough for the conversion to succeed.
- `error` if the source sequence is ill formed.
- `noconv` if the function performs no conversion.

Requirements

Header: <locale>

Namespace: std

See also

[Thread Safety in the C++ Standard Library](#)

codecvt_byname Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

A derived template class that describes an object that can serve as a collate facet of a given locale, enabling the retrieval of information specific to a cultural area concerning conversions.

Syntax

```
template <class CharType, class Byte, class StateType>
class codecvt_byname: public codecvt<CharType, Byte, StateType> {
public:
    explicit codecvt_byname(
        const char* _Locname,
        size_t _Refs = 0);
```

```
    explicit codecvt_byname(
        const string& _Locname,
        size_t _Refs = 0);
```

```
protected:
    virtual ~codecvt_byname();

};
```

Parameters

_Locname

A named locale.

_Refs

An initial reference count.

Remarks

Byname facets are automatically created when a named locale is constructed.

Its behavior is determined by the named locale *_Locname*. Each constructor initializes its base object with `codecvt<CharType, Byte, StateType>(_Refs)`.

Requirements

Header: <locale>

Namespace: std

See also

[Thread Safety in the C++ Standard Library](#)

collate Class

10/31/2018 • 7 minutes to read • [Edit Online](#)

A template class that describes an object that can serve as a locale facet to control the ordering and grouping of characters within a string, comparisons between them and the hashing of strings.

Syntax

```
template <class CharType>
class collate : public locale::facet;
```

Parameters

CharType

The type used within a program to encode characters.

Remarks

As with any locale facet, the static object ID has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in `id`. In some languages, characters are grouped and treated as a single character, and in others, individual characters are treated as if they were two characters. The collating services provided by the collate class provide the way to sort these cases.

Constructors

CONSTRUCTOR	DESCRIPTION
collate	The constructor for objects of class <code>collate</code> that serves as a locale facet to handle string sorting conventions.

Typedefs

TYPE NAME	DESCRIPTION
char_type	A type that describes a character of type <code>CharType</code> .
string_type	A type that describes a string of type <code>basic_string</code> containing characters of type <code>CharType</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
compare	Compares two character sequences according to their facet-specific rules for equality or inequality.
do_compare	A virtual function called to compare two character sequences according to their facet-specific rules for equality or inequality.
do_hash	A virtual function called to determine the hash value of sequences according to their facet-specific rules.

MEMBER FUNCTION	DESCRIPTION
do_transform	A virtual function called to convert a character sequence from a locale to a string that may be used in lexicographical comparisons with other character sequences similarly converted from the same locale.
hash	Determines the hash value of sequence according to their facet-specific rules.
transform	Converts a character sequence from a locale to a string that may be used in lexicographical comparisons with other character sequences similarly converted from the same locale.

Requirements

Header: <locale>

Namespace: std

collate::char_type

A type that describes a character of type `CharType`.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter `CharType`.

collate::collate

The constructor for objects of class collate that serves as a locale facet to handle string sorting conventions.

```
public:
    explicit collate(
        size_t _Refs = 0);

protected:
    collate(
        const char* _Locname,
        size_t _Refs = 0);
```

Parameters

_Refs

Integer value used to specify the type of memory management for the object.

_Locname

The name of the locale.

Remarks

The possible values for the *_Refs* parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.

- > 1: These values are not defined.

The constructor initializes its base object with **locale::facet**(`_Refs`).

collate::compare

Compares two character sequences according to their facet-specific rules for equality or inequality.

```
int compare(const CharType* first1,
            const CharType* last1,
            const CharType* first2,
            const CharType* last2) const;
```

Parameters

first1

Pointer to the first element in the first sequence to be compared.

last1

Pointer to the last element in the first sequence to be compared.

first2

Pointer to the first element in the second sequence to be compared.

last2

Pointer to the last element in the second sequence to be compared.

Return Value

The member function returns:

- -1 if the first sequence compares less than the second sequence.
- +1 if the second sequence compares less than the first sequence.
- 0 if the sequences are equivalent.

Remarks

The first sequence compares less if it has the smaller element in the earliest unequal pair in the sequences, or, if no unequal pairs exist, but the first sequence is shorter.

The member function returns `do_compare`(`first1`, `last1`, `first2`, `last2`).

Example

```

// collate_compare.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <tchar.h>
using namespace std;

int main() {
    locale loc ( "German_germany" );
    _TCHAR * s1 = _T("Das ist wei\x00dfzz."); // \x00df is the German sharp-s, it comes before z in the German
    alphabet
    _TCHAR * s2 = _T("Das ist weizzz.");
    int result1 = use_facet<collate<_TCHAR> > ( loc ).
        compare ( s1, &s1[_tcslen( s1 )-1 ], s2, &s2[_tcslen( s2 )-1 ] );
    cout << result1 << endl;

    locale loc2 ( "C" );
    int result2 = use_facet<collate<_TCHAR> > ( loc2 ).
        compare ( s1, &s1[_tcslen( s1 )-1 ], s2, &s2[_tcslen( s2 )-1 ] );
    cout << result2 << endl;
}

```

collate::do_compare

A virtual function called to compare two character sequences according to their facet-specific rules for equality or inequality.

```

virtual int do_compare(const CharType* first1,
    const CharType* last1,
    const CharType* first2,
    const CharType* last2) const;

```

Parameters

first1

Pointer to the first element in the first sequence to be compared.

last1

Pointer to the last element in the first sequence to be compared.

first2

Pointer to the first element in the second sequence to be compared.

last2

Pointer to the last element in the second sequence to be compared.

Return Value

The member function returns:

- -1 if the first sequence compares less than the second sequence.
- +1 if the second sequence compares less than the first sequence.
- 0 if the sequences are equivalent.

Remarks

The protected virtual member function compares the sequence at [*first1*, *Last1*)* with the sequence at [*first2*, *last2*). It compares values by applying `operator<` between pairs of corresponding elements of type `CharType`. The first sequence compares less if it has the smaller element in the earliest unequal pair in the sequences or if no unequal pairs exist but the first sequence is shorter.

Example

See the example for [collate::compare](#), which calls `do_compare`.

collate::do_hash

A virtual function called to determine the hash value of sequences according to their facet-specific rules.

```
virtual long do_hash(const CharType* first, const CharType* last) const;
```

Parameters

first

A pointer to the first character in the sequence whose has value is to be determined.

last

A pointer to the last character in the sequence whose has value is to be determined.

Return Value

A hash value of type **long** for the sequence.

Remarks

A hash value can be useful, for example, in distributing sequences pseudo-randomly across an array of lists.

Example

See the example for [hash](#), which calls `do_hash`.

collate::do_transform

A virtual function called to convert a character sequence from a locale to a string that may be used in lexicographical comparisons with other character sequences similarly converted from the same locale.

```
virtual string_type do_transform(const CharType* first, const CharType* last) const;
```

Parameters

first

A pointer to the first character in the sequence to be converted.

last

A pointer to the last character in the sequence to be converted.

Return Value

A string that is the transformed character sequence.

Remarks

The protected virtual member function returns an object of class [string_type](#) whose controlled sequence is a copy of the sequence [`first`, `last`). If a class derived from `collate< CharType >` overrides [do_compare](#), it should also override `do_transform` to match. When passed to `collate::compare`, two transformed strings should yield the same result that you would get from passing the untransformed strings to `compare` in the derived class.

Example

See the example for [transform](#), which calls `do_transform`.

collate::hash

Determines the hash value of sequence according to their facet-specific rules.

```
long hash(const CharType* first, const CharType* last) const;
```

Parameters

first

A pointer to the first character in the sequence whose has value is to be determined.

last

A pointer to the last character in the sequence whose has value is to be determined.

Return Value

A hash value of type **long** for the sequence.

Remarks

The member function returns `do_hash(first, last)`.

A hash value can be useful, for example, in distributing sequences pseudo-randomly across an array of lists.

Example

```
// collate_hash.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <tchar.h>
using namespace std;

int main( )
{
    locale loc ( "German_germany" );
    _TCHAR * s1 = _T("\x00dfzz abc."); // \x00df is the German sharp-s (looks like beta), it comes before z in
the alphabet
    _TCHAR * s2 = _T("zzz abc."); // \x00df is the German sharp-s (looks like beta), it comes before z in the
alphabet

    long r1 = use_facet< collate<_TCHAR> > ( loc ).
        hash (s1, &s1[_tcslen( s1 )-1 ] );
    long r2 = use_facet< collate<_TCHAR> > ( loc ).
        hash (s2, &s2[_tcslen( s2 )-1 ] );
    cout << r1 << " " << r2 << endl;
}
```

```
541187293 551279837
```

collate::string_type

A type that describes a string of type `basic_string` containing characters of type `CharType`.

```
typedef basic_string<CharType> string_type;
```

Remarks

The type describes a specialization of template class `basic_string` whose objects can store copies of the source sequence.

Example

For an example of how to declare and use `string_type`, see [transform](#).

collate::transform

Converts a character sequence from a locale to a string that may be used in lexicographical comparisons with other character sequences similarly converted from the same locale.

```
string_type transform(const CharType* first, const CharType* last) const;
```

Parameters

first

A pointer to the first character in the sequence to be converted.

last

A pointer to the last character in the sequence to be converted.

Return Value

A string that contains the transformed character sequence.

Remarks

The member function returns [do_transform](#)(`first`, `last`).

Example

```
// collate_transform.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <tchar.h>
using namespace std;

int main( )
{
    locale loc ( "German_Germany" );
    _TCHAR* s1 = _T("\x00dfzz abc.");
    // \x00df is the German sharp-s (looks like beta),
    // it comes before z in the alphabet
    _TCHAR* s2 = _T("zzz abc.");

    collate<_TCHAR>::string_type r1; // OK for typedef
    r1 = use_facet< collate<_TCHAR> > ( loc ).
        transform (s1, &s1[_tcslen( s1 )-1 ]);

    cout << r1 << endl;

    basic_string<_TCHAR> r2 = use_facet< collate<_TCHAR> > ( loc ).
        transform (s2, &s2[_tcslen( s2 )-1 ]);

    cout << r2 << endl;

    int result1 = use_facet<collate<_TCHAR> > ( loc ).compare
        (s1, &s1[_tcslen( s1 )-1 ], s2, &s2[_tcslen( s2 )-1 ] );

    cout << _tcscmp(r1.c_str( ),r2.c_str( )) << result1
        << _tcscmp(s1,s2) <<endl;
}
```

[<locale>](#)

[Thread Safety in the C++ Standard Library](#)

collate_byname Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

A derived template class that describes an object that can serve as a collate facet of a given locale, enabling the retrieval of information specific to a cultural area concerning string sorting conventions.

Syntax

```
template <class CharType>
class collate_byname : public collate<CharType> {
public:
    explicit collate_byname(
        const char* _Locname,
        size_t _Refs = 0);

    explicit collate_byname(
        const string& _Locname,
        size_t _Refs = 0);

protected:
    virtual ~collate_byname();

};
```

Parameters

_Locname

A named locale.

_Refs

An initial reference count.

Remarks

The template class describes an object that can serve as a [locale facet](#) of type `collate<CharType>`. Its behavior is determined by the [named](#) locale *_Locname*. Each constructor initializes its base object with `collate<CharType>(_Refs)`.

Requirements

Header: <locale>

Namespace: std

See also

[Thread Safety in the C++ Standard Library](#)

ctype Class

10/31/2018 • 17 minutes to read • [Edit Online](#)

A class that provides a facet that is used to classify characters, convert from upper and lower cases, and convert between the native character set and that set used by the locale.

Syntax

```
template <class CharType>
class ctype : public ctype_base;
```

Parameters

CharType

The type used within a program to encode characters.

Remarks

As with any locale facet, the static object `ID` has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in `id`. Classification criteria are provided a nested bitmask type in the base class `ctype_base`.

The C++ Standard Library defines two explicit specializations of this template class:

- `ctype<char>`, an explicit specialization whose differences are described separately. For more information, see [ctype<char> Class](#).
- `ctype<wchar_t>`, which treats elements as wide characters.

Other specializations of template class `ctype<CharType>`:

- Convert a value *ch* of type *CharType* to a value of type **char** with the expression `(char)ch`.
- Convert a value *byte* of type **char** to a value of type *CharType* with the expression `CharType(byte)`.

All other operations are performed on **char** values in the same way as for the explicit specialization

`ctype<char>`.

Constructors

CONSTRUCTOR	DESCRIPTION
ctype	Constructor for objects of class <code>ctype</code> that serve as locale facets for characters.

Typedefs

TYPE NAME	DESCRIPTION
char_type	A type that describes a character used by a locale.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>do_is</code>	A virtual function called to test whether a single character has a particular attribute, or classify the attributes of each character in a range and stores them in an array.
<code>do_narrow</code>	A virtual function called to convert a character of type <code>CharType</code> used by a locale to the corresponding character of type char in the native character set.
<code>do_scan_is</code>	A virtual function called to locate the first character in a range that matches a specified mask.
<code>do_scan_not</code>	A virtual function called to locate the first character in a range that does not match a specified mask.
<code>do_tolower</code>	A virtual function called to convert a character or a range of characters to their lower case.
<code>do_toupper</code>	A virtual function called to convert a character or a range of characters to upper case.
<code>do_widen</code>	A virtual function called to converts a character of type char in the native character set to the corresponding character of type <code>CharType</code> used by a locale.
<code>is</code>	Tests whether a single character has a particular attribute, or classifies the attributes of each character in a range and stores them in an array.
<code>narrow</code>	Converts a character of type <code>CharType</code> used by a locale to the corresponding character of type <code>char</code> in the native character set.
<code>scan_is</code>	Locates the first character in a range that matches a specified mask.
<code>scan_not</code>	Locates the first character in a range that does not match a specified mask.
<code>tolower</code>	Converts a character or a range of characters to lower case.
<code>toupper</code>	Converts a character or a range of characters to upper case.
<code>widen</code>	Converts a character of type char in the native character set to the corresponding character of type <code>CharType</code> used by a locale.

Requirements

Header: `<locale>`

Namespace: `std`

`ctype::char_type`

A type that describes a character used by a locale.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter *CharType*.

Example

See the member function [widen](#) for an example that uses `char_type` as a return value.

ctype::ctype

Constructor for objects of class `ctype` that serve as locale facets for characters.

```
explicit ctype(size_t _Refs = 0);
```

Parameters

_Refs

Integer value used to specify the type of memory management for the object.

Remarks

The possible values for the *_Refs* parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.
- > 1: These values are not defined.

No direct examples are possible, because the destructor is protected.

The constructor initializes its `locale::facet` base object with **`locale::facet`**(`_Refs`).

ctype::do_is

A virtual function called to test whether a single character has a particular attribute, or classify the attributes of each character in a range and stores them in an array.

```
virtual bool do_is(
    mask maskVal,
    CharType ch) const;

virtual const CharType *do_is(
    const CharType* first,
    const CharType* last,
    mask* dest) const;
```

Parameters

maskVal

The mask value for which the character is to be tested.

ch

The character whose attributes are to be tested.

first

A pointer to the first character in the range whose attributes are to be classified.

last

A pointer to the character immediately following the last character in the range whose attributes are to be classified.

dest

A pointer to the beginning of the array where the mask values characterizing the attributes of each of the characters are to be stored.

Return Value

The first member function returns a Boolean value that is **true** if the character tested has the attribute described by the mask value; **false** if it fails to have the attribute.

The second member function returns an array containing the mask values characterizing the attributes of each of the characters in the range.

Remarks

The mask values classifying the attributes of the characters are provided by the class `ctype_base`, from which `ctype` derives. The first member function can accept expressions for its first parameter referred to as bitmasks and formed from the combination of mask values by the logical bitwise operators (`|`, `&`, `^`, `~`).

Example

See the example for `is`, which calls `do_is`.

`ctype::do_narrow`

A virtual function called to convert a character of type `CharType` used by a locale to the corresponding character of type **char** in the native character set.

```
virtual char do_narrow(
    CharType ch,
    char default = '\0') const;

virtual const CharType* do_narrow(
    const CharType* first,
    const CharType* last,
    char default,
    char* dest) const;
```

Parameters

ch

The character of type `CharType` used by the locale to be converted.

default

The default value to be assigned by the member function to characters of type `CharType` that do not have counterpart characters of type **char**.

first

A pointer to the first character in the range of characters to be converted.

last

A pointer to the character immediately following the last character in the range of characters to be converted.

dest

A const pointer to the first character of type **char** in the destination range that stores the converted range of characters.

Return Value

The first protected member function returns the native character of type `char` that corresponds to the parameter character of type `CharType` or *default* if no counterpart is defined.

The second protected member function returns a pointer to the destination range of native characters converted from characters of type `CharType`.

Remarks

The second protected member template function stores in `dest [I]` the value `do_narrow (first [I], default)`, for `I` in the interval `[0, last - first)`.

Example

See the example for [narrow](#), which calls `do_narrow`.

ctype::do_scan_is

A virtual function called to locate the first character in a range that matches a specified mask.

```
virtual const CharType *do_scan_is(  
    mask maskVal,  
    const CharType* first,  
    const CharType* last) const;
```

Parameters

maskVal

The mask value to be matched by a character.

first

A pointer to the first character in the range to be scanned.

last

A pointer to the character immediately following the last character in the range to be scanned.

Return Value

A pointer to the first character in a range that does match a specified mask. If no such value exists, the function returns *last*.

Remarks

The protected member function returns the smallest pointer `ptr` in the range `[first , last)` for which `do_is(maskVal , * ptr)` is true.

Example

See the example for [scan_is](#), which calls `do_scan_is`.

ctype::do_scan_not

A virtual function called to locate the first character in a range that does not match a specified mask.

```
virtual const CharType *do_scan_not(  
    mask maskVal,  
    const CharType* first,  
    const CharType* last) const;
```

Parameters

maskVal

The mask value not to be matched by a character.

first

A pointer to the first character in the range to be scanned.

last

A pointer to the character immediately following the last character in the range to be scanned.

Return Value

A pointer to the first character in a range that doesn't match a specified mask. If no such value exists, the function returns *last*.

Remarks

The protected member function returns the smallest pointer `ptr` in the range [`first`, `last`) for which `do_is(maskVal, * ptr)` is false.

Example

See the example for [scan_not](#), which calls `do_scan_not`.

ctype::do_tolower

A virtual function called to convert a character or a range of characters to lower case.

```
virtual CharType do_tolower(CharType ch) const;

virtual const CharType *do_tolower(
    CharType* first,
    const CharType* last) const;
```

Parameters

ch

The character to be converted to lower case.

first

A pointer to the first character in the range of characters whose cases are to be converted.

last

A pointer to the character immediately following the last character in the range of characters whose cases are to be converted.

Return Value

The first protected member function returns the lowercase form of the parameter *ch*. If no lowercase form exists, it returns *ch*. The second protected member function returns *last*.

Remarks

The second protected member template function replaces each element `first` [`I`], for `I` in the interval [0, `last` - `first`), with `do_tolower` (`first` [`I`]).

Example

See the example for [tolower](#), which calls `do_tolower`.

ctype::do_toupper

A virtual function called to convert a character or a range of characters to upper case.

```
virtual CharType do_toupper(CharType ch) const;

virtual const CharType *do_toupper(
    CharType* first,
    const CharType* last) const;
```

Parameters

ch

The character to be converted to upper case.

first

A pointer to the first character in the range of characters whose cases are to be converted.

last

A pointer to character immediately following the last character in the range of characters whose cases are to be converted.

Return Value

The first protected member function returns the uppercase form of the parameter *ch*. If no uppercase form exists, it returns *ch*. The second protected member function returns *last*.

Remarks

The second protected member template function replaces each element `first [I]`, for `I` in the interval `[0, last - first)`, with `do_toupper (first [I])`.

Example

See the example for [toupper](#), which calls `do_toupper`.

ctype::do_widen

A virtual function called to converts a character of type **char** in the native character set to the corresponding character of type `CharType` used by a locale.

```
virtual CharType do_widen(char byte) const;

virtual const char *do_widen(
    const char* first,
    const char* last,
    CharType* dest) const;
```

Parameters

byte

The character of type **char** in the native character set to be converted.

first

A pointer to the first character in the range of characters to be converted.

last

A pointer to the character immediately following the last character in the range of characters to be converted.

dest

A pointer to the first character of type `CharType` in the destination range that stores the converted range of characters.

Return Value

The first protected member function returns the character of type `CharType` that corresponds to the parameter character of native type **char**.

The second protected member function returns a pointer to the destination range of characters of type `CharType` used by a locale converted from native characters of type **char**.

Remarks

The second protected member template function stores in `dest [I]` the value `do_widen (first [I])`, for `I` in the interval `[0, last - first)`.

Example

See the example for [widen](#), which calls `do_widen`.

ctype::is

Tests whether a single character has a particular attribute or classifies the attributes of each character in a range and stores them in an array.

```
bool is(mask maskVal, CharType ch) const;

const CharType *is(
    const CharType* first,
    const CharType* last,
    mask* dest) const;
```

Parameters

maskVal

The mask value for which the character is to be tested.

ch

The character whose attributes are to be tested.

first

A pointer to the first character in the range whose attributes are to be classified.

last

A pointer to the character immediately following the last character in the range whose attributes are to be classified.

dest

A pointer to the beginning of the array where the mask values characterizing the attributes of each of the characters are to be stored.

Return Value

The first member function returns **true** if the character tested has the attribute described by the mask value; **false** if it fails to have the attribute.

The second member function returns a pointer to the last character in the range whose attributes are to be classified.

Remarks

The mask values classifying the attributes of the characters are provided by the class [ctype_base Class](#), from which `ctype` derives. The first member function can accept expressions for its first parameter referred to as bitmasks and formed from the combination of mask values by the logical bitwise operators (`|`, `&`, `^`, `~`).

Example

```

// ctype_is.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main() {
    locale loc1 ( "German_Germany" ), loc2 ( "English_Australia" );

    if (use_facet<ctype<char> > ( loc1 ).is( ctype_base::alpha, 'a' ))
        cout << "The character 'a' in locale loc1 is alphabetic."
              << endl;
    else
        cout << "The character 'a' in locale loc1 is not alphabetic."
              << endl;

    if (use_facet<ctype<char> > ( loc2 ).is( ctype_base::alpha, '!' ))
        cout << "The character '!' in locale loc2 is alphabetic."
              << endl;
    else
        cout << "The character '!' in locale loc2 is not alphabetic."
              << endl;

    char *string = "Hello, my name is John!";
    ctype<char>::mask maskarray[30];
    use_facet<ctype<char> > ( loc2 ).is(
        string, string + strlen(string), maskarray );
    for (unsigned int i = 0; i < strlen(string); i++) {
        cout << string[i] << ": "
              << (maskarray[i] & ctype_base::alpha ? "alpha"
                  : "not alpha")
              << endl;
    }
}

```

ctype::narrow

Converts characters of type `CharType` used by a locale to the corresponding characters of type **char** in the native character set.

```

char narrow(CharType ch, char default = '\0') const;

const CharType* narrow(
    const CharType* first,
    const CharType* last,
    char default,
    char* dest) const;

```

Parameters

ch

The character of type `CharType` used by the locale to be converted.

default

The default value to be assigned by the member function to characters of type `CharType` that do not have counterpart characters of type **char**.

first

A pointer to the first character in the range of characters to be converted.

last

A pointer to the character immediately following the last character in the range of characters to be converted.

dest

A const pointer to the first character of type **char** in the destination range that stores the converted range of characters.

Return Value

The first member function returns the native character of type **char** that corresponds to the parameter character of type `CharType default` if not counterpart is defined.

The second member function returns a pointer to the destination range of native characters converted from characters of type `CharType`.

Remarks

The first member function returns `do_narrow(ch, default)`. The second member function returns `do_narrow (first, last, default, dest)`. Only the basic source characters are guaranteed to have a unique inverse image `CharType` under `narrow`. For these basic source characters, the following invariant holds: `narrow (widen (c), 0) == c`.

Example

```
// ctype_narrow.cpp
// compile with: /EHsc /W3
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc1 ( "english" );
    wchar_t *str1 = L"\x0392fhello everyone";
    char str2 [16];
    bool result1 = (use_facet<ctype<wchar_t> > ( loc1 ).narrow
        ( str1, str1 + wcslen(str1), 'X', &str2[0] ) != 0); // C4996
    str2[wcslen(str1)] = '\0';
    wcout << str1 << endl;
    cout << &str2[0] << endl;
}
```

Xhello everyone

ctype::scan_is

Locates the first character in a range that matches a specified mask.

```
const CharType *scan_is(
    mask maskVal,
    const CharType* first,
    const CharType* last) const;
```

Parameters

maskVal

The mask value to be matched by a character.

first

A pointer to the first character in the range to be scanned.

last

A pointer to the character immediately following the last character in the range to be scanned.

Return Value

A pointer to the first character in a range that does match a specified mask. If no such value exists, the function returns *last*.

Remarks

The member function returns `do_scan_is(maskVal, first, last)`.

Example

```
// ctype_scan_is.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc1 ( "German_Germany" );

    char *string = "Hello, my name is John!";

    const char* i = use_facet<ctype<char> > ( loc1 ).scan_is
        ( ctype_base::punct, string, string + strlen(string) );
    cout << "The first punctuation is \"" << *i << "\" at position: "
        << i - string << endl;
}
```

The first punctuation is "," at position: 5

ctype::scan_not

Locates the first character in a range that does not match a specified mask.

```
const CharType *scan_not(
    mask maskVal,
    const CharType* first,
    const CharType* last) const;
```

Parameters

maskVal

The mask value not to be matched by a character.

first

A pointer to the first character in the range to be scanned.

last

A pointer to the character immediately following the last character in the range to be scanned.

Return Value

A pointer to the first character in a range that does not match a specified mask. If no such value exists, the function returns *last*.

Remarks

The member function returns `do_scan_not(maskVal, first, last)`.

Example

```
// ctype_scan_not.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc1 ( "German_Germany" );

    char *string = "Hello, my name is John!";

    const char* i = use_facet<ctype<char> > ( loc1 ).scan_not
        ( ctype_base::alpha, string, string + strlen(string) );
    cout << "First nonalpha character is \"" << *i << "\" at position: "
        << i - string << endl;
}
```

```
First nonalpha character is ", " at position: 5
```

ctype::tolower

Converts a character or a range of characters to lower case.

```
CharType tolower(CharType ch) const;

const CharType *tolower(CharType* first, const CharType* last) const;
```

Parameters

ch

The character to be converted to lower case.

first

A pointer to the first character in the range of characters whose cases are to be converted.

last

A pointer to the character immediately following the last character in the range of characters whose cases are to be converted.

Return Value

The first member function returns the lowercase form of the parameter *ch*. If no lowercase form exists, it returns *ch*.

The second member function returns *last*.

Remarks

The first member function returns `do_tolower(ch)`. The second member function returns `do_tolower(first, last)`.

Example

```
// ctype_tolower.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc1 ( "German_Germany" );

    char string[] = "HELLO, MY NAME IS JOHN";

    use_facet<ctype<char> > ( loc1 ).tolower
        ( string, string + strlen(string) );
    cout << "The lowercase string is: " << string << endl;
}
```

The lowercase string is: hello, my name is john

ctype::toupper

Converts a character or a range of characters to upper case.

```
CharType toupper(CharType ch) const;
const CharType *toupper(CharType* first, const CharType* last) const;
```

Parameters

ch

The character to be converted to uppercase.

first

A pointer to the first character in the range of characters whose cases are to be converted.

last

A pointer to the character immediately following the last character in the range of characters whose cases are to be converted.

Return Value

The first member function returns the uppercase form of the parameter *ch*. If no uppercase form exists, it returns *ch*.

The second member function returns *last*.

Remarks

The first member function returns `do_toupper(ch)`. The second member function returns `do_toupper(first , last)`.

Example

```
// ctype_toupper.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc1 ( "German_Germany" );

    char string[] = "Hello, my name is John";

    use_facet<ctype<char> > ( loc1 ).toupper
        ( string, string + strlen(string) );
    cout << "The uppercase string is: " << string << endl;
}
```

The uppercase string is: HELLO, MY NAME IS JOHN

ctype::widen

Converts a character of type **char** in the native character set to the corresponding character of type `CharType` used by a locale.

```
CharType widen(char byte) const;
const char *widen(const char* first, const char* last, CharType* dest) const;
```

Parameters

byte

The character of type `char` in the native character set to be converted.

first

A pointer to the first character in the range of characters to be converted.

last

A pointer to the character immediately following the last character in the range of characters to be converted.

dest

A pointer to the first character of type `CharType` in the destination range that stores the converted range of characters.

Return Value

The first member function returns the character of type `CharType` that corresponds to the parameter character of native type **char**.

The second member function returns a pointer to the destination range of characters of type `CharType` used by a locale converted from native characters of type **char**.

Remarks

The first member function returns `do_widen(byte)`. The second member function returns `do_widen(first, last, dest)`.

Example

```
// ctype_widen.cpp
// compile with: /EHsc /W3
#include <locale>
#include <iostream>
using namespace std;

int main( )
{
    locale loc1 ( "English" );
    char *str1 = "Hello everyone!";
    wchar_t str2 [16];
    bool result1 = (use_facet<ctype<wchar_t> > ( loc1 ).widen
        ( str1, str1 + strlen(str1), &str2[0] ) != 0); // C4996
    str2[strlen(str1)] = '\0';
    cout << str1 << endl;
    wcout << &str2[0] << endl;

    ctype<wchar_t>::char_type charT;
    charT = use_facet<ctype<char> > ( loc1 ).widen( 'a' );
}
```

```
Hello everyone!
Hello everyone!
```

ctype<char> Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The class is an explicit specialization of template class `ctype<CharType>` to type **char**, describing an object that can serve as a locale facet to characterize various properties of a character of type **char**.

Syntax
