```
template <>
class ctype<char>
: public ctype_base
{
public:
    typedef char _Elem;
    typedef _Elem char_type;
    bool is(
        mask _Maskval,
        _Elem _Ch) const;

    const _Elem* is(
        const _Elem* first,
        const _Elem* last,
        mask* dest) const;

    const _Elem* scan_is(
        mask _Maskval,
        const _Elem* first,
        const _Elem* last) const;

    const _Elem* scan_not(
        mask _Maskval,
        const _Elem* first,
        const _Elem* last) const;

    _Elem tolower(
        _Elem _Ch) const;

    const _Elem* tolower(
        _Elem* first,
        const _Elem* last) const;

    _Elem toupper(
        _Elem _Ch) const;

    const _Elem* toupper(
        _Elem* first,
        const _Elem* last) const;

    _Elem widen(
        char _Byte) const;

    const _Elem* widen(
        const char* first,
        const char* last,
        _Elem* dest) const;

    const _Elem* _Widen_s(
        const char* first,
        const char* last,
        _Elem* dest,
        size_t dest_size) const;
```

```

_Elem narrow(
    _Elem _Ch,
    char _Dflt = '\0') const;

const _Elem* narrow(
    const _Elem* first,
    const _Elem* last,
    char _Dflt,
    char* dest) const;

const _Elem* _Narrow_s(
    const _Elem* first,
    const _Elem* last,
    char _Dflt,
    char* dest,
    size_t dest_size) const;

static locale::id& id;
explicit ctype(
    const mask* _Table = 0,
    bool _Deletetable = false,
    size_t _Refs = 0);

protected:
    virtual ~ctype();
    //other protected members
};

```

Remarks

The explicit specialization differs from the template class in several ways:

- An object of class `ctype< char >` stores a pointer to the first element of a ctype mask table, an array of `UCHAR_MAX + 1` elements of type `ctype_base::mask`. It also stores a Boolean object that indicates whether the array should be deleted (using `operator delete[]`) when the `ctype< Elem >` object is destroyed.
- Its sole public constructor lets you specify `tab`, the ctype mask table, and `del`, the Boolean object that is true if the array should be deleted when the `ctype< char >` object is destroyed, as well as the reference-count parameter `refs`.
- The protected member function `table` returns the stored ctype mask table.
- The static member object `table_size` specifies the minimum number of elements in a ctype mask table.
- The protected static member function `classic_table` (returns the ctype mask table appropriate to the "C" locale.
- There are no protected virtual member functions `do_is`, `do_scan_is`, or `do_scan_not`. The corresponding public member functions perform the equivalent operations themselves.

The member functions `do_narrow` and `do_widen` copy elements unaltered.

Requirements

Header: `<locale>`

Namespace: `std`

[facet Class](#)

[ctype_base Class](#)

[Thread Safety in the C++ Standard Library](#)

ctype_base Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The class serves as a base class for facets of template class [ctype](#). A base class for the ctype class that is used to define enumeration types used to classify or test characters either individually or within entire ranges.

Syntax

```
struct ctype_base : public locale::facet
{
    enum
    {
        alnum,
        alpha,
        cntrl,
        digit,
        graph,
        lower,
        print,
        punct,
        space,
        upper,
        xdigit
    };
    typedef short mask;

    ctype_base( size_t _Refs = 0 );
    ~ctype_base();
};
```

Remarks

It defines an enumeration mask. Each enumeration constant characterizes a different way to classify characters, as defined by the functions with similar names declared in the header `<ctype.h>`. The constants are:

- **space** (function [isspace](#))
- **print** (function [isprint](#))
- **cntrl** (function [iscntrl](#))
- **upper** (function [isupper](#))
- **lower** (function [islower](#))
- **digit** (function [isdigit](#))
- **punct** (function [ispunct](#))
- **xdigit** (function [isxdigit](#))
- **alpha** (function [isalpha](#))
- **alnum** (function [isalnum](#))
- **graph** (function [isgraph](#))

You can characterize a combination of classifications by ORing these constants. In particular, it is always true that **alnum** == (**alpha** | **digit**) and **graph** == (**alnum** | **punct**).

Requirements

Header: <locale>

Namespace: std

[Thread Safety in the C++ Standard Library](#)

ctype_byname Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The derived template class describes an object that can serve as a ctype facet of a given locale, enabling the classification of characters and conversion of characters between case and native and locale specified character sets.

Syntax

```
template <class _Elem>
class ctype_byname : public ctype<_Elem>
{
public:
    explicit ctype_byname(
        const char* _Locname,
        size_t _Refs = 0);

    explicit ctype_byname(
        const string& _Locname,
        size_t _Refs = 0);

protected:
    virtual __CLR_OR_THIS_CALL ~ctype_byname();

};
```

Remarks

Its behavior is determined by the named locale `_Locname`. Each constructor initializes its base object with `ctype<CharType>(_Refs)` or the equivalent for base class `ctype<char>`.

Requirements

Header: <locale>

Namespace: std

See also

[Thread Safety in the C++ Standard Library](#)

locale Class

3/20/2019 • 13 minutes to read • [Edit Online](#)

The class that describes a locale object that encapsulates culture-specific information as a set of facets that collectively define a specific localized environment.

Syntax

```
class locale;
```

Remarks

A facet is a pointer to an object of a class derived from class [facet](#) that has a public object of the form:

```
static locale::id id;
```

You can define an open-ended set of these facets. You can also construct a locale object that designates an arbitrary number of facets.

Predefined groups of these facets represent the [locale categories](#) traditionally managed in the Standard C Library by the function `setlocale`.

Category collate (LC_COLLATE) includes the facets:

```
collate<char>  
collate<wchar_t>
```

Category ctype (LC_CTYPE) includes the facets:

```
ctype<char>  
ctype<wchar_t>  
codecvt<char, char, mbstate_t>  
codecvt<wchar_t, char, mbstate_t>  
codecvt<char16_t, char, mbstate_t>  
codecvt<char32_t, char, mbstate_t>
```

Category monetary (LC_MONETARY) includes the facets:

```
moneypunct<char, false>  
moneypunct<wchar_t, false>  
moneypunct<char, true>  
moneypunct<wchar_t, true>  
money_get<char, istreambuf_iterator<char>>  
money_get<wchar_t, istreambuf_iterator<wchar_t>>  
money_put<char, ostreambuf_iterator<char>>  
money_put<wchar_t, ostreambuf_iterator<wchar_t>>
```

Category numeric (LC_NUMERIC) includes the facets:

```
num_get<char, istreambuf_iterator<char>>
num_get<wchar_t, istreambuf_iterator<wchar_t>>
num_put<char, ostreambuf_iterator<char>>
num_put<wchar_t, ostreambuf_iterator<wchar_t>>
numpunct<char>
numpunct<wchar_t>
```

Category time (LC_TIME) includes the facets:

```
time_get<char, istreambuf_iterator<char>>
time_get<wchar_t, istreambuf_iterator<wchar_t>>
time_put<char, ostreambuf_iterator<char>>
time_put<wchar_t, ostreambuf_iterator<wchar_t>>
```

Category messages (LC_MESSAGES) includes the facets:

```
messages<char>
messages<wchar_t>
```

(The last category is required by Posix, but not the C Standard.)

Some of these predefined facets are used by the iostreams classes, to control the conversion of numeric values to and from text sequences.

An object of class `locale` also stores a locale name as an object of class `string`. Using an invalid locale name to construct a locale facet or a locale object throws an object of class `runtime_error`. The stored locale name is `"*"` if the locale object cannot be certain that a C-style locale corresponds exactly to that represented by the object. Otherwise, you can establish a matching locale within the Standard C Library, for the locale object `Loc`, by calling `setlocale(LC_ALL, Loc.name().c_str())`.

In this implementation, you can also call the static member function:

```
static locale empty();
```

to construct a locale object that has no facets. It is also a transparent locale; if the template functions `has_facet` and `use_facet` cannot find the requested facet in a transparent locale, they consult first the global locale and then, if that is transparent, the classic locale. Thus, you can write:

```
cout.imbue(locale::empty());
```

Subsequent insertions to `cout` are mediated by the current state of the global locale. You can even write:

```
locale loc(locale::empty(),
           locale::classic(),
           locale::numeric);

cout.imbue(loc);
```

Numeric formatting rules for subsequent insertions to `cout` remain the same as in the C locale, even as the global locale supplies changing rules for inserting dates and monetary amounts.

Constructors

CONSTRUCTOR	DESCRIPTION
locale	Creates a locale, or a copy of a locale, or a copy of locale where a facet or a category has been replaced by a facet or category from another locale.

Typedefs

TYPE NAME	DESCRIPTION
category	An integer type that provides bitmask values to denote standard facet families.

Member functions

MEMBER FUNCTION	DESCRIPTION
combine	Inserts a facet from a specified locale into a target locale.
name	Returns the stored locale name.

Static Functions

classic	The static member function returns a locale object that represents the classic C locale.
global	Resets the default local for the program.

Operators

OPERATOR	DESCRIPTION
operator!=	Tests two locales for inequality.
operator()	Compares two <code>basic_string</code> objects.
operator==	Tests two locales for equality.

Classes

CLASS	DESCRIPTION
facet	A class that serves as the base class for all locale facets.
id	The member class provides a unique facet identification used as an index for looking up facets in a locale.

Requirements

Header: <locale>

Namespace: std

locale::category

An integer type that provides bitmask values to denote standard facet families.

```
typedef int category;
static const int collate = LC_COLLATE;
static const int ctype = LC_CTYPE;
static const int monetary = LC_MONETARY;
static const int numeric = LC_NUMERIC;
static const int time = LC_TIME;
static const int messages = LC_MESSAGES;
static const int all = LC_ALL;
static const int none = 0;
```

Remarks

The type is a synonym for an **int** type that can represent a group of distinct elements of a bitmask type local to class locale or can be used to represent any of the corresponding C locale categories. The elements are:

- `collate`, corresponding to the C category LC_COLLATE
- `ctype`, corresponding to the C category LC_CTYPE
- `monetary`, corresponding to the C category LC_MONETARY
- `numeric`, corresponding to the C category LC_NUMERIC
- `time`, corresponding to the C category LC_TIME
- `messages`, corresponding to the Posix category LC_MESSAGES

In addition, two useful values are:

- `none`, corresponding to none of the C categories
- `all`, corresponding to the C union of all categories LC_ALL

You can represent an arbitrary group of categories by using `OR` with these constants, as in `monetary | time`.

locale::classic

The static member function returns a locale object that represents the classic C locale.

```
static const locale& classic();
```

Return Value

A reference to the C locale.

Remarks

The classic C locale is the U.S. English ASCII locale within the Standard C Library that is implicitly used in programs that are not internationalized.

Example

```
// locale_classic.cpp
// compile with: /EHsc
#include <iostream>
#include <string>
#include <locale>

using namespace std;

int main( )
{
    locale loc1( "german" );
    locale loc2 = locale::global( loc1 );
    cout << "The name of the previous locale is: " << loc2.name( )
        << "." << endl;
    cout << "The name of the current locale is: " << loc1.name( )
        << "." << endl;

    if (loc2 == locale::classic( ) )
        cout << "The previous locale was classic." << endl;
    else
        cout << "The previous locale was not classic." << endl;

    if (loc1 == locale::classic( ) )
        cout << "The current locale is classic." << endl;
    else
        cout << "The current locale is not classic." << endl;
}
```

```
The name of the previous locale is: C.
The name of the current locale is: German_Germany.1252.
The previous locale was classic.
The current locale is not classic.
```

locale::combine

Inserts a facet from a specified locale into a target locale.

```
template <class Facet>
locale combine(const locale& Loc) const;
```

Parameters

Loc

The locale containing the facet to be inserted into the target locale.

Return Value

The member function returns a locale object that replaces in or adds to ***this** the facet `Facet` listed in *Loc*.

Example

```

// locale_combine.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <tchar.h>
using namespace std;

int main() {
    locale loc ( "German_germany" );
    _TCHAR * s1 = _T("Das ist wei\x00dfzz."); // \x00df is the German sharp-s; it comes before z in the German
    alphabet
    _TCHAR * s2 = _T("Das ist weizzz.");
    int result1 = use_facet<collate<_TCHAR> > ( loc ).
        compare (s1, &s1[_tcslen( s1 )-1 ], s2, &s2[_tcslen( s2 )-1 ] );
    cout << isalpha (_T ( '\x00df' ), loc ) << result1 << endl;

    locale loc2 ( "C" );
    int result2 = use_facet<collate<_TCHAR> > ( loc2 ).
        compare (s1, &s1[_tcslen( s1 )-1 ], s2, &s2[_tcslen( s2 )-1 ] );
    cout << isalpha (_T ( '\x00df' ), loc2 ) << result2 << endl;

    locale loc3 = loc2.combine<collate<_TCHAR> > (loc);
    int result3 = use_facet<collate<_TCHAR> > ( loc3 ).
        compare (s1, &s1[_tcslen( s1 )-1 ], s2, &s2[_tcslen( s2 )-1 ] );
    cout << isalpha (_T ( '\x00df' ), loc3 ) << result3 << endl;
}

```

facet Class

A class that serves as the base class for all locale facets.

```

class facet {
protected:
    explicit facet(size_t _Refs = 0);
    virtual ~facet();
private:
    facet(const facet&)
    // not defined void operator=(const facet&)
    // not defined
};

```

Remarks

Note that you cannot copy or assign an object of class facet. You can construct and destroy objects derived from class `locale::facet` but not objects of the base class proper. Typically, you construct an object `_Myfac` derived from facet when you construct a locale, as in **localeloc**(`locale::classic` (), **new** `_Myfac`);

In such cases, the constructor for the base class facet should have a zero `_Refs` argument. When the object is no longer needed, it is deleted. Thus, you supply a nonzero `_Refs` argument only in those rare cases where you take responsibility for the lifetime of the object.

locale::global

Resets the default locale for the program. This affects the global locale for both C and C++.

```

static locale global(const locale& Loc);

```

Parameters

Loc

The locale to be used as the default locale by the program.

Return Value

The previous locale before the default locale was reset.

Remarks

At program startup, the global locale is the same as the classic locale. The `global()` function calls `setlocale(LC_ALL, loc.name. c_str())` to establish a matching locale in the Standard C library.

Example

```
// locale_global.cpp
// compile by using: /EHsc
#include <locale>
#include <iostream>
#include <tchar.h>
using namespace std;

int main( )
{
    locale loc ( "German_germany" );
    locale loc1;
    cout << "The initial locale is: " << loc1.name( ) << endl;
    locale loc2 = locale::global ( loc );
    locale loc3;
    cout << "The current locale is: " << loc3.name( ) << endl;
    cout << "The previous locale was: " << loc2.name( ) << endl;
}
```

```
The initial locale is: C
The current locale is: German_Germany.1252
The previous locale was: C
```

id Class

The member class provides a unique facet identification used as an index for looking up facets in a locale.

```
class id
{
    protected:    id();
    private:      id(const id&)
    void operator=(const id&) // not defined
};
```

Remarks

The member class describes the static member object required by each unique locale facet. Note that you cannot copy or assign an object of class `id`.

locale::locale

Creates a locale, or a copy of a locale, or a copy of locale where a facet or a category has been replaced by a facet or category from another locale.

```

locale();

explicit locale(const char* Locname, category Cat = all);
explicit locale(const string& Locname);
locale( const locale& Loc);
locale(const locale& Loc, const locale& Other, category Cat);
locale(const locale& Loc, const char* Locname, category Cat);

template <class Facet>
locale(const locale& Loc, const Facet* Fac);

```

Parameters

Locname

Name of a locale.

Loc

A locale that is to be copied in constructing the new locale.

Other

A locale from which to select a category.

Cat

The category to be substituted into the constructed locale.

Fac

The facet to be substituted into the constructed locale.

Remarks

The first constructor initializes the object to match the global locale. The second and third constructors initialize all the locale categories to have behavior consistent with the locale name *Locname*. The remaining constructors copy *Loc*, with the exceptions noted:

```
locale(const locale& Loc, const locale& Other, category Cat);
```

replaces from *Other* those facets corresponding to a category *C* for which *C* & *Cat* is nonzero.

```
locale(const locale& Loc, const char* Locname, category Cat);
```

```
locale(const locale& Loc, const string& Locname, category Cat);
```

replaces from `locale(Locname, _All)` those facets corresponding to a category *C* for which *C* & *Cat* is nonzero.

```
template<class Facet> locale(const locale& Loc, Facet* Fac);
```

replaces in (or adds to) *Loc* the facet *Fac*, if *Fac* is not a null pointer.

If a locale name *Locname* is a null pointer or otherwise invalid, the function throws [runtime_error](#).

Example

```

// locale_locale.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <tchar.h>
using namespace std;

int main( ) {

    // Second constructor
    locale loc ( "German_germany" );
    _TCHAR * s1 = _T("Das ist wei\x00dfzz."); // \x00df is the German sharp-s, it comes before z in the German
    alphabet
    _TCHAR * s2 = _T("Das ist weizzz.");
    int result1 = use_facet<collate<_TCHAR> > ( loc ).
        compare (s1, &s1[_tcslen( s1 )-1 ], s2, &s2[_tcslen( s2 )-1 ] );
    cout << isalpha (_T ( '\x00df' ), loc ) << result1 << endl;

    // The first (default) constructor
    locale loc2;
    int result2 = use_facet<collate<_TCHAR> > ( loc2 ).
        compare (s1, &s1[_tcslen( s1 )-1 ], s2, &s2[_tcslen( s2 )-1 ] );
    cout << isalpha (_T ( '\x00df' ), loc2 ) << result2 << endl;

    // Third constructor
    locale loc3 (loc2,loc, _M_COLLATE );
    int result3 = use_facet<collate<_TCHAR> > ( loc3 ).
        compare (s1, &s1[_tcslen( s1 )-1 ], s2, &s2[_tcslen( s2 )-1 ] );
    cout << isalpha (_T ( '\x00df' ), loc3 ) << result3 << endl;

    // Fourth constructor
    locale loc4 (loc2, "German_Germany", _M_COLLATE );
    int result4 = use_facet<collate<_TCHAR> > ( loc4 ).
        compare (s1, &s1[_tcslen( s1 )-1 ], s2, &s2[_tcslen( s2 )-1 ] );
    cout << isalpha (_T ( '\x00df' ), loc4 ) << result4 << endl;
}

```

locale::name

Returns the stored locale name.

```
string name() const;
```

Return Value

A string giving the name of the locale.

Example

```
// locale_name.cpp
// compile with: /EHsc
#include <iostream>
#include <string>
#include <locale>

using namespace std;

int main( )
{
    locale loc1( "german" );
    locale loc2 = locale::global( loc1 );
    cout << "The name of the previous locale is: "
         << loc2.name( ) << "." << endl;
    cout << "The name of the current locale is: "
         << loc1.name( ) << "." << endl;
}
```

```
The name of the previous locale is: C.
The name of the current locale is: German_Germany.1252.
```

locale::operator!=

Tests two locales for inequality.

```
bool operator!=(const locale& right) const;
```

Parameters

right

One of the locales to be tested for inequality.

Return Value

A Boolean value that is **true** if the locales are not copies of the same locale; **false** if the locales are copies of the same locale.

Remarks

Two locales are equal if they are the same locale, if one is a copy of the other, or if they have identical names.

Example

```
// locale_op_ne.cpp
// compile with: /EHsc
#include <iostream>
#include <string>
#include <locale>

using namespace std;

int main( )
{
    locale loc1( "German_Germany" );
    locale loc2( "German_Germany" );
    locale loc3( "English" );

    if ( loc1 != loc2 )
        cout << "locales loc1 (" << loc1.name( )
        << ") and\n loc2 (" << loc2.name( ) << ") are not equal." << endl;
    else
        cout << "locales loc1 (" << loc1.name( )
        << ") and\n loc2 (" << loc2.name( ) << ") are equal." << endl;

    if ( loc1 != loc3 )
        cout << "locales loc1 (" << loc1.name( )
        << ") and\n loc3 (" << loc3.name( ) << ") are not equal." << endl;
    else
        cout << "locales loc1 (" << loc1.name( )
        << ") and\n loc3 (" << loc3.name( ) << ") are equal." << endl;
}
```

```
locales loc1 (German_Germany.1252) and
loc2 (German_Germany.1252) are equal.
locales loc1 (German_Germany.1252) and
loc3 (English_United States.1252) are not equal.
```

locale::operator()

Compares two `basic_string` objects.

```
template <class CharType, class Traits, class Allocator>
bool operator()(
    const basic_string<CharType, Traits, Allocator>& left,
    const basic_string<CharType, Traits, Allocator>& right) const;
```

Parameters

left

The left string.

right

The right string.

Return Value

The member function returns:

- -1 if the first sequence compares less than the second sequence.
- +1 if the second sequence compares less than the first sequence.
- 0 if the sequences are equivalent.

Remarks

The member function effectively executes:

```
const collate<CharType>& fac = use_fac<collate<CharType>>(*this);

return (fac.compare(left.begin(), left.end(), right.begin(), right.end()) < 0);
```

Thus, you can use a locale object as a function object.

Example

```
// locale_op_compare.cpp
// compile with: /EHsc
#include <iostream>
#include <string>
#include <locale>

int main( )
{
    using namespace std;
    wchar_t *sa = L"ztesting";
    wchar_t *sb = L"\0x00DFtesting";
    basic_string<wchar_t> a( sa );
    basic_string<wchar_t> b( sb );

    locale loc( "German_Germany" );
    cout << loc( a,b ) << endl;

    const collate<wchar_t>& fac = use_facet<collate<wchar_t>>( loc );
    cout << ( fac.compare( sa, sa + a.length( ),
        sb, sb + b.length( ) ) < 0 ) << endl;
}
```

```
0
0
```

locale::operator==

Tests two locales for equality.

```
bool operator==(const locale& right) const;
```

Parameters

right

One of the locales to be tested for equality.

Return Value

A Boolean value that is **true** if the locales are copies of the same locale; **false** if the locales are not copies of the same locale.

Remarks

Two locales are equal if they are the same locale, if one is a copy of the other, or if they have identical names.

Example

```

// locale_op_eq.cpp
// compile with: /EHsc
#include <iostream>
#include <string>
#include <locale>

using namespace std;

int main( )
{
    locale loc1( "German_Germany" );
    locale loc2( "German_Germany" );
    locale loc3( "English" );

    if ( loc1 == loc2 )
        cout << "locales loc1 ( " << loc1.name( )
        << " )\n and loc2 ( " << loc2.name( ) << " ) are equal."
        << endl;
    else
        cout << "locales loc1 ( " << loc1.name( )
        << " )\n and loc2 ( " << loc2.name( ) << " ) are not equal."
        << endl;

    if ( loc1 == loc3 )
        cout << "locales loc1 ( " << loc1.name( )
        << " )\n and loc3 ( " << loc3.name( ) << " ) are equal."
        << endl;
    else
        cout << "locales loc1 ( " << loc1.name( )
        << " )\n and loc3 ( " << loc3.name( ) << " ) are not equal."
        << endl;
}

```

```

locales loc1 (German_Germany.1252)
and loc2 (German_Germany.1252) are equal.
locales loc1 (German_Germany.1252)
and loc3 (English_United States.1252) are not equal.

```

messages Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

The template class describes an object that can serve as a locale facet to retrieve localized messages from a catalog of internationalized messages for a given locale.

Currently, while the messages class is implemented, there are no messages.

Syntax

```
template <class CharType>
class messages : public messages_base;
```

Parameters

CharType

The type used within a program to encode characters in a locale.

Remarks

As with any locale facet, the static object ID has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in **id**.

This facet basically opens a catalog of messages defined in the base class `messages_base`, retrieves the information required, and closes the catalog.

Constructors

CONSTRUCTOR	DESCRIPTION
messages	The message facet constructor function.

Typedefs

TYPE NAME	DESCRIPTION
char_type	A character type that is used display messages.
string_type	A type that describes a string of type <code>basic_string</code> containing characters of type <code>CharType</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
close	Closes the message catalog.
do_close	A virtual function called to lose the message catalog.
do_get	A virtual function called to retrieve the message catalog.

MEMBER FUNCTION	DESCRIPTION
do_open	A virtual function called to open the message catalog.
get	Retrieves the message catalog.
open	Opens the message catalog.

Requirements

Header: <locale>

Namespace: std

messages::char_type

A character type that is used display messages.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter **CharType**.

messages::close

Closes the message catalog.

```
void close(catalog _Catval) const;
```

Parameters

_Catval

The catalog to be closed.

Remarks

The member function calls [do_close](#)(*_Catval*).

messages::do_close

A virtual function called to lose the message catalog.

```
virtual void do_close(catalog _Catval) const;
```

Parameters

_Catval

The catalog to be closed.

Remarks

The protected member function closes the message catalog *_Catval*, which must have been opened by an earlier call to [do_open](#).

_Catval must be obtained from a previously opened catalog that is not closed.

Example

See the example for [close](#), which calls `do_close` .

messages::do_get

A virtual function called to retrieve the message catalog.

```
virtual string_type do_get(  
    catalog _Catval,  
    int _Set,  
    int _Message,  
    const string_type& _Dfault) const;
```

Parameters

_Catval

The identification value specifying the message catalog to be searched.

_Set

The first identified used to locate a message in a message catalog.

_Message

The second identified used to locate a message in a message catalog.

_Dfault

The string to be returned on failure.

Return Value

It returns a copy of *_Dfault* on failure. Otherwise, it returns a copy of the specified message sequence.

Remarks

The protected member function tries to obtain a message sequence from the message catalog *_Catval*. It may make use of *_Set*, *_Message*, and *_Dfault* in doing so.

Example

See the example for [get](#), which calls `do_get` .

messages::do_open

A virtual function called to open the message catalog.

```
virtual catalog do_open(  
    const string& _Catname,  
    const locale& _Loc) const;
```

Parameters

_Catname

The name of the catalog to be searched.

_Loc

The locale being searched for in the catalog.

Return Value

It returns a value that compares less than zero on failure. Otherwise, the returned value can be used as the first argument on a later call to [get](#).

Remarks

The protected member function tries to open a message catalog whose name is *_Catname*. It may make use of the *locale_Loc* in doing so

The return value should be used as the argument on a later call to [close](#).

Example

See the example for [open](#), which calls `do_open`.

messages::get

Retrieves the message catalog.

```
string_type get(
    catalog _CatVal,
    int _Set,
    int _Message,
    const string_type& _Dfault) const;
```

Parameters

_Catval

The identification value specifying the message catalog to be searched.

_Set

The first identified used to locate a message in a message catalog.

_Message

The second identified used to locate a message in a message catalog.

_Dfault

The string to be returned on failure.

Return Value

It returns a copy of *_Dfault* on failure. Otherwise, it returns a copy of the specified message sequence.

Remarks

The member function returns [do_get](#)(`_Catval` , `_Set` , `_Message` , `_Dfault`).

messages::messages

The message facet constructor function.

```
explicit messages(
    size_t _Refs = 0);

protected: messages(
    const char* _Locname,
    size_t _Refs = 0);
```

Parameters

_Refs

Integer value used to specify the type of memory management for the object.

_Locname

The name of the locale.

Remarks

The possible values for the `_Refs` parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.
- > 1: These values are not defined.

No direct examples are possible, because the destructor is protected.

The constructor initializes its base object with `locale::facet(_Refs)`.

messages::open

Opens the message catalog.

```
catalog open(  
    const string& _Catname,  
    const locale& _Loc) const;
```

Parameters

`_Catname`

The name of the catalog to be searched.

`_Loc`

The locale being searched for in the catalog.

Return Value

It returns a value that compares less than zero on failure. Otherwise, the returned value can be used as the first argument on a later call to [get](#).

Remarks

The member function returns `do_open(_Catname , _Loc)`.

messages::string_type

A type that describes a string of type `basic_string` containing characters of type `CharType`.

```
typedef basic_string<CharType, Traits, Allocator> string_type;
```

Remarks

The type describes a specialization of template class [basic_string](#) whose objects can store copies of the message sequences.

See also

[<locale>](#)

[messages_base](#) Class

[Thread Safety in the C++ Standard Library](#)

messages_base Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The base class describes an **int** type for the catalog of messages.

Syntax

```
struct messages_base : locale::facet {  
    typedef int catalog;  
    explicit messages_base(size_t _Refs = 0)  
};
```

Remarks

The type catalog is a synonym for type **int** that describes the possible return values from `messages::do_open`.

Requirements

Header: <locale>

Namespace: std

See also

[Thread Safety in the C++ Standard Library](#)

messages_byname Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The derived template class describes an object that can serve as a message facet of a given locale, enabling the retrieval of localized messages.

Syntax

```
template <class CharType>
class messages_byname : public messages<CharType> {
public:
    explicit messages_byname(
        const char *_Locname,
        size_t _Refs = 0);

    explicit messages_byname(
        const string& _Locname,
        size_t _Refs = 0);

protected:
    virtual ~messages_byname();

};
```

Parameters

_Locname

A named locale.

_Refs

An initial reference count.

Remarks

Its behavior is determined by the named locale *_Locname*. Each constructor initializes its base object with `messages<CharType>(_Refs)`.

Requirements

Header: <locale>

Namespace: std

See also

[Thread Safety in the C++ Standard Library](#)

money_base Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The class describes an enumeration and a structure common to all specializations of template class [moneypunct](#).

Syntax

```
struct pattern
{
    char field[_PATTERN_FIELD_SIZE];
};
```

Remarks

The enumeration `part` describes the possible values in elements of the array field in the structure pattern. The values of `part` are:

- `none` to match zero or more spaces or generate nothing.
- `sign` to match or generate a positive or negative sign.
- `space` to match zero or more spaces or generate a space.
- `symbol` to match or generate a currency symbol.
- `value` to match or generate a monetary value.

Requirements

Header: <locale>

Namespace: std

See also

[Thread Safety in the C++ Standard Library](#)

money_get Class

10/31/2018 • 7 minutes to read • [Edit Online](#)

The template class describes an object that can serve as a locale facet to control conversions of sequences of type `CharType` to monetary values.

Syntax

```
template <class CharType, class InputIterator = istreambuf_iterator<CharType>>
class money_get : public locale::facet;
```

Parameters

CharType

The type used within a program to encode characters in a locale.

InputIterator

The type of iterator from which the get functions read their input.

Remarks

As with any locale facet, the static object `ID` has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in **`id`**.

Constructors

CONSTRUCTOR	DESCRIPTION
money_get	The constructor for objects of type <code>money_get</code> that are used to extract numerical values from sequences representing monetary values.

Typedefs

TYPE NAME	DESCRIPTION
char_type	A type that is used to describe a character used by a locale.
iter_type	A type that describes an input iterator.
string_type	A type that describes a string containing characters of type <code>CharType</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
do_get	A virtual function called to extracts a numerical value from a character sequence that represents a monetary value.

MEMBER FUNCTION	DESCRIPTION
get	Extracts a numerical value from a character sequence that represents a monetary value.

Requirements

Header: <locale>

Namespace: std

money_get::char_type

A type that is used to describe a character used by a locale.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter *CharType*.

money_get::do_get

Virtual function called to extracts a numerical value from a character sequence that represents a monetary value.

```
virtual iter_type do_get(iter_type first,
    iter_type last,
    bool Intl,
    ios_base& Iosbase,
    ios_base::iostate& State,
    long double& val) const virtual iter_type do_get(iter_type first,
    iter_type last,
    bool Intl,
    ios_base& Iosbase,
    ios_base::iostate& State,
    string_type& val) const
```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

Intl

A Boolean value indicating the type of currency symbol expected in the sequence: **true** if international, **false** if domestic.

Iosbase

A format flag which when set indicates that the currency symbol is optional; otherwise, it is required.

State

Sets the appropriate bitmask elements for the stream state according to whether the operations succeeded or not.

val

A string storing the converted sequence.

Return Value

An input iterator addressing the first element beyond the monetary input field.

Remarks

The first virtual protected member function tries to match sequential elements beginning at first in the sequence [first, last) until it has recognized a complete, nonempty monetary input field. If successful, it converts this field to a sequence of one or more decimal digits, optionally preceded by a minus sign (-), to represent the amount and stores the result in the `string_type` object *val*. It returns an iterator designating the first element beyond the monetary input field. Otherwise, the function stores an empty sequence in *val* and sets `ios_base::failbit` in *State*. It returns an iterator designating the first element beyond any prefix of a valid monetary input field. In either case, if the return value equals `last`, the function sets `ios_base::eofbit` in *State*.

The second virtual protected member function behaves the same as the first, except that if successful it converts the optionally signed digit sequence to a value of type **long double** and stores that value in *val*.

The format of a monetary input field is determined by the `locale facet` *fac* returned by the effective call `use_facet < money_punct < CharType, intl > > (iosbase.getloc())`.

Specifically:

- **fac.neg_format** determines the order in which components of the field occur.
- **fac.curr_symbol** determines the sequence of elements that constitutes a currency symbol.
- **fac.positive_sign** determines the sequence of elements that constitutes a positive sign.
- **fac.negative_sign** determines the sequence of elements that constitutes a negative sign.
- **fac.grouping** determines how digits are grouped to the left of any decimal point.
- **fac.thousands_sep** determines the element that separates groups of digits to the left of any decimal point.
- **fac.decimal_point** determines the element that separates the integer digits from the fraction digits.
- **fac.frac_digits** determines the number of significant fraction digits to the right of any decimal point. When parsing a monetary amount with more fraction digits than are called for by `frac_digits`, `do_get` stops parsing after consuming at most `frac_digits` characters.

If the sign string (**fac.negative_sign** or **fac.positive_sign**) has more than one element, only the first element is matched where the element equal to **money_base::sign** appears in the format pattern (**fac.neg_format**). Any remaining elements are matched at the end of the monetary input field. If neither string has a first element that matches the next element in the monetary input field, the sign string is taken as empty and the sign is positive.

If **iosbase.flags** & **showbase** is nonzero, the string **fac.curr_symbol** must match where the element equal to **money_base::symbol** appears in the format pattern. Otherwise, if **money_base::symbol** occurs at the end of the format pattern, and if no elements of the sign string remain to be matched, the currency symbol is not matched. Otherwise, the currency symbol is optionally matched.

If no instances of **fac.thousands_sep** occur in the value portion of the monetary input field (where the element equal to **money_base::value** appears in the format pattern), no grouping constraint is imposed. Otherwise, any grouping constraints imposed by **fac.grouping** is enforced. Note that the resulting digit sequence represents an integer whose low-order **fac.frac_digits** decimal digits are considered to the right of the decimal point.

Arbitrary white space is matched where the element equal to **money_base::space** appears in the format pattern, if it appears other than at the end of the format pattern. Otherwise, no internal white space is matched. An element *ch* is considered white space if `use_facet < ctype < CharType > > (iosbase.getloc()). is(ctype_base::space, ch)` is **true**.

Example

See the example for [get](#), which calls `do_get`.

money_get::get

Extracts a numerical value from a character sequence that represents a monetary value.

```
iter_type get(iter_type first,
              iter_type last,
              bool Intl,
              ios_base& Iosbase,
              ios_base::iostate& State,
              long double& val) const;

iter_type get(iter_type first,
              iter_type last,
              bool Intl,
              ios_base& Iosbase,
              ios_base::iostate& State,
              string_type& val) const;
```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

Intl

A Boolean value indicating the type of currency symbol expected in the sequence: **true** if international, **false** if domestic.

Iosbase

A format flag which when set indicates that the currency symbol is optional; otherwise, it is required

State

Sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

val

A string storing the converted sequence.

Return Value

An input iterator addressing the first element beyond the monetary input field.

Remarks

Both member functions return `do_get`(`first`, `last`, `Intl`, `Iosbase`, `State`, `val`).

Example

```

// money_get_get.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;

int main( )
{
    locale loc( "german_germany" );

    basic_stringstream< char > psz;
    psz << use_facet<moneypunct<char, 1> >(loc).curr_symbol() << "-1.000,56";
    basic_stringstream< char > psz2;
    psz2 << "-100056" << use_facet<moneypunct<char, 1> >(loc).curr_symbol();

    ios_base::iostate st = 0;
    long double fVal;

    psz.flags( psz.flags( )|ios_base::showbase );
    // Which forced the READING the currency symbol
    psz.imbue(loc);
    use_facet < money_get < char > >( loc ).
        get( basic_istream<char>::_Iter( psz.rdbuf( ) ),
            basic_istream<char>::_Iter( 0 ), true, psz, st, fVal );

    if ( st & ios_base::failbit )
        cout << "money_get(" << psz.str( ) << ", intl = 1) FAILED"
            << endl;
    else
        cout << "money_get(" << psz.str( ) << ", intl = 1) = "
            << fVal/100.0 << endl;

    use_facet < money_get < char > >( loc ).
        get(basic_istream<char>::_Iter(psz2.rdbuf( )),
            basic_istream<char>::_Iter(0), false, psz2, st, fVal);

    if ( st & ios_base::failbit )
        cout << "money_get(" << psz2.str( ) << ", intl = 0) FAILED"
            << endl;
    else
        cout << "money_get(" << psz2.str( ) << ", intl = 0) = "
            << fVal/100.0 << endl;
};

```

money_get::iter_type

A type that describes an input iterator.

```
typedef InputIterator iter_type;
```

Remarks

The type is a synonym for the template parameter **InputIterator**.

money_get::money_get

The constructor for objects of type `money_get` that are used to extract numerical values from sequences representing monetary values.

```
explicit money_get(size_t _Refs = 0);
```

Parameters

_Refs

Integer value used to specify the type of memory management for the object.

Remarks

The possible values for the *_Refs* parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.
- > 1: These values are not defined.

No direct examples are possible, because the destructor is protected.

The constructor initializes its base object with **locale::facet**(*_Refs*).

money_get::string_type

A type that describes a string containing characters of type **CharType**.

```
typedef basic_string<CharType, Traits, Allocator> string_type;
```

Remarks

The type describes a specialization of template class [basic_string](#).

See also

[<locale>](#)

[facet](#) Class

[Thread Safety in the C++ Standard Library](#)

money_put Class

11/2/2018 • 6 minutes to read • [Edit Online](#)

The template class describes an object that can serve as a locale facet to control conversions of monetary values to sequences of type `CharType`.

Syntax

```
template <class CharType,  
         class OutputIterator = ostreambuf_iterator<CharType>>  
class money_put : public locale::facet;
```

Parameters

CharType

The type used within a program to encode characters in a locale.

OutputIterator

The type of iterator to which the monetary put functions write their output.

Remarks

As with any locale facet, the static object `ID` has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in **`id`**.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>money_put</code>	The constructor for objects of type <code>money_put</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>char_type</code>	A type that is used to describe a character used by a locale.
<code>iter_type</code>	A type that describes an output iterator.
<code>string_type</code>	A type that describes a string containing characters of type <code>CharType</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>do_put</code>	A virtual function called to convert either number or a string to a character sequence that represents a monetary value.
<code>put</code>	Converts either number or a string to a character sequence that represents a monetary value.

Requirements

Header: <locale>

Namespace: std

money_put::char_type

A type that is used to describe a character used by a locale.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter **CharType**.

money_put::do_put

A virtual function called to convert either number or a string to a character sequence that represents a monetary value.

```
virtual iter_type do_put(
    iter_type next,
    bool _Intl,
    ios_base& _Iosbase,
    CharType _Fill,
    const string_type& val) const;

virtual iter_type do_put(
    iter_type next,
    bool _Intl,
    ios_base& _Iosbase,
    CharType _Fill,
    long double val) const;
```

Parameters

next

An iterator addressing the first element of the inserted string.

_Intl

A Boolean value indicating the type of currency symbol expected in the sequence: **true** if international, **false** if domestic.

_Iosbase

A format flag which when set indicates that the currency symbol is optional; otherwise, it is required

_Fill

A character which is used for spacing.

val

A string object to be converted.

Return Value

An output iterator the addresses the position one beyond the last element produced.

Remarks

The first virtual protected member function generates sequential elements beginning at *next* to produce a monetary output field from the [string_type](#) object *val*. The sequence controlled by *val* must begin with one or

more decimal digits, optionally preceded by a minus sign (-), which represents the amount. The function returns an iterator designating the first element beyond the generated monetary output field.

The second virtual protected member function behaves the same as the first, except that it effectively first converts *val* to a sequence of decimal digits, optionally preceded by a minus sign, then converts that sequence as above.

The format of a monetary output field is determined by the [locale facet](#) `fac` returned by the (effective) call `use_facet < money_punct < CharType, intl > > (iosbase.getloc)`.

Specifically:

- **fac.** [pos_format](#) determines the order in which components of the field are generated for a nonnegative value.
- **fac.** [neg_format](#) determines the order in which components of the field are generated for a negative value.
- **fac.** [curr_symbol](#) determines the sequence of elements to generate for a currency symbol.
- **fac.** [positive_sign](#) determines the sequence of elements to generate for a positive sign.
- **fac.** [negative_sign](#) determines the sequence of elements to generate for a negative sign.
- **fac.** [grouping](#) determines how digits are grouped to the left of any decimal point.
- **fac.** [thousands_sep](#) determines the element that separates groups of digits to the left of any decimal point.
- **fac.** [decimal_point](#) determines the element that separates the integer digits from any fraction digits.
- **fac.** [frac_digits](#) determines the number of significant fraction digits to the right of any decimal point.

If the sign string (**fac.** [negative_sign](#) or **fac.** [positive_sign](#)) has more than one element, only the first element is generated where the element equal to **money_base::sign** appears in the format pattern (**fac.** [neg_format](#) or **fac.** [pos_format](#)). Any remaining elements are generated at the end of the monetary output field.

If **iosbase.flags** & **showbase** is nonzero, the string **fac.** [curr_symbol](#) is generated where the element equal to **money_base::symbol** appears in the format pattern. Otherwise, no currency symbol is generated.

If no grouping constraints are imposed by **fac.grouping** (its first element has the value `CHAR_MAX`), then no instances of **fac.** [thousands_sep](#) are generated in the value portion of the monetary output field (where the element equal to **money_base::value** appears in the format pattern). If **fac.** [frac_digits](#) is zero, then no instance of **fac.** [decimal_point](#) is generated after the decimal digits. Otherwise, the resulting monetary output field places the low-order **fac.** [frac_digits](#) decimal digits to the right of the decimal point.

Padding occurs as for any numeric output field, except that if **iosbase.flags** & **iosbase.internal** is nonzero, any internal padding is generated where the element equal to **money_base::space** appears in the format pattern, if it does appear. Otherwise, internal padding occurs before the generated sequence. The padding character is **fill**.

The function calls **iosbase.width**(0) to reset the field width to zero.

Example

See the example for [put](#), where the virtual member function is called by **put**.

money_put::iter_type

A type that describes an output iterator.

```
typedef OutputIterator iter_type;
```

Remarks

The type is a synonym for the template parameter **OutputIterator**.

money_put::money_put

The constructor for objects of type `money_put`.

```
explicit money_put(size_t _Refs = 0);
```

Parameters

_Refs

Integer value used to specify the type of memory management for the object.

Remarks

The possible values for the *_Refs* parameter and their significance are:

- 0: the lifetime of the object is managed by the locales that contain it.
- 1: the lifetime of the object must be manually managed.
- > 1: these values are not defined.

No direct examples are possible, because the destructor is protected.

The constructor initializes its base object with **locale::facet**(`_Refs`).

money_put::put

Converts either number or a string to a character sequence that represents a monetary value.

```
iter_type put(
    iter_type next,
    bool _Intl,
    ios_base& _Iosbase,
    CharType _Fill,
    const string_type& val) const;

iter_type put(
    iter_type next,
    bool _Intl,
    ios_base& _Iosbase,
    CharType _Fill,
    long double val) const;
```

Parameters

next

An iterator addressing the first element of the inserted string.

_Intl

A Boolean value indicating the type of currency symbol expected in the sequence: **true** if international, **false** if domestic.

_Iosbase

A format flag which when set indicates that the currency symbol is optional; otherwise, it is required

_Fill

A character which is used for spacing.

val

A string object to be converted.

Return Value

An output iterator the addresses the position one beyond the last element produced.

Remarks

Both member functions return `do_put(next, _Intl, _Iosbase, _Fill, val)`.

Example

```
// money_put_put.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>

int main()
{
    std::locale loc( "german_germany" );
    std::basic_stringstream<char> psz;

    psz.imbue(loc);
    psz.flags(psz.flags() | std::ios_base::showbase); // force the printing of the currency symbol
    std::use_facet<std::money_put<char> >(loc).put(std::basic_ostream<char>::_Iter(psz.rdbuf()), true, psz, '
', 100012);
    if (psz.fail())
        std::cout << "money_put() FAILED" << std::endl;
    else
        std::cout << "money_put() = \"" << psz.rdbuf()->str() << "\"" << std::endl;
}
```

```
money_put() = "EUR1.000,12"
```

money_put::string_type

A type that describes a string containing characters of type `CharType` .

```
typedef basic_string<CharType, Traits, Allocator> string_type;
```

Remarks

The type describes a specialization of template class `basic_string` whose objects can store sequences of elements from the source sequence.

[Thread Safety in the C++ Standard Library](#)

moneypunct Class

10/31/2018 • 14 minutes to read • [Edit Online](#)

The template class describes an object that can serve as a locale facet to describe the sequences of type *CharType* used to represent a monetary input field or a monetary output field. If the template parameter *Intl* is *true*, international conventions are observed.

Syntax

```
template <class CharType, bool Intl>
class moneypunct;
```

Parameters

CharType

The type used within a program to encode characters.

Intl

A flag specifying whether international conventions are to be observed.

Remarks

As with any locale facet, the static object *ID* has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in **id**.

The const static object *intl* stores the value of the template parameter *Intl*.

Constructors

CONSTRUCTOR	DESCRIPTION
moneypunct	Constructor of objects of type <code>moneypunct</code> .

Typedefs

TYPE NAME	DESCRIPTION
char_type	A type that is used to describe a character used by a locale.
string_type	A type that describes a string containing characters of type <code>CharType</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
curr_symbol	Returns a locale-specific sequence of elements to use as a currency symbol.
decimal_point	Returns a locale-specific sequence of elements to use as a decimal point symbol.

MEMBER FUNCTION	DESCRIPTION
do_curr_symbol	A protected virtual member function that returns a locale-specific sequence of elements to use as a currency symbol.
do_decimal_point	A protected virtual member function that is called to return a locale-specific sequence of elements to use as a decimal point symbol.
do_frac_digits	The protected virtual member function returns a locale-specific count of the number of digits to display to the right of any decimal point.
do_grouping	The protected virtual member function returns a locale-specific rule for determining how digits are grouped to the left of any decimal point.
do_neg_format	A protected virtual member function that is called to return a locale-specific rule for formatting outputs with negative amounts.
do_negative_sign	A protected virtual member function that is called to return a locale-specific sequence of elements to use as a negative sign symbol.
do_pos_format	A protected virtual member function that is called to return a locale-specific rule for formatting outputs with positive amounts.
do_positive_sign	A protected virtual member function that is called to return a locale-specific sequence of elements to use as a positive sign symbol.
do_thousands_sep	A protected virtual member function that is called to return a locale-specific sequence of elements to use as a thousands separator symbol.
frac_digits	Returns a locale-specific count of the number of digits to display to the right of any decimal point.
grouping	Returns a locale-specific rule for determining how digits are grouped to the left of any decimal point.
neg_format	Returns a locale-specific rule for formatting outputs with negative amounts.
negative_sign	Returns a locale-specific sequence of elements to use as a negative sign symbol.
pos_format	Returns a locale-specific rule for formatting outputs with positive amounts.
positive_sign	Returns a locale-specific sequence of elements to use as a positive sign symbol.
thousands_sep	Returns a locale-specific sequence of elements to use as a thousands separator symbol.

MEMBER FUNCTION	DESCRIPTION
-----------------	-------------

Requirements

Header: <locale>

Namespace: std

moneypunct::char_type

A type that is used to describe a character used by a locale.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter **CharType**.

moneypunct::curr_symbol

Returns a locale-specific sequence of elements to use as a currency symbol.

```
string_type curr_symbol() const;
```

Return Value

A string containing the currency symbol.

Remarks

The member function returns [do_curr_symbol](#).

Example

```
// moneypunct_curr_symbol.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "german_germany" );

    const moneypunct< char, true > &mpunct = use_facet< moneypunct< char, true >>(loc);
    cout << loc.name( ) << " international currency symbol "<< mpunct.curr_symbol( ) << endl;

    const moneypunct< char, false> &mpunct2 = use_facet< moneypunct< char, false>>(loc);
    cout << loc.name( ) << " domestic currency symbol "<< mpunct2.curr_symbol( ) << endl;
};
```

moneypunct::decimal_point

Returns a locale-specific sequence of elements to use as a decimal point symbol.

```
CharType decimal_point() const;
```

Return Value

A locale-specific sequence of elements to use as a decimal point symbol.

Remarks

The member function returns [do_decimal_point](#).

Example

```
// moneypunct_decimal_pt.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc("german_germany");

    const moneypunct < char, true > &mpunct = use_facet
        < moneypunct < char, true > >(loc);
    cout << loc.name( ) << " international decimal point "
        << mpunct.decimal_point( ) << endl;

    const moneypunct < char, false> &mpunct2 = use_facet
        < moneypunct < char, false> >(loc);
    cout << loc.name( ) << " domestic decimal point "
        << mpunct2.decimal_point( ) << endl;
}
```

```
German_Germany.1252 international decimal point ,
German_Germany.1252 domestic decimal point ,
```

moneypunct::do_curr_symbol

A protected virtual member function that returns a locale-specific sequence of elements to use as a currency symbol.

```
virtual string_type do_curr_symbol() const;
```

Return Value

A locale-specific sequence of elements to use as a decimal point symbol.

Example

See the example for [curr_symbol](#), where the virtual member function is called by `curr_symbol`.

moneypunct::do_decimal_point

A protected virtual member function that returns a locale-specific sequence of elements to use as a decimal point symbol.

```
virtual CharType do_decimal_point() const;
```

Return Value

A locale-specific sequence of elements to use as a decimal point symbol.

Example

See the example for [decimal_point](#), where the virtual member function is called by `decimal_point`.

moneypunct::do_frac_digits

A protected virtual member function that returns a locale-specific count of the number of digits to display to the right of any decimal point.

```
virtual int do_frac_digits() const;
```

Return Value

A locale-specific count of the number of digits to display to the right of any decimal point.

Example

See the example for [frac_digits](#), where the virtual member function is called by `frac_digits`.

moneypunct::do_grouping

A protected virtual member function that returns a locale-specific rule for determining how digits are grouped to the left of any decimal point.

```
virtual string do_grouping() const;
```

Return Value

A locale-specific rule for determining how digits are grouped to the left of any decimal point.

Example

See the example for [grouping](#), where the virtual member function is called by `grouping`.

moneypunct::do_neg_format

A protected virtual member function that is called to return a locale-specific rule for formatting outputs with negative amounts.

```
virtual pattern do_neg_format() const;
```

Return Value

The protected virtual member function returns a locale-specific rule for determining how to generate a monetary output field for a negative amount. Each of the four elements of `pattern::field` can have the values:

- `none` to match zero or more spaces or generate nothing.
- `sign` to match or generate a positive or negative sign.
- `space` to match zero or more spaces or generate a space.
- `symbol` to match or generate a currency symbol.
- `value` to match or generate a monetary value.

Components of a monetary output field are generated and components of a monetary input field are matched in the order in which these elements appear in `pattern::field`. Each of the values `sign`, `symbol`, `value`, and either `none` or `space` must appear exactly once. The value `none` must not appear first. The value `space` **must** not appear first or last. If `Intl` is true, the order is `symbol`, `sign`, `none`, then `value`.

The template version of `moneypunct` < **CharType**, **Intl** > returns `{ money_base::symbol, money_base::sign, money_base::value, money_base::none }`.

Example

See the example for [neg_format](#), where the virtual member function is called by `neg_format`.

moneypunct::do_negative_sign

A protected virtual member function that is called to return a locale-specific sequence of elements to use as a negative sign symbol.

```
virtual string_type do_negative_sign() const;
```

Return Value

A locale-specific sequence of elements to use as a negative sign.

Example

See the example for [negative_sign](#), where the virtual member function is called by `negative_sign`.

moneypunct::do_pos_format

A protected virtual member function that is called to return a locale-specific rule for formatting outputs with positive amounts.

```
virtual pattern do_pos_format() const;
```

Return Value

The protected virtual member function returns a locale-specific rule for determining how to generate a monetary output field for a positive amount. (It also determines how to match the components of a monetary input field.) The encoding is the same as for [do_neg_format](#).

The template version of `moneypunct` < **CharType**, **InputIterator** > returns `{ money_base::symbol, money_base::sign, money_base::value, money_base::none }`.

Example

See the example for [pos_format](#), where the virtual member function is called by `pos_format`.

moneypunct::do_positive_sign

A protected virtual member function that returns a locale-specific sequence of elements to use as a positive sign.

```
virtual string_type do_positive_sign() const;
```

Return Value

A locale-specific sequence of elements to use as a positive sign.

Example

See the example for [positive_sign](#), where the virtual member function is called by `positive_sign`.

money_punct::do_thousands_sep

A protected virtual member function that returns a locale-specific element to use as a group separator to the left of any decimal point.

```
virtual CharType do_thousands_sep() const;
```

Return Value

A locale-specific element to use as a group separator to the left of any decimal point.

Example

See the example for [thousands_sep](#), where the virtual member function is called by `thousands_sep`.

money_punct::frac_digits

Returns a locale-specific count of the number of digits to display to the right of any decimal point.

```
int frac_digits() const;
```

Return Value

A locale-specific count of the number of digits to display to the right of any decimal point.

Remarks

The member function returns [do_frac_digits](#).

Example

```

// moneypunct_frac_digits.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "german_germany" );

    const moneypunct <char, true> &mpunct =
        use_facet <moneypunct <char, true> >(loc);
    for (unsigned int i = 0; i < mpunct.grouping( ).length( ); i++ )
    {
        cout << loc.name( ) << " international grouping:\n the "
            << i << "th group to the left of the radix character "
            << "is of size " << (int)(mpunct.grouping ( )[i])
            << endl;
    }
    cout << loc.name( ) << " international frac_digits\n to the right"
        << " of the radix character: "
        << mpunct.frac_digits ( ) << endl << endl;

    const moneypunct <char, false> &mpunct2 =
        use_facet <moneypunct <char, false> >(loc);
    for (unsigned int i = 0; i < mpunct2.grouping( ).length( ); i++ )
    {
        cout << loc.name( ) << " domestic grouping:\n the "
            << i << "th group to the left of the radix character "
            << "is of size " << (int)(mpunct2.grouping ( )[i])
            << endl;
    }
    cout << loc.name( ) << " domestic frac_digits\n to the right"
        << " of the radix character: "
        << mpunct2.frac_digits ( ) << endl << endl;
}

```

```

German_Germany.1252 international grouping:
the 0th group to the left of the radix character is of size 3
German_Germany.1252 international frac_digits
to the right of the radix character: 2

German_Germany.1252 domestic grouping:
the 0th group to the left of the radix character is of size 3
German_Germany.1252 domestic frac_digits
to the right of the radix character: 2

```

moneypunct::grouping

Returns a locale-specific rule for determining how digits are grouped to the left of any decimal point.

```
string grouping() const;
```

Return Value

A locale-specific rule for determining how digits are grouped to the left of any decimal point.

Remarks

The member function returns [do_grouping](#).

Example

```

// moneypunct_grouping.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "german_germany" );

    const moneypunct <char, true> &mpunct =
        use_facet <moneypunct <char, true> >( loc );
    for (unsigned int i = 0; i <mpunct.grouping( ).length( ); i++ )
    {
        cout << loc.name( ) << " international grouping:\n the "
            << i <<"th group to the left of the radix character "
            << "is of size " << (int)(mpunct.grouping ( )[i])
            << endl;
    }
    cout << loc.name( ) << " international frac_digits\n to the right"
        << " of the radix character: "
        << mpunct.frac_digits ( ) << endl << endl;

    const moneypunct <char, false> &mpunct2 =
        use_facet <moneypunct <char, false> >( loc );
    for (unsigned int i = 0; i <mpunct2.grouping( ).length( ); i++ )
    {
        cout << loc.name( ) << " domestic grouping:\n the "
            << i <<"th group to the left of the radix character "
            << "is of size " << (int)(mpunct2.grouping ( )[i])
            << endl;
    }
    cout << loc.name( ) << " domestic frac_digits\n to the right"
        << " of the radix character: "
        << mpunct2.frac_digits ( ) << endl << endl;
}

```

```

German_Germany.1252 international grouping:
the 0th group to the left of the radix character is of size 3
German_Germany.1252 international frac_digits
to the right of the radix character: 2

German_Germany.1252 domestic grouping:
the 0th group to the left of the radix character is of size 3
German_Germany.1252 domestic frac_digits
to the right of the radix character: 2

```

moneypunct::moneypunct

Constructor of objects of type `moneypunct`.

```
explicit moneypunct(size_t _Refs = 0);
```

Parameters

_Refs

Integer value used to specify the type of memory management for the object.

Remarks

The possible values for the *_Refs* parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.
- > 1: These values are not defined.

No direct examples are possible, because the destructor is protected.

The constructor initializes its base object with [locale::facet\(_ Refs\)](#).

moneypunct::neg_format

Returns a locale-specific rule for formatting outputs with negative amounts.

```
pattern neg_format() const;
```

Return Value

A locale-specific rule for formatting outputs with negative amounts.

Remarks

The member function returns [do_neg_format](#).

Example

```
// moneypunct_neg_format.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>

using namespace std;

int main( ) {
    locale loc( "german_germany" );

    const moneypunct <char, true> &mpunct =
        use_facet <moneypunct <char, true> >(loc);
    cout << loc.name( ) << " international negative number format: "
        << mpunct.neg_format( ).field[0]
        << mpunct.neg_format( ).field[1]
        << mpunct.neg_format( ).field[2]
        << mpunct.neg_format( ).field[3] << endl;

    const moneypunct <char, false> &mpunct2 =
        use_facet <moneypunct <char, false> >(loc);
    cout << loc.name( ) << " domestic negative number format: "
        << mpunct2.neg_format( ).field[0]
        << mpunct2.neg_format( ).field[1]
        << mpunct2.neg_format( ).field[2]
        << mpunct2.neg_format( ).field[3] << endl;
}
```

moneypunct::negative_sign

Returns a locale-specific sequence of elements to use as a negative sign symbol.

```
string_type negative_sign() const;
```

Return Value

Returns a locale-specific sequence of elements to use as a negative sign symbol.

Remarks

The member function returns [do_negative_sign](#).

Example

```
// moneypunct_neg_sign.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>

using namespace std;

int main( )
{
    locale loc( "german_germany" );

    const moneypunct <char, true> &mpunct =
        use_facet <moneypunct <char, true> >(loc);
    cout << loc.name( ) << " international negative sign: "
        << mpunct.negative_sign( ) << endl;

    const moneypunct <char, false> &mpunct2 =
        use_facet <moneypunct <char, false> >(loc);
    cout << loc.name( ) << " domestic negative sign: "
        << mpunct2.negative_sign( ) << endl;

    locale loc2( "French" );

    const moneypunct <char, true> &mpunct3 =
        use_facet <moneypunct <char, true> >(loc2);
    cout << loc2.name( ) << " international negative sign: "
        << mpunct3.negative_sign( ) << endl;

    const moneypunct <char, false> &mpunct4 =
        use_facet <moneypunct <char, false> >(loc2);
    cout << loc2.name( ) << " domestic negative sign: "
        << mpunct4.negative_sign( ) << endl;
};
```

```
German_Germany.1252 international negative sign: -
German_Germany.1252 domestic negative sign: -
French_France.1252 international negative sign: -
French_France.1252 domestic negative sign: -
```

moneypunct::pos_format

Returns a locale-specific rule for formatting outputs with positive amounts.

```
pattern pos_format() const;
```

Return Value

A locale-specific rule for formatting outputs with positive amounts.

Remarks

The member function returns [do_pos_format](#).

Example

```

// moneypunct_pos_format.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>

using namespace std;

int main() {
    locale loc( "german_germany" );

    const moneypunct <char, true> &mpunct =
        use_facet <moneypunct <char, true> >(loc);
    cout << loc.name( ) << " international positive number format: "
        << mpunct.pos_format( ).field[0]
        << mpunct.pos_format( ).field[1]
        << mpunct.pos_format( ).field[2]
        << mpunct.pos_format( ).field[3] << endl;

    const moneypunct <char, false> &mpunct2 =
        use_facet <moneypunct <char, false> >(loc);
    cout << loc.name( ) << " domestic positive number format: "
        << mpunct2.pos_format( ).field[0]
        << mpunct2.pos_format( ).field[1]
        << mpunct2.pos_format( ).field[2]
        << mpunct2.pos_format( ).field[3] << endl;
}

```

moneypunct::positive_sign

Returns a locale-specific sequence of elements to use as a positive sign symbol.

```
string_type positive_sign() const;
```

Return Value

A locale-specific sequence of elements to use as a positive sign symbol.

Remarks

The member function returns [do_positive_sign](#).

Example

```

// moneypunct_pos_sign.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>

using namespace std;

int main( )
{
    locale loc( "german_germany" );

    const moneypunct <char, true> &mpunct =
        use_facet <moneypunct <char, true> >(loc);
    cout << loc.name( ) << " international positive sign:"
        << mpunct.positive_sign( ) << endl;

    const moneypunct <char, false> &mpunct2 =
        use_facet <moneypunct <char, false> >(loc);
    cout << loc.name( ) << " domestic positive sign:"
        << mpunct2.positive_sign( ) << endl;

    locale loc2( "French" );

    const moneypunct <char, true> &mpunct3 =
        use_facet <moneypunct <char, true> >(loc2);
    cout << loc2.name( ) << " international positive sign:"
        << mpunct3.positive_sign( ) << endl;

    const moneypunct <char, false> &mpunct4 =
        use_facet <moneypunct <char, false> >(loc2);
    cout << loc2.name( ) << " domestic positive sign:"
        << mpunct4.positive_sign( ) << endl;
};

```

```

German_Germany.1252 international positive sign:
German_Germany.1252 domestic positive sign:
French_France.1252 international positive sign:
French_France.1252 domestic positive sign:

```

moneypunct::string_type

A type that describes a string containing characters of type **CharType**.

```
typedef basic_string<CharType, Traits, Allocator> string_type;
```

Remarks

The type describes a specialization of template class [basic_string](#) whose objects can store copies of the punctuation sequences.

moneypunct::thousands_sep

Returns a locale-specific sequence of elements to use as a thousands separator symbol.

```
CharType thousands_sep() const;
```

Return Value

A locale-specific sequence of elements to use as a thousands separator

Remarks

The member function returns [do_thousands_sep](#).

Example

```
// moneypunct_thou_sep.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "german_germany" );

    const moneypunct <char, true> &mpunct =
        use_facet <moneypunct <char, true> >(loc);
    cout << loc.name( ) << " international thousands separator: "
        << mpunct.thousands_sep( ) << endl;

    const moneypunct <char, false> &mpunct2 =
        use_facet <moneypunct <char, false> >(loc);
    cout << loc.name( ) << " domestic thousands separator: "
        << mpunct2.thousands_sep( ) << endl << endl;

    locale loc2( "english_canada" );

    const moneypunct <char, true> &mpunct3 =
        use_facet <moneypunct <char, true> >(loc2);
    cout << loc2.name( ) << " international thousands separator: "
        << mpunct3.thousands_sep( ) << endl;

    const moneypunct <char, false> &mpunct4 =
        use_facet <moneypunct <char, false> >(loc2);
    cout << loc2.name( ) << " domestic thousands separator: "
        << mpunct4.thousands_sep( ) << endl;
}
```

```
German_Germany.1252 international thousands separator: .
German_Germany.1252 domestic thousands separator: .

English_Canada.1252 international thousands separator: ,
English_Canada.1252 domestic thousands separator: ,
```

[Thread Safety in the C++ Standard Library](#)

moneypunct_byname Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

A derived template class that describes an object that can serve as a `moneypunct` facet of a given locale, enabling the formatting monetary input field or monetary output fields.

Syntax

```
template <class CharType, bool Intl = false>
class moneypunct_byname : public moneypunct<CharType, Intl>
{
public:
    explicit moneypunct_byname(
        const char* _Locname,
        size_t _Refs = 0);

    explicit moneypunct_byname(
        const string& _Locname,
        size_t _Refs = 0);

protected:
    virtual ~moneypunct_byname();

};
```

Remarks

Its behavior is determined by the named locale `_Locname`. Each constructor initializes its base object with `moneypunct<CharType, Intl>(_Refs)`.

Requirements

Header: <locale>

Namespace: std

num_get Class

10/31/2018 • 11 minutes to read • [Edit Online](#)

A template class that describes an object that can serve as a locale facet to control conversions of sequences of type `CharType` to numeric values.

Syntax

```
template <class CharType, class InputIterator = istreambuf_iterator<CharType>>
class num_get : public locale::facet;
```

Parameters

CharType

The type used within a program to encode characters in a locale.

InputIterator

The type of iterator from which the numeric get functions read their input.

Remarks

As with any locale facet, the static object `ID` has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in **`id`**.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>num_get</code>	The constructor for objects of type <code>num_get</code> that are used to extract numerical values from sequences.

Typedefs

TYPE NAME	DESCRIPTION
<code>char_type</code>	A type that is used to describe a character used by a locale.
<code>iter_type</code>	A type that describes an input iterator.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>do_get</code>	A virtual function that is called to extracts a numerical or Boolean value from a character sequence.
<code>get</code>	Extracts a numerical or Boolean value from a character sequence.

Requirements

Header: <locale>

Namespace: std

num_get::char_type

A type that is used to describe a character used by a locale.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter **CharType**.

num_get::do_get

A virtual function that is called to extracts a numerical or Boolean value from a character sequence.

```
virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    long& val) const;

virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    unsigned short& val) const;

virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    unsigned int& val) const;

virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    unsigned long& val) const;

virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    long long& val) const;

virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    unsigned long long& val) const;

virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
```

```

        ios_base::iostate& _State,
        float& val) const;

    virtual iter_type do_get(
        iter_type first,
        iter_type last,
        ios_base& _Iosbase,
        ios_base::iostate& _State,
        double& val) const;

    virtual iter_type do_get(
        iter_type first,
        iter_type last,
        ios_base& _Iosbase,
        ios_base::iostate& _State,
        long double& val) const;

    virtual iter_type do_get(
        iter_type first,
        iter_type last,
        ios_base& _Iosbase,
        ios_base::iostate& _State,
        void *& val) const;

    virtual iter_type do_get(
        iter_type first,
        iter_type last,
        ios_base& _Iosbase,
        ios_base::iostate& _State,
        bool& val) const;

```

Parameters

first

The beginning of the range of characters from which to read the number.

last

The end of the range of characters from which to read the number.

_Iosbase

The [ios_base](#) whose flags are used by the conversion.

_State

The state to which failbit (see [ios_base::iostate](#)) is added upon failure.

val

The value that was read.

Return Value

The iterator after the value has been read.

Remarks

The first virtual protected member function,

```

    virtual iter_type do_get(
        iter_type first,
        iter_type last,
        ios_base& _Iosbase,
        ios_base::iostate& _State,
        long& val) const;

```

matches sequential elements beginning at *first* in the sequence `[first, last)` until it has recognized a complete, nonempty integer input field. If successful, it converts this field to its equivalent value as type **long**, and stores the

result in *val*. It returns an iterator designating the first element beyond the numeric input field. Otherwise, the function stores nothing in *val* and sets `ios_base::failbit` in `state`. It returns an iterator designating the first element beyond any prefix of a valid integer input field. In either case, if the return value equals `last`, the function sets `ios_base::eofbit` in `state`.

The integer input field is converted by the same rules used by the scan functions for matching and converting a series of **char** elements from a file. (Each such **char** element is assumed to map to an equivalent element of type `Elem` by a simple, one-to-one, mapping.) The equivalent scan conversion specification is determined as follows:

If `iosbase.ios_base::flags()` & `ios_base::basefield` == `ios_base::oct`, the conversion specification is `lo`.

If `iosbase.flags()` & `ios_base::basefield` == `ios_base::hex`, the conversion specification is `lx`.

If `iosbase.flags()` & `ios_base::basefield` == `0`, the conversion specification is `li`.

Otherwise, the conversion specification is `ld`.

The format of an integer input field is further determined by the locale facet `fac` returned by the call `use_facet<num_punct>(iosbase.ios_base::getloc())`. Specifically:

`fac.num_punct::grouping()` determines how digits are grouped to the left of any decimal point

`fac.num_punct::thousands_sep()` determines the sequence that separates groups of digits to the left of any decimal point.

If no instances of `fac.thousands_sep()` occur in the numeric input field, no grouping constraint is imposed. Otherwise, any grouping constraints imposed by `fac.grouping()` are enforced and separators are removed before the scan conversion occurs.

The fourth virtual protected member function:

```
virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    unsigned long& val) const;
```

behaves the same as the first, except that it replaces a conversion specification of `ld` with `lu`. If successful it converts the numeric input field to a value of type **unsigned long** and stores that value in *val*.

The fifth virtual protected member function:

```
virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    long long& val) const;
```

behaves the same as the first, except that it replaces a conversion specification of `ld` with `lld`. If successful it converts the numeric input field to a value of type **long long** and stores that value in *val*.

The sixth virtual protected member function:

```
virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    unsigned long long& val) const;
```

behaves the same as the first, except that it replaces a conversion specification of `ld` with `llu`. If successful it converts the numeric input field to a value of type **unsigned long long** and stores that value in *val*.

The seventh virtual protected member function:

```
virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    float& val) const;
```

behaves the same as the first, except that it endeavors to match a complete, nonempty floating-point input field.

`fac. numpunct::decimal_point()` determines the sequence that separates the integer digits from the fraction digits. The equivalent scan conversion specifier is `lf`.

The eighth virtual protected member function:

```
virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    double& val) const;
```

behaves the same as the first, except that it endeavors to match a complete, nonempty floating-point input field.

`fac. numpunct::decimal_point()` determines the sequence that separates the integer digits from the fraction digits. The equivalent scan conversion specifier is `lf`.

The ninth virtual protected member function:

```
virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    long double& val) const;
```

behaves the same as the eighth, except that the equivalent scan conversion specifier is `Lf`.

The tenth virtual protected member function:

```
virtual iter_type do_get(
    iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    void *& val) const;
```

behaves the same the first, except that the equivalent scan conversion specifier is `p`.

The last (eleventh) virtual protected member function:

```
virtual iter_type do_get(  
    iter_type first,  
    iter_type last,  
    ios_base& _Iosbase,  
    ios_base::iostate& _State,  
    bool& val) const;
```

behaves the same as the first, except that it endeavors to match a complete, nonempty Boolean input field. If successful it converts the Boolean input field to a value of type **bool** and stores that value in *val*.

A Boolean input field takes one of two forms. If `iosbase.flags() & ios_base::boolalpha` is false, it is the same as an integer input field, except that the converted value must be either 0 (for false) or 1 (for true). Otherwise, the sequence must match either `fac. numpunct::falsename()` (for false), or `fac. numpunct::truename()` (for true).

Example

See the example for [get](#), where the virtual member function is called by `do_get`.

num_get::get

Extracts a numerical or Boolean value from a character sequence.

```
iter_type get(  
    iter_type first,  
    iter_type last,  
    ios_base& _Iosbase,  
    ios_base::iostate& _State,  
    bool& val) const;  
  
iter_type get(  
    iter_type first,  
    iter_type last,  
    ios_base& _Iosbase,  
    ios_base::iostate& _State,  
    unsigned short& val) const;  
  
iter_type get(  
    iter_type first,  
    iter_type last,  
    ios_base& _Iosbase,  
    ios_base::iostate& _State,  
    unsigned int& val) const;  
  
iter_type get(  
    iter_type first,  
    iter_type last,  
    ios_base& _Iosbase,  
    ios_base::iostate& _State,  
    long& val) const;  
  
iter_type get(  
    iter_type first,  
    iter_type last,  
    ios_base& _Iosbase,  
    ios_base::iostate& _State,  
    unsigned long& val) const;  
  
iter_type get(  
    iter_type first,  
    iter_type last,  
    ios_base& _Iosbase,  
    ios_base::iostate& _State,
```

```

        long long& val) const;

    iter_type get(
        iter_type first,
        iter_type last,
        ios_base& _Iosbase,
        ios_base::iostate& _State,
        unsigned long long& val) const;

    iter_type get(
        iter_type first,
        iter_type last,
        ios_base& _Iosbase,
        ios_base::iostate& _State,
        float& val) const;

    iter_type get(
        iter_type first,
        iter_type last,
        ios_base& _Iosbase,
        ios_base::iostate& _State,
        double& val) const;

    iter_type get(
        iter_type first,
        iter_type last,
        ios_base& _Iosbase,
        ios_base::iostate& _State,
        long double& val) const;

    iter_type get(
        iter_type first,
        iter_type last,
        ios_base& _Iosbase,
        ios_base::iostate& _State,
        void *& val) const;

```

Parameters

first

The beginning of the range of characters from which to read the number.

last

The end of the range of characters from which to read the number.

_Iosbase

The [ios_base](#) whose flags are used by the conversion.

_State

The state to which failbit (see [ios_base::iostate](#)) is added upon failure.

val

The value that was read.

Return Value

The iterator after the value has been read.

Remarks

All member functions return [do_get](#)([first](#), [last](#), [_Iosbase](#), [_State](#), [val](#)).

The first virtual protected member function tries to match sequential elements beginning at [first](#) in the sequence [[first](#), [last](#)) until it has recognized a complete, nonempty integer input field. If successful, it converts this field to its equivalent value as type **long** and stores the result in [val](#). It returns an iterator designating the first element beyond the numeric input field. Otherwise, the function stores nothing in [val](#) and sets [ios_base::failbit](#) in [_State](#).

It returns an iterator designating the first element beyond any prefix of a valid integer input field. In either case, if the return value equals *last*, the function sets `ios_base::eofbit` in `_State`.

The integer input field is converted by the same rules used by the scan functions for matching and converting a series of **char** elements from a file. Each such **char** element is assumed to map to an equivalent element of type `charType` by a simple, one-to-one mapping. The equivalent scan conversion specification is determined as follows:

- If `iosbase.flags & ios_base::basefield == ios_base::oct`, the conversion specification is `lo`.
- If `iosbase.flags & ios_base::basefield == ios_base::hex`, the conversion specification is `lx`.
- If `iosbase.flags & ios_base::basefield == 0`, the conversion specification is `li`.
- Otherwise, the conversion specification is `ld`.

The format of an integer input field is further determined by the `locale facet` `fac` returned by the call `use_facet < num_punct > (iosbase.getloc())`. Specifically:

- **fac.grouping** determines how digits are grouped to the left of any decimal point.
- **fac.thousands_sep** determines the sequence that separates groups of digits to the left of any decimal point.

If no instances of **fac.thousands_sep** occur in the numeric input field, no grouping constraint is imposed. Otherwise, any grouping constraints imposed by **fac.grouping** is enforced and separators are removed before the scan conversion occurs.

The second virtual protected member function:

```
virtual iter_type do_get(iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    unsigned long& val) const;
```

behaves the same as the first, except that it replaces a conversion specification of `ld` with `lu`. If successful, it converts the numeric input field to a value of type **unsigned long** and stores that value in *val*.

The third virtual protected member function:

```
virtual iter_type do_get(iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    double& val) const;
```

behaves the same as the first, except that it tries to match a complete, nonempty floating-point input field. **fac.decimal_point** determines the sequence that separates the integer digits from the fraction digits. The equivalent scan conversion specifier is `lf`.

The fourth virtual protected member function:

```
virtual iter_type do_get(iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    long double& val) const;
```

behaves the same the third, except that the equivalent scan conversion specifier is `Lf`.

The fifth virtual protected member function:

```
virtual iter_type do_get(iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    void *& val) const;
```

behaves the same the first, except that the equivalent scan conversion specifier is `p`.

The sixth virtual protected member function:

```
virtual iter_type do_get(iter_type first,
    iter_type last,
    ios_base& _Iosbase,
    ios_base::iostate& _State,
    bool& val) const;
```

behaves the same as the first, except that it tries to match a complete, nonempty boolean input field. If successful it converts the Boolean input field to a value of type **bool** and stores that value in *val*.

A boolean input field takes one of two forms. If **iosbase.flags** & `ios_base::boolalpha` is **false**, it is the same as an integer input field, except that the converted value must be either 0 (for **false**) or 1 (for **true**). Otherwise, the sequence must match either **fac.falsename** (for **false**), or **fac.true name** (for **true**).

Example

```
// num_get_get.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "german_germany" );

    basic_stringstream<char> psz, psz2;
    psz << "-1000,56";

    ios_base::iostate st = 0;
    long double fVal;
    cout << use_facet <num_punct <char> >(loc).thousands_sep( ) << endl;

    psz.imbue( loc );
    use_facet <num_get <char> >
    (loc).get( basic_istream<char>::_Iter( psz.rdbuf( ) ),
        basic_istream<char>::_Iter(0), psz, st, fVal );

    if ( st & ios_base::failbit )
        cout << "money_get( ) FAILED" << endl;
    else
        cout << "money_get( ) = " << fVal << endl;
}
```

num_get::iter_type

A type that describes an input iterator.

```
typedef InputIterator iter_type;
```

Remarks

The type is a synonym for the template parameter `InputIterator`.

num_get::num_get

The constructor for objects of type `num_get` that are used to extract numerical values from sequences.

```
explicit num_get(size_t _Refs = 0);
```

Parameters

_Refs

Integer value used to specify the type of memory management for the object.

Remarks

The possible values for the *_Refs* parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.
- > 1: These values are not defined.

No direct examples are possible, because the destructor is protected.

The constructor initializes its base object with `locale::facet(_Refs)`.

num_put Class

11/8/2018 • 8 minutes to read • [Edit Online](#)

A template class that describes an object that can serve as a locale facet to control conversions of numeric values to sequences of type `CharType`.

Syntax

```
template <class CharType,  
        class OutputIterator = ostreambuf_iterator<CharType>>  
class num_put : public locale::facet;
```

Parameters

CharType

The type used within a program to encode characters in a locale.

OutputIterator

The type of iterator to which the numeric put functions write their output.

Remarks

As with any locale facet, the static object `ID` has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in `id`.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>num_put</code>	The constructor for objects of type <code>num_put</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>char_type</code>	A type that is used to describe a character used by a locale.
<code>iter_type</code>	A type that describes an output iterator.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>do_put</code>	A virtual function that is called to convert a number into a sequence of <code>CharType</code> s that represents the number formatted for a given locale.
<code>put</code>	Converts a number into a sequence of <code>CharType</code> s which represents the number formatted for a given locale.

Requirements

Header: <locale>

Namespace: std

num_put::char_type

A type that is used to describe a character used by a locale.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter `CharType`.

num_put::do_put

A virtual function that is called to convert a number into a sequence of `CharType`s that represents the number formatted for a given locale.

```

virtual iter_type do_put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    bool val) const;

virtual iter_type do_put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    long val) const;

virtual iter_type do_put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    unsigned long val) const;

virtual iter_type do_put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    double val) const;

virtual iter_type do_put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    long double val) const;

virtual iter_type do_put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    const void* val) const;

virtual iter_type do_put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    const long long val) const;

virtual iter_type do_put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    const unsigned long long val) const;

```

Parameters

next

An iterator addressing the first element of the inserted string.

_Iosbase

Specified the stream which contains locale with the numpunct facet used to punctuate the output and flags for formatting the output.

_Fill

A character that is used for spacing.

val

The number or Boolean type that is to be output.

Return Value

An output iterator the addresses the position one beyond the last element produced.

Remarks

The first virtual protected member function generates sequential elements beginning at *next* to produce an integer output field from the value of *val*. The function returns an iterator designating the next place to insert an element beyond the generated integer output field.

The integer output field is generated by the same rules used by the print functions for generating a series of **char** elements to a file. Each such char element is assumed to map to an equivalent element of type `CharType` by a simple, one-to-one mapping. Where a print function pads a field with either spaces or the digit 0, however, `do_put` instead uses `fill`. The equivalent print conversion specification is determined as follows:

- If `iosbase.flags & ios_base::basefield == ios_base::oct`, the conversion specification is `lo`.
- If `iosbase.flags & ios_base::basefield == ios_base::hex`, the conversion specification is `lx`.
- Otherwise, the conversion specification is `ld`.

If `iosbase.width` is nonzero, a field width of this value is prepended. The function then calls `iosbase.width(0)` to reset the field width to zero.

Padding occurs only if the minimum number of elements *N* required to specify the output field is less than `iosbase.width`. Such padding consists of a sequence of *N* - **width** copies of `fill`. Padding then occurs as follows:

- If `iosbase.flags & ios_base::adjustfield == ios_base::left`, the flag - is prepended. (Padding occurs after the generated text.)
- If `iosbase.flags & ios_base::adjustfield == ios_base::internal`, the flag 0 is prepended. (For a numeric output field, padding occurs where the print functions pad with 0.)
- Otherwise, no additional flag is prepended. (Padding occurs before the generated sequence.)

Finally:

- If `iosbase.flags & ios_base::showpos` is nonzero, the flag + is prepended to the conversion specification.
- If `iosbase.flags & ios_base::showbase` is nonzero, the flag # is prepended to the conversion specification.

The format of an integer output field is further determined by the `locale facet` returned by the call `use_facet < num_punct < Elem > (iosbase.getloc)`. Specifically:

- **fac.grouping** determines how digits are grouped to the left of any decimal point
- **fac.thousands_sep** determines the sequence that separates groups of digits to the left of any decimal point

If no grouping constraints are imposed by **fac.grouping** (its first element has the value `CHAR_MAX`), then no instances of **fac.thousands_sep** are generated in the output field. Otherwise, separators are inserted after the print conversion occurs.

The second virtual protected member function:

```
virtual iter_type do_put(iter_type next,
    ios_base& _Iosbase,
    CharType _Fill,
    unsigned long val) const;
```

behaves the same as the first, except that it replaces a conversion specification of `ld` with `lu`.

The third virtual protected member function:

```
virtual iter_type do_put(iter_type next,
    ios_base& _Iosbase,
    CharType _Fill,
    double val) const;
```

behaves the same as the first, except that it produces a floating-point output field from the value of **val**. **fac**. [decimal_point](#) determines the sequence that separates the integer digits from the fraction digits. The equivalent print conversion specification is determined as follows:

- If **iosbase.flags** & `ios_base::floatfield` == `ios_base::fixed`, the conversion specification is `lf`.
- If **iosbase.flags** & `ios_base::floatfield` == `ios_base::scientific`, the conversion specification is `le`. If **iosbase.flags** & `ios_base::uppercase` is nonzero, `e` is replaced with `E`.
- Otherwise, the conversion specification is **lg**. If **iosbase.flags** & `ios_base::uppercase` is nonzero, `g` is replaced with `G`.

If **iosbase.flags** & `ios_base::fixed` is nonzero or if **iosbase.precision** is greater than zero, a precision with the value **iosbase.precision** is prepended to the conversion specification. Any padding behaves the same as for an integer output field. The padding character is **fill**. Finally:

- If **iosbase.flags** & `ios_base::showpos` is nonzero, the flag `+` is prepended to the conversion specification.
- If **iosbase.flags** & `ios_base::showpoint` is nonzero, the flag `#` is prepended to the conversion specification.

The fourth virtual protected member function:

```
virtual iter_type do_put(iter_type next,
    ios_base& _Iosbase,
    CharType _Fill,
    long double val) const;
```

behaves the same the third, except that the qualifier `l` in the conversion specification is replaced with `L`.

The fifth virtual protected member function:

```
virtual iter_type do_put(iter_type next,
    ios_base& _Iosbase,
    CharType _Fill,
    const void* val) const;
```

behaves the same the first, except that the conversion specification is `p`, plus any qualifier needed to specify padding.

The sixth virtual protected member function:

```
virtual iter_type do_put(iter_type next,
    ios_base& _Iosbase,
    CharType _Fill,
    bool val) const;
```

behaves the same as the first, except that it generates a Boolean output field from *val*.

A Boolean output field takes one of two forms. If `iosbase.flags` & `ios_base::boolalpha` is **false**, the member function returns `do_put(_Next, _Iosbase, _Fill, (long)val)`, which typically produces a generated sequence of either 0 (for **false**) or 1 (for **true**). Otherwise, the generated sequence is either *fac.falsename* (for **false**), or

`fac.truename` (for **true**).

The seventh virtual protected member function:

```
virtual iter_type do_put(iter_type next,
    ios_base& iosbase,
    Elem fill,
    long long val) const;
```

behaves the same as the first, except that it replaces a conversion specification of `ld` with `lld`.

The eighth virtual protected member function:

```
virtual iter_type do_put(iter_type next,
    ios_base& iosbase,
    Elem fill,
    unsigned long long val) const;
```

behaves the same as the first, except that it replaces a conversion specification of `ld` with `llu`.

Example

See the example for `put`, which calls `do_put`.

num_put::iter_type

A type that describes an output iterator.

```
typedef OutputIterator iter_type;
```

Remarks

The type is a synonym for the template parameter **OutputIterator**.

num_put::num_put

The constructor for objects of type `num_put`.

```
explicit num_put(size_t _Refs = 0);
```

Parameters

`_Refs`

Integer value used to specify the type of memory management for the object.

Remarks

The possible values for the `_Refs` parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.
- > 1: These values are not defined.

No direct examples are possible, because the destructor is protected.

The constructor initializes its base object with `locale::facet(_Refs)`.

num_put::put

Converts a number into a sequence of `CharType`s that represents the number formatted for a given locale.

```
iter_type put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    bool val) const;

iter_type put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    long val) const;

iter_type put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    unsigned long val) const;

iter_type put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    Long long val) const;

iter_type put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    Unsigned long long val) const;

iter_type put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    double val) const;

iter_type put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    long double val) const;

iter_type put(
    iter_type dest,
    ios_base& _Iosbase,
    _Elem _Fill,
    const void* val) const;
```

Parameters

dest

An iterator addressing the first element of the inserted string.

_Iosbase

Specified the stream that contains locale with the `numput` facet used to punctuate the output and flags for formatting the output.

_Fill

A character that is used for spacing.

val

The number or Boolean type that is to be output.

Return Value

An output iterator the addresses the position one beyond the last element produced.

Remarks

All member functions return `do_put(next, _Iosbase, _Fill, val)`.

Example

```
// num_put_put.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "german_germany" );
    basic_stringstream<char> psz2;
    ios_base::iostate st = 0;
    long double fVal;
    cout << "The thousands separator is: "
         << use_facet < numpunct <char> >(loc).thousands_sep( )
         << endl;

    psz2.imbue( loc );
    use_facet < num_put < char > >
        ( loc ).put(basic_ostream<char>::_Iter(psz2.rdbuf( )),
                psz2, ' ', fVal=1000.67);

    if ( st & ios_base::failbit )
        cout << "num_put( ) FAILED" << endl;
    else
        cout << "num_put( ) = " << psz2.rdbuf( )->str( ) << endl;
}
```

```
The thousands separator is: .
num_put( ) = 1.000,67
```

See also

[<locale>](#)

[facet Class](#)

[Thread Safety in the C++ Standard Library](#)

numpunct Class

10/31/2018 • 7 minutes to read • [Edit Online](#)

A template class that describes an object that can serve as a local facet to describe the sequences of type `CharType` used to represent information about the formatting and punctuation of numeric and Boolean expressions.

Syntax

```
template <class CharType>
class numpunct : public locale::facet;
```

Parameters

CharType

The type used within a program to encode characters in a locale.

Remarks

As with any locale facet, the static object ID has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in **id**.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>numpunct</code>	The constructor for objects of type <code>numpunct</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>char_type</code>	A type that is used to describe a character used by a locale.
<code>string_type</code>	A type that describes a string containing characters of type <code>CharType</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>decimal_point</code>	Returns a locale-specific element to use as a decimal point.
<code>do_decimal_point</code>	A protected virtual member function that is called to return a locale-specific element to use as a decimal point.
<code>do_falsename</code>	A protected virtual member function that is called to return a string to use as a text representation of the value false .

MEMBER FUNCTION	DESCRIPTION
do_grouping	A protected virtual member function that is called to return a locale-specific rule for determining how digits are grouped to the left of any decimal point.
do_thousands_sep	A protected virtual member function that is called to return a locale-specific element to use as a thousands separator.
do_truename	A protected virtual member function that is called to return a string to use as a text representation of the value true .
falsename	Returns a string to use as a text representation of the value false .
grouping	Returns a locale-specific rule for determining how digits are grouped to the left of any decimal point.
thousands_sep	Returns a locale-specific element to use as a thousands separator.
truename	Returns a string to use as a text representation of the value true .

Requirements

Header: <locale>

Namespace: std

num_punct::char_type

A type that is used to describe a character used by a locale.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter **CharType**.

num_punct::decimal_point

Returns a locale-specific element to use as a decimal point.

```
CharType decimal_point() const;
```

Return Value

A locale-specific element to use as a decimal point.

Remarks

The member function returns [do_decimal_point](#).

Example

```
// numpunct_decimal_point.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "german_germany" );

    const numpunct <char> &npunct =
        use_facet <numpunct <char> >( loc);
    cout << loc.name( ) << " decimal point "<<
        npunct.decimal_point( ) << endl;
    cout << loc.name( ) << " thousands separator "
        << npunct.thousands_sep( ) << endl;
};
```

```
German_Germany.1252 decimal point ,
German_Germany.1252 thousands separator .
```

numpunct::do_decimal_point

A protected virtual member function that is called to return a locale-specific element to use as a decimal point.

```
virtual CharType do_decimal_point() const;
```

Return Value

A locale-specific element to use as a decimal point.

Example

See the example for [decimal_point](#), where the virtual member function is called by `decimal_point`.

numpunct::do_falsename

The protected virtual member function returns a sequence to use as a text representation of the value **false**.

```
virtual string_type do_falsename() const;
```

Return Value

A string containing a sequence to use as a text representation of the value **false**.

Remarks

The member function returns the string "false" to represent the value **false** in all locales.

Example

See the example for [falsename](#), where the virtual member function is called by `falsename`.

numpunct::do_grouping

A protected virtual member function that is called to return a locale-specific rule for determining how digits are grouped to the left of any decimal point.

```
virtual string do_grouping() const;
```

Return Value

A locale-specific rule for determining how digits are grouped to the left of any decimal point.

Remarks

The protected virtual member function returns a locale-specific rule for determining how digits are grouped to the left of any decimal point. The encoding is the same as for **lconv::grouping**.

Example

See the example for [grouping](#), where the virtual member function is called by `grouping`.

numpunct::do_thousands_sep

A protected virtual member function that is called to return a locale-specific element to use as a thousands separator.

```
virtual CharType do_thousands_sep() const;
```

Return Value

Returns a locale-specific element to use as a thousands separator.

Remarks

The protected virtual member function returns a locale-specific element of type `CharType` to use as a group separator to the left of any decimal point.

Example

See the example for [thousands_sep](#), where the virtual member function is called by `thousands_sep`.

numpunct::do_truename

A protected virtual member function that is called to return a string to use as a text representation of the value **true**.

```
virtual string_type do_truename() const;
```

Remarks

A string to use as a text representation of the value **true**.

All locales return a string "true" to represent the value **true**.

Example

See the example for [truename](#), where the virtual member function is called by `truename`.

numpunct::falsename

Returns a string to use as a text representation of the value **false**.

```
string_type falsename() const;
```

Return Value

A string containing a sequence of `CharType`s to use as a text representation of the value **false**.

Remarks

The member function returns the string "false" to represent the value **false** in all locales.

The member function returns [do_falsename](#).

Example

```
// numpunct_falsename.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "English" );

    const numpunct<char> &npunct = use_facet<numpunct<char>>( loc );
    cout << loc.name( ) << " truename "<< npunct.truename( ) << endl;
    cout << loc.name( ) << " falsename "<< npunct.falsename( ) << endl;

    locale loc2( "French" );
    const numpunct<char> &npunct2 = use_facet<numpunct<char>>(loc2);
    cout << loc2.name( ) << " truename "<< npunct2.truename( ) << endl;
    cout << loc2.name( ) << " falsename "<< npunct2.falsename( ) << endl;
}
```

```
English_United States.1252 truename true
English_United States.1252 falsename false
French_France.1252 truename true
French_France.1252 falsename false
```

numpunct::grouping

Returns a locale-specific rule for determining how digits are grouped to the left of any decimal point.

```
string grouping() const;
```

Return Value

A locale-specific rule for determining how digits are grouped to the left of any decimal point.

Remarks

The member function returns [do_grouping](#).

Example

```
// numpunct_grouping.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "german_germany");

    const numpunct <char> &npunct =
        use_facet < numpunct <char> >( loc );
    for (unsigned int i = 0; i < npunct.grouping( ).length( ); i++)
    {
        cout << loc.name( ) << " international grouping:\n the "
            << i <<"th group to the left of the radix character "
            << "is of size " << (int)(npunct.grouping ( )[i])
            << endl;
    }
}
```

German_Germany.1252 international grouping:
the 0th group to the left of the radix character is of size 3

numpunct::numpunct

The constructor for objects of type `numpunct`.

```
explicit numpunct(size_t _Refs = 0);
```

Parameters

_Refs

Integer value used to specify the type of memory management for the object.

Remarks

The possible values for the *_Refs* parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.
- > 1: These values are not defined.

No direct examples are possible, because the destructor is protected.

The constructor initializes its base object with `locale::facet`(`_Refs`).

numpunct::string_type

A type that describes a string containing characters of type **CharType**.

```
typedef basic_string<CharType, Traits, Allocator> string_type;
```

Remarks

The type describes a specialization of template class `basic_string` whose objects can store copies of the punctuation sequences.

numpunct::thousands_sep

Returns a locale-specific element to use as a thousands separator.

```
CharType thousands_sep() const;
```

Return Value

A locale-specific element to use as a thousands separator.

Remarks

The member function returns [do_thousands_sep](#).

Example

```
// numpunct_thou_sep.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "german_germany" );

    const numpunct <char> &npunct =
        use_facet < numpunct < char > >( loc );
    cout << loc.name( ) << " decimal point "<<
        npunct.decimal_point( ) << endl;
    cout << loc.name( ) << " thousands separator "
        << npunct.thousands_sep( ) << endl;
};
```

```
German_Germany.1252 decimal point ,
German_Germany.1252 thousands separator .
```

numpunct::truename

Returns a string to use as a text representation of the value **true**.

```
string_type falsename() const;
```

Return Value

A string to use as a text representation of the value **true**.

Remarks

The member function returns [do_truename](#).

All locales return a string "true" to represent the value **true**.

Example

```

// numpunct_truename.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
using namespace std;
int main( )
{
    locale loc( "English" );

    const numpunct < char> &npunct = use_facet <numpunct <char> >( loc );
    cout << loc.name( ) << " truename "<< npunct.truename( ) << endl;
    cout << loc.name( ) << " falsename "<< npunct.falsename( ) << endl;

    locale loc2("French");
    const numpunct <char> &npunct2 = use_facet <numpunct <char> >( loc2 );
    cout << loc2.name( ) << " truename "<< npunct2.truename( ) << endl;
    cout << loc2.name( ) << " falsename "<< npunct2.falsename( ) << endl;
}

```

```

English_United States.1252 truename true
English_United States.1252 falsename false
French_France.1252 truename true
French_France.1252 falsename false

```

[<locale>](#)

[facet Class](#)

[Thread Safety in the C++ Standard Library](#)

numpunct_byname Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The derived template class describes an object that can serve as a `numpunct` facet of a given locale enabling the formatting and punctuation of numeric and Boolean expressions.

Syntax

```
template <class CharType>
class numpunct_byname : public numpunct<Elem> {
public:
    explicit numpunct_byname(
        const char* _Locname,
        size_t _Refs = 0);

    explicit numpunct_byname(
        const string& _Locname,
        size_t _Refs = 0);

protected:
    virtual ~numpunct_byname();

};
```

Remarks

Its behavior is determined by the [named](#) locale `_Locname`. The constructor initializes its base object with `numpunct<CharType>(_Refs)`.

Requirements

Header: <locale>

Namespace: std

See also

[Thread Safety in the C++ Standard Library](#)

time_base Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The class serves as a base class for facets of template class `time_get`, defining just the enumerated type `dateorder` and several constants of this type.

Syntax

```
class time_base : public locale::facet {
public:
    enum dateorder {
        no_order,
        dmy,
        mdy,
        ymd,
        ydm
    };
    time_base(size_t _Refs = 0)
    ~time_base();
};
```

Remarks

Each constant characterizes a different way to order the components of a date. The constants are:

- `no_order` specifies no particular order.
- `dmy` specifies the order day, month, then year, as in 2 December 1979.
- `mdy` specifies the order month, day, then year, as in December 2, 1979.
- `ymd` specifies the order year, month, then day, as in 1979/12/2.
- `ydm` specifies the order year, day, then month, as in 1979: 2 Dec.

Requirements

Header: <locale>

Namespace: std

See also

[Thread Safety in the C++ Standard Library](#)

time_get Class

10/31/2018 • 21 minutes to read • [Edit Online](#)

The template class describes an object that can serve as a locale facet to control conversions of sequences of type `CharType` to time values.

Syntax

```
template <class CharType,  
         class InputIterator = istreambuf_iterator<CharType>>  
class time_get : public time_base;
```

Parameters

CharType

The type used within a program to encode characters.

InputIterator

The iterator from which the time values are read.

Remarks

As with any locale facet, the static object `ID` has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in **`id`**.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>time_get</code>	The constructor for objects of type <code>time_get</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>char_type</code>	A type that is used to describe a character used by a locale.
<code>iter_type</code>	A type that describes an input iterator.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>date_order</code>	Returns the date order used by a facet.
<code>do_date_order</code>	A protected virtual member function that is called to return the date order used by a facet.
<code>do_get</code>	Reads and converts character data to a time value.

MEMBER FUNCTION	DESCRIPTION
do_get_date	A protected virtual member function that is called to parse a string as the date produced by the <code>x</code> specifier for <code>strptime</code> .
do_get_monthname	A protected virtual member function that is called to parse a string as the name of the month.
do_get_time	A protected virtual member function that is called to parse a string as the date produced by the <code>x</code> specifier for <code>strptime</code> .
do_get_weekday	A protected virtual member function that is called to parse a string as the name of the day of the week.
do_get_year	A protected virtual member function that is called to parse a string as the name of the year.
get	Reads from a source of character data and converts that data to a time that is stored in a time struct.
get_date	Parses a string as the date produced by the <code>x</code> specifier for <code>strptime</code> .
get_monthname	Parses a string as the name of the month.
get_time	Parses a string as the date produced by the <code>x</code> specifier for <code>strptime</code> .
get_weekday	Parses a string as the name of the day of the week.
get_year	Parses a string as the name of the year.

Requirements

Header: <locale>

Namespace: std

time_get::char_type

A type that is used to describe a character used by a locale.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter **CharType**.

time_get::date_order

Returns the date order used by a facet.

```
dateorder date_order() const;
```

Return Value

The date order used by a facet.

Remarks

The member function returns [do_date_order](#).

Example

```
// time_get_date_order.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
#include <time.h>
using namespace std;
void po( char *p )
{
    locale loc( p );

    time_get <char>::dateorder order = use_facet <time_get <char> >( loc ).date_order ( );
    cout << loc.name( );
    switch (order){
        case time_base::dmy: cout << "(day, month, year)" << endl;
            break;
        case time_base::mdy: cout << "(month, day, year)" << endl;
            break;
        case time_base::ydm: cout << "(year, day, month)" << endl;
            break;
        case time_base::ymd: cout << "(year, month, day)"<< endl;
            break;
        case time_base::no_order: cout << "(no_order)"<< endl;
            break;
    }
}

int main( )
{
    po( "C" );
    po( "german" );
    po( "English_Britain" );
}
```

```
C(month, day, year)
German_Germany.1252(day, month, year)
English_United Kingdom.1252(day, month, year)
```

time_get::do_date_order

A protected virtual member function that is called to return the date order used by a facet.

```
virtual dateorder do_date_order() const;
```

Return Value

The date order used by a facet.

Remarks

The virtual protected member function returns a value of type **time_base::dateorder**, which describes the order in which date components are matched by [do_get_date](#). In this implementation, the value is **time_base::mdy**, corresponding to dates of the form December 2, 1979.

Example

See the example for [date_order](#), which calls `do_date_order`.

time_get::do_get

Reads and converts character data to a time value. Accepts one conversion specifier and modifier.

```
virtual iter_type
do_get(
iter_type first,
iter_type last,
ios_base& iosbase,
ios_base::iostate& state,
tm* ptm,
char fmt,
char mod) const;
```

Parameters

first

An Input iterator that indicates the start of the sequence to convert.

last

An Input iterator that indicates the end of the sequence.

iosbase

A stream object.

state

A field in iosbase where appropriate bitmask elements are set to indicate errors.

ptm

A pointer to the time structure where the time is to be stored.

fmt

A conversion specifier character.

mod

An optional modifier character.

Return Value

Returns an iterator that designates the first unconverted element. A conversion failure sets `ios_base::failbit` in `state` and returns *first*.

Remarks

The virtual member function converts and skips one or more input elements in the range [`first`, `last`) to determine the values stored in one or more members of `*pt`. A conversion failure sets `ios_base::failbit` in `state` and returns *first*. Otherwise, the function returns an iterator designating the first unconverted element.

The conversion specifiers are:

`'a'` or `'A'` -- behaves the same as [time_get::get_weekday](#).

`'b'`, `'B'`, or `'h'` -- behaves the same as [time_get::get_monthname](#).

'c' -- behaves the same as "%b %d %H : %M : %S %Y" .

'C' -- converts a decimal input field in the range [0, 99] to the value `val` and stores `val * 100 - 1900` in `pt-&tm_year` .

'd' or 'e' -- converts a decimal input field in the range [1, 31] and stores its value in `pt-&tm_mday` .

'D' -- behaves the same as "%m / %d / %y" .

'H' -- converts a decimal input field in the range [0, 23] and stores its value in `pt-&tm_hour` .

'I' -- converts a decimal input field in the range [0, 11] and stores its value in `pt-&tm_hour` .

'j' -- converts a decimal input field in the range [1, 366] and stores its value in `pt-&tm_yday` .

'm' -- converts a decimal input field in the range [1, 12] to the value `val` and stores `val - 1` in and stores its value in `pt-&tm_mon` .

'M' -- converts a decimal input field in the range [0, 59] and stores its value in `pt-&tm_min` .

'n' or 't' -- behaves the same as " " .

'p' -- converts "AM" or "am" to zero and "PM" or "PM" to 12 and adds this value to `pt-&tm_hour` .

'r' -- behaves the same as "%I : %M : %S %p" .

'R' -- behaves the same as "%H %M" .

's' -- converts a decimal input field in the range [0, 59] and stores its value in `pt-&tm_sec` .

'T' or 'X' -- behaves the same as "%H : %M : S" .

'U' -- converts a decimal input field in the range [0, 53] and stores its value in `pt-&tm_yday` .

'w' -- converts a decimal input field in the range [0, 6] and stores its value in `pt-&tm_wday` .

'W' -- converts a decimal input field in the range [0, 53] and stores its value in `pt-&tm_yday` .

'x' -- behaves the same as "%d / %m / %y" .

'y' -- converts a decimal input field in the range [0, 99] to the value `val` and stores `val < 69 val + 100 : val` in `pt-&tm_year` .

'Y' -- behaves the same as [time_get::get_year](#) .

Any other conversion specifier sets `ios_base::failbit` in `state` and returns. In this implementation, any modifier has no effect.

time_get::do_get_date

A protected virtual member function that is called to parse a string as the date produced by the `x` specifier for `strptime` .

```
virtual iter_type do_get_date(iter_type first,
    iter_type last,
    ios_base& iosbase,
    ios_base::iostate& state,
    tm* ptm) const;
```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

iosbase

A format flag which when set indicates that the currency symbol is optional; otherwise, it is required.

state

Sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

ptm

A pointer to where the date information is to be stored.

Return Value

An input iterator addressing the first element beyond the input field.

Remarks

The virtual protected member function tries to match sequential elements beginning at first in the sequence [`first`, `last`) until it has recognized a complete, nonempty date input field. If successful, it converts this field to its equivalent value as the components **tm::tm_mon**, **tm::tm_day**, and **tm::tm_year**, and stores the results in `ptm->tm_mon`, `ptm->tm_day`, and `ptm->tm_year`, respectively. It returns an iterator designating the first element beyond the date input field. Otherwise, the function sets `iosbase::failbit` in *state*. It returns an iterator designating the first element beyond any prefix of a valid date input field. In either case, if the return value equals *last*, the function sets `ios_base::eofbit` in *state*.

The format for the date input field is locale dependent. For the default locale, the date input field has the form MMM DD, YYYY, where:

- MMM is matched by calling [get_monthname](#), giving the month.
- DD is a sequence of decimal digits whose corresponding numeric value must be in the range [1, 31], giving the day of the month.
- YYYY is matched by calling [get_year](#), giving the year.

The literal spaces and commas must match corresponding elements in the input sequence.

Example

See the example for [get_date](#), which calls `do_get_date`.

time_get::do_get_monthname

A protected virtual member function that is called to parse a string as the name of the month.

```
virtual iter_type do_get_monthname(iter_type first,
    iter_type last,
    ios_base& iosbase,
    ios_base::iostate& state,
    tm* ptm) const;
```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

iosbase

Unused.

state

An output parameter that sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

ptm

A pointer to where the month information is to be stored.

Return Value

An input iterator addressing the first element beyond the input field.

Remarks

The virtual protected member function tries to match sequential elements beginning at first in the sequence [`first`, `last`) until it has recognized a complete, nonempty month input field. If successful, it converts this field to its equivalent value as the component **tm::tm_mon**, and stores the result in `ptm->tm_mon`. It returns an iterator designating the first element beyond the month input field. Otherwise, the function sets `ios_base::failbit` in *state*. It returns an iterator designating the first element beyond any prefix of a valid month input field. In either case, if the return value equals *last*, the function sets `ios_base::eofbit` in *state*.

The month input field is a sequence that matches the longest of a set of locale-specific sequences, such as Jan, January, Feb, February, and so on. The converted value is the number of months since January.

Example

See the example for [get_monthname](#), which calls `do_get_monthname`.

time_get::do_get_time

A protected virtual member function that is called to parse a string as the date produced by the *X* specifier for `strftime`.

```
virtual iter_type do_get_time(iter_type first,
    iter_type last,
    ios_base& iosbase,
    ios_base::iostate& state,
    tm* ptm) const;
```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

iosbase

Unused.

state

Sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

ptm

A pointer to where the date information is to be stored.

Return Value

An input iterator addressing the first element beyond the input field.

Remarks

The virtual protected member function tries to match sequential elements beginning at first in the sequence [`first`, `last`) until it has recognized a complete, nonempty time input field. If successful, it converts this field to its equivalent value as the components `tm::tm_hour`, `tm::tm_min`, and `tm::tm_sec`, and stores the results in `ptm->tm_hour`, `ptm->tm_min`, and `ptm->tm_sec`, respectively. It returns an iterator designating the first element beyond the time input field. Otherwise, the function sets `ios_base::failbit` in *state*. It returns an iterator designating the first element beyond any prefix of a valid time input field. In either case, if the return value equals *last*, the function sets `ios_base::eofbit` in *state*.

In this implementation, the time input field has the form HH:MM:SS, where:

- HH is a sequence of decimal digits whose corresponding numeric value must be in the range [0, 24), giving the hour of the day.
- MM is a sequence of decimal digits whose corresponding numeric value must be in the range [0, 60), giving the minutes past the hour.
- SS is a sequence of decimal digits whose corresponding numeric value must be in the range [0, 60), giving the seconds past the minute.

The literal colons must match corresponding elements in the input sequence.

Example

See the example for [get_time](#), which calls `do_get_time`.

time_get::do_get_weekday

A protected virtual member function that is called to parse a string as the name of the day of the week.

```
virtual iter_type do_get_weekday(iter_type first,
                                iter_type last,
                                ios_base& iosbase,
                                ios_base::iostate& state,
                                tm* ptm) const;
```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

iosbase

A format flag which when set indicates that the currency symbol is optional; otherwise, it is required.

state

Sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

ptm

A pointer to where the weekday information is to be stored.

Return Value

An input iterator addressing the first element beyond the input field.

Remarks

The virtual protected member function tries to match sequential elements beginning at *first* in the sequence [`first`, `last`) until it has recognized a complete, nonempty weekday input field. If successful, it converts this field

to its equivalent value as the component **tm::tm_wday**, and stores the result in `ptm->tm_wday`. It returns an iterator designating the first element beyond the weekday input field. Otherwise, the function sets `ios_base::failbit` in *state*. It returns an iterator designating the first element beyond any prefix of a valid weekday input field. In either case, if the return value equals *last*, the function sets `ios_base::eofbit` in *state*.

The weekday input field is a sequence that matches the longest of a set of locale-specific sequences, such as Sun, Sunday, Mon, Monday, and so on. The converted value is the number of days since Sunday.

Example

See the example for [get_weekday](#), which calls `do_get_weekday`.

time_get::do_get_year

A protected virtual member function that is called to parse a string as the name of the year.

```
virtual iter_type do_get_year(iter_type first,
                             iter_type last,
                             ios_base& iosbase,
                             ios_base::iostate& state,
                             tm* ptm) const;
```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

iosbase

A format flag which when set indicates that the currency symbol is optional; otherwise, it is required.

state

Sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

ptm

A pointer to where the year information is to be stored.

Return Value

An input iterator addressing the first element beyond the input field.

Remarks

The virtual protected member function tries to match sequential elements beginning at *first* in the sequence [`first`, `last`) until it has recognized a complete, nonempty year input field. If successful, it converts this field to its equivalent value as the component **tm::tm_year**, and stores the result in `ptm->tm_year`. It returns an iterator designating the first element beyond the year input field. Otherwise, the function sets `ios_base::failbit` in *state*. It returns an iterator designating the first element beyond any prefix of a valid year input field. In either case, if the return value equals *last*, the function sets `ios_base::eofbit` in *state*.

The year input field is a sequence of decimal digits whose corresponding numeric value must be in the range [1900, 2036). The stored value is this value minus 1900. In this implementation, values in the range [69, 136) represent the range of years [1969, 2036). Values in the range [0, 69) are also permissible, but may represent either the range of years [1900, 1969) or [2000, 2069), depending on the specific translation environment.

Example

See the example for [get_year](#), which calls `do_get_year`.

time_get::get

Reads from a source of character data and converts that data to a time that is stored in a time struct. The first function accepts one conversion specifier and modifier, the second accepts several.

```
iter_type get(
    iter_type first,
    iter_type last,
    ios_base& iosbase,
    ios_base::iostate& state,
    tm* ptm,
    char fmt,
    char mod) const;

iter_type get(
    iter_type first,
    iter_type last,
    ios_base& iosbase,
    ios_base::iostate& state,
    tm* ptm,
    char_type* fmt_first,
    char_type* fmt_last) const;
```

Parameters

first

Input iterator that indicates where the sequence to be converted starts.

last

Input iterator that indicates the end of the sequence to be converted.

iosbase

The stream.

state

The appropriate bitmask elements are set for the stream state to indicate errors.

ptm

Pointer to the time structure where the time is to be stored.

fmt

A conversion specifier character.

mod

An optional modifier character.

fmt_first

Points to where the format directives start.

fmt_last

Points to the end of the format directives.

Return Value

Returns an iterator to the first character after the data that was used to assign the time struct `*ptm`.

Remarks

The first member function returns `do_get(first, last, iosbase, state, ptm, fmt, mod)`.

The second member function calls `do_get` under the control of the format delimited by `[fmt_first, fmt_last)`. It treats the format as a sequence of fields, each of which determines the conversion of zero or more input elements

delimited by `[first, last)`. It returns an iterator designating the first unconverted element. There are three kinds of fields:

A per cent (%) in the format, followed by an optional modifier *mod* in the set [EOQ#], followed by a conversion specifier *fmt*, replaces *first* with the value returned by `do_get(first, last, iosbase, state, ptm, fmt, mod)`. A conversion failure sets `ios_base::failbit` in *state* and returns.

A whitespace element in the format skips past zero or more input whitespace elements.

Any other element in the format must match the next input element, which is skipped. A match failure sets `ios_base::failbit` in *state* and returns.

time_get::get_date

Parses a string as the date produced by the *x* specifier for `strftime`.

```
iter_type get_date(iter_type first,
    iter_type last,
    ios_base& iosbase,
    ios_base::iostate& state,
    tm* ptm) const;
```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

iosbase

A format flag which when set indicates that the currency symbol is optional; otherwise, it is required.

state

Sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

ptm

A pointer to where the date information is to be stored.

Return Value

An input iterator addressing the first element beyond the input field.

Remarks

The member function returns `do_get_date(first, last, iosbase, state, ptm)`.

Note that months are counted from 0 to 11.

Example

```

// time_get_get_date.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
#include <time.h>
using namespace std;
int main( )
{
    locale loc;
    basic_stringstream< char > pszGetF, pszPutF, pszGetI, pszPutI;
    ios_base::iostate st = 0;
    struct tm t;
    memset(&t, 0, sizeof(struct tm));

    pszGetF << "July 4, 2000";
    pszGetF.imbue( loc );
    basic_istream<char>::_Iter i = use_facet <time_get<char> >
    (loc).get_date(basic_istream<char>::_Iter(pszGetF.rdbuf( )),
        basic_istream<char>::_Iter(0), pszGetF, st, &t);

    if ( st & ios_base::failbit )
        cout << "time_get("<< pszGetF.rdbuf( )->str( )<< ") FAILED on char: " << *i << endl;
    else

        cout << "time_get("<< pszGetF.rdbuf( )->str( )<< ") ="
        << "\ntm_sec: " << t.tm_sec
        << "\ntm_min: " << t.tm_min
        << "\ntm_hour: " << t.tm_hour
        << "\ntm_mday: " << t.tm_mday
        << "\ntm_mon: " << t.tm_mon
        << "\ntm_year: " << t.tm_year
        << "\ntm_wday: " << t.tm_wday
        << "\ntm_yday: " << t.tm_yday
        << "\ntm_isdst: " << t.tm_isdst
        << endl;
}

```

```

time_get(July 4, 2000) =
tm_sec: 0
tm_min: 0
tm_hour: 0
tm_mday: 4
tm_mon: 6
tm_year: 100
tm_wday: 0
tm_yday: 0
tm_isdst: 0

```

time_get::get_monthname

Parses a string as the name of the month.

```

iter_type get_monthname(iter_type first,
    iter_type last,
    ios_base& iosbase,
    ios_base::iostate& state,
    tm* ptm) const;

```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

iosbase

Unused.

state

An output parameter that sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

ptm

A pointer to where the month information is to be stored.

Return Value

An input iterator addressing the first element beyond the input field.

Remarks

The member function returns `do_get_monthname`(`first`, `last`, `iosbase`, `state`, `ptm`).

Example

```
// time_get_get_monthname.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
#include <time.h>
using namespace std;
int main( )
{
    locale loc ( "French" );
    basic_stringstream<char> pszGetF, pszPutF, pszGetI, pszPutI;
    ios_base::iostate st = 0;
    struct tm t;
    memset( &t, 0, sizeof( struct tm ) );

    pszGetF << "juillet";
    pszGetF.imbue( loc );
    basic_istream<char>::_Iter i = use_facet <time_get <char> >
    (loc).get_monthname(basic_istream<char>::_Iter(pszGetF.rdbuf( )),
        basic_istream<char>::_Iter(0), pszGetF, st, &t);

    if (st & ios_base::failbit)
        cout << "time_get("<< pszGetF.rdbuf( )->str( )<< ") FAILED on char: " << *i << endl;
    else

        cout << "time_get("<< pszGetF.rdbuf( )->str( )<< ") ="
        << "\ntm_sec: " << t.tm_sec
        << "\ntm_min: " << t.tm_min
        << "\ntm_hour: " << t.tm_hour
        << "\ntm_mday: " << t.tm_mday
        << "\ntm_mon: " << t.tm_mon
        << "\ntm_year: " << t.tm_year
        << "\ntm_wday: " << t.tm_wday
        << "\ntm_yday: " << t.tm_yday
        << "\ntm_isdst: " << t.tm_isdst
        << endl;
}
```

```
time_get(juillet) =  
tm_sec: 0  
tm_min: 0  
tm_hour: 0  
tm_mday: 0  
tm_mon: 6  
tm_year: 0  
tm_wday: 0  
tm_yday: 0  
tm_isdst: 0
```

time_get::get_time

Parses a string as the date produced by the *X* specifier for `strftime`.

```
iter_type get_time(iter_type first,  
    iter_type last,  
    ios_base& iosbase,  
    ios_base::iostate& state,  
    tm* ptm) const;
```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

iosbase

Unused.

state

Sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

ptm

A pointer to where the date information is to be stored.

Return Value

An input iterator addressing the first element beyond the input field.

Remarks

The member function returns `do_get_time`(`first`, `last`, `iosbase`, `state`, `ptm`).

Example

```

// time_get_get_time.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
#include <time.h>
using namespace std;
int main( )
{
    locale loc;
    basic_stringstream<char> pszGetF, pszPutF, pszGetI, pszPutI;
    ios_base::iostate st = 0;
    struct tm t;
    memset( &t, 0, sizeof( struct tm ) );

    pszGetF << "11:13:20";
    pszGetF.imbue( loc );
    basic_istream<char>::_Iter i = use_facet
        <time_get<char>>
        (loc).get_time(basic_istream<char>::_Iter(pszGetF.rdbuf( )),
            basic_istream<char>::_Iter(0), pszGetF, st, &t);

    if (st & ios_base::failbit)
        cout << "time_get::get_time("<< pszGetF.rdbuf( )->str( )<< ") FAILED on char: " << *i << endl;
    else

        cout << "time_get::get_time("<< pszGetF.rdbuf( )->str( )<< ") ="
            << "\ntm_sec: " << t.tm_sec
            << "\ntm_min: " << t.tm_min
            << "\ntm_hour: " << t.tm_hour
            << endl;
}

```

```

time_get::get_time(11:13:20) =
tm_sec: 20
tm_min: 13
tm_hour: 11

```

time_get::get_weekday

Parses a string as the name of the day of the week.

```

iter_type get_weekday(iter_type first,
    iter_type last,
    ios_base& iosbase,
    ios_base::iostate& state,
    tm* ptm) const;

```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

iosbase

A format flag which when set indicates that the currency symbol is optional; otherwise, it is required.

state

Sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

ptm

A pointer to where the weekday information is to be stored.

Return Value

An input iterator addressing the first element beyond the input field.

Remarks

The member function returns `do_get_weekday(first, last, iosbase, state, ptm)`.

Example

```
// time_get_get_weekday.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
#include <time.h>
using namespace std;
int main( )
{
    locale loc ( "French" );
    basic_stringstream< char > pszGetF, pszPutF, pszGetI, pszPutI;
    ios_base::iostate st = 0;
    struct tm t;
    memset( &t, 0, sizeof( struct tm ) );

    pszGetF << "mercredi";
    pszGetF.imbue(loc);
    basic_istream<char>::_Iter i = use_facet
        <time_get<char> >
        (loc).get_weekday(basic_istream<char>::_Iter(pszGetF.rdbuf( )),
            basic_istream<char>::_Iter(0), pszGetF, st, &t);

    if (st & ios_base::failbit)
        cout << "time_get::get_time("<< pszGetF.rdbuf( )->str( )<< ") FAILED on char: " << *i << endl;
    else

        cout << "time_get::get_time("<< pszGetF.rdbuf( )->str( )<< ") ="
            << "\ntm_wday: " << t.tm_wday
            << endl;
}
```

```
time_get::get_time(mercredi) =
tm_wday: 3
```

time_get::get_year

Parses a string as the name of the year.

```
iter_type get_year(iter_type first,
    iter_type last,
    ios_base& iosbase,
    ios_base::iostate& state,
    tm* ptm) const;
```

Parameters

first

Input iterator addressing the beginning of the sequence to be converted.

last

Input iterator addressing the end of the sequence to be converted.

iosbase

A format flag which when set indicates that the currency symbol is optional; otherwise, it is required.

state

Sets the appropriate bitmask elements for the stream state according to whether the operations succeeded.

ptm

A pointer to where the year information is to be stored.

Return Value

An input iterator addressing the first element beyond the input field.

Remarks

The member function returns `do_get_year(first, last, iosbase, state, ptm)`.

Example

```
// time_get_get_year.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
#include <time.h>
using namespace std;
int main( )
{
    locale loc;
    basic_stringstream<char> pszGetF, pszPutF, pszGetI, pszPutI;
    ios_base::iostate st = 0;
    struct tm t;
    memset( &t, 0, sizeof( struct tm ) );

    pszGetF << "1928";

    pszGetF.imbue( loc );
    basic_istream<char>::_Iter i = use_facet
        <time_get<char> >
        (loc).get_year(basic_istream<char>::_Iter(pszGetF.rdbuf( )),
            basic_istream<char>::_Iter(0), pszGetF, st, &t);

    if (st & ios_base::failbit)
        cout << "time_get::get_year("<< pszGetF.rdbuf( )->str( )<< ") FAILED on char: " << *i << endl;
    else

        cout << "time_get::get_year("<< pszGetF.rdbuf( )->str( )<< ") ="
            << "\ntm_year: " << t.tm_year
            << endl;
}
```

```
time_get::get_year(1928) =
tm_year: 28
```

time_get::iter_type

A type that describes an input iterator.

```
typedef InputIterator iter_type;
```

Remarks

The type is a synonym for the template parameter **InputIterator**.

time_get::time_get

The constructor for objects of type `time_get` .

```
explicit time_get(size_t refs = 0);
```

Parameters

refs

Integer value used to specify the type of memory management for the object.

Remarks

The possible values for the *refs* parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.
- > 1: These values are not defined.

No direct examples are possible, because the destructor is protected.

The constructor initializes its base object with **locale::facet**(`refs`).

time_get_byname Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The derived template class describes an object that can serve as a locale facet of type `time_get<CharType, InputIterator>`.

Syntax

```
template <class Elem, class InputIterator =  
    istreambuf_iterator<CharType, char_traits<CharType>>>  
class time_get_byname : public time_get<CharType, InputIterator>  
{  
public:  
    explicit time_get_byname(  
        const char* _Locname,  
        size_t _Refs = 0);  
  
    explicit time_get_byname(  
        const string& _Locname,  
        size_t _Refs = 0);  
  
protected:  
    virtual ~time_get_byname()  
};
```

Parameters

_Locname

A named locale.

_Refs

An initial reference count.

Requirements

Its behavior is determined by the named locale *_Locname*. Each constructor initializes its base object with `time_get<CharType, InputIterator>(_Refs)`.

Requirements

Header: <locale>

Namespace: std

[Thread Safety in the C++ Standard Library](#)

time_put Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

The template class describes an object that can serve as a locale facet to control conversions of time values to sequences of type `CharType`.

Syntax

```
template <class CharType,  
         class OutputIterator = ostreambuf_iterator<CharType>>  
class time_put : public locale::facet;
```

Parameters

CharType

The type used within a program to encode characters.

OutputIterator

The type of iterator into which the time put functions write their output.

Remarks

As with any locale facet, the static object `ID` has an initial stored value of zero. The first attempt to access its stored value stores a unique positive value in `id`.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>time_put</code>	The constructor for objects of type <code>time_put</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>char_type</code>	A type that is used to describe a character used by a locale.
<code>iter_type</code>	A type that describes an output iterator.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>do_put</code>	A virtual function that outputs time and date information as a sequence of <code>CharType</code> s.
<code>put</code>	Outputs time and date information as a sequence of <code>CharType</code> s.

Requirements

Header: <locale>

Namespace: std

time_put::char_type

A type that is used to describe a character used by a locale.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter `CharType`.

time_put::do_put

A virtual function that outputs time and date information as a sequence of `CharType` s.

```
virtual iter_type do_put(  
    iter_type next,  
    ios_base& _Iosbase,  
    const tm* _Pt,  
    char _Fmt,  
    char _Mod = 0) const;
```

Parameters

next

An output iterator where the sequence of characters representing time and date are to be inserted.

_Iosbase

Unused.

_Pt

The time and date information being output.

_Fmt

The format of the output. See [strftime](#), [wcsftime](#), [_strftime_l](#), [_wcsftime_l](#) for valid values.

_Mod

A modifier for the format. See [strftime](#), [wcsftime](#), [_strftime_l](#), [_wcsftime_l](#) for valid values.

Return Value

An iterator to the first position after the last element inserted.

Remarks

The virtual protected member function generates sequential elements beginning at `next` from time values stored in the object * `_Pt`, of type `tm`. The function returns an iterator designating the next place to insert an element beyond the generated output.

The output is generated by the same rules used by `strftime`, with a last argument of `_Pt`, for generating a series of **char** elements into an array. Each such **char** element is assumed to map to an equivalent element of type `CharType` by a simple, one-to-one mapping. If `_Mod` equals zero, the effective format is "%F", where F is replaced by `_Fmt`. Otherwise, the effective format is "%MF", where M is replaced by `_Mod`.

Example

See the example for [put](#), which calls `do_put`.

time_put::iter_type

A type that describes an output iterator.

```
typedef OutputIterator iter_type;
```

Remarks

The type is a synonym for the template parameter `OutputIterator`.

time_put::put

Outputs time and date information as a sequence of `CharType` s.

```
iter_type put(iter_type next,
              ios_base& _Iosbase,
              char_type _Fill,
              const tm* _Pt,
              char _Fmt,
              char _Mod = 0) const;

iter_type put(iter_type next,
              ios_base& _Iosbase,
              char_type _Fill,
              const tm* _Pt,
              const CharType* first,
              const CharType* last) const;
```

Parameters

next

An output iterator where the sequence of characters representing time and date are to be inserted.

_Iosbase

Unused.

_Fill

The character of type `CharType` used for spacing.

_Pt

The time and date information being output.

_Fmt

The format of the output. See [strftime](#), [wcsftime](#), [_strftime_l](#), [_wcsftime_l](#) for valid values.

_Mod

A modifier for the format. See [strftime](#), [wcsftime](#), [_strftime_l](#), [_wcsftime_l](#) for valid values.

first

The beginning of the formatting string for the output. See [strftime](#), [wcsftime](#), [_strftime_l](#), [_wcsftime_l](#) for valid values.

last

The end of the formatting string for the output. See [strftime](#), [wcsftime](#), [_strftime_l](#), [_wcsftime_l](#) for valid values.

Return Value

An iterator to the first position after the last element inserted.

Remarks

The first member function returns `do_put(next, _Iosbase, _Fill, _Pt, _Fmt, _Mod)`. The second member function copies to * `next` ++ any element in the interval [`first`, `last`) other than a percent (%). For a percent followed by a character C in the interval [`first`, `last`), the function instead evaluates `next = do_put(next, _Iosbase, _Fill, _Pt, C, 0)` and skips past C. If, however, C is a qualifier character from the set EOQ#, followed by a character `c2` in the interval [`first`, `last`), the function instead evaluates `next = do_put(next, _Iosbase, _Fill, _Pt, c2, C)` and skips past `c2`.

Example

```
// time_put_put.cpp
// compile with: /EHsc
#include <locale>
#include <iostream>
#include <sstream>
#include <time.h>
using namespace std;
int main( )
{
    locale loc;
    basic_stringstream<char> pszPutI;
    ios_base::iostate st = 0;
    struct tm t;
    memset( &t, 0, sizeof( struct tm ) );

    t.tm_hour = 5;
    t.tm_min = 30;
    t.tm_sec = 40;
    t.tm_year = 00;
    t.tm_mday = 4;
    t.tm_mon = 6;

    pszPutI.imbue( loc );
    char *pattern = "x: %X %x";
    use_facet <time_put <char> >
    (loc).put(basic_ostream<char>::_Iter(pszPutI.rdbuf( )),
             pszPutI, ' ', &t, pattern, pattern+strlen(pattern));

    cout << "num_put( ) = " << pszPutI.rdbuf( )->str( ) << endl;

    char strftimebuf[255];
    strftime(&strftimebuf[0], 255, pattern, &t);
    cout << "strftime( ) = " << &strftimebuf[0] << endl;
}
```

```
num_put( ) = x: 05:30:40 07/04/00
strftime( ) = x: 05:30:40 07/04/00
```

time_put::time_put

Constructor for objects of type `time_put`.

```
explicit time_put(size_t _Refs = 0);
```

Parameters

_Refs

Integer value used to specify the type of memory management for the object.

Remarks

The possible values for the *_Refs* parameter and their significance are:

- 0: The lifetime of the object is managed by the locales that contain it.
- 1: The lifetime of the object must be manually managed.
- > 1: These values are not defined.

The constructor initializes its base object with [locale::facet\(_Refs\)](#).

[<locale>](#)

[time_base Class](#)

[Thread Safety in the C++ Standard Library](#)

time_put_byname Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The derived template class describes an object that can serve as a locale facet of type `time_put< CharType, OutputIterator >`.

Syntax

```
template <class CharType, class OutIt = ostreambuf_iterator<CharType, char_traits<CharType>>>
class time_put_byname : public time_put<CharType, OutputIterator>
{
public:
    explicit time_put_byname(
        const char* _Locname,
        size_t _Refs = 0);

    explicit time_put_byname(
        const string& _Locname,
        size_t _Refs = 0);

protected:
    virtual ~time_put_byname();

};
```

Parameters

_Locname

A locale name.

_Refs

An initial reference count.

Remarks

Its behavior is determined by the [named](#) locale *_Locname*. Each constructor initializes its base object with `time_put<CharType, OutputIterator>(_Refs)`.

Requirements

Header: <locale>

Namespace: std

wbuffer_convert Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes a stream buffer that controls the transmission of elements to and from a byte stream buffer.

Syntax

```
template <class Codecvt, class Elem = wchar_t, class Traits = std::char_traits<Elem>>
class wbuffer_convert
    : public std::basic_streambuf<Elem, Traits>
```

Parameters

PARAMETER	DESCRIPTION
<i>Codecvt</i>	The locale facet that represents the conversion object.
<i>Elem</i>	The wide-character element type.
<i>Traits</i>	The traits associated with <i>Elem</i> .

Remarks

This template class describes a stream buffer that controls the transmission of elements of type `_Elem`, whose character traits are described by the class `Traits`, to and from a byte stream buffer of type `std::streambuf`.

Conversion between a sequence of `Elem` values and multibyte sequences is performed by an object of class `Codecvt<Elem, char, std::mbstate_t>`, which meets the requirements of the standard code-conversion facet `std::codecvt<Elem, char, std::mbstate_t>`.

An object of this template class stores:

- A pointer to its underlying byte stream buffer
- A pointer to the allocated conversion object (which is freed when the [wbuffer_convert](#)

wstring_convert Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

The template class `wstring_convert` performs conversions between a wide string and a byte string.

Syntax

```
template <class Codecvt, class Elem = wchar_t>
class wstring_convert
```

Parameters

Codecvt

The [locale](#) facet that represents the conversion object.

Elem

The wide-character element type.

Remarks

The template class describes an object that controls conversions between wide string objects of class `std::basic_string<Elem>` and byte string objects of class `std::basic_string<char>` (also known as `std::string`). The template class defines the types `wide_string` and `byte_string` as synonyms for these two types. Conversion between a sequence of `Elem` values (stored in a `wide_string` object) and multibyte sequences (stored in a `byte_string` object) is performed by an object of class `Codecvt<Elem, char, std::mbstate_t>`, which meets the requirements of the standard code-conversion facet `std::codecvt<Elem, char, std::mbstate_t>`.

An object of this template class stores:

- A byte string to display on errors
- A wide string to display on errors
- A pointer to the allocated conversion object (which is freed when the `wbuffer_convert` object is destroyed)
- A conversion state object of type [state_type](#)
- A conversion count

Constructors

CONSTRUCTOR	DESCRIPTION
wstring_convert	Constructs an object of type <code>wstring_convert</code> .

Typedefs

TYPE NAME	DESCRIPTION
byte_string	A type that represents a byte string.
wide_string	A type that represents a wide string.

TYPE NAME	DESCRIPTION
<code>state_type</code>	A type that represents the conversion state.
<code>int_type</code>	A type that represents an integer.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>from_bytes</code>	Converts a byte string to a wide string.
<code>to_bytes</code>	Converts a wide string to a byte string.
<code>converted</code>	Returns the number of successful conversions.
<code>state</code>	Returns an object representing the state of the conversion.

Requirements

Header: `<locale>`

Namespace: `std`

`wstring_convert::byte_string`

A type that represents a byte string.

```
typedef std::basic_string<char> byte_string;
```

Remarks

The type is a synonym for `std::basic_string<char>`.

`wstring_convert::converted`

Returns the number of successful conversions.

```
size_t converted() const;
```

Return Value

The number of successful conversions.

Remarks

The number of successful conversions is stored in the conversion count object.

`wstring_convert::from_bytes`

Converts a byte string to a wide string.

```

wide_string from_bytes(char Byte);
wide_string from_bytes(const char* ptr);
wide_string from_bytes(const byte_string& Bstr);
wide_string from_bytes(const char* first, const char* last);

```

Parameters

PARAMETER	DESCRIPTION
<i>Byte</i>	The single-element byte sequence to be converted.
<i>ptr</i>	The C-style, null-terminated sequence of characters to be converted.
<i>Bstr</i>	The byte_string to be converted.
<i>first</i>	The first character in a range of characters to be converted.
<i>last</i>	The last character in a range of characters to be converted.

Return Value

A wide string object resulting from the conversion.

Remarks

If the [conversion state](#) object was *not* constructed with an explicit value, it is set to its default value (the initial conversion state) before the conversion begins. Otherwise it is left unchanged.

The number of input elements successfully converted is stored in the conversion count object. If no conversion error occurs, the member function returns the converted wide string. Otherwise, if the object was constructed with an initializer for the wide-string error message, the member function returns the wide-string error message object. Otherwise, the member function throws an object of class [range_error](#).

wstring_convert::int_type

A type that represents an integer.

```

typedef typename wide_string::traits_type::int_type int_type;

```

Remarks

The type is a synonym for `wide_string::traits_type::int_type`.

wstring_convert::state

Returns an object representing the state of the conversion.

```

state_type state() const;

```

Return Value

The [conversion state](#) object that represents the state of the conversion.

Remarks

wstring_convert::state_type

A type that represents the conversion state.

```
typedef typename Codecvt::state_type state_type;
```

Remarks

The type describes an object that can represent a conversion state. The type is a synonym for `Codecvt::state_type`.

wstring_convert::to_bytes

Converts a wide string to a byte string.

```
byte_string to_bytes(Elem Char);
byte_string to_bytes(const Elem* Wptr);
byte_string to_bytes(const wide_string& Wstr);
byte_string to_bytes(const Elem* first, const Elem* last);
```

Parameters

PARAMETER	DESCRIPTION
<i>Char</i>	The wide character to be converted.
<i>Wptr</i>	The C-style, null-terminated sequence, beginning at <code>wptr</code> , to be converted.
<i>Wstr</i>	The wide_string to be converted.
<i>first</i>	The first element in a range of elements to be converted.
<i>last</i>	The last element in a range of elements to be converted.

Remarks

If the [conversion state](#) object was *not* constructed with an explicit value, it is set to its default value (the initial conversion state) before the conversion begins. Otherwise it is left unchanged.

The number of input elements successfully converted is stored in the conversion count object. If no conversion error occurs, the member function returns the converted byte string. Otherwise, if the object was constructed with an initializer for the byte-string error message, the member function returns the byte-string error message object. Otherwise, the member function throws an object of class [range_error](#).

wstring_convert::wide_string

A type that represents a wide string.

```
typedef std::basic_string<Elem> wide_string;
```

Remarks

The type is a synonym for `std::basic_string<Elem>`.

wstring_convert::wstring_convert

Constructs an object of type `wstring_convert` .

```
wstring_convert(Codecvt *Pcvt = new Codecvt);
wstring_convert(Codecvt *Pcvt, state_type _State);
wstring_convert(const byte_string& _Berr, const wide_string& Werr = wide_string());
```

Parameters

PARAMETER	DESCRIPTION
<i>*Pcvt</i>	The object of type <code>Codecvt</code> to perform the conversion.
<i>_State</i>	The object of type <code>state_type</code> representing the conversion state.
<i>_Berr</i>	The <code>byte_string</code> to display on errors.
<i>Werr</i>	The <code>wide_string</code> to display on errors.

Remarks

The first constructor stores *Pcvt_arg* in the `conversion object`

<map>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template classes map and multimap and their supporting templates.

Syntax

```
#include <map>
```

Members

Operators

MAP VERSION	MULTIMAP VERSION	DESCRIPTION
<code>operator!= (map)</code>	<code>operator!= (multimap)</code>	Tests if the map or multimap object on the left side of the operator is not equal to the map or multimap object on the right side.
<code>operator< (map)</code>	<code>operator< (multimap)</code>	Tests if the map or multimap object on the left side of the operator is less than the map or multimap object on the right side.
<code>operator<= (map)</code>	<code>operator<= (multimap)</code>	Tests if the map or multimap object on the left side of the operator is less than or equal to the map or multimap object on the right side.
<code>operator== (map)</code>	<code>operator== (multimap)</code>	Tests if the map or multimap object on the left side of the operator is equal to the map or multimap object on the right side.
<code>operator> (map)</code>	<code>operator> (multimap)</code>	Tests if the map or multimap object on the left side of the operator is greater than the map or multimap object on the right side.
<code>operator>= (map)</code>	<code>operator>= (multimap)</code>	Tests if the map or multimap object on the left side of the operator is greater than or equal to the map or multimap object on the right side.

Specialized Template Functions

MAP VERSION	MULTIMAP VERSION	DESCRIPTION
<code>swap (map)</code>	<code>swap (multimap)</code>	Exchanges the elements of two maps or multimaps.

Classes

CLASS	DESCRIPTION
value_compare Class	Provides a function object that can compare the elements of a map by comparing the values of their keys to determine their relative order in the map.
map Class	Used for the storage and retrieval of data from a collection in which the each of the elements has a unique key with which the data is automatically ordered.
multimap Class	Used for the storage and retrieval of data from a collection in which the each of the elements has a key with which the data is automatically ordered and the keys do not need to have unique values.

<map> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

[swap \(map\)](#)

[swap \(multimap\)](#)

swap (map)

Exchanges the elements of two maps.

```
template <class key, class T, class _Pr, class _Alloc>
void swap(
    map<Key, Traits, Compare, Allocator>& left,
    map<Key, Traits, Compare, Allocator>& right);
```

Parameters

right

The map providing the elements to be swapped, or the map whose elements are to be exchanged with those of the map *left*.

left

The map whose elements are to be exchanged with those of the map *right*.

Remarks

The template function is an algorithm specialized on the container class `map` to execute the member function `left.swap(right)`. This is an instance of the partial ordering of function templates by the compiler. When template functions are overloaded in such a way that the match of the template with the function call is not unique, then the compiler will select the most specialized version of the template function. The general version of the template function, **template < class T> void swap(T&, T&)**, in the algorithm class works by assignment and is a slow operation. The specialized version in each container is much faster as it can work with the internal representation of the container class.

Example

See the code example for member function `map::swap` for an example that uses the template version of `swap`.

swap (multimap)

Exchanges the elements of two multimaps.

```
template <class key, class T, class _Pr, class _Alloc>
void swap(
    multimap<Key, Traits, Compare, Allocator>& left,
    multimap<Key, Traits, Compare, Allocator>& right);
```

Parameters

right

The multimap providing the elements to be swapped, or the multimap whose elements are to be exchanged with those of the multimap *left*.

left

The multimap whose elements are to be exchanged with those of the multimap *right*.

Remarks

The template function is an algorithm specialized on the container class `map` to execute on the container class `multimap` to execute the member function `left.swap(right)`. This is an instance of the partial ordering of function templates by the compiler. When template functions are overloaded in such a way that the match of the template with the function call is not unique, then the compiler will select the most specialized version of the template function. The general version of the template function, **template < class T> void swap(T&, T&)**, in the `algorithm` class works by assignment and is a slow operation. The specialized version in each container is much faster as it can work with the internal representation of the container class.

Example

See the code example for member function `multimap::swap` for an example that uses the template version of `swap`.

[<map>](#)

<map> operators

3/28/2019 • 15 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<=</code>	<code>operator==</code>
<code>operator!= (multimap)</code>	<code>operator> (multimap)</code>	<code>operator>= (multimap)</code>
<code>operator< (multimap)</code>	<code>operator<= (multimap)</code>	<code>operator== (multimap)</code>

operator!=

Tests if the map object on the left side of the operator is not equal to the map object on the right side.

```
bool operator!=(  
    const map <Key, Type, Traits, Allocator>& left,  
    const map <Key, Type, Traits, Allocator>& right);
```

Parameters

left

An object of type `map`.

right

An object of type `map`.

Return Value

true if the maps are not equal; **false** if maps are equal.

Remarks

The comparison between map objects is based on a pairwise comparison of their elements. Two maps are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```

// map_op_ne.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1, m2, m3;
    int i;
    typedef pair <int, int> Int_Pair;

    for ( i = 0 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i ) );
    }

    if ( m1 != m2 )
        cout << "The maps m1 and m2 are not equal." << endl;
    else
        cout << "The maps m1 and m2 are equal." << endl;

    if ( m1 != m3 )
        cout << "The maps m1 and m3 are not equal." << endl;
    else
        cout << "The maps m1 and m3 are equal." << endl;
}
/* Output:
The maps m1 and m2 are not equal.
The maps m1 and m3 are equal.
*/

```

operator<

Tests if the map object on the left side of the operator is less than the map object on the right side.

```

bool operator<(
    const map <Key, Type, Traits, Allocator>& left,
    const map <Key, Type, Traits, Allocator>& right);

```

Parameters

left

An object of type `map`.

right

An object of type `map`.

Return Value

true if the map on the left side of the operator is strictly less than the map on the right side of the operator; otherwise **false**.

Remarks

The comparison between map objects is based on a pairwise comparison of their elements. The less-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// map_op_lt.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map<int, int> m1, m2, m3;
    int i;
    typedef pair<int, int> Int_Pair;

    for ( i = 1 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i - 1 ) );
    }

    if ( m1 < m2 )
        cout << "The map m1 is less than the map m2." << endl;
    else
        cout << "The map m1 is not less than the map m2." << endl;

    if ( m1 < m3 )
        cout << "The map m1 is less than the map m3." << endl;
    else
        cout << "The map m1 is not less than the map m3." << endl;
}
/* Output:
The map m1 is less than the map m2.
The map m1 is not less than the map m3.
*/

```

operator<=

Tests if the map object on the left side of the operator is less than or equal to the map object on the right side.

```

bool operator<=(
    const map <Key, Type, Traits, Allocator>& left,
    const map <Key, Type, Traits, Allocator>& right);

```

Parameters

left

An object of type `map`.

right

An object of type `map`.

Return Value

true if the map on the left side of the operator is less than or equal to the map on the right side of the operator; otherwise **false**.

Example

```

// map_op_le.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1, m2, m3, m4;
    int i;
    typedef pair <int, int> Int_Pair;

    for ( i = 1 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i - 1 ) );
        m4.insert ( Int_Pair ( i, i ) );
    }

    if ( m1 <= m2 )
        cout << "The map m1 is less than or equal to the map m2." << endl;
    else
        cout << "The map m1 is greater than the map m2." << endl;

    if ( m1 <= m3 )
        cout << "The map m1 is less than or equal to the map m3." << endl;
    else
        cout << "The map m1 is greater than the map m3." << endl;

    if ( m1 <= m4 )
        cout << "The map m1 is less than or equal to the map m4." << endl;
    else
        cout << "The map m1 is greater than the map m4." << endl;
}
/* Output:
The map m1 is less than or equal to the map m2.
The map m1 is greater than the map m3.
The map m1 is less than or equal to the map m4.
*/

```

operator==

Tests if the map object on the left side of the operator is equal to the map object on the right side.

```

bool operator==(
    const map <Key, Type, Traits, Allocator>& left,
    const map <Key, Type, Traits, Allocator>& right);

```

Parameters

left

An object of type `map` .

right

An object of type `map` .

Return Value

true if the map on the left side of the operator is equal to the map on the right side of the operator; otherwise **false**.

Remarks

The comparison between map objects is based on a pairwise comparison of their elements. Two maps are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// map_op_eq.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map < int, int > m1, m2, m3;
    int i;
    typedef pair < int, int > Int_Pair;

    for ( i = 0 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i ) );
    }

    if ( m1 == m2 )
        cout << "The maps m1 and m2 are equal." << endl;
    else
        cout << "The maps m1 and m2 are not equal." << endl;

    if ( m1 == m3 )
        cout << "The maps m1 and m3 are equal." << endl;
    else
        cout << "The maps m1 and m3 are not equal." << endl;
}
/* Output:
The maps m1 and m2 are not equal.
The maps m1 and m3 are equal.
*/
```

operator>

Tests if the map object on the left side of the operator is greater than the map object on the right side.

```
bool operator>(
    const map <Key, Type, Traits, Allocator>& left,
    const map <Key, Type, Traits, Allocator>& right);
```

Parameters

left

An object of type `map`.

right

An object of type `map`.

Return Value

true if the map on the left side of the operator is greater than the map on the right side of the operator; otherwise **false**.

Remarks

The comparison between map objects is based on a pairwise comparison of their elements. The greater-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```
// map_op_gt.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map < int, int > m1, m2, m3;
    int i;
    typedef pair < int, int > Int_Pair;

    for ( i = 0 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i - 1 ) );
    }

    if ( m1 > m2 )
        cout << "The map m1 is greater than the map m2." << endl;
    else
        cout << "The map m1 is not greater than the map m2." << endl;

    if ( m1 > m3 )
        cout << "The map m1 is greater than the map m3." << endl;
    else
        cout << "The map m1 is not greater than the map m3." << endl;
}
/* Output:
The map m1 is not greater than the map m2.
The map m1 is greater than the map m3.
*/
```

operator>=

Tests if the map object on the left side of the operator is greater than or equal to the map object on the right side.

```
bool operator>=(
    const map <Key, Type, Traits, Allocator>& left,
    const map <Key, Type, Traits, Allocator>& right);
```

Parameters

left

An object of type `map` .

right

An object of type `map` .

Return Value

true if the map on the left side of the operator is greater than or equal to the map on the right side of the list; otherwise **false**.

Example

```

// map_op_ge.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map < int, int > m1, m2, m3, m4;
    int i;
    typedef pair < int, int > Int_Pair;

    for ( i = 1 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i - 1 ) );
        m4.insert ( Int_Pair ( i, i ) );
    }

    if ( m1 >= m2 )
        cout << "Map m1 is greater than or equal to map m2." << endl;
    else
        cout << "The map m1 is less than the map m2." << endl;

    if ( m1 >= m3 )
        cout << "Map m1 is greater than or equal to map m3." << endl;
    else
        cout << "The map m1 is less than the map m3." << endl;

    if ( m1 >= m4 )
        cout << "Map m1 is greater than or equal to map m4." << endl;
    else
        cout << "The map m1 is less than the map m4." << endl;
}
/* Output:
The map m1 is less than the map m2.
Map m1 is greater than or equal to map m3.
Map m1 is greater than or equal to map m4.
*/

```

operator!= (multimap)

Tests if the multimap object on the left side of the operator is not equal to the multimap object on the right side.

```

bool operator!=(
    const multimap <Key, Type, Traits, Allocator>& left,
    const multimap <Key, Type, Traits, Allocator>& right);

```

Parameters

left

An object of type `multimap`.

right

An object of type `multimap`.

Return Value

true if the multimaps are not equal; **false** if multimaps are equal.

Remarks

The comparison between multimap objects is based on a pairwise comparison of their elements. Two multimaps

are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// multimap_op_ne.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1, m2, m3;
    int i;
    typedef pair <int, int> Int_Pair;

    for ( i = 0 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i ) );
    }

    if ( m1 != m2 )
        cout << "The multimaps m1 and m2 are not equal." << endl;
    else
        cout << "The multimaps m1 and m2 are equal." << endl;

    if ( m1 != m3 )
        cout << "The multimaps m1 and m3 are not equal." << endl;
    else
        cout << "The multimaps m1 and m3 are equal." << endl;
}
/* Output:
The multimaps m1 and m2 are not equal.
The multimaps m1 and m3 are equal.
*/
```

operator<

Tests if the multimap object on the left side of the operator is less than the multimap object on the right side.

```
bool operator<(
    const multimap <Key, Type, Traits, Allocator>& left,
    const multimap <Key, Type, Traits, Allocator>& right);
```

Parameters

left

An object of type `multimap`.

right

An object of type `multimap`.

Return Value

true if the multimap on the left side of the operator is strictly less than the multimap on the right side of the operator; otherwise **false**.

Remarks

The comparison between multimap objects is based on a pairwise comparison of their elements. The less-than

relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```
// multimap_op_lt.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap < int, int > m1, m2, m3;
    int i;
    typedef pair < int, int > Int_Pair;

    for ( i = 1 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i - 1 ) );
    }

    if ( m1 < m2 )
        cout << "The multimap m1 is less than the multimap m2." << endl;
    else
        cout << "The multimap m1 is not less than the multimap m2." << endl;

    if ( m1 < m3 )
        cout << "The multimap m1 is less than the multimap m3." << endl;
    else
        cout << "The multimap m1 is not less than the multimap m3." << endl;
}
/* Output:
The multimap m1 is less than the multimap m2.
The multimap m1 is not less than the multimap m3.
*/
```

operator<=

Tests if the multimap object on the left side of the operator is less than or equal to the multimap object on the right side.

```
bool operator<=(
    const multimap <Key, Type, Traits, Allocator>& left,
    const multimap <Key, Type, Traits, Allocator>& right);
```

Parameters

left

An object of type `multimap`.

right

An object of type `multimap`.

Return Value

true if the multimap on the left side of the operator is less than or equal to the multimap on the right side of the operator; otherwise **false**.

Example

```

// multimap_op_le.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1, m2, m3, m4;
    int i;
    typedef pair <int, int> Int_Pair;

    for ( i = 1 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i - 1 ) );
        m4.insert ( Int_Pair ( i, i ) );
    }

    if ( m1 <= m2 )
        cout << "m1 is less than or equal to m2" << endl;
    else
        cout << "m1 is greater than m2" << endl;

    if ( m1 <= m3 )
        cout << "m1 is less than or equal to m3" << endl;
    else
        cout << "m1 is greater than m3" << endl;

    if ( m1 <= m4 )
        cout << "m1 is less than or equal to m4" << endl;
    else
        cout << "m1 is greater than m4" << endl;
}
/* Output:
m1 is less than or equal to m2
m1 is greater than m3
m1 is less than or equal to m4
*/

```

operator==

Tests if the multimap object on the left side of the operator is equal to the multimap object on the right side.

```

bool operator==(
    const multimap <Key, Type, Traits, Allocator>& left,
    const multimap <Key, Type, Traits, Allocator>& right);

```

Parameters

left

An object of type `multimap`.

right

An object of type `multimap`.

Return Value

true if the multimap on the left side of the operator is equal to the multimap on the right side of the operator; otherwise **false**.

Remarks

The comparison between multimap objects is based on a pairwise comparison of their elements. Two multimaps are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// multimap_op_eq.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap<int, int> m1, m2, m3;
    int i;
    typedef pair<int, int> Int_Pair;

    for (i = 0; i < 3; i++)
    {
        m1.insert(Int_Pair(i, i));
        m2.insert(Int_Pair(i, i*i));
        m3.insert(Int_Pair(i, i));
    }

    if ( m1 == m2 )
        cout << "m1 and m2 are equal" << endl;
    else
        cout << "m1 and m2 are not equal" << endl;

    if ( m1 == m3 )
        cout << "m1 and m3 are equal" << endl;
    else
        cout << "m1 and m3 are not equal" << endl;
}
/* Output:
m1 and m2 are not equal
m1 and m3 are equal
*/
```

operator>

Tests if the multimap object on the left side of the operator is greater than the multimap object on the right side.

```
bool operator>(
    const multimap <Key, Type, Traits, Allocator>& left,
    const multimap <Key, Type, Traits, Allocator>& right);
```

Parameters

left

An object of type `multimap`.

right

An object of type `multimap`.

Return Value

true if the multimap on the left side of the operator is greater than the multimap on the right side of the operator; otherwise **false**.

Remarks

The comparison between multimap objects is based on a pairwise comparison of their elements. The greater-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```
// multimap_op_gt.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap < int, int > m1, m2, m3;
    int i;
    typedef pair < int, int > Int_Pair;

    for ( i = 0 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i - 1 ) );
    }

    if ( m1 > m2 )
        cout << "The multimap m1 is greater than the multimap m2." << endl;
    else
        cout << "Multimap m1 is not greater than multimap m2." << endl;

    if ( m1 > m3 )
        cout << "The multimap m1 is greater than the multimap m3." << endl;
    else
        cout << "The multimap m1 is not greater than the multimap m3." << endl;
}
/* Output:
Multimap m1 is not greater than multimap m2.
The multimap m1 is greater than the multimap m3.
*/
```

operator>=

Tests if the multimap object on the left side of the operator is greater than or equal to the multimap object on the right side.

```
bool operator>=(
    const multimap <Key, Type, Traits, Allocator>& left,
    const multimap <Key, Type, Traits, Allocator>& right);
```

Parameters

left

An object of type `multimap`.

right

An object of type `multimap`.

Return Value

true if the multimap on the left side of the operator is greater than or equal to the multimap on the right side of the list; otherwise **false**.

Example

```

// multimap_op_ge.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap < int, int > m1, m2, m3, m4;
    int i;
    typedef pair < int, int > Int_Pair;

    for ( i = 1 ; i < 3 ; i++ )
    {
        m1.insert ( Int_Pair ( i, i ) );
        m2.insert ( Int_Pair ( i, i * i ) );
        m3.insert ( Int_Pair ( i, i - 1 ) );
        m4.insert ( Int_Pair ( i, i ) );
    }

    if ( m1 >= m2 )
        cout << "The multimap m1 is greater than or equal to the multimap m2." << endl;
    else
        cout << "The multimap m1 is less than the multimap m2." << endl;

    if ( m1 >= m3 )
        cout << "The multimap m1 is greater than or equal to the multimap m3." << endl;
    else
        cout << "The multimap m1 is less than the multimap m3." << endl;

    if ( m1 >= m4 )
        cout << "The multimap m1 is greater than or equal to the multimap m4." << endl;
    else
        cout << "The multimap m1 is less than the multimap m4." << endl;
}
/* Output:
The multimap m1 is less than the multimap m2.
The multimap m1 is greater than or equal to the multimap m3.
The multimap m1 is greater than or equal to the multimap m4.
*/

```

[<map>](#)

map Class

11/15/2018 • 59 minutes to read • [Edit Online](#)

Used for the storage and retrieval of data from a collection in which each element is a pair that has both a data value and a sort key. The value of the key is unique and is used to automatically sort the data.

The value of an element in a map can be changed directly. The key value is a constant and cannot be changed. Instead, key values associated with old elements must be deleted, and new key values must be inserted for new elements.

Syntax

```
template <class Key,  
          class Type,  
          class Traits = less<Key>,  
          class Allocator=allocator<pair <const Key, Type>>>  
class map;
```

Parameters

Key

The key data type to be stored in the map.

Type

The element data type to be stored in the map.

Traits

The type that provides a function object that can compare two element values as sort keys to determine their relative order in the map. This argument is optional and the binary predicate `less<Key>` is the default value.

In C++14 you can enable heterogeneous lookup by specifying the `std::less<>` predicate that has no type parameters. For more information, see [Heterogeneous Lookup in Associative Containers](#)

Allocator

The type that represents the stored allocator object that encapsulates details about the map's allocation and deallocation of memory. This argument is optional and the default value is `allocator<pair<const Key, Type>>`.

Remarks

The C++ Standard Library map class is:

- A container of variable size that efficiently retrieves element values based on associated key values.
- Reversible, because it provides bidirectional iterators to access its elements.
- Sorted, because its elements are ordered by key values according to a specified comparison function.
- Unique. because each of its elements must have a unique key.
- A pair-associative container, because its element data values are distinct from its key values.
- A template class, because the functionality it provides is generic and independent of element or key type. The data types used for elements and keys are specified as parameters in the class template together with the comparison function and allocator.

The iterator provided by the map class is a bidirectional iterator, but the [insert](#) and [map](#) class member functions have versions that take as template parameters a weaker input iterator, whose functionality requirements are fewer than those guaranteed by the class of bidirectional iterators. The different iterator concepts are related by refinements in their functionality. Each iterator concept has its own set of requirements, and the algorithms that work with it must be limited by those requirements. An input iterator may be dereferenced to refer to some object and may be incremented to the next iterator in the sequence.

We recommend that you base the choice of container type on the kind of searching and inserting that is required by the application. Associative containers are optimized for the operations of lookup, insertion, and removal. The member functions that explicitly support these operations perform them in a worst-case time that is proportional to the logarithm of the number of elements in the container. Inserting elements invalidates no iterators, and removing elements invalidates only those iterators that specifically pointed to the removed elements.

We recommend that you make the map the associative container of choice when conditions that associate values with keys are satisfied by the application. A model for this kind of structure is an ordered list of uniquely occurring key words that have associated string values that provide definitions. If a word has more than one correct definition, so that key is not unique, then a multimap would be the container of choice. If just the list of words is being stored, then a set would be the appropriate container. If multiple occurrences of the words are allowed, then a multiset would be appropriate.

The map orders the elements it controls by calling a stored function object of type [key_compare](#). This stored object is a comparison function that is accessed by calling the [key_comp](#) method. In general, any two given elements are compared to determine whether one is less than the other or whether they are equivalent. As all elements are compared, an ordered sequence of non-equivalent elements is created.

NOTE

The comparison function is a binary predicate that induces a strict weak ordering in the standard mathematical sense. A binary predicate $f(x,y)$ is a function object that has two argument objects x and y , and a return value of **true** or **false**. An ordering imposed on a set is a strict weak ordering if the binary predicate is irreflexive, antisymmetric, and transitive, and if equivalence is transitive, where two objects x and y are defined to be equivalent when both $f(x,y)$ and $f(y,x)$ are **false**. If the stronger condition of equality between keys replaces that of equivalence, the ordering becomes total (in the sense that all the elements are ordered with regard to one other), and the keys matched will be indiscernible from one other.

In C++14 you can enable heterogeneous lookup by specifying the `std::less<>` or `std::greater<>` predicate that has no type parameters. For more information, see [Heterogeneous Lookup in Associative Containers](#)

Members

Constructors

CONSTRUCTOR	DESCRIPTION
map	Constructs a list of a specific size or with elements of a specific value or with a specific <code>allocator</code> or as a copy of some other map.

Typedefs

TYPE NAME	DESCRIPTION
allocator_type	A typedef for the <code>allocator</code> class for the map object.
const_iterator	A typedef for a bidirectional iterator that can read a const element in the map.

TYPE NAME	DESCRIPTION
<code>const_pointer</code>	A typedef for a pointer to a const element in a map.
<code>const_reference</code>	A typedef for a reference to a const element stored in a map for reading and performing const operations.
<code>const_reverse_iterator</code>	A type that provides a bidirectional iterator that can read any const element in the map.
<code>difference_type</code>	A signed integer typedef for the number of elements of a map in a range between elements pointed to by iterators.
<code>iterator</code>	A typedef for a bidirectional iterator that can read or modify any element in a map.
<code>key_compare</code>	A typedef for a function object that can compare two sort keys to determine the relative order of two elements in the map.
<code>key_type</code>	A typedef for the sort key stored in each element of the map.
<code>mapped_type</code>	A typedef for the data stored in each element of a map.
<code>pointer</code>	A typedef for a pointer to a const element in a map.
<code>reference</code>	A typedef for a reference to an element stored in a map.
<code>reverse_iterator</code>	A typedef for a bidirectional iterator that can read or modify an element in a reversed map.
<code>size_type</code>	An unsigned integer typedef for the number of elements in a map
<code>value_type</code>	A typedef for the type of object stored as an element in a map.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>at</code>	Finds an element with a specified key value.
<code>begin</code>	Returns an iterator that points to the first element in the map.
<code>cbegin</code>	Returns a const iterator that points to the first element in the map.
<code>cend</code>	Returns a const past-the-end iterator.
<code>clear</code>	Erases all the elements of a map.
<code>count</code>	Returns the number of elements in a map whose key matches the key specified in a parameter.

MEMBER FUNCTION	DESCRIPTION
<code>crbegin</code>	Returns a const iterator that points to the first element in a reversed map.
<code>crend</code>	Returns a const iterator that points to the location after the last element in a reversed map.
<code>emplace</code>	Inserts an element constructed in place into the map.
<code>emplace_hint</code>	Inserts an element constructed in place into the map, with a placement hint.
<code>empty</code>	Returns true if a map is empty.
<code>end</code>	Returns the past-the-end iterator.
<code>equal_range</code>	Returns a pair of iterators. The first iterator in the pair points to the first element in a <code>map</code> with a key that is greater than a specified key. The second iterator in the pair points to the first element in the <code>map</code> with a key that is equal to or greater than the key.
<code>erase</code>	Removes an element or a range of elements in a map from the specified positions.
<code>find</code>	Returns an iterator that points to the location of an element in a map that has a key equal to a specified key.
<code>get_allocator</code>	Returns a copy of the <code>allocator</code> object that is used to construct the map.
<code>insert</code>	Inserts an element or a range of elements into the map at a specified position.
<code>key_comp</code>	Returns a copy of the comparison object that used to order keys in a map.
<code>lower_bound</code>	Returns an iterator to the first element in a map that has a key value that is equal to or greater than that of a specified key.
<code>max_size</code>	Returns the maximum length of the map.
<code>rbegin</code>	Returns an iterator that points to the first element in a reversed map.
<code>rend</code>	Returns an iterator that points to the location after the last element in a reversed map.
<code>size</code>	Returns the number of elements in the map.
<code>swap</code>	Exchanges the elements of two maps.

MEMBER FUNCTION	DESCRIPTION
upper_bound	Returns an iterator to the first element in a map that has a key value that is greater than that of a specified key.
value_comp	Retrieves a copy of the comparison object that is used to order element values in a map.

Operators

OPERATOR	DESCRIPTION
operator[]	Inserts an element into a map with a specified key value.
operator=	Replaces the elements of a map with a copy of another map.

Requirements

Header: <map>

Namespace: std

map::allocator_type

A type that represents the allocator class for the map object.

```
typedef Allocator allocator_type;
```

Example

See example for [get_allocator](#) for an example that uses `allocator_type`.

map::at

Finds an element with a specified key value.

```
Type& at(const Key& key);

const Type& at(const Key& key) const;
```

Parameters

PARAMETER	DESCRIPTION
Parameter	Description
<i>key</i>	The key value to find.

Return Value

A reference to the data value of the element found.

Remarks

If the argument key value is not found, then the function throws an object of class [out_of_range Class](#).

Example

```
// map_at.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

typedef std::map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // find and show elements
    std::cout << "c1.at('a') == " << c1.at('a') << std::endl;
    std::cout << "c1.at('b') == " << c1.at('b') << std::endl;
    std::cout << "c1.at('c') == " << c1.at('c') << std::endl;

    return (0);
}
```

map::begin

Returns an iterator addressing the first element in the map.

```
const_iterator begin() const;

iterator begin();
```

Return Value

A bidirectional iterator addressing the first element in the map or the location succeeding an empty map.

Example

```

// map_begin.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1;

    map <int, int> :: iterator m1_Iter;
    map <int, int> :: const_iterator m1_cIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 0, 0 ) );
    m1.insert ( Int_Pair ( 1, 1 ) );
    m1.insert ( Int_Pair ( 2, 4 ) );

    m1_cIter = m1.begin ( );
    cout << "The first element of m1 is " << m1_cIter -> first << endl;

    m1_Iter = m1.begin ( );
    m1.erase ( m1_Iter );

    // The following 2 lines would err because the iterator is const
    // m1_cIter = m1.begin ( );
    // m1.erase ( m1_cIter );

    m1_cIter = m1.begin( );
    cout << "The first element of m1 is now " << m1_cIter -> first << endl;
}

```

```

The first element of m1 is 0
The first element of m1 is now 1

```

map::cbegin

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cbegin() const;
```

Return Value

A **const** bidirectional iterator addressing the first element in the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin`, the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the [auto](#) type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

map::cend

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A **const** bidirectional-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non-**const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

map::clear

Erases all the elements of a map.

```
void clear();
```

Example

The following example demonstrates the use of the `map::clear` member function.

```
// map_clear.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main()
{
    using namespace std;
    map<int, int> m1;
    map<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    m1.insert(Int_Pair(1, 1));
    m1.insert(Int_Pair(2, 4));

    i = m1.size();
    cout << "The size of the map is initially "
         << i << "." << endl;

    m1.clear();
    i = m1.size();
    cout << "The size of the map after clearing is "
         << i << "." << endl;
}
```

```
The size of the map is initially 2.
The size of the map after clearing is 0.
```

map::const_iterator

A type that provides a bidirectional iterator that can read a **const** element in the map.

```
typedef implementation-defined const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

The `const_iterator` defined by map points to elements that are objects of [value_type](#), that is of type `pair < constKey, Type >`, whose first member is the key to the element and whose second member is the mapped datum held by the element.

To dereference a `const_iterator cIter` pointing to an element in a map, use the `->` operator.

To access the value of the key for the element, use `cIter -> first`, which is equivalent to `(* cIter).first`.

To access the value of the mapped datum for the element, use `cIter -> second`, which is equivalent to `(* cIter).second`.

Example

See example for [begin](#) for an example that uses `const_iterator`.

map::const_pointer

A type that provides a pointer to a **const** element in a map.

```
typedef typename allocator_type::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a map object.

map::const_reference

A type that provides a reference to a **const** element stored in a map for reading and performing **const** operations.

```
typedef typename allocator_type::const_reference const_reference;
```

Example

```
// map_const_ref.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );

    // Declare and initialize a const_reference &Ref1
    // to the key of the first element
    const int &Ref1 = ( m1.begin( ) -> first );

    // The following line would cause an error as the
    // non-const_reference cannot be used to access the key
    // int &Ref1 = ( m1.begin( ) -> first );

    cout << "The key of first element in the map is "
         << Ref1 << "." << endl;

    // Declare and initialize a reference &Ref2
    // to the data value of the first element
    int &Ref2 = ( m1.begin( ) -> second );

    cout << "The data value of first element in the map is "
         << Ref2 << "." << endl;
}
```

```
The key of first element in the map is 1.
The data value of first element in the map is 10.
```

map::const_reverse_iterator

A type that provides a bidirectional iterator that can read any **const** element in the map.

```
typedef std::reverse_iterator<const_iterator> const_reverse_iterator;
```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is used to iterate through the map in reverse.

The `const_reverse_iterator` defined by map points to elements that are objects of `value_type`, that is of type `pair<const Key, Type>`, whose first member is the key to the element and whose second member is the mapped datum held by the element.

To dereference a `const_reverse_iterator crIter` pointing to an element in a map, use the `->` operator.

To access the value of the key for the element, use `crIter -> first`, which is equivalent to `(*crIter).first`.

To access the value of the mapped datum for the element, use `crIter -> second`, which is equivalent to `(*crIter).second`.

Example

See the example for [rend](#) for an example of how to declare and use `const_reverse_iterator`.

map::count

Returns the number of elements in a map whose key matches a parameter-specified key.

```
size_type count(const Key& key) const;
```

Parameters

key

The key value of the elements to be matched from the map.

Return Value

1 if the map contains an element whose sort key matches the parameter key; 0 if the map does not contain an element with a matching key.

Remarks

The member function returns the number of elements *x* in the range

`[lower_bound(key), upper_bound(key))`

which is 0 or 1 in the case of map, which is a unique associative container.

Example

The following example demonstrates the use of the `map::count` member function.

```

// map_count.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main()
{
    using namespace std;
    map<int, int> m1;
    map<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    m1.insert(Int_Pair(1, 1));
    m1.insert(Int_Pair(2, 1));
    m1.insert(Int_Pair(1, 4));
    m1.insert(Int_Pair(2, 1));

    // Keys must be unique in map, so duplicates are ignored
    i = m1.count(1);
    cout << "The number of elements in m1 with a sort key of 1 is: "
         << i << "." << endl;

    i = m1.count(2);
    cout << "The number of elements in m1 with a sort key of 2 is: "
         << i << "." << endl;

    i = m1.count(3);
    cout << "The number of elements in m1 with a sort key of 3 is: "
         << i << "." << endl;
}

```

```

The number of elements in m1 with a sort key of 1 is: 1.
The number of elements in m1 with a sort key of 2 is: 1.
The number of elements in m1 with a sort key of 3 is: 0.

```

map::crbegin

Returns a const iterator addressing the first element in a reversed map.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse bidirectional iterator addressing the first element in a reversed [map](#) or addressing what had been the last element in the unreversed [map](#).

Remarks

[crbegin](#) is used with a reversed [map](#) just as [begin](#) is used with a [map](#).

With the return value of [crbegin](#), the [map](#) object cannot be modified

[crbegin](#) can be used to iterate through a [map](#) backwards.

Example

```
// map_crbegin.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1;

    map <int, int> :: const_reverse_iterator m1_crIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_crIter = m1.crbegin( );
    cout << "The first element of the reversed map m1 is "
         << m1_crIter -> first << "." << endl;
}
```

The first element of the reversed map m1 is 3.

map::crend

Returns a const iterator that addresses the location succeeding the last element in a reversed map.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse bidirectional iterator that addresses the location succeeding the last element in a reversed [map](#) (the location that had preceded the first element in the unreversed [map](#)).

Remarks

[crend](#) is used with a reversed map just as [end](#) is used with a [map](#) .

With the return value of [crend](#) , the [map](#) object cannot be modified.

[crend](#) can be used to test to whether a reverse iterator has reached the end of its [map](#) .

The value returned by [crend](#) should not be dereferenced.

Example

```

// map_crend.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1;

    map <int, int> :: const_reverse_iterator m1_crIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_crIter = m1.crend( );
    m1_crIter--;
    cout << "The last element of the reversed map m1 is "
         << m1_crIter -> first << "." << endl;
}

```

The last element of the reversed map m1 is 1.

map::difference_type

A signed integer type that can be used to represent the number of elements of a map in a range between elements pointed to by iterators.

```
typedef allocator_type::difference_type difference_type;
```

Remarks

The `difference_type` is the type returned when subtracting or incrementing through iterators of the container. The `difference_type` is typically used to represent the number of elements in the range $[first, last)$ between the iterators `first` and `last`, includes the element pointed to by `first` and the range of elements up to, but not including, the element pointed to by `last`.

Note that although `difference_type` is available for all iterators that satisfy the requirements of an input iterator, which includes the class of bidirectional iterators supported by reversible containers such as set, subtraction between iterators is only supported by random access iterators provided by a random access container such as vector.

Example

```

// map_diff_type.cpp
// compile with: /EHsc
#include <iostream>
#include <map>
#include <algorithm>

int main( )
{
    using namespace std;
    map <int, int> m1;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 3, 20 ) );
    m1.insert ( Int_Pair ( 2, 30 ) );

    map <int, int>::iterator m1_Iter, m1_bIter, m1_eIter;
    m1_bIter = m1.begin( );
    m1_eIter = m1.end( );

    // Count the number of elements in a map
    map <int, int>::difference_type df_count = 1;
    m1_Iter = m1.begin( );
    while ( m1_Iter != m1_eIter)
    {
        df_count++;
        m1_Iter++;
    }

    cout << "The number of elements in the map m1 is: "
         << df_count << "." << endl;
}

```

The number of elements in the map m1 is: 4.

map::emplace

Inserts an element constructed in place (no copy or move operations are performed) into a map.

```

template <class... Args>
pair<iterator, bool>
emplace(
    Args&&... args);

```

Parameters

PARAMETER	DESCRIPTION
Parameter	Description
<i>args</i>	The arguments forwarded to construct an element to be inserted into the map unless it already contains an element whose value is equivalently ordered.

Return Value

A [pair](#) whose **bool** component is true if an insertion was made, and false if the map already contained an element of equivalent value in the ordering. The iterator component of the return-value pair points to the newly inserted

element if the **bool** component is true, or to the existing element if the **bool** component is false.

To access the iterator component of a `pair` `pr`, use `pr.first`; to dereference it, use `*pr.first`. To access the **bool** component, use `pr.second`. For an example, see the sample code later in this article.

Remarks

No iterators or references are invalidated by this function.

During emplacement, if an exception is thrown, the container's state is not modified.

The [value_type](#) of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

Example

```

// map_emplace.cpp
// compile with: /EHsc
#include <map>
#include <string>
#include <iostream>

using namespace std;

template <typename M> void print(const M& m) {
    cout << m.size() << " elements: ";

    for (const auto& p : m) {
        cout << "(" << p.first << ", " << p.second << ") ";
    }

    cout << endl;
}

int main()
{
    map<int, string> m1;

    auto ret = m1.emplace(10, "ten");

    if (!ret.second){
        auto pr = *ret.first;
        cout << "Emplace failed, element with key 10 already exists."
              << endl << " The existing element is (" << pr.first << ", " << pr.second << ")"
              << endl;
        cout << "map not modified" << endl;
    }
    else{
        cout << "map modified, now contains ";
        print(m1);
    }
    cout << endl;

    ret = m1.emplace(10, "one zero");

    if (!ret.second){
        auto pr = *ret.first;
        cout << "Emplace failed, element with key 10 already exists."
              << endl << " The existing element is (" << pr.first << ", " << pr.second << ")"
              << endl;
    }
    else{
        cout << "map modified, now contains ";
        print(m1);
    }
    cout << endl;
}

```

map::emplace_hint

Inserts an element constructed in place (no copy or move operations are performed), with a placement hint.

```

template <class... Args>
iterator emplace_hint(
    const_iterator where,
    Args&&... args);

```

Parameters

PARAMETER	DESCRIPTION
Parameter	Description
<i>args</i>	The arguments forwarded to construct an element to be inserted into the map unless the map already contains that element or, more generally, unless it already contains an element whose key is equivalently ordered.
<i>where</i>	The place to start searching for the correct point of insertion. (If that point immediately precedes <i>where</i> , insertion can occur in amortized constant time instead of logarithmic time.)

Return Value

An iterator to the newly inserted element.

If the insertion failed because the element already exists, returns an iterator to the existing element with its key.

Remarks

No iterators or references are invalidated by this function.

During emplacement, if an exception is thrown, the container's state is not modified.

The [value_type](#) of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

Example

```

// map_emplace.cpp
// compile with: /EHsc
#include <map>
#include <string>
#include <iostream>

using namespace std;

template <typename M> void print(const M& m) {
    cout << m.size() << " elements: " << endl;

    for (const auto& p : m) {
        cout << "(" << p.first << ", " << p.second << ") ";
    }

    cout << endl;
}

int main()
{
    map<string, string> m1;

    // Emplace some test data
    m1.emplace("Anna", "Accounting");
    m1.emplace("Bob", "Accounting");
    m1.emplace("Carmine", "Engineering");

    cout << "map starting data: ";
    print(m1);
    cout << endl;

    // Emplace with hint
    // m1.end() should be the "next" element after this emplacement
    m1.emplace_hint(m1.end(), "Doug", "Engineering");

    cout << "map modified, now contains ";
    print(m1);
    cout << endl;
}

```

map::empty

Tests if a map is empty.

```
bool empty() const;
```

Return Value

true if the map is empty; **false** if the map is nonempty.

Example

```
// map_empty.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1, m2;

    typedef pair <int, int> Int_Pair;
    m1.insert ( Int_Pair ( 1, 1 ) );

    if ( m1.empty( ) )
        cout << "The map m1 is empty." << endl;
    else
        cout << "The map m1 is not empty." << endl;

    if ( m2.empty( ) )
        cout << "The map m2 is empty." << endl;
    else
        cout << "The map m2 is not empty." << endl;
}
```

```
The map m1 is not empty.
The map m2 is empty.
```

map::end

Returns the past-the-end iterator.

```
const_iterator end() const;

iterator end();
```

Return Value

The past-the-end iterator. If the map is empty, then `map::end() == map::begin()`.

Remarks

`end` is used to test whether an iterator has passed the end of its map.

The value returned by `end` should not be dereferenced.

For a code example, see [map::find](#).

map::equal_range

Returns a pair of iterators that represent the [lower_bound](#) of the key and the [upper_bound](#) of the key.

```
pair <const_iterator, const_iterator> equal_range (const Key& key) const;

pair <iterator, iterator> equal_range (const Key& key);
```

Parameters

key

The argument key value to be compared with the sort key of an element from the map being searched.

Return Value

To access the first iterator of a pair `pr` returned by the member function, use `pr.first`, and to dereference the lower bound iterator, use `*(pr.first)`. To access the second iterator of a pair `pr` returned by the member function, use `pr.second`, and to dereference the upper bound iterator, use `*(pr.second)`.

Example

```
// map_equal_range.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    typedef map <int, int, less<int> > IntMap;
    IntMap m1;
    map <int, int> :: const_iterator m1_RcIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    pair <IntMap::const_iterator, IntMap::const_iterator> p1, p2;
    p1 = m1.equal_range( 2 );

    cout << "The lower bound of the element with "
         << "a key of 2 in the map m1 is: "
         << p1.first -> second << "." << endl;

    cout << "The upper bound of the element with "
         << "a key of 2 in the map m1 is: "
         << p1.second -> second << "." << endl;

    // Compare the upper_bound called directly
    m1_RcIter = m1.upper_bound( 2 );

    cout << "A direct call of upper_bound( 2 ) gives "
         << m1_RcIter -> second << "," << endl
         << "matching the 2nd element of the pair"
         << " returned by equal_range( 2 )." << endl;

    p2 = m1.equal_range( 4 );

    // If no match is found for the key,
    // both elements of the pair return end( )
    if ( ( p2.first == m1.end( ) ) && ( p2.second == m1.end( ) ) )
        cout << "The map m1 doesn't have an element "
             << "with a key less than 40." << endl;
    else
        cout << "The element of map m1 with a key >= 40 is: "
             << p2.first -> first << "." << endl;
}
```

The lower bound of the element with a key of 2 in the map m1 is: 20.
The upper bound of the element with a key of 2 in the map m1 is: 30.
A direct call of upper_bound(2) gives 30,
matching the 2nd element of the pair returned by equal_range(2).
The map m1 doesn't have an element with a key less than 40.

map::erase

Removes an element or a range of elements in a map from specified positions or removes elements that match a specified key.

```
iterator erase(
    const_iterator Where);

iterator erase(
    const_iterator First,
    const_iterator Last);

size_type erase(
    const key_type& Key);
```

Parameters

Where

Position of the element to be removed.

First

Position of the first element to be removed.

Last

Position just beyond the last element to be removed.

Key

The key value of the elements to be removed.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or an element that is the end of the map if no such element exists.

For the third member function, returns the number of elements that have been removed from the map.

Example

```
// map_erase.cpp
// compile with: /EHsc
#include <map>
#include <string>
#include <iostream>
#include <iterator> // next() and prev() helper functions
#include <utility>   // make_pair()

using namespace std;

using mymap = map<int, string>;

void printmap(const mymap& m) {
    for (const auto& elem : m) {
        cout << " [" << elem.first << ", " << elem.second << "]\n";
    }
    cout << endl << "size() == " << m.size() << endl << endl;
}

int main()
{
    mymap m1;

    // Fill in some data to test with, one at a time
    m1.insert(make_pair(1, "A"));
    m1.insert(make_pair(2, "B"));
    m1.insert(make_pair(3, "C"));
    m1.insert(make_pair(4, "D"));
    m1.insert(make_pair(5, "E"));
```

```

cout << "Starting data of map m1 is:" << endl;
printmap(m1);
// The 1st member function removes an element at a given position
m1.erase(next(m1.begin()));
cout << "After the 2nd element is deleted, the map m1 is:" << endl;
printmap(m1);

// Fill in some data to test with, one at a time, using an initializer list
mymap m2
{
    { 10, "Bob" },
    { 11, "Rob" },
    { 12, "Robert" },
    { 13, "Bert" },
    { 14, "Bobby" }
};

cout << "Starting data of map m2 is:" << endl;
printmap(m2);
// The 2nd member function removes elements
// in the range [First, Last)
m2.erase(next(m2.begin()), prev(m2.end()));
cout << "After the middle elements are deleted, the map m2 is:" << endl;
printmap(m2);

mymap m3;

// Fill in some data to test with, one at a time, using emplace
m3.emplace(1, "red");
m3.emplace(2, "yellow");
m3.emplace(3, "blue");
m3.emplace(4, "green");
m3.emplace(5, "orange");
m3.emplace(6, "purple");
m3.emplace(7, "pink");

cout << "Starting data of map m3 is:" << endl;
printmap(m3);
// The 3rd member function removes elements with a given Key
mymap::size_type count = m3.erase(2);
// The 3rd member function also returns the number of elements removed
cout << "The number of elements removed from m3 is: " << count << "." << endl;
cout << "After the element with a key of 2 is deleted, the map m3 is:" << endl;
printmap(m3);
}

```

map::find

Returns an iterator that refers to the location of an element in a map that has a key equivalent to a specified key.

```

iterator find(const Key& key);

const_iterator find(const Key& key) const;

```

Parameters

key

The key value to be matched by the sort key of an element from the map being searched.

Return Value

An iterator that refers to the location of an element with a specified key, or the location succeeding the last element in the map (`map::end()`) if no match is found for the key.

Remarks

The member function returns an iterator that refers to an element in the map whose sort key is equivalent to the argument key under a binary predicate that induces an ordering based on a less than comparability relation.

If the return value of `find` is assigned to a `const_iterator`, the map object cannot be modified. If the return value of `find` is assigned to an `iterator`, the map object can be modified

Example

```

// compile with: /EHsc /W4 /MTd
#include <map>
#include <iostream>
#include <vector>
#include <string>
#include <utility> // make_pair()

using namespace std;

template <typename A, typename B> void print_elem(const pair<A, B>& p) {
    cout << "(" << p.first << ", " << p.second << ")" << endl;
}

template <typename T> void print_collection(const T& t) {
    cout << t.size() << " elements: ";

    for (const auto& p : t) {
        print_elem(p);
    }
    cout << endl;
}

template <typename C, class T> void findit(const C& c, T val) {
    cout << "Trying find() on value " << val << endl;
    auto result = c.find(val);
    if (result != c.end()) {
        cout << "Element found: "; print_elem(*result); cout << endl;
    } else {
        cout << "Element not found." << endl;
    }
}

int main()
{
    map<int, string> m1({ { 40, "Zr" }, { 45, "Rh" } });
    cout << "The starting map m1 is (key, value):" << endl;
    print_collection(m1);

    vector<pair<int, string>> v;
    v.push_back(make_pair(43, "Tc"));
    v.push_back(make_pair(41, "Nb"));
    v.push_back(make_pair(46, "Pd"));
    v.push_back(make_pair(42, "Mo"));
    v.push_back(make_pair(44, "Ru"));
    v.push_back(make_pair(44, "Ru")); // attempt a duplicate

    cout << "Inserting the following vector data into m1:" << endl;
    print_collection(v);

    m1.insert(v.begin(), v.end());

    cout << "The modified map m1 is (key, value):" << endl;
    print_collection(m1);
    cout << endl;
    findit(m1, 45);
    findit(m1, 6);
}

```

map::get_allocator

Returns a copy of the allocator object used to construct the map.

```
allocator_type get_allocator() const;
```

Return Value

The allocator used by the map.

Remarks

Allocators for the map class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```
// map_get_allocator.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int>::allocator_type m1_Alloc;
    map <int, int>::allocator_type m2_Alloc;
    map <int, double>::allocator_type m3_Alloc;
    map <int, int>::allocator_type m4_Alloc;

    // The following lines declare objects
    // that use the default allocator.
    map <int, int> m1;
    map <int, int, allocator<int> > m2;
    map <int, double, allocator<double> > m3;

    m1_Alloc = m1.get_allocator( );
    m2_Alloc = m2.get_allocator( );
    m3_Alloc = m3.get_allocator( );

    cout << "The number of integers that can be allocated\n"
         << "before free memory is exhausted: "
         << m2.max_size( ) << ".\n" << endl;

    cout << "The number of doubles that can be allocated\n"
         << "before free memory is exhausted: "
         << m3.max_size( ) << ".\n" << endl;

    // The following line creates a map m4
    // with the allocator of map m1.
    map <int, int> m4( less<int>( ), m1_Alloc );

    m4_Alloc = m4.get_allocator( );

    // Two allocators are interchangeable if
    // storage allocated from each can be
    // deallocated with the other
    if( m1_Alloc == m4_Alloc )
    {
        cout << "The allocators are interchangeable." << endl;
    }
    else
    {
        cout << "The allocators are not interchangeable." << endl;
    }
}
```

map::insert

Inserts an element or a range of elements into a map.

```

// (1) single element
pair<iterator, bool> insert(
    const value_type& Val);

// (2) single element, perfect forwarded
template <class ValTy>
pair<iterator, bool>
insert(
    ValTy&& Val);

// (3) single element with hint
iterator insert(
    const_iterator Where,
    const value_type& Val);

// (4) single element, perfect forwarded, with hint
template <class ValTy>
iterator insert(
    const_iterator Where,
    ValTy&& Val);

// (5) range
template <class InputIterator>
void insert(
    InputIterator First,
    InputIterator Last);

// (6) initializer list
void insert(
    initializer_list<value_type>
    IList);

```

Parameters

PARAMETER	DESCRIPTION
Parameter	Description
<i>Val</i>	The value of an element to be inserted into the map unless it already contains an element whose key is equivalently ordered.
<i>Where</i>	The place to start searching for the correct point of insertion. (If that point immediately precedes <i>Where</i> , insertion can occur in amortized constant time instead of logarithmic time.)
<i>ValTy</i>	Template parameter that specifies the argument type that the map can use to construct an element of value_type , and perfect-forwards <i>Val</i> as an argument.
<i>First</i>	The position of the first element to be copied.
<i>Last</i>	The position just beyond the last element to be copied.
<i>InputIterator</i>	Template function argument that meets the requirements of an input iterator that points to elements of a type that can be used to construct value_type objects.
<i>IList</i>	The initializer_list from which to copy the elements.

Return Value

The single-element member functions, (1) and (2), return a [pair](#) whose **bool** component is true if an insertion was made, and false if the map already contained an element whose key had an equivalent value in the ordering. The iterator component of the return-value pair points to the newly inserted element if the **bool** component is true, or to the existing element if the **bool** component is false.

The single-element-with-hint member functions, (3) and (4), return an iterator that points to the position where the new element was inserted into the map or, if an element with an equivalent key already exists, to the existing element.

Remarks

No iterators, pointers, or references are invalidated by this function.

During the insertion of just one element, if an exception is thrown, the container's state is not modified. During the insertion of multiple elements, if an exception is thrown, the container is left in an unspecified but valid state.

To access the iterator component of a `pair` `pr` that's returned by the single-element member functions, use `pr.first`; to dereference the iterator within the returned pair, use `*pr.first`, giving you an element. To access the **bool** component, use `pr.second`. For an example, see the sample code later in this article.

The [value_type](#) of a container is a typedef that belongs to the container, and for map, `map<K, V>::value_type` is `pair<const K, V>`. The value of an element is an ordered pair in which the first component is equal to the key value and the second component is equal to the data value of the element.

The range member function (5) inserts the sequence of element values into a map that corresponds to each element addressed by an iterator in the range `[First, Last)`; therefore, `Last` does not get inserted. The container member function `end()` refers to the position just after the last element in the container—for example, the statement `m.insert(v.begin(), v.end());` attempts to insert all elements of `v` into `m`. Only elements that have unique values in the range are inserted; duplicates are ignored. To observe which elements are rejected, use the single-element versions of `insert`.

The initializer list member function (6) uses an [initializer_list](#) to copy elements into the map.

For insertion of an element constructed in place—that is, no copy or move operations are performed—see [map::emplace](#) and [map::emplace_hint](#).

Example

```
// map_insert.cpp
// compile with: /EHsc
#include <map>
#include <iostream>
#include <string>
#include <vector>
#include <utility> // make_pair()

using namespace std;

template <typename M> void print(const M& m) {
    cout << m.size() << " elements: ";

    for (const auto& p : m) {
        cout << "(" << p.first << ", " << p.second << ") ";
    }

    cout << endl;
}

int main()
{
```

```

// insert single values
map<int, int> m1;
// call insert(const value_type&) version
m1.insert({ 1, 10 });
// call insert(ValTy&&) version
m1.insert(make_pair(2, 20));

cout << "The original key and mapped values of m1 are:" << endl;
print(m1);

// intentionally attempt a duplicate, single element
auto ret = m1.insert(make_pair(1, 111));
if (!ret.second){
    auto pr = *ret.first;
    cout << "Insert failed, element with key value 1 already exists."
        << endl << " The existing element is (" << pr.first << ", " << pr.second << ")"
        << endl;
}
else{
    cout << "The modified key and mapped values of m1 are:" << endl;
    print(m1);
}
cout << endl;

// single element, with hint
m1.insert(m1.end(), make_pair(3, 30));
cout << "The modified key and mapped values of m1 are:" << endl;
print(m1);
cout << endl;

// The templated version inserting a jumbled range
map<int, int> m2;
vector<pair<int, int>> v;
v.push_back(make_pair(43, 294));
v.push_back(make_pair(41, 262));
v.push_back(make_pair(45, 330));
v.push_back(make_pair(42, 277));
v.push_back(make_pair(44, 311));

cout << "Inserting the following vector data into m2:" << endl;
print(v);

m2.insert(v.begin(), v.end());

cout << "The modified key and mapped values of m2 are:" << endl;
print(m2);
cout << endl;

// The templated versions move-constructing elements
map<int, string> m3;
pair<int, string> ip1(475, "blue"), ip2(510, "green");

// single element
m3.insert(move(ip1));
cout << "After the first move insertion, m3 contains:" << endl;
print(m3);

// single element with hint
m3.insert(m3.end(), move(ip2));
cout << "After the second move insertion, m3 contains:" << endl;
print(m3);
cout << endl;

map<int, int> m4;
// Insert the elements from an initializer_list
m4.insert({ { 4, 44 }, { 2, 22 }, { 3, 33 }, { 1, 11 }, { 5, 55 } });
cout << "After initializer_list insertion, m4 contains:" << endl;
print(m4);
cout << endl;

```

```
}
```

map::iterator

A type that provides a bidirectional iterator that can read or modify any element in a map.

```
typedef implementation-defined iterator;
```

Remarks

The iterator defined by map points to elements that are objects of `value_type`, that is of type

`pair<const Key, Type>`, whose first member is the key to the element and whose second member is the mapped datum held by the element.

To dereference an iterator *Iter* pointing to an element in a map, use the `->` operator.

To access the value of the key for the element, use `Iter->first`, which is equivalent to `(*Iter).first`. To access the value of the mapped datum for the element, use `Iter->second`, which is equivalent to `(*Iter).second`.

Example

See example for [begin](#) for an example of how to declare and use `iterator`.

map::key_comp

Retrieves a copy of the comparison object used to order keys in a map.

```
key_compare key_comp() const;
```

Return Value

Returns the function object that a map uses to order its elements.

Remarks

The stored object defines the member function

```
bool operator(const Key& left, const Key& right);
```

which returns **true** if `left` precedes and is not equal to `right` in the sort order.

Example

```

// map_key_comp.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;

    map <int, int, less<int> > m1;
    map <int, int, less<int> >::key_compare kc1 = m1.key_comp( );
    bool result1 = kc1( 2, 3 );
    if( result1 == true )
    {
        cout << "kc1( 2,3 ) returns value of true, "
              << "where kc1 is the function object of m1."
              << endl;
    }
    else
    {
        cout << "kc1( 2,3 ) returns value of false "
              << "where kc1 is the function object of m1."
              << endl;
    }

    map <int, int, greater<int> > m2;
    map <int, int, greater<int> >::key_compare kc2 = m2.key_comp( );
    bool result2 = kc2( 2, 3 );
    if( result2 == true )
    {
        cout << "kc2( 2,3 ) returns value of true, "
              << "where kc2 is the function object of m2."
              << endl;
    }
    else
    {
        cout << "kc2( 2,3 ) returns value of false, "
              << "where kc2 is the function object of m2."
              << endl;
    }
}

```

```

kc1( 2,3 ) returns value of true, where kc1 is the function object of m1.
kc2( 2,3 ) returns value of false, where kc2 is the function object of m2.

```

map::key_compare

A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the map.

```
typedef Traits key_compare;
```

Remarks

`key_compare` is a synonym for the template parameter *Traits*.

For more information on *Traits* see the [map Class](#) topic.

Example

See example for [key_comp](#) for an example of how to declare and use `key_compare`.

map::key_type

A type that describes the sort key stored in each element of the map.

```
typedef Key key_type;
```

Remarks

`key_type` is a synonym for the template parameter *Key*.

For more information on *Key*, see the Remarks section of the [map Class](#) topic.

Example

See example for [value_type](#) for an example of how to declare and use `key_type`.

map::lower_bound

Returns an iterator to the first element in a map with a key value that is equal to or greater than that of a specified key.

```
iterator lower_bound(const Key& key);  
  
const_iterator lower_bound(const Key& key) const;
```

Parameters

key

The argument key value to be compared with the sort key of an element from the map being searched.

Return Value

An `iterator` or `const_iterator` that addresses the location of an element in a map that with a key that is equal to or greater than the argument key, or that addresses the location succeeding the last element in the map if no match is found for the key.

If the return value of `lower_bound` is assigned to a `const_iterator`, the map object cannot be modified. If the return value of `lower_bound` is assigned to an `iterator`, the map object can be modified.

Example

```

// map_lower_bound.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1;
    map <int, int> :: const_iterator m1_AcIter, m1_RcIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_RcIter = m1.lower_bound( 2 );
    cout << "The first element of map m1 with a key of 2 is: "
         << m1_RcIter -> second << "." << endl;

    // If no match is found for this key, end( ) is returned
    m1_RcIter = m1.lower_bound ( 4 );

    if ( m1_RcIter == m1.end( ) )
        cout << "The map m1 doesn't have an element "
             << "with a key of 4." << endl;
    else
        cout << "The element of map m1 with a key of 4 is: "
             << m1_RcIter -> second << "." << endl;

    // The element at a specific location in the map can be found
    // using a dereferenced iterator addressing the location
    m1_AcIter = m1.end( );
    m1_AcIter--;
    m1_RcIter = m1.lower_bound ( m1_AcIter -> first );
    cout << "The element of m1 with a key matching "
         << "that of the last element is: "
         << m1_RcIter -> second << "." << endl;
}

```

```

The first element of map m1 with a key of 2 is: 20.
The map m1 doesn't have an element with a key of 4.
The element of m1 with a key matching that of the last element is: 30.

```

map::map

Constructs a map that is empty or that is a copy of all or part of some other map.

```

map();

explicit map(
    const Traits& Comp);

map(
    const Traits& Comp,
    const Allocator& Al);

map(
    const map& Right);

map(
    map&& Right);

map(
    initializer_list<value_type> IList);

map(
    initializer_list<value_type> IList,
    const Traits& Comp);

map(
    initializer_list<value_type> IList,
    const Traits& Comp,
    const Allocator& Allocator);

template <class InputIterator>
map(
    InputIterator First,
    InputIterator Last);

template <class InputIterator>
map(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp);

template <class InputIterator>
map(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp,
    const Allocator& Al);

```

Parameters

PARAMETER	DESCRIPTION
Parameter	Description
<i>Al</i>	The storage allocator class to be used for this map object, which defaults to <code>Allocator</code> .
<i>Comp</i>	The comparison function of type <code>const Traits</code> used to order the elements in the map, which defaults to <code>hash_compare</code> .
<i>Right</i>	The map of which the constructed set is to be a copy.
<i>First</i>	The position of the first element in the range of elements to be copied.

PARAMETER	DESCRIPTION
<i>Last</i>	The position of the first element beyond the range of elements to be copied.
<i>lList</i>	The initializer_list from which the elements are to be copied.

Remarks

All constructors store a type of allocator object that manages memory storage for the map and that can later be returned by calling [get_allocator](#). The allocator parameter is often omitted in the class declarations and preprocessing macros used to substitute alternative allocators.

All constructors initialize their map.

All constructors store a function object of type Traits that is used to establish an order among the keys of the map and that can later be returned by calling [key_comp](#).

The first three constructors specify an empty initial map, the second specifying the type of comparison function (*Comp*) to be used in establishing the order of the elements and the third explicitly specifying the allocator type (*Al*) to be used. The key word **explicit** suppresses certain kinds of automatic type conversion.

The fourth constructor specifies a copy of the map *Right*.

The fifth constructor specifies a copy of the map by moving *Right*.

The sixth, seventh, and eighth constructors use an initializer_list from which to copy the members.

The next three constructors copy the range [First, Last) of a map with increasing explicitness in specifying the type of comparison function of class Traits and allocator.

Example

```
// map_map.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main()
{
    using namespace std;
    typedef pair <int, int> Int_Pair;
    map <int, int>::iterator m1_Iter, m3_Iter, m4_Iter, m5_Iter, m6_Iter, m7_Iter;
    map <int, int, less<int> >::iterator m2_Iter;

    // Create an empty map m0 of key type integer
    map <int, int> m0;

    // Create an empty map m1 with the key comparison
    // function of less than, then insert 4 elements
    map <int, int, less<int> > m1;
    m1.insert(Int_Pair(1, 10));
    m1.insert(Int_Pair(2, 20));
    m1.insert(Int_Pair(3, 30));
    m1.insert(Int_Pair(4, 40));

    // Create an empty map m2 with the key comparison
    // function of greater than, then insert 2 elements
    map <int, int, less<int> > m2;
    m2.insert(Int_Pair(1, 10));
    m2.insert(Int_Pair(2, 20));

    // Create a map m3 with the
    // allocator of map m1
```

```

map<int, int>::allocator_type m1_Alloc;
m1_Alloc = m1.get_allocator();
map<int, int> m3(less<int>(), m1_Alloc);
m3.insert(Int_Pair(3, 30));

// Create a copy, map m4, of map m1
map<int, int> m4(m1);

// Create a map m5 by copying the range m1[ first, last)
map<int, int>::const_iterator m1_bcIter, m1_ecIter;
m1_bcIter = m1.begin();
m1_ecIter = m1.begin();
m1_ecIter++;
m1_ecIter++;
map<int, int> m5(m1_bcIter, m1_ecIter);

// Create a map m6 by copying the range m4[ first, last)
// and with the allocator of map m2
map<int, int>::allocator_type m2_Alloc;
m2_Alloc = m2.get_allocator();
map<int, int> m6(m4.begin(), ++m4.begin(), less<int>(), m2_Alloc);

cout << "m1 =";
for (auto i : m1)
    cout << i.first << " " << i.second << ", ";
cout << endl;

cout << "m2 =";
for(auto i : m2)
    cout << i.first << " " << i.second << ", ";
cout << endl;

cout << "m3 =";
for (auto i : m3)
    cout << i.first << " " << i.second << ", ";
cout << endl;

cout << "m4 =";
for (auto i : m4)
    cout << i.first << " " << i.second << ", ";
cout << endl;

cout << "m5 =";
for (auto i : m5)
    cout << i.first << " " << i.second << ", ";
cout << endl;

cout << "m6 =";
for (auto i : m6)
    cout << i.first << " " << i.second << ", ";
cout << endl;

// Create a map m7 by moving m5
cout << "m7 =";
map<int, int> m7(move(m5));
for (auto i : m7)
    cout << i.first << " " << i.second << ", ";
cout << endl;

// Create a map m8 by copying in an initializer_list
map<int, int> m8{ { { 1, 1 }, { 2, 2 }, { 3, 3 }, { 4, 4 } } };
cout << "m8: = ";
for (auto i : m8)
    cout << i.first << " " << i.second << ", ";
cout << endl;

// Create a map m9 with an initializer_list and a comparator
map<int, int> m9({ { 5, 5 }, { 6, 6 }, { 7, 7 }, { 8, 8 } }, less<int>());
cout << "m9: = ";

```

```

    cout << m9;
    for (auto i : m9)
        cout << i.first << " " << i.second << ", ";
    cout << endl;

    // Create a map m10 with an initializer_list, a comparator, and an allocator
    map<int, int> m10({ { 9, 9 }, { 10, 10 }, { 11, 11 }, { 12, 12 } }, less<int>(), m9.get_allocator());
    cout << "m10: = ";
    for (auto i : m10)
        cout << i.first << " " << i.second << ", ";
    cout << endl;
}

```

map::mapped_type

A type that represents the data stored in a map.

```
typedef Type mapped_type;
```

Remarks

The type `mapped_type` is a synonym for the class's *Type* template parameter.

For more information on *Type* see the [map Class](#) topic.

Example

See example for [value_type](#) for an example of how to declare and use `mapped_type`.

map::max_size

Returns the maximum length of the map.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the map.

Example

```

// map_max_size.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1;
    map <int, int> :: size_type i;

    i = m1.max_size( );
    cout << "The maximum possible length "
        << "of the map is " << i << "."
        << endl << "(Magnitude is machine specific.);";
}

```

map::operator[]

Inserts an element into a map with a specified key value.

```
Type& operator[](const Key& key);
```

```
Type& operator[](Key&& key);
```

Parameters

PARAMETER	DESCRIPTION
Parameter	Description
<i>key</i>	The key value of the element that is to be inserted.

Return Value

A reference to the data value of the inserted element.

Remarks

If the argument key value is not found, then it is inserted along with the default value of the data type.

`operator[]` may be used to insert elements into a map `m` using `m[key] = DataValue;` where `DataValue` is the value of the `mapped_type` of the element with a key value of `key`.

When using `operator[]` to insert elements, the returned reference does not indicate whether an insertion is changing a pre-existing element or creating a new one. The member functions [find](#) and [insert](#) can be used to determine whether an element with a specified key is already present before an insertion.

Example

```

// map_op_insert.cpp
// compile with: /EHsc
#include <map>
#include <iostream>
#include <string>

int main( )
{
    using namespace std;
    typedef pair <const int, int> cInt2Int;
    map <int, int> m1;
    map <int, int> :: iterator pIter;

    // Insert a data value of 10 with a key of 1
    // into a map using the operator[] member function
    m1[ 1 ] = 10;

    // Compare other ways to insert objects into a map
    m1.insert ( map <int, int> :: value_type ( 2, 20 ) );
    m1.insert ( cInt2Int ( 3, 30 ) );

    cout << "The keys of the mapped elements are:";
    for ( pIter = m1.begin( ) ; pIter != m1.end( ) ; pIter++ )
        cout << " " << pIter -> first;
    cout << "." << endl;

    cout << "The values of the mapped elements are:";
    for ( pIter = m1.begin( ) ; pIter != m1.end( ) ; pIter++ )
        cout << " " << pIter -> second;
    cout << "." << endl;

    // If the key already exists, operator[]
    // changes the value of the datum in the element
    m1[ 2 ] = 40;

    // operator[] will also insert the value of the data
    // type's default constructor if the value is unspecified
    m1[5];

    cout << "The keys of the mapped elements are now:";
    for ( pIter = m1.begin( ) ; pIter != m1.end( ) ; pIter++ )
        cout << " " << pIter -> first;
    cout << "." << endl;

    cout << "The values of the mapped elements are now:";
    for ( pIter = m1.begin( ) ; pIter != m1.end( ) ; pIter++ )
        cout << " " << pIter -> second;
    cout << "." << endl;

    // insert by moving key
    map<string, int> c2;
    string str("abc");
    cout << "c2[move(str)] == " << c2[move(str)] << endl;
    cout << "c2[\"abc\"] == " << c2["abc"] << endl;

    return (0);
}

```

The keys of the mapped elements are: 1 2 3.
 The values of the mapped elements are: 10 20 30.
 The keys of the mapped elements are now: 1 2 3 5.
 The values of the mapped elements are now: 10 40 30 0.
 c2[move(str)] == 0
 c2["abc"] == 1

map::operator=

Replaces the elements of a map with a copy of another map.

```
map& operator=(const map& right);

map& operator=(map&& right);
```

Parameters

PARAMETER	DESCRIPTION
Parameter	Description
<i>right</i>	The map being copied into the <code>map</code> .

Remarks

After erasing any existing elements in a `map`, `operator=` either copies or moves the contents of *right* into the map.

Example

```
// map_operator_as.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map<int, int> v1, v2, v3;
    map<int, int>::iterator iter;

    v1.insert(pair<int, int>(1, 10));

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;
}
```

map::pointer

A type that provides a pointer to an element in a map.

```
typedef typename allocator_type::pointer pointer;
```

Remarks

A type `pointer` can be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a map object.

map::rbegin

Returns an iterator addressing the first element in a reversed map.

```
const_reverse_iterator rbegin() const;  
  
reverse_iterator rbegin();
```

Return Value

A reverse bidirectional iterator addressing the first element in a reversed map or addressing what had been the last element in the unreversed map.

Remarks

`rbegin` is used with a reversed map just as [begin](#) is used with a map.

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, then the map object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, then the map object can be modified.

`rbegin` can be used to iterate through a map backwards.

Example

```

// map_rbegin.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1;

    map <int, int> :: iterator m1_Iter;
    map <int, int> :: reverse_iterator m1_rIter;
    map <int, int> :: const_reverse_iterator m1_crIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_rIter = m1.rbegin( );
    cout << "The first element of the reversed map m1 is "
         << m1_rIter -> first << "." << endl;

    // begin can be used to start an iteration
    // through a map in a forward order
    cout << "The map is: ";
    for ( m1_Iter = m1.begin( ) ; m1_Iter != m1.end( ); m1_Iter++)
        cout << m1_Iter -> first << " ";
    cout << "." << endl;

    // rbegin can be used to start an iteration
    // through a map in a reverse order
    cout << "The reversed map is: ";
    for ( m1_rIter = m1.rbegin( ) ; m1_rIter != m1.rend( ); m1_rIter++)
        cout << m1_rIter -> first << " ";
    cout << "." << endl;

    // A map element can be erased by dereferencing to its key
    m1_rIter = m1.rbegin( );
    m1.erase ( m1_rIter -> first );

    m1_rIter = m1.rbegin( );
    cout << "After the erasure, the first element "
         << "in the reversed map is "
         << m1_rIter -> first << "." << endl;
}

```

```

The first element of the reversed map m1 is 3.
The map is: 1 2 3 .
The reversed map is: 3 2 1 .
After the erasure, the first element in the reversed map is 2.

```

map::reference

A type that provides a reference to an element stored in a map.

```

typedef typename allocator_type::reference reference;

```

Example

```

// map_reference.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );

    // Declare and initialize a const_reference &Ref1
    // to the key of the first element
    const int &Ref1 = ( m1.begin( ) -> first );

    // The following line would cause an error because the
    // non-const_reference cannot be used to access the key
    // int &Ref1 = ( m1.begin( ) -> first );

    cout << "The key of first element in the map is "
         << Ref1 << "." << endl;

    // Declare and initialize a reference &Ref2
    // to the data value of the first element
    int &Ref2 = ( m1.begin( ) -> second );

    cout << "The data value of first element in the map is "
         << Ref2 << "." << endl;

    //The non-const_reference can be used to modify the
    //data value of the first element
    Ref2 = Ref2 + 5;
    cout << "The modified data value of first element is "
         << Ref2 << "." << endl;
}

```

```

The key of first element in the map is 1.
The data value of first element in the map is 10.
The modified data value of first element is 15.

```

map::rend

Returns an iterator that addresses the location succeeding the last element in a reversed map.

```

const_reverse_iterator rend() const;

reverse_iterator rend();

```

Return Value

A reverse bidirectional iterator that addresses the location succeeding the last element in a reversed map (the location that had preceded the first element in the unreversed map).

Remarks

`rend` is used with a reversed map just as `end` is used with a map.

If the return value of `rend` is assigned to a `const_reverse_iterator`, then the map object cannot be modified. If the return value of `rend` is assigned to a `reverse_iterator`, then the map object can be modified.

`rend` can be used to test to whether a reverse iterator has reached the end of its map.

The value returned by `rend` should not be dereferenced.

Example

```
// map_rend.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1;

    map <int, int> :: iterator m1_Iter;
    map <int, int> :: reverse_iterator m1_rIter;
    map <int, int> :: const_reverse_iterator m1_crIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_rIter = m1.rend( );
    m1_rIter--;
    cout << "The last element of the reversed map m1 is "
         << m1_rIter -> first << "." << endl;

    // begin can be used to start an iteration
    // through a map in a forward order
    cout << "The map is: ";
    for ( m1_Iter = m1.begin( ); m1_Iter != m1.end( ); m1_Iter++)
        cout << m1_Iter -> first << " ";
    cout << "." << endl;

    // rbegin can be used to start an iteration
    // through a map in a reverse order
    cout << "The reversed map is: ";
    for ( m1_rIter = m1.rbegin( ); m1_rIter != m1.rend( ); m1_rIter++)
        cout << m1_rIter -> first << " ";
    cout << "." << endl;

    // A map element can be erased by dereferencing to its key
    m1_rIter = --m1.rend( );
    m1.erase ( m1_rIter -> first );

    m1_rIter = m1.rend( );
    m1_rIter--;
    cout << "After the erasure, the last element "
         << "in the reversed map is "
         << m1_rIter -> first << "." << endl;
}
```

```
The last element of the reversed map m1 is 1.
The map is: 1 2 3 .
The reversed map is: 3 2 1 .
After the erasure, the last element in the reversed map is 2.
```

map::reverse_iterator

A type that provides a bidirectional iterator that can read or modify an element in a reversed map.

```
typedef std::reverse_iterator<iterator> reverse_iterator;
```

Remarks

A type `reverse_iterator` cannot modify the value of an element and is used to iterate through the map in reverse.

The `reverse_iterator` defined by map points to elements that are objects of [value_type](#), that is of type `pair<const Key, Type>`, whose first member is the key to the element and whose second member is the mapped datum held by the element.

To dereference a `reverse_iterator` *rIter* pointing to an element in a map, use the `->` operator.

To access the value of the key for the element, use `rIter -> first`, which is equivalent to `(* rIter).first`. To access the value of the mapped datum for the element, use `rIter -> second`, which is equivalent to `(* rIter).second`.

Example

See example for [rbegin](#) for an example of how to declare and use `reverse_iterator`.

map::size

Returns the number of elements in the map.

```
size_type size() const;
```

Return Value

The current length of the map.

Example

The following example demonstrates the use of the `map::size` member function.

```
// map_size.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main()
{
    using namespace std;
    map<int, int> m1, m2;
    map<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    m1.insert(Int_Pair(1, 1));
    i = m1.size();
    cout << "The map length is " << i << "." << endl;

    m1.insert(Int_Pair(2, 4));
    i = m1.size();
    cout << "The map length is now " << i << "." << endl;
}
```

```
The map length is 1.
The map length is now 2.
```

map::size_type

An unsigned integer type that can represent the number of elements in a map.

```
typedef typename allocator_type::size_type size_type;
```

Example

See the example for [size](#) for an example of how to declare and use `size_type`.

map::swap

Exchanges the elements of two maps.

```
void swap(  
    map<Key, Type, Traits, Allocator>& right);
```

Parameters

right

The argument map providing the elements to be swapped with the target map.

Remarks

The member function invalidates no references, pointers, or iterators that designate elements in the two maps whose elements are being exchanged.

Example

```

// map_swap.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1, m2, m3;
    map <int, int>::iterator m1_Iter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );
    m2.insert ( Int_Pair ( 10, 100 ) );
    m2.insert ( Int_Pair ( 20, 200 ) );
    m3.insert ( Int_Pair ( 30, 300 ) );

    cout << "The original map m1 is:";
    for ( m1_Iter = m1.begin( ); m1_Iter != m1.end( ); m1_Iter++ )
        cout << " " << m1_Iter -> second;
    cout << "." << endl;

    // This is the member function version of swap
    //m2 is said to be the argument map; m1 the target map
    m1.swap( m2 );

    cout << "After swapping with m2, map m1 is:";
    for ( m1_Iter = m1.begin( ); m1_Iter != m1.end( ); m1_Iter++ )
        cout << " " << m1_Iter -> second;
    cout << "." << endl;

    // This is the specialized template version of swap
    swap( m1, m3 );

    cout << "After swapping with m3, map m1 is:";
    for ( m1_Iter = m1.begin( ); m1_Iter != m1.end( ); m1_Iter++ )
        cout << " " << m1_Iter -> second;
    cout << "." << endl;
}

```

```

The original map m1 is: 10 20 30.
After swapping with m2, map m1 is: 100 200.
After swapping with m3, map m1 is: 300.

```

map::upper_bound

Returns an iterator to the first element in a map that with a key having a value that is greater than that of a specified key.

```

iterator upper_bound(const Key& key);

const_iterator upper_bound(const Key& key) const;

```

Parameters

key

The argument key value to be compared with the sort key value of an element from the map being searched.

Return Value

An `iterator` or `const_iterator` that addresses the location of an element in a map that with a key that is greater than the argument key, or that addresses the location succeeding the last element in the map if no match is found for the key.

If the return value is assigned to a `const_iterator`, the map object cannot be modified. If the return value is assigned to a `iterator`, the map object can be modified.

Example

```
// map_upper_bound.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    map <int, int> m1;
    map <int, int> :: const_iterator m1_AcIter, m1_RcIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_RcIter = m1.upper_bound( 2 );
    cout << "The first element of map m1 with a key "
         << "greater than 2 is: "
         << m1_RcIter -> second << "." << endl;

    // If no match is found for the key, end is returned
    m1_RcIter = m1.upper_bound ( 4 );

    if ( m1_RcIter == m1.end( ) )
        cout << "The map m1 doesn't have an element "
             << "with a key greater than 4." << endl;
    else
        cout << "The element of map m1 with a key > 4 is: "
             << m1_RcIter -> second << "." << endl;

    // The element at a specific location in the map can be found
    // using a dereferenced iterator addressing the location
    m1_AcIter = m1.begin( );
    m1_RcIter = m1.upper_bound ( m1_AcIter -> first );
    cout << "The 1st element of m1 with a key greater than\n"
         << "that of the initial element of m1 is: "
         << m1_RcIter -> second << "." << endl;
}
```

```
The first element of map m1 with a key greater than 2 is: 30.
The map m1 doesn't have an element with a key greater than 4.
The 1st element of m1 with a key greater than
that of the initial element of m1 is: 20.
```

map::value_comp

The member function returns a function object that determines the order of elements in a map by comparing their key values.

```
value_compare value_comp() const;
```

Return Value

Returns the comparison function object that a map uses to order its elements.

Remarks

For a map m , if two elements $e1(k1, d1)$ and $e2(k2, d2)$ are objects of type `value_type`, where $k1$ and $k2$ are their keys of type `key_type` and $d1$ and $d2$ are their data of type `mapped_type`, then `m.value_comp(e1, e2)` is equivalent to `m.key_comp(k1, k2)`. A stored object defines the member function

```
bool operator( value_type& left, value_type& right);
```

which returns **true** if the key value of `left` precedes and is not equal to the key value of `right` in the sort order.

Example

```
// map_value_comp.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;

    map <int, int, less<int> > m1;
    map <int, int, less<int> >::value_compare vc1 = m1.value_comp( );
    pair< map<int,int>::iterator, bool > pr1, pr2;

    pr1= m1.insert ( map <int, int> :: value_type ( 1, 10 ) );
    pr2= m1.insert ( map <int, int> :: value_type ( 2, 5 ) );

    if( vc1( *pr1.first, *pr2.first ) == true )
    {
        cout << "The element ( 1,10 ) precedes the element ( 2,5 )."
              << endl;
    }
    else
    {
        cout << "The element ( 1,10 ) does not precede the element ( 2,5 )."
              << endl;
    }

    if(vc1( *pr2.first, *pr1.first ) == true )
    {
        cout << "The element ( 2,5 ) precedes the element ( 1,10 )."
              << endl;
    }
    else
    {
        cout << "The element ( 2,5 ) does not precede the element ( 1,10 )."
              << endl;
    }
}
```

```
The element ( 1,10 ) precedes the element ( 2,5 ).
The element ( 2,5 ) does not precede the element ( 1,10 ).
```

map::value_type

The type of object stored as an element in a map.

```
typedef pair<const Key, Type> value_type;
```

Example

```
// map_value_type.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    typedef pair <const int, int> cInt2Int;
    map <int, int> m1;
    map <int, int> :: key_type key1;
    map <int, int> :: mapped_type mapped1;
    map <int, int> :: value_type value1;
    map <int, int> :: iterator pIter;

    // value_type can be used to pass the correct type
    // explicitly to avoid implicit type conversion
    m1.insert ( map <int, int> :: value_type ( 1, 10 ) );

    // Compare other ways to insert objects into a map
    m1.insert ( cInt2Int ( 2, 20 ) );
    m1[ 3 ] = 30;

    // Initializing key1 and mapped1
    key1 = ( m1.begin( ) -> first );
    mapped1 = ( m1.begin( ) -> second );

    cout << "The key of first element in the map is "
          << key1 << "." << endl;

    cout << "The data value of first element in the map is "
          << mapped1 << "." << endl;

    // The following line would cause an error because
    // the value_type is not assignable
    // value1 = cInt2Int ( 4, 40 );

    cout << "The keys of the mapped elements are:";
    for ( pIter = m1.begin( ) ; pIter != m1.end( ) ; pIter++ )
        cout << " " << pIter -> first;
    cout << "." << endl;

    cout << "The values of the mapped elements are:";
    for ( pIter = m1.begin( ) ; pIter != m1.end( ) ; pIter++ )
        cout << " " << pIter -> second;
    cout << "." << endl;
}
```

multimap Class

11/14/2018 • 53 minutes to read • [Edit Online](#)

The C++ Standard Library multimap class is used for the storage and retrieval of data from a collection in which the each element is a pair that has both a data value and a sort key. The value of the key does not need to be unique and is used to order the data automatically. The value of an element in a multimap, but not its associated key value, may be changed directly. Instead, key values associated with old elements must be deleted and new key values associated with new elements inserted.

Syntax

```
template <class Key,  
          class Type,  
          class Traits=less <Key>,  
          class Allocator=allocator <pair <const Key, Type>>>  
class multimap;
```

Parameters

Key

The key data type to be stored in the multimap.

Type

The element data type to be stored in the multimap.

Traits

The type that provides a function object that can compare two element values as sort keys to determine their relative order in the multimap. The binary predicate `less<Key>` is the default value.

In C++ 14 you can enable heterogeneous lookup by specifying the `std::less<>` or `std::greater<>` predicate that has no type parameters. For more information, see [Heterogeneous Lookup in Associative Containers](#)

Allocator

The type that represents the stored allocator object that encapsulates details about the map's allocation and deallocation of memory. This argument is optional and the default value is `allocator<pair <const Key, Type> >`.

Remarks

The C++ Standard Library multimap class is

- An associative container, which a variable size container that supports the efficient retrieval of element values based on an associated key value.
- Reversible, because it provides bidirectional iterators to access its elements.
- Sorted, because its elements are ordered by key values within the container in accordance with a specified comparison function.
- Multiple, because its elements do not need to have a unique keys, so that one key value may have many element data values associated with it.
- A pair associative container, because its element data values are distinct from its key values.
- A template class, because the functionality it provides is generic and so independent of the specific type of

data contained as elements or keys. The data types to be used for elements and keys are, instead, specified as parameters in the class template along with the comparison function and allocator.

The iterator provided by the map class is a bidirectional iterator, but the class member functions [insert](#) and [multimap](#) have versions that take as template parameters a weaker input iterator, whose functionality requirements are more minimal than those guaranteed by the class of bidirectional iterators. The different iterator concepts form a family related by refinements in their functionality. Each iterator concept has its own set of requirements and the algorithms that work with them must limit their assumptions to the requirements provided by that type of iterator. It may be assumed that an input iterator may be dereferenced to refer to some object and that it may be incremented to the next iterator in the sequence. This is a minimal set of functionality, but it is enough to be able to talk meaningfully about a range of iterators `[First, Last)` in the context of the class's member functions.

The choice of container type should be based in general on the type of searching and inserting required by the application. Associative containers are optimized for the operations of lookup, insertion and removal. The member functions that explicitly support these operations are efficient, performing them in a time that is on average proportional to the logarithm of the number of elements in the container. Inserting elements invalidates no iterators, and removing elements invalidates only those iterators that had specifically pointed at the removed elements.

The multimap should be the associative container of choice when the conditions associating the values with their keys are satisfied by the application. A model for this type of structure is an ordered list of key words with associated string values providing, say, definitions, where the words were not always uniquely defined. If, instead, the key words were uniquely defined so that keys were unique, then a map would be the container of choice. If, on the other hand, just the list of words were being stored, then a set would be the correct container. If multiple occurrences of the words were allowed, then a multiset would be the appropriate container structure.

The multimap orders the sequence it controls by calling a stored function object of type [key_compare](#). This stored object is a comparison function that may be accessed by calling the member function [key_comp](#). In general, the elements need be merely less than comparable to establish this order: so that, given any two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. On a more technical note, the comparison function is a binary predicate that induces a strict weak ordering in the standard mathematical sense. A binary predicate `f(x,y)` is a function object that has two argument objects `x` and `y` and a return value of true or false. An ordering imposed on a set is a strict weak ordering if the binary predicate is irreflexive, antisymmetric, and transitive and if equivalence is transitive, where two objects `x` and `y` are defined to be equivalent when both `f(x,y)` and `f(y,x)` are false. If the stronger condition of equality between keys replaces that of equivalence, then the ordering becomes total (in the sense that all the elements are ordered with respect to each other) and the keys matched will be indiscernible from each other.

In C++14 you can enable heterogeneous lookup by specifying the `std::less<>` or `std::greater<>` predicate that has no type parameters. For more information, see [Heterogeneous Lookup in Associative Containers](#)

Members

Constructors

CONSTRUCTOR	DESCRIPTION
multimap	Constructs a <code>multimap</code> that is empty or that is a copy of all or part of some other <code>multimap</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>allocator_type</code>	A type that represents the <code>allocator</code> class for the <code>multimap</code> object.
<code>const_iterator</code>	A type that provides a bidirectional iterator that can read a const element in the <code>multimap</code> .
<code>const_pointer</code>	A type that provides a pointer to a const element in a <code>multimap</code> .
<code>const_reference</code>	A type that provides a reference to a const element stored in a <code>multimap</code> for reading and performing const operations.
<code>const_reverse_iterator</code>	A type that provides a bidirectional iterator that can read any const element in the <code>multimap</code> .
<code>difference_type</code>	A signed integer type that can be used to represent the number of elements of a <code>multimap</code> in a range between elements pointed to by iterators.
<code>iterator</code>	A type that provides the difference between two iterators that refer to elements within the same <code>multimap</code> .
<code>key_compare</code>	A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the <code>multimap</code> .
<code>key_type</code>	A type that describes the sort key object that constitutes each element of the <code>multimap</code> .
<code>mapped_type</code>	A type that represents the data type stored in a <code>multimap</code> .
<code>pointer</code>	A type that provides a pointer to a const element in a <code>multimap</code> .
<code>reference</code>	A type that provides a reference to an element stored in a <code>multimap</code> .
<code>reverse_iterator</code>	A type that provides a bidirectional iterator that can read or modify an element in a reversed <code>multimap</code> .
<code>size_type</code>	An unsigned integer type that provides a pointer to a const element in a <code>multimap</code> .
<code>value_type</code>	A type that provides a function object that can compare two elements as sort keys to determine their relative order in the <code>multimap</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
-----------------	-------------

MEMBER FUNCTION	DESCRIPTION
<code>begin</code>	Returns an iterator addressing the first element in the <code>multimap</code> .
<code>cbegin</code>	Returns a const iterator addressing the first element in the <code>multimap</code> .
<code>cend</code>	Returns a const iterator that addresses the location succeeding the last element in a <code>multimap</code> .
<code>clear</code>	Erases all the elements of a <code>multimap</code> .
<code>count</code>	Returns the number of elements in a <code>multimap</code> whose key matches a parameter-specified key.
<code>crbegin</code>	Returns a const iterator addressing the first element in a reversed <code>multimap</code> .
<code>crend</code>	Returns a const iterator that addresses the location succeeding the last element in a reversed <code>multimap</code> .
<code>emplace</code>	Inserts an element constructed in place into a <code>multimap</code> .
<code>emplace_hint</code>	Inserts an element constructed in place into a <code>multimap</code> , with a placement hint
<code>empty</code>	Tests if a <code>multimap</code> is empty.
<code>end</code>	Returns an iterator that addresses the location succeeding the last element in a <code>multimap</code> .
<code>equal_range</code>	Finds the range of elements where the key of the element matches a specified value.
<code>erase</code>	Removes an element or a range of elements in a <code>multimap</code> from specified positions or removes elements that match a specified key.
<code>find</code>	Returns an iterator addressing the first location of an element in a <code>multimap</code> that has a key equivalent to a specified key.
<code>get_allocator</code>	Returns a copy of the <code>allocator</code> object used to construct the <code>multimap</code> .
<code>insert</code>	Inserts an element or a range of elements into a <code>multimap</code> .
<code>key_comp</code>	Retrieves a copy of the comparison object used to order keys in a <code>multimap</code> .
<code>lower_bound</code>	Returns an iterator to the first element in a <code>multimap</code> that with a key that is equal to or greater than a specified key.

MEMBER FUNCTION	DESCRIPTION
max_size	Returns the maximum length of the <code>multimap</code> .
rbegin	Returns an iterator addressing the first element in a reversed <code>multimap</code> .
rend	Returns an iterator that addresses the location succeeding the last element in a reversed <code>multimap</code> .
size	Returns the number of elements in the <code>multimap</code> .
swap	Exchanges the elements of two <code>multimap</code> s.
upper_bound	Returns an iterator to the first element in a <code>multimap</code> that with a key that is greater than a specified key.
value_comp	The member function returns a function object that determines the order of elements in a <code>multimap</code> by comparing their key values.

Operators

OPERATOR	DESCRIPTION
operator=	Replaces the elements of a <code>multimap</code> with a copy of another <code>multimap</code> .

Requirements

Header: `<map>`

Namespace: `std`

The (**key**, **value**) pairs are stored in a `multimap` as objects of type `pair`. The `pair` class requires the header `<utility>`, which is automatically included by `<map>`.

`multimap::allocator_type`

A type that represents the allocator class for the `multimap` object.

```
typedef Allocator allocator_type;
```

Example

See the example for [get_allocator](#) for an example using `allocator_type`.

`multimap::begin`

Returns an iterator addressing the first element in the `multimap`.

```
const_iterator begin() const;

iterator begin();
```

Return Value

A bidirectional iterator addressing the first element in the multimap or the location succeeding an empty multimap.

Example

```
// multimap_begin.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1;

    multimap <int, int> :: iterator m1_Iter;
    multimap <int, int> :: const_iterator m1_cIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 0, 0 ) );
    m1.insert ( Int_Pair ( 1, 1 ) );
    m1.insert ( Int_Pair ( 2, 4 ) );

    m1_cIter = m1.begin ( );
    cout << "The first element of m1 is " << m1_cIter -> first << endl;

    m1_Iter = m1.begin ( );
    m1.erase ( m1_Iter );

    // The following 2 lines would err as the iterator is const
    // m1_cIter = m1.begin ( );
    // m1.erase ( m1_cIter );

    m1_cIter = m1.begin( );
    cout << "First element of m1 is now " << m1_cIter -> first << endl;
}
```

```
The first element of m1 is 0
First element of m1 is now 1
```

multimap::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** bidirectional-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin`, the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non-**const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

`multimap::cend`

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A **const** bidirectional-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non-**const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

`multimap::clear`

Erases all the elements of a multimap.

```
void clear();
```

Example

The following example demonstrates the use of the `multimap::clear` member function.

```
// multimap_clear.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap<int, int> m1;
    multimap<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    m1.insert(Int_Pair(1, 1));
    m1.insert(Int_Pair(2, 4));

    i = m1.size();
    cout << "The size of the multimap is initially "
         << i << "." << endl;

    m1.clear();
    i = m1.size();
    cout << "The size of the multimap after clearing is "
         << i << "." << endl;
}
```

```
The size of the multimap is initially 2.
The size of the multimap after clearing is 0.
```

multimap::const_iterator

A type that provides a bidirectional iterator that can read a **const** element in the multimap.

```
typedef implementation-defined const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

The `const_iterator` defined by multimap points to objects of [value_type](#), which are of type `pair<const Key, Type>`. The value of the key is available through the first member pair and the value of the mapped element is available through the second member of the pair.

To dereference a `const_iterator` *cIter* pointing to an element in a multimap, use the `->` operator.

To access the value of the key for the element, use `cIter->first`, which is equivalent to `(*cIter).first`. To access the value of the mapped datum for the element, use `cIter->second`, which is equivalent to `(*cIter).second`.

Example

See the example for [begin](#) for an example using `const_iterator`.

multimap::const_pointer

A type that provides a pointer to a **const** element in a multimap.

```
typedef typename allocator_type::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a multimap object.

multimap::const_reference

A type that provides a reference to a **const** element stored in a multimap for reading and performing **const** operations.

```
typedef typename allocator_type::const_reference const_reference;
```

Example

```
// multimap_const_ref.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );

    // Declare and initialize a const_reference &Ref1
    // to the key of the first element
    const int &Ref1 = ( m1.begin( ) -> first );

    // The following line would cause an error because the
    // non-const_reference cannot be used to access the key
    // int &Ref1 = ( m1.begin( ) -> first );

    cout << "The key of the first element in the multimap is "
         << Ref1 << "." << endl;

    // Declare and initialize a reference &Ref2
    // to the data value of the first element
    int &Ref2 = ( m1.begin( ) -> second );

    cout << "The data value of the first element in the multimap is "
         << Ref2 << "." << endl;
}
```

```
The key of the first element in the multimap is 1.
The data value of the first element in the multimap is 10.
```

multimap::const_reverse_iterator

A type that provides a bidirectional iterator that can read any **const** element in the multimap.

```
typedef std::reverse_iterator<const_iterator> const_reverse_iterator;
```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is use to iterate through the multimap in reverse.

The `const_reverse_iterator` defined by `multimap` points to objects of `value_type`, which are of type `pair<const Key, Type>`. The value of the key is available through the first member pair and the value of the mapped element is available through the second member of the pair.

To dereference a `const_reverse_iterator` *crIter* pointing to an element in a `multimap`, use the `->` operator.

To access the value of the key for the element, use `crIter->first`, which is equivalent to `(*crIter).first`. To access the value of the mapped datum for the element, use `crIter->second`, which is equivalent to `(*crIter).second`.

Example

See the example for [rend](#) for an example of how to declare and use `const_reverse_iterator`.

multimap::count

Returns the number of elements in a `multimap` whose keys match a parameter-specified key.

```
size_type count(const Key& key) const;
```

Parameters

key

The key of the elements to be matched from the `multimap`.

Return Value

The number of elements whose sort keys match the parameter `key`; 0 if the `multimap` doesn't contain an element with a matching key.

Remarks

The member function returns the number of elements in the range

`[lower_bound(key), upper_bound(key))`

that have a key value *key*.

Example

The following example demonstrates the use of the `multimap::count` member function.

```

// multimap_count.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap<int, int> m1;
    multimap<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    m1.insert(Int_Pair(1, 1));
    m1.insert(Int_Pair(2, 1));
    m1.insert(Int_Pair(1, 4));
    m1.insert(Int_Pair(2, 1));

    // Elements do not need to have unique keys in multimap,
    // so duplicates are allowed and counted
    i = m1.count(1);
    cout << "The number of elements in m1 with a sort key of 1 is: "
         << i << "." << endl;

    i = m1.count(2);
    cout << "The number of elements in m1 with a sort key of 2 is: "
         << i << "." << endl;

    i = m1.count(3);
    cout << "The number of elements in m1 with a sort key of 3 is: "
         << i << "." << endl;
}

```

```

The number of elements in m1 with a sort key of 1 is: 2.
The number of elements in m1 with a sort key of 2 is: 2.
The number of elements in m1 with a sort key of 3 is: 0.

```

multimap::crbegin

Returns a const iterator addressing the first element in a reversed multimap.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse bidirectional iterator addressing the first element in a reversed [multimap](#) or addressing what had been the last element in the unreversed `multimap`.

Remarks

`crbegin` is used with a reversed `multimap` just as [begin](#) is used with a `multimap`.

With the return value of `crbegin`, the `multimap` object cannot be modified.

`crbegin` can be used to iterate through a `multimap` backwards.

Example

```

// multimap_crbegin.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1;

    multimap <int, int> :: const_reverse_iterator m1_crIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_crIter = m1.crbegin( );
    cout << "The first element of the reversed multimap m1 is "
         << m1_crIter -> first << "." << endl;
}

```

The first element of the reversed multimap m1 is 3.

multimap::crend

Returns a const iterator that addresses the location succeeding the last element in a reversed multimap.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse bidirectional iterator that addresses the location succeeding the last element in a reversed [multimap](#) (the location that had preceded the first element in the unreversed `multimap`).

Remarks

`crend` is used with a reversed `multimap` just as [multimap::end](#) is used with a `multimap`.

With the return value of `crend`, the `multimap` object cannot be modified.

`crend` can be used to test to whether a reverse iterator has reached the end of its `multimap`.

The value returned by `crend` should not be dereferenced.

Example

```

// multimap_crend.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1;

    multimap <int, int> :: const_reverse_iterator m1_crIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_crIter = m1.crend( );
    m1_crIter--;
    cout << "The last element of the reversed multimap m1 is "
         << m1_crIter -> first << "." << endl;
}

```

The last element of the reversed multimap m1 is 1.

multimap::difference_type

A signed integer type that can be used to represent the number of elements of a multimap in a range between elements pointed to by iterators.

```
typedef typename allocator_type::difference_type difference_type;
```

Remarks

The `difference_type` is the type returned when subtracting or incrementing through iterators of the container. The `difference_type` is typically used to represent the number of elements in the range *[first, last)* between the iterators `first` and `last`, includes the element pointed to by `first` and the range of elements up to, but not including, the element pointed to by `last`.

Note that although `difference_type` is available for all iterators that satisfy the requirements of an input iterator, which includes the class of bidirectional iterators supported by reversible containers such as set, subtraction between iterators is only supported by random-access iterators provided by a random-access container such as vector.

Example

```

// multimap_diff_type.cpp
// compile with: /EHsc
#include <iostream>
#include <map>
#include <algorithm>

int main( )
{
    using namespace std;
    multimap <int, int> m1;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 3, 20 ) );

    // The following will insert as multimap keys are not unique
    m1.insert ( Int_Pair ( 2, 30 ) );

    multimap <int, int>::iterator m1_Iter, m1_bIter, m1_eIter;
    m1_bIter = m1.begin( );
    m1_eIter = m1.end( );

    // Count the number of elements in a multimap
    multimap <int, int>::difference_type df_count = 0;
    m1_Iter = m1.begin( );
    while ( m1_Iter != m1_eIter )
    {
        df_count++;
        m1_Iter++;
    }

    cout << "The number of elements in the multimap m1 is: "
         << df_count << "." << endl;
}

```

```
The number of elements in the multimap m1 is: 4.
```

multimap::emplace

Inserts an element constructed in place (no copy or move operations are performed).

```

template <class... Args>
iterator emplace(Args&&... args);

```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the multimap.

Return Value

An iterator to the newly inserted element.

Remarks

No references to container elements are invalidated by this function, but it may invalidate all iterators to the container.

If an exception is thrown during the insertion, the container is left unaltered and the exception is rethrown.

The [value_type](#) of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

Example

```
// multimap_emplace.cpp
// compile with: /EHsc
#include <map>
#include <string>
#include <iostream>

using namespace std;

template <typename M> void print(const M& m) {
    cout << m.size() << " elements: " << endl;

    for (const auto& p : m) {
        cout << "(" << p.first << ", " << p.second << ") ";
    }

    cout << endl;
}

int main()
{
    multimap<string, string> m1;

    m1.emplace("Anna", "Accounting");
    m1.emplace("Bob", "Accounting");
    m1.emplace("Carmine", "Engineering");

    cout << "multimap modified, now contains ";
    print(m1);
    cout << endl;

    m1.emplace("Bob", "Engineering");

    cout << "multimap modified, now contains ";
    print(m1);
    cout << endl;
}
```

multimap::emplace_hint

Inserts an element constructed in place (no copy or move operations are performed), with a placement hint.

```
template <class... Args>
iterator emplace_hint(
    const_iterator where,
    Args&&... args);
```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the multimap.

PARAMETER	DESCRIPTION
<i>where</i>	The place to start searching for the correct point of insertion. (If that point immediately precedes <i>where</i> , insertion can occur in amortized constant time instead of logarithmic time.)

Return Value

An iterator to the newly inserted element.

Remarks

No references to container elements are invalidated by this function, but it may invalidate all iterators to the container.

During emplacement, if an exception is thrown, the container's state is not modified.

The [value_type](#) of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

For a code example, see [map::emplace_hint](#).

multimap::empty

Tests if a multimap is empty.

```
bool empty() const;
```

Return Value

true if the multimap is empty; **false** if the multimap is nonempty.

Example

```
// multimap_empty.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1, m2;

    typedef pair <int, int> Int_Pair;
    m1.insert ( Int_Pair ( 1, 1 ) );

    if ( m1.empty( ) )
        cout << "The multimap m1 is empty." << endl;
    else
        cout << "The multimap m1 is not empty." << endl;

    if ( m2.empty( ) )
        cout << "The multimap m2 is empty." << endl;
    else
        cout << "The multimap m2 is not empty." << endl;
}
```

```
The multimap m1 is not empty.
The multimap m2 is empty.
```

multimap::end

Returns the past-the-end iterator.

```
const_iterator end() const;

iterator end();
```

Return Value

The past-the-end iterator. If the multimap is empty, then `multimap::end() == multimap::begin()`.

Remarks

end is used to test whether an iterator has passed the end of its multimap.

The value returned by **end** should not be dereferenced.

For a code example, see [multimap::find](#).

multimap::equal_range

Finds the range of elements where the key of the element matches a specified value.

```
pair <const_iterator, const_iterator> equal_range (const Key& key) const;

pair <iterator, iterator> equal_range (const Key& key);
```

Parameters

key

The argument key to be compared with the sort key of an element from the multimap being searched.

Return Value

A pair of iterators such that the first is the [lower_bound](#) of the key and the second is the [upper_bound](#) of the key.

To access the first iterator of a pair `pr` returned by the member function, use `pr.first` and to dereference the lower bound iterator, use `*(pr.first)`. To access the second iterator of a pair `pr` returned by the member function, use `pr.second` and to dereference the upper bound iterator, use `*(pr.second)`.

Example

```

// multimap_equal_range.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    typedef multimap <int, int, less<int> > IntMMap;
    IntMMap m1;
    multimap <int, int> :: const_iterator m1_RcIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    pair <IntMMap::const_iterator, IntMMap::const_iterator> p1, p2;
    p1 = m1.equal_range( 2 );

    cout << "The lower bound of the element with "
         << "a key of 2 in the multimap m1 is: "
         << p1.first -> second << "." << endl;

    cout << "The upper bound of the element with "
         << "a key of 2 in the multimap m1 is: "
         << p1.second -> second << "." << endl;

    // Compare the upper_bound called directly
    m1_RcIter = m1.upper_bound( 2 );

    cout << "A direct call of upper_bound( 2 ) gives "
         << m1_RcIter -> second << "," << endl
         << "matching the 2nd element of the pair "
         << "returned by equal_range( 2 )." << endl;

    p2 = m1.equal_range( 4 );

    // If no match is found for the key,
    // both elements of the pair return end( )
    if ( ( p2.first == m1.end( ) ) && ( p2.second == m1.end( ) ) )
        cout << "The multimap m1 doesn't have an element "
             << "with a key less than 4." << endl;
    else
        cout << "The element of multimap m1 with a key >= 40 is: "
             << p1.first -> first << "." << endl;
}

```

```

The lower bound of the element with a key of 2 in the multimap m1 is: 20.
The upper bound of the element with a key of 2 in the multimap m1 is: 30.
A direct call of upper_bound( 2 ) gives 30,
matching the 2nd element of the pair returned by equal_range( 2 ).
The multimap m1 doesn't have an element with a key less than 4.

```

multimap::erase

Removes an element or a range of elements in a multimap from specified positions or removes elements that match a specified key.

```
iterator erase(
    const_iterator Where);

iterator erase(
    const_iterator First,
    const_iterator Last);

size_type erase(
    const key_type& Key);
```

Parameters

Where

Position of the element to be removed.

First

Position of the first element to be removed.

Last

Position just beyond the last element to be removed.

Key

The key of the elements to be removed.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or an element that is the end of the map if no such element exists.

For the third member function, returns the number of elements that have been removed from the multimap.

Remarks

For a code example, see [map::erase](#).

multimap::find

Returns an iterator that refers to the first location of an element in a multimap that has a key equivalent to a specified key.

```
iterator find(const Key& key);

const_iterator find(const Key& key) const;
```

Parameters

key

The key value to be matched by the sort key of an element from the multimap being searched.

Return Value

An iterator that refers to the location of an element with a specified key, or the location succeeding the last element in the multimap (`multimap::end()`) if no match is found for the key.

Remarks

The member function returns an iterator that refers to an element in the multimap whose sort key is equivalent to the argument key under a binary predicate that induces an ordering based on a less than comparability relation.

If the return value of `find` is assigned to a `const_iterator`, the multimap object cannot be modified. If the return value of `find` is assigned to an `iterator`, the multimap object can be modified.

Example

```
// compile with: /EHsc /W4 /MTd
#include <map>
#include <iostream>
#include <vector>
#include <string>
#include <utility> // make_pair()

using namespace std;

template <typename A, typename B> void print_elem(const pair<A, B>& p) {
    cout << "(" << p.first << ", " << p.second << ") ";
}

template <typename T> void print_collection(const T& t) {
    cout << t.size() << " elements: ";

    for (const auto& p : t) {
        print_elem(p);
    }
    cout << endl;
}

template <typename C, class T> void findit(const C& c, T val) {
    cout << "Trying find() on value " << val << endl;
    auto result = c.find(val);
    if (result != c.end()) {
        cout << "Element found: "; print_elem(*result); cout << endl;
    } else {
        cout << "Element not found." << endl;
    }
}

int main()
{
    multimap<int, string> m1({ { 40, "Zr" }, { 45, "Rh" } });
    cout << "The starting multimap m1 is (key, value):" << endl;
    print_collection(m1);

    vector<pair<int, string>> v;
    v.push_back(make_pair(43, "Tc"));
    v.push_back(make_pair(41, "Nb"));
    v.push_back(make_pair(46, "Pd"));
    v.push_back(make_pair(42, "Mo"));
    v.push_back(make_pair(44, "Ru"));
    v.push_back(make_pair(44, "Ru")); // attempt a duplicate

    cout << "Inserting the following vector data into m1:" << endl;
    print_collection(v);

    m1.insert(v.begin(), v.end());

    cout << "The modified multimap m1 is (key, value):" << endl;
    print_collection(m1);
    cout << endl;
    findit(m1, 45);
    findit(m1, 6);
}
```

multimap::get_allocator

Returns a copy of the allocator object used to construct the multimap.

```
allocator_type get_allocator() const;
```

Return Value

The allocator used by the multimap.

Remarks

Allocators for the multimap class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```
// multimap_get_allocator.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int>::allocator_type m1_Alloc;
    multimap <int, int>::allocator_type m2_Alloc;
    multimap <int, double>::allocator_type m3_Alloc;
    multimap <int, int>::allocator_type m4_Alloc;

    // The following lines declare objects
    // that use the default allocator.
    multimap <int, int> m1;
    multimap <int, int, allocator<int> > m2;
    multimap <int, double, allocator<double> > m3;

    m1_Alloc = m1.get_allocator( );
    m2_Alloc = m2.get_allocator( );
    m3_Alloc = m3.get_allocator( );

    cout << "The number of integers that can be allocated"
         << endl << "before free memory is exhausted: "
         << m2.max_size( ) << ".\n" << endl;

    cout << "The number of doubles that can be allocated"
         << endl << "before free memory is exhausted: "
         << m3.max_size( ) << ".\n" << endl;

    // The following line creates a multimap m4
    // with the allocator of multimap m1.
    map <int, int> m4( less<int>( ), m1_Alloc );

    m4_Alloc = m4.get_allocator( );

    // Two allocators are interchangeable if
    // storage allocated from each can be
    // deallocated via the other
    if( m1_Alloc == m4_Alloc )
    {
        cout << "The allocators are interchangeable."
             << endl;
    }
    else
    {
        cout << "The allocators are not interchangeable."
             << endl;
    }
}
```

multimap::insert

Inserts an element or a range of elements into a multimap.

```
// (1) single element
pair<iterator, bool> insert(
    const value_type& Val);

// (2) single element, perfect forwarded
template <class ValTy>
pair<iterator, bool>
insert(
    ValTy&& Val);

// (3) single element with hint
iterator insert(
    const_iterator Where,
    const value_type& Val);

// (4) single element, perfect forwarded, with hint
template <class ValTy>
iterator insert(
    const_iterator Where,
    ValTy&& Val);

// (5) range
template <class InputIterator>
void insert(
    InputIterator First,
    InputIterator Last);

// (6) initializer list
void insert(
    initializer_list<value_type>
    IList);
```

Parameters

PARAMETER	DESCRIPTION
<i>Val</i>	The value of an element to be inserted into the multimap.
<i>Where</i>	The place to start searching for the correct point of insertion. (If that point immediately precedes <i>Where</i> , insertion can occur in amortized constant time instead of logarithmic time.)
<i>ValTy</i>	Template parameter that specifies the argument type that the map can use to construct an element of value_type , and perfect-forwards <i>Val</i> as an argument.
<i>First</i>	The position of the first element to be copied.
<i>Last</i>	The position just beyond the last element to be copied.
<i>InputIterator</i>	Template function argument that meets the requirements of an input iterator that points to elements of a type that can be used to construct value_type objects.
<i>IList</i>	The initializer_list from which to copy the elements.

Return Value

The single-element-insert member functions, (1) and (2), return an iterator to the position where the new element was inserted into the multimap.

The single-element-with-hint member functions, (3) and (4), return an iterator that points to the position where the new element was inserted into the multimap.

Remarks

No pointers or references are invalidated by this function, but it may invalidate all iterators to the container.

During the insertion of just one element, if an exception is thrown, the container's state is not modified. During the insertion of multiple elements, if an exception is thrown, the container is left in an unspecified but valid state.

The [value_type](#) of a container is a typedef that belongs to the container, and for map, `multimap<K, V>::value_type` is `pair<const K, V>`. The value of an element is an ordered pair in which the first component is equal to the key value and the second component is equal to the data value of the element.

The range member function (5) inserts the sequence of element values into a multimap that corresponds to each element addressed by an iterator in the range `[First, Last)`; therefore, *Last* does not get inserted. The container member function `end()` refers to the position just after the last element in the container—for example, the statement `m.insert(v.begin(), v.end());` inserts all elements of `v` into `m`.

The initializer list member function (6) uses an [initializer_list](#) to copy elements into the map.

For insertion of an element constructed in place—that is, no copy or move operations are performed—see [multimap::emplace](#) and [multimap::emplace_hint](#).

Example

```
// multimap_insert.cpp
// compile with: /EHsc
#include <map>
#include <iostream>
#include <string>
#include <vector>
#include <utility> // make_pair()

using namespace std;

template <typename M> void print(const M& m) {
    cout << m.size() << " elements: ";

    for (const auto& p : m) {
        cout << "(" << p.first << ", " << p.second << ") ";
    }

    cout << endl;
}

int main()
{
    // insert single values
    multimap<int, int> m1;
    // call insert(const value_type&) version
    m1.insert({ 1, 10 });
    // call insert(ValTy&&) version
    m1.insert(make_pair(2, 20));

    cout << "The original key and mapped values of m1 are:" << endl;
    print(m1);

    // intentionally attempt a duplicate, single element
    m1.insert(make_pair(1, 11));
}
```

```

cout << "The modified key and mapped values of m1 are:" << endl;
print(m1);

// single element, with hint
m1.insert(m1.end(), make_pair(3, 30));
cout << "The modified key and mapped values of m1 are:" << endl;
print(m1);
cout << endl;

// The templated version inserting a jumbled range
multimap<int, int> m2;
vector<pair<int, int>> v;
v.push_back(make_pair(43, 294));
v.push_back(make_pair(41, 262));
v.push_back(make_pair(45, 330));
v.push_back(make_pair(42, 277));
v.push_back(make_pair(44, 311));

cout << "Inserting the following vector data into m2:" << endl;
print(v);

m2.insert(v.begin(), v.end());

cout << "The modified key and mapped values of m2 are:" << endl;
print(m2);
cout << endl;

// The templated versions move-constructing elements
multimap<int, string> m3;
pair<int, string> ip1(475, "blue"), ip2(510, "green");

// single element
m3.insert(move(ip1));
cout << "After the first move insertion, m3 contains:" << endl;
print(m3);

// single element with hint
m3.insert(m3.end(), move(ip2));
cout << "After the second move insertion, m3 contains:" << endl;
print(m3);
cout << endl;

multimap<int, int> m4;
// Insert the elements from an initializer_list
m4.insert({ { 4, 44 }, { 2, 22 }, { 3, 33 }, { 1, 11 }, { 5, 55 } });
cout << "After initializer_list insertion, m4 contains:" << endl;
print(m4);
cout << endl;
}

```

multimap::iterator

A type that provides a bidirectional iterator that can read or modify any element in a multimap.

```
typedef implementation-defined iterator;
```

Remarks

The `iterator` defined by `multimap` points to objects of `value_type`, which are of type `pair<const Key, Type>`. The value of the key is available through the first member `pair` and the value of the mapped element is available through the second member of the `pair`.

To dereference an `iterator` *Iter* pointing to an element in a multimap, use the `->` operator.

To access the value of the key for the element, use `Iter->first`, which is equivalent to `(*Iter).first`. To access the value of the mapped datum for the element, use `Iter->second`, which is equivalent to `(*Iter).second`.

A type `iterator` can be used to modify the value of an element.

Example

See the example for [begin](#) for an example of how to declare and use `iterator`.

multimap::key_comp

Retrieves a copy of the comparison object used to order keys in a multimap.

```
key_compare key_comp() const;
```

Return Value

Returns the function object that a multimap uses to order its elements.

Remarks

The stored object defines the member function

```
bool operator( const Key& x, const Key& y);
```

which returns true if *x* strictly precedes *y* in the sort order.

Example

```

// multimap_key_comp.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;

    multimap <int, int, less<int> > m1;
    multimap <int, int, less<int> >::key_compare kc1 = m1.key_comp( ) ;
    bool result1 = kc1( 2, 3 ) ;
    if( result1 == true )
    {
        cout << "kc1( 2,3 ) returns value of true, "
              << "where kc1 is the function object of m1."
              << endl;
    }
    else
    {
        cout << "kc1( 2,3 ) returns value of false "
              << "where kc1 is the function object of m1."
              << endl;
    }

    multimap <int, int, greater<int> > m2;
    multimap <int, int, greater<int> >::key_compare kc2 = m2.key_comp( ) ;
    bool result2 = kc2( 2, 3 ) ;
    if( result2 == true )
    {
        cout << "kc2( 2,3 ) returns value of true, "
              << "where kc2 is the function object of m2."
              << endl;
    }
    else
    {
        cout << "kc2( 2,3 ) returns value of false, "
              << "where kc2 is the function object of m2."
              << endl;
    }
}

```

```

kc1( 2,3 ) returns value of true, where kc1 is the function object of m1.
kc2( 2,3 ) returns value of false, where kc2 is the function object of m2.

```

multimap::key_compare

A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the multimap.

```
typedef Traits key_compare;
```

Remarks

`key_compare` is a synonym for the template parameter `Traits`.

For more information on `Traits` see the [multimap Class](#) topic.

Example

See the example for [key_comp](#) for an example of how to declare and use `key_compare`.

multimap::key_type

A type that describes the sort key object that constitutes each element of the multimap.

```
typedef Key key_type;
```

Remarks

`key_type` is a synonym for the template parameter `Key`.

For more information on `Key`, see the Remarks section of the [multimap Class](#) topic.

Example

See the example for [value_type](#) for an example of how to declare and use `key_type`.

multimap::lower_bound

Returns an iterator to the first element in a multimap that with a key that is equal to or greater than a specified key.

```
iterator lower_bound(const Key& key);  
  
const_iterator lower_bound(const Key& key) const;
```

Parameters

key

The argument key to be compared with the sort key of an element from the multimap being searched.

Return Value

An iterator or `const_iterator` that addresses the location of an element in a multimap that with a key that is equal to or greater than the argument key, or that addresses the location succeeding the last element in the multimap if no match is found for the key.

If the return value of `lower_bound` is assigned to a `const_iterator`, the multimap object cannot be modified. If the return value of `lower_bound` is assigned to an **iterator**, the multimap object can be modified.

Example

```

// multimap_lower_bound.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1;
    multimap <int, int> :: const_iterator m1_AcIter, m1_RcIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_RcIter = m1.lower_bound( 2 );
    cout << "The element of multimap m1 with a key of 2 is: "
         << m1_RcIter -> second << "." << endl;

    m1_RcIter = m1.lower_bound( 3 );
    cout << "The first element of multimap m1 with a key of 3 is: "
         << m1_RcIter -> second << "." << endl;

    // If no match is found for the key, end( ) is returned
    m1_RcIter = m1.lower_bound( 4 );

    if ( m1_RcIter == m1.end( ) )
        cout << "The multimap m1 doesn't have an element "
             << "with a key of 4." << endl;
    else
        cout << "The element of multimap m1 with a key of 4 is: "
             << m1_RcIter -> second << "." << endl;

    // The element at a specific location in the multimap can be
    // found using a dereferenced iterator addressing the location
    m1_AcIter = m1.end( );
    m1_AcIter--;
    m1_RcIter = m1.lower_bound( m1_AcIter -> first );
    cout << "The first element of m1 with a key matching\n"
         << "that of the last element is: "
         << m1_RcIter -> second << "." << endl;

    // Note that the first element with a key equal to
    // the key of the last element is not the last element
    if ( m1_RcIter == --m1.end( ) )
        cout << "This is the last element of multimap m1."
             << endl;
    else
        cout << "This is not the last element of multimap m1."
             << endl;
}

```

```

The element of multimap m1 with a key of 2 is: 20.
The first element of multimap m1 with a key of 3 is: 20.
The multimap m1 doesn't have an element with a key of 4.
The first element of m1 with a key matching
that of the last element is: 20.
This is not the last element of multimap m1.

```

multimap::mapped_type

A type that represents the data type stored in a multimap.

```
typedef Type mapped_type;
```

Remarks

`mapped_type` is a synonym for the template parameter `Type` .

For more information on `Type` see the [multimap Class](#) topic.

Example

See the example for [value_type](#) for an example of how to declare and use `key_type` .

multimap::max_size

Returns the maximum length of the multimap.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the multimap.

Example

```
// multimap_max_size.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1;
    multimap <int, int> :: size_type i;

    i = m1.max_size( );
    cout << "The maximum possible length "
         << "of the multimap is " << i << "." << endl;
}
```

multimap::multimap

Constructs a multimap that is empty or that is a copy of all or part of some other multimap.

```

multimap();

explicit multimap(
    const Traits& Comp);

multimap(
    const Traits& Comp,
    const Allocator& Al);

map(
    const multimap& Right);

multimap(
    multimap&& Right);

multimap(
    initializer_list<value_type> IList);

multimap(
    initializer_list<value_type> IList,
    const Compare& Comp);

multimap(
    initializer_list<value_type> IList,
    const Compare& Comp,
    const Allocator& Al);

template <class InputIterator>
multimap(
    InputIterator First,
    InputIterator Last);

template <class InputIterator>
multimap(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp);

template <class InputIterator>
multimap(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp,
    const Allocator& Al);

```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The storage allocator class to be used for this multimap object, which defaults to Allocator.
<i>Comp</i>	The comparison function of type <code>constTraits</code> used to order the elements in the map, which defaults to <code>Traits</code> .
<i>Right</i>	The map of which the constructed set is to be a copy.
<i>First</i>	The position of the first element in the range of elements to be copied.
<i>Last</i>	The position of the first element beyond the range of elements to be copied.

PARAMETER	DESCRIPTION
<i>lList</i>	The initializer_list from which to copy the elements.

Remarks

All constructors store a type of allocator object that manages memory storage for the multimap and that can later be returned by calling [get_allocator](#). The allocator parameter is often omitted in the class declarations and preprocessing macros used to substitute alternative allocators.

All constructors initialize their multimap.

All constructors store a function object of type `Traits` that is used to establish an order among the keys of the multimap and that can later be returned by calling [key_comp](#).

The first three constructors specify an empty initial multimap, the second specifying the type of comparison function (*Comp*) to be used in establishing the order of the elements and the third explicitly specifying the allocator type (*Al*) to be used. The key word **explicit** suppresses certain kinds of automatic type conversion.

The fourth constructor specifies a copy of the multimap *Right*.

The fifth constructor specifies a copy of the multimap by moving *Right*.

The sixth, seventh, and eighth constructors copy the members of an initializer_list.

The next three constructors copy the range `[First, Last)` of a map with increasing explicitness in specifying the type of comparison function of class `Traits` and allocator.

Example

```
// multimap_ctor.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main()
{
    using namespace std;
    typedef pair <int, int> Int_Pair;

    // Create an empty multimap m0 of key type integer
    multimap <int, int> m0;

    // Create an empty multimap m1 with the key comparison
    // function of less than, then insert 4 elements
    multimap <int, int, less<int> > m1;
    m1.insert(Int_Pair(1, 10));
    m1.insert(Int_Pair(2, 20));
    m1.insert(Int_Pair(3, 30));
    m1.insert(Int_Pair(4, 40));

    // Create an empty multimap m2 with the key comparison
    // function of greater than, then insert 2 elements
    multimap <int, int, less<int> > m2;
    m2.insert(Int_Pair(1, 10));
    m2.insert(Int_Pair(2, 20));

    // Create a multimap m3 with the
    // allocator of multimap m1
    multimap <int, int>::allocator_type m1_Alloc;
    m1_Alloc = m1.get_allocator();
    multimap <int, int> m3(less<int>(), m1_Alloc);
    m3.insert(Int_Pair(3, 30));
```

```

// Create a copy, multimap m4, of multimap m1
multimap<int, int> m4(m1);

// Create a multimap m5 by copying the range m1[ first, last)
multimap<int, int>::const_iterator m1_bcIter, m1_ecIter;
m1_bcIter = m1.begin();
m1_ecIter = m1.begin();
m1_ecIter++;
m1_ecIter++;
multimap<int, int> m5(m1_bcIter, m1_ecIter);

// Create a multimap m6 by copying the range m4[ first, last)
// and with the allocator of multimap m2
multimap<int, int>::allocator_type m2_Alloc;
m2_Alloc = m2.get_allocator();
multimap<int, int> m6(m4.begin(), ++m4.begin(), less<int>(), m2_Alloc);

cout << "m1 =";
for (auto i : m1)
    cout << i.first << " " << i.second << ", ";
cout << endl;

cout << "m2 =";
for (auto i : m2)
    cout << i.first << " " << i.second << ", ";
cout << endl;

cout << "m3 =";
for (auto i : m3)
    cout << i.first << " " << i.second << ", ";
cout << endl;

cout << "m4 =";
for (auto i : m4)
    cout << i.first << " " << i.second << ", ";
cout << endl;

cout << "m5 =";
for (auto i : m5)
    cout << i.first << " " << i.second << ", ";
cout << endl;

cout << "m6 =";
for (auto i : m6)
    cout << i.first << " " << i.second << ", ";
cout << endl;

// Create a multimap m8 by copying in an initializer_list
multimap<int, int> m8{ { 1, 1 }, { 2, 2 }, { 3, 3 }, { 4, 4 } };
cout << "m8: = ";
for (auto i : m8)
    cout << i.first << " " << i.second << ", ";
cout << endl;

// Create a multimap m9 with an initializer_list and a comparator
multimap<int, int> m9({ { 5, 5 }, { 6, 6 }, { 7, 7 }, { 8, 8 } }, less<int>());
cout << "m9: = ";
for (auto i : m9)
    cout << i.first << " " << i.second << ", ";
cout << endl;

// Create a multimap m10 with an initializer_list, a comparator, and an allocator
multimap<int, int> m10({ { 9, 9 }, { 10, 10 }, { 11, 11 }, { 12, 12 } }, less<int>(),
m9.get_allocator());
cout << "m10: = ";
for (auto i : m10)
    cout << i.first << " " << i.second << ", ";
cout << endl;

```

```
}
```

multimap::operator=

Replaces the elements of a multimap with a copy of another multimap.

```
multimap& operator=(const multimap& right);

multimap& operator=(multimap&& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The multimap being copied into the <code>multimap</code> .

Remarks

After erasing any existing elements in a `multimap`, `operator=` either copies or moves the contents of *right* into the `multimap`.

Example

```
// multimap_operator_as.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap<int, int> v1, v2, v3;
    multimap<int, int>::iterator iter;

    v1.insert(pair<int, int>(1, 10));

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;
}
```

multimap::pointer

A type that provides a pointer to an element in a multimap.

```
typedef typename allocator_type::pointer pointer;
```

Remarks

A type `pointer` can be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a multimap object.

multimap::rbegin

Returns an iterator addressing the first element in a reversed multimap.

```
const_reverse_iterator rbegin() const;  
  
reverse_iterator rbegin();
```

Return Value

A reverse bidirectional iterator addressing the first element in a reversed multimap or addressing what had been the last element in the unreversed multimap.

Remarks

`rbegin` is used with a reversed multimap just as [begin](#) is used with a multimap.

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, then the multimap object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, then the multimap object can be modified.

`rbegin` can be used to iterate through a multimap backwards.

Example

```

// multimap_rbegin.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1;

    multimap <int, int> :: iterator m1_Iter;
    multimap <int, int> :: reverse_iterator m1_rIter;
    multimap <int, int> :: const_reverse_iterator m1_crIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_rIter = m1.rbegin( );
    cout << "The first element of the reversed multimap m1 is "
         << m1_rIter -> first << "." << endl;

    // begin can be used to start an iteration
    // through a multimap in a forward order
    cout << "The multimap is: ";
    for ( m1_Iter = m1.begin( ) ; m1_Iter != m1.end( ); m1_Iter++)
        cout << m1_Iter -> first << " ";
    cout << "." << endl;

    // rbegin can be used to start an iteration
    // through a multimap in a reverse order
    cout << "The reversed multimap is: ";
    for ( m1_rIter = m1.rbegin( ) ; m1_rIter != m1.rend( ); m1_rIter++)
        cout << m1_rIter -> first << " ";
    cout << "." << endl;

    // A multimap element can be erased by dereferencing its key
    m1_rIter = m1.rbegin( );
    m1.erase ( m1_rIter -> first );

    m1_rIter = m1.rbegin( );
    cout << "After the erasure, the first element "
         << "in the reversed multimap is "
         << m1_rIter -> first << "." << endl;
}

```

```

The first element of the reversed multimap m1 is 3.
The multimap is: 1 2 3 .
The reversed multimap is: 3 2 1 .
After the erasure, the first element in the reversed multimap is 2.

```

multimap::reference

A type that provides a reference to an element stored in a multimap.

```

typedef typename allocator_type::reference reference;

```

Example

```

// multimap_ref.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );

    // Declare and initialize a const_reference &Ref1
    // to the key of the first element
    const int &Ref1 = ( m1.begin( ) -> first );

    // The following line would cause an error because the
    // non-const_reference cannot be used to access the key
    // int &Ref1 = ( m1.begin( ) -> first );

    cout << "The key of first element in the multimap is "
         << Ref1 << "." << endl;

    // Declare and initialize a reference &Ref2
    // to the data value of the first element
    int &Ref2 = ( m1.begin( ) -> second );

    cout << "The data value of first element in the multimap is "
         << Ref2 << "." << endl;

    // The non-const_reference can be used to modify the
    // data value of the first element
    Ref2 = Ref2 + 5;
    cout << "The modified data value of first element is "
         << Ref2 << "." << endl;
}

```

```

The key of first element in the multimap is 1.
The data value of first element in the multimap is 10.
The modified data value of first element is 15.

```

multimap::rend

Returns an iterator that addresses the location succeeding the last element in a reversed multimap.

```

const_reverse_iterator rend() const;

reverse_iterator rend();

```

Return Value

A reverse bidirectional iterator that addresses the location succeeding the last element in a reversed multimap (the location that had preceded the first element in the unreversed multimap).

Remarks

`rend` is used with a reversed multimap just as `end` is used with a multimap.

If the return value of `rend` is assigned to a `const_reverse_iterator`, then the multimap object cannot be modified. If the return value of `rend` is assigned to a `reverse_iterator`, then the multimap object can be

modified.

`rend` can be used to test to whether a reverse iterator has reached the end of its multimap.

The value returned by `rend` should not be dereferenced.

Example

```
// multimap_rend.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1;

    multimap <int, int> :: iterator m1_Iter;
    multimap <int, int> :: reverse_iterator m1_rIter;
    multimap <int, int> :: const_reverse_iterator m1_crIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );

    m1_rIter = m1.rend( );
    m1_rIter--;
    cout << "The last element of the reversed multimap m1 is "
         << m1_rIter -> first << "." << endl;

    // begin can be used to start an iteration
    // through a multimap in a forward order
    cout << "The multimap is: ";
    for ( m1_Iter = m1.begin( ) ; m1_Iter != m1.end( ) ; m1_Iter++)
        cout << m1_Iter -> first << " ";
    cout << "." << endl;

    // rbegin can be used to start an iteration
    // through a multimap in a reverse order
    cout << "The reversed multimap is: ";
    for ( m1_rIter = m1.rbegin( ) ; m1_rIter != m1.rend( ) ; m1_rIter++)
        cout << m1_rIter -> first << " ";
    cout << "." << endl;

    // A multimap element can be erased by dereferencing to its key
    m1_rIter = --m1.rend( );
    m1.erase ( m1_rIter -> first );

    m1_rIter = m1.rend( );
    m1_rIter--;
    cout << "After the erasure, the last element "
         << "in the reversed multimap is "
         << m1_rIter -> first << "." << endl;
}
```

```
The last element of the reversed multimap m1 is 1.
The multimap is: 1 2 3 .
The reversed multimap is: 3 2 1 .
After the erasure, the last element in the reversed multimap is 2.
```

multimap::reverse_iterator

A type that provides a bidirectional iterator that can read or modify an element in a reversed multimap.

```
typedef std::reverse_iterator<iterator> reverse_iterator;
```

Remarks

A type `reverse_iterator` is use to iterate through the multimap in reverse.

The `reverse_iterator` defined by multimap points to objects of [value_type](#), which are of type `pair<const Key, Type>`. The value of the key is available through the first member pair and the value of the mapped element is available through the second member of the pair.

To dereference a `reverse_iterator` *rIter* pointing to an element in a multimap, use the `->` operator.

To access the value of the key for the element, use `rIter->first`, which is equivalent to `(*rIter).first`. To access the value of the mapped datum for the element, use `rIter->second`, which is equivalent to `(*rIter).second`.

Example

See the example for [rbegin](#) for an example of how to declare and use `reverse_iterator`.

multimap::size

Returns the number of elements in the multimap.

```
size_type size() const;
```

Return Value

The current length of the multimap.

Example

The following example demonstrates the use of the `multimap::size` member function.

```
// multimap_size.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main()
{
    using namespace std;
    multimap<int, int> m1, m2;
    multimap<int, int>::size_type i;
    typedef pair<int, int> Int_Pair;

    m1.insert(Int_Pair(1, 1));
    i = m1.size();
    cout << "The multimap length is " << i << "." << endl;

    m1.insert(Int_Pair(2, 4));
    i = m1.size();
    cout << "The multimap length is now " << i << "." << endl;
}
```

```
The multimap length is 1.
The multimap length is now 2.
```

multimap::size_type

An unsigned integer type that counts the number of elements in a multimap.

```
typedef typename allocator_type::size_type size_type;
```

Example

See the example for [size](#) for an example of how to declare and use `size_type`

multimap::swap

Exchanges the elements of two multimaps.

```
void swap(  
    multimap<Key, Type, Traits, Allocator>& right);
```

Parameters

right

The multimap providing the elements to be swapped, or the multimap whose elements are to be exchanged with those of the multimap `left`.

Remarks

The member function invalidates no references, pointers, or iterators that designate elements in the two multimaps whose elements are being exchanged.

Example

```

// multimap_swap.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1, m2, m3;
    multimap <int, int>::iterator m1_Iter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );
    m2.insert ( Int_Pair ( 10, 100 ) );
    m2.insert ( Int_Pair ( 20, 200 ) );
    m3.insert ( Int_Pair ( 30, 300 ) );

    cout << "The original multimap m1 is:";
    for ( m1_Iter = m1.begin( ); m1_Iter != m1.end( ); m1_Iter++ )
        cout << " " << m1_Iter->second;
    cout << "." << endl;

    // This is the member function version of swap
    m1.swap( m2 );

    cout << "After swapping with m2, multimap m1 is:";
    for ( m1_Iter = m1.begin( ); m1_Iter != m1.end( ); m1_Iter++ )
        cout << " " << m1_Iter->second;
    cout << "." << endl;

    // This is the specialized template version of swap
    swap( m1, m3 );

    cout << "After swapping with m3, multimap m1 is:";
    for ( m1_Iter = m1.begin( ); m1_Iter != m1.end( ); m1_Iter++ )
        cout << " " << m1_Iter->second;
    cout << "." << endl;
}

```

The original multimap m1 is: 10 20 30.
 After swapping with m2, multimap m1 is: 100 200.
 After swapping with m3, multimap m1 is: 300.

multimap::upper_bound

Returns an iterator to the first element in a multimap that with a key that is greater than a specified key.

```

iterator upper_bound(const Key& key);

const_iterator upper_bound(const Key& key) const;

```

Parameters

key

The argument key to be compared with the sort key of an element from the multimap being searched.

Return Value

An iterator or `const_iterator` that addresses the location of an element in a multimap that with a key that is greater than the argument key, or that addresses the location succeeding the last element in the multimap if no

match is found for the key.

If the return value is assigned to a `const_iterator`, the multimap object cannot be modified. If the return value is assigned to a `iterator`, the multimap object can be modified.

Example

```
// multimap_upper_bound.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    multimap <int, int> m1;
    multimap <int, int> :: const_iterator m1_AcIter, m1_RcIter;
    typedef pair <int, int> Int_Pair;

    m1.insert ( Int_Pair ( 1, 10 ) );
    m1.insert ( Int_Pair ( 2, 20 ) );
    m1.insert ( Int_Pair ( 3, 30 ) );
    m1.insert ( Int_Pair ( 3, 40 ) );

    m1_RcIter = m1.upper_bound( 1 );
    cout << "The 1st element of multimap m1 with "
         << "a key greater than 1 is: "
         << m1_RcIter -> second << "." << endl;

    m1_RcIter = m1.upper_bound( 2 );
    cout << "The first element of multimap m1 with a key "
         << " greater than 2 is: "
         << m1_RcIter -> second << "." << endl;

    // If no match is found for the key, end( ) is returned
    m1_RcIter = m1.lower_bound( 4 );

    if ( m1_RcIter == m1.end( ) )
        cout << "The multimap m1 doesn't have an element "
             << "with a key of 4." << endl;
    else
        cout << "The element of multimap m1 with a key of 4 is: "
             << m1_RcIter -> second << "." << endl;

    // The element at a specific location in the multimap can be
    // found using a dereferenced iterator addressing the location
    m1_AcIter = m1.begin( );
    m1_RcIter = m1.upper_bound( m1_AcIter -> first );
    cout << "The first element of m1 with a key greater than\n"
         << "that of the initial element of m1 is: "
         << m1_RcIter -> second << "." << endl;
}
```

```
The 1st element of multimap m1 with a key greater than 1 is: 20.
The first element of multimap m1 with a key greater than 2 is: 30.
The multimap m1 doesn't have an element with a key of 4.
The first element of m1 with a key greater than
that of the initial element of m1 is: 20.
```

multimap::value_comp

The member function returns a function object that determines the order of elements in a multimap by comparing their key values.

```
value_compare value_comp() const;
```

Return Value

Returns the comparison function object that a multimap uses to order its elements.

Remarks

For a multimap m , if two elements $e1(k1, d1)$ and $e2(k2, d2)$ are objects of type `value_type`, where $k1$ and $k2$ are their keys of type `key_type` and $d1$ and $d2$ are their data of type `mapped_type`, then `m.value_comp(e1, e2)` is equivalent to `m.key_comp(k1, k2)`.

Example

```
// multimap_value_comp.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;

    multimap <int, int, less<int> > m1;
    multimap <int, int, less<int> >::value_compare vc1 = m1.value_comp( );
    multimap<int,int>::iterator Iter1, Iter2;

    Iter1= m1.insert ( multimap <int, int> :: value_type ( 1, 10 ) );
    Iter2= m1.insert ( multimap <int, int> :: value_type ( 2, 5 ) );

    if( vc1( *Iter1, *Iter2 ) == true )
    {
        cout << "The element ( 1,10 ) precedes the element ( 2,5 )."
              << endl;
    }
    else
    {
        cout << "The element ( 1,10 ) does "
              << "not precede the element ( 2,5 )."
              << endl;
    }

    if( vc1( *Iter2, *Iter1 ) == true )
    {
        cout << "The element ( 2,5 ) precedes the element ( 1,10 )."
              << endl;
    }
    else
    {
        cout << "The element ( 2,5 ) does "
              << "not precede the element ( 1,10 )."
              << endl;
    }
}
```

```
The element ( 1,10 ) precedes the element ( 2,5 ).
The element ( 2,5 ) does not precede the element ( 1,10 ).
```

multimap::value_type

A type that represents the type of object stored as an element in a map.

```
typedef pair<const Key, Type> value_type;
```

Example

```
// multimap_value_type.cpp
// compile with: /EHsc
#include <map>
#include <iostream>

int main( )
{
    using namespace std;
    typedef pair <const int, int> cInt2Int;
    multimap <int, int> m1;
    multimap <int, int> :: key_type key1;
    multimap <int, int> :: mapped_type mapped1;
    multimap <int, int> :: value_type value1;
    multimap <int, int> :: iterator pIter;

    // value_type can be used to pass the correct type
    // explicitly to avoid implicit type conversion
    m1.insert ( multimap <int, int> :: value_type ( 1, 10 ) );

    // Compare another way to insert objects into a hash_multimap
    m1.insert ( cInt2Int ( 2, 20 ) );

    // Initializing key1 and mapped1
    key1 = ( m1.begin( ) -> first );
    mapped1 = ( m1.begin( ) -> second );

    cout << "The key of first element in the multimap is "
         << key1 << "." << endl;

    cout << "The data value of first element in the multimap is "
         << mapped1 << "." << endl;

    // The following line would cause an error because
    // the value_type is not assignable
    // value1 = cInt2Int ( 4, 40 );

    cout << "The keys of the mapped elements are:";
    for ( pIter = m1.begin( ) ; pIter != m1.end( ) ; pIter++ )
        cout << " " << pIter -> first;
    cout << "." << endl;

    cout << "The values of the mapped elements are:";
    for ( pIter = m1.begin( ) ; pIter != m1.end( ) ; pIter++ )
        cout << " " << pIter -> second;
    cout << "." << endl;
}
```

```
The key of first element in the multimap is 1.
The data value of first element in the multimap is 10.
The keys of the mapped elements are: 1 2.
The values of the mapped elements are: 10 20.
```

value_compare Class (<map>)

10/31/2018 • 2 minutes to read • [Edit Online](#)

Provides a function object that can compare the elements of a map by comparing the values of their keys to determine their relative order in the map.

Syntax

```
class value_compare : public binary_function<value_type, value_type, bool>
{
public:
    bool operator()(const value_type& left, const value_type& right) const;
    value_compare(key_compare pred) : comp(pred);
protected:
    key_compare comp;
};
```

Remarks

The comparison criterion provided by `value_compare` between `value_types` of whole elements contained by a map is induced from a comparison between the keys of the respective elements by the auxiliary class construction. The member function operator uses the object `comp` of type `key_compare` stored in the function object provided by `value_compare` to compare the sort-key components of two elements.

For sets and multisets, which are simple containers where the key values are identical to the element values, `value_compare` is equivalent to `key_compare`; for maps and multimaps they are not, as the value of the type `pair` elements is not identical to the value of the element's key.

Example

See example for [value_comp](#) for an example of how to declare and use `value_compare`.

Requirements

Header: <map>

Namespace: std

Defines a class, an operator, and several templates that help allocate and free objects.

Syntax

```
#include <memory>
```

Members

Functions

FUNCTION	DESCRIPTION
addressof	Gets the true address of an object.
align	Returns a pointer to a range of a given size, based on the provided alignment and starting address.
allocate_shared	Creates a <code>shared_ptr</code> to objects that are allocated and constructed for a given type with a specified allocator.
const_pointer_cast	Const cast to <code>shared_ptr</code> .
declare_no_pointers	Informs a garbage collector that the characters starting at a specified address and falling within the indicated block size contain no traceable pointers.
declare_reachable	Informs garbage collection that the indicated address is to allocated storage and is reachable.
default_delete	Deletes objects allocated with <code>operator new</code> . Suitable for use with <code>unique_ptr</code> .
dynamic_pointer_cast	Dynamic cast to <code>shared_ptr</code> .
get_deleter	Get deleter from <code>shared_ptr</code> .
get_pointer_safety	Returns the type of pointer safety assumed by any garbage collector.
get_temporary_buffer	Allocates temporary storage for a sequence of elements that does not exceed a specified number of elements.
make_shared	Creates and returns a <code>shared_ptr</code> that points to the allocated object constructed from zero or more arguments using the default allocator.

FUNCTION	DESCRIPTION
<code>make_unique</code>	Creates and returns a <code>unique_ptr</code> that points to the allocated object constructed from zero or more arguments.
<code>owner_less</code>	Allows ownership-based mixed comparisons of shared and weak pointers.
<code>pointer_safety</code>	An enumeration of all the possible return values for <code>get_pointer_safety</code> .
<code>return_temporary_buffer</code>	Deallocates the temporary memory that was allocated using the <code>get_temporary_buffer</code> template function.
<code>static_pointer_cast</code>	Static cast to <code>shared_ptr</code> .
<code>swap</code>	Swap two <code>shared_ptr</code> or <code>weak_ptr</code> objects.
<code>undecare_no_pointers</code>	Informs a garbage collector that the characters in the memory block defined by a base address pointer and block size may now contain traceable pointers.
<code>undecare_reachable</code>	Informs a <code>garbage_collector</code> that a specified memory location is not reachable.
<code>uninitialized_copy</code>	Copies objects from a specified input range into an uninitialized destination range.
<code>uninitialized_copy_n</code>	Creates a copy of a specified number of elements from an input iterator. The copies are put in a forward iterator.
<code>uninitialized_fill</code>	Copies objects of a specified value into an uninitialized destination range.
<code>uninitialized_fill_n</code>	Copies objects of a specified value into specified number of elements an uninitialized destination range.

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests for inequality between allocator objects of a specified class.
<code>operator==</code>	Tests for equality between allocator objects of a specified class.
<code>operator>=</code>	Tests for one allocator object being greater than or equal to a second allocator object, of a specified class.
<code>operator<</code>	Tests for one object being less than a second object of a specified class.
<code>operator<=</code>	Tests for one object being less than or equal to a second object of a specified class.

OPERATOR	DESCRIPTION
<code>operator></code>	Tests for one object being greater than a second object of a specified class.
<code>operator<<</code>	<code>shared_ptr</code> inserter.

Classes

CLASS	DESCRIPTION
<code>allocator</code>	The template class describes an object that manages storage allocation and freeing for arrays of objects of type Type .
<code>allocator_traits</code>	Describes an object that determines all the information that is needed by an allocator-enabled container.
<code>auto_ptr</code>	The template class describes an object that stores a pointer to an allocated object of type Type * that ensures the object to which it points gets deleted when its enclosing <code>auto_ptr</code> gets destroyed.
<code>bad_weak_ptr</code>	Reports bad <code>weak_ptr</code> exception.
<code>enabled_shared_from_this</code>	Helps generate a <code>shared_ptr</code> .
<code>pointer_traits</code>	Supplies information that is needed by an object of template class <code>allocator_traits</code> to describe an allocator with pointer type <code>Ptr</code> .
<code>raw_storage_iterator</code>	An adaptor class that is provided to enable algorithms to store their results into uninitialized memory.
<code>shared_ptr</code>	Wraps a reference-counted smart pointer around a dynamically allocated object.
<code>unique_ptr</code>	Stores a pointer to an owned object. The pointer is owned by no other <code>unique_ptr</code> . The <code>unique_ptr</code> is destroyed when the owner is destroyed.
<code>weak_ptr</code>	Wraps a weakly linked pointer.

Specializations

<code>allocator<void></code>	A specialization of the template class <code>allocator</code> to type <code>void</code> , defining the only the member types that make sense in this specialized context.
------------------------------------	---

<memory> functions

2/6/2019 • 20 minutes to read • [Edit Online](#)

addressof	align	allocate_shared
const_pointer_cast	declare_no_pointers	declare_reachable
default_delete	dynamic_pointer_cast	get_deleter
get_pointer_safety	get_temporary_buffer	make_shared
make_unique	owner_less	return_temporary_buffer
static_pointer_cast	swap (C++ Standard Library)	undecare_no_pointers
undecare_reachable	uninitialized_copy	uninitialized_copy_n
uninitialized_fill	uninitialized_fill_n	

addressof

Gets the true address of an object.

```
template <class T>
T* addressof(T& Val);
```

Parameters

Val

The object or function for which to obtain the true address.

Return Value

The actual address of the object or function referenced by *Val*, even if an overloaded `operator&()` exists.

Remarks

align

Fits storage of the given size—aligned by the given alignment specification—into the first possible address of the given storage.

```
void* align(
    size_t Alignment, // input
    size_t Size,      // input
    void*& Ptr,        // input/output
    size_t& Space      // input/output
);
```

Parameters

Alignment

The alignment bound to attempt.

Size

The size in bytes for the aligned storage.

Ptr

The starting address of the available contiguous storage pool to use. This parameter is also an output parameter, and is set to contain the new starting address if the alignment is successful. If `align()` is unsuccessful, this parameter is not modified.

Space

The total space available to `align()` to use in creating the aligned storage. This parameter is also an output parameter, and contains the adjusted space left in the storage buffer after the aligned storage and any associated overhead is subtracted.

If `align()` is unsuccessful, this parameter is not modified.

Return Value

A null pointer if the requested aligned buffer would not fit into the available space; otherwise, the new value of *Ptr*.

Remarks

The modified *Ptr* and *Space* parameters enable you to call `align()` repeatedly on the same buffer, possibly with different values for *Alignment* and *Size*. The following code snippet shows one use of `align()`.

```
#include <type_traits> // std::alignment_of()
#include <memory>
//...
char buffer[256]; // for simplicity
size_t alignment = std::alignment_of<int>::value;
void * ptr = buffer;
std::size_t space = sizeof(buffer); // Be sure this results in the true size of your buffer

while (std::align(alignment, sizeof(MyObj), ptr, space)) {
    // You now have storage the size of MyObj, starting at ptr, aligned on
    // int boundary. Use it here if you like, or save off the starting address
    // contained in ptr for later use.
    // ...
    // Last, move starting pointer and decrease available space before
    // the while loop restarts.
    ptr = reinterpret_cast<char*>(ptr) + sizeof(MyObj);
    space -= sizeof(MyObj);
}
// At this point, align() has returned a null pointer, signaling it is not
// possible to allow more aligned storage in this buffer.
```

allocate_shared

Creates a `shared_ptr` to objects that are allocated and constructed for a given type by using a specified allocator. Returns the `shared_ptr`.

```
template <class Type, class Allocator, class... Types>
shared_ptr<Type>
allocate_shared(Allocator Alloc, Types&&... Args);
```

Parameters

Alloc

The allocator used to create objects.

Args

The zero or more arguments that become the objects.

Remarks

The function creates the object `shared_ptr<Type>`, a pointer to `Type(Args...)` as allocated and constructed by *Alloc*.

const_pointer_cast

Const cast to shared_ptr.

```
template <class Ty, class Other>
shared_ptr<Ty>
const_pointer_cast(const shared_ptr<Other>& sp);
```

Parameters

Ty

The type controlled by the returned shared pointer.

Other

The type controlled by the argument shared pointer.

Other

The argument shared pointer.

Remarks

The template function returns an empty shared_ptr object if `const_cast<Ty*>(sp.get())` returns a null pointer; otherwise it returns a [shared_ptr Class](#)<Ty> object that owns the resource that is owned by `sp`. The expression

`const_cast<Ty*>(sp.get())` must be valid.

Example

```
// std__memory__const_pointer_cast.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0(new int);
    std::shared_ptr<const int> sp1 =
        std::const_pointer_cast<const int>(sp0);

    *sp0 = 3;
    std::cout << "sp1 == " << *sp1 << std::endl;

    return (0);
}
```

```
sp1 == 3
```

declare_no_pointers

Informs a garbage collector that the characters in the memory block defined by a base address pointer and block size contains no traceable pointers.

```
void declare_no_pointers(
    char* ptr,
    size_t _Size);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	Address of first character that no longer contains traceable pointers.
<i>_Size</i>	Size of block that starts at <i>ptr</i> that contains no traceable pointers.

Remarks

The function informs any garbage collector that the range of addresses [*ptr*, *ptr* + *_Size*) no longer contain traceable pointers. (Any pointers to allocated storage must not be dereferenced unless made reachable.)

declare_reachable

Informs garbage collection that the indicated address is to allocated storage and is reachable.

```
void declare_reachable(void* ptr);
```

Parameters

ptr

A pointer to a reachable, allocated, valid storage area.

Remarks

If *ptr* is not null, the function informs any garbage collector that *ptr* is hereafter reachable (points to valid allocated storage).

default_delete

Deletes objects allocated with **operator new**. Suitable for use with `unique_ptr`.

```
struct default_delete {
    constexpr default_delete() noexcept = default;
    template <class Other, class = typename enable_if<is_convertible<Other*, T*>::value, void>::type>>
    default_delete(const default_delete<Other>&) noexcept;
    void operator()(T* Ptr) const noexcept;
};
```

Parameters

Ptr

Pointer to the object to delete.

Other

The type of elements in the array to be deleted.

Remarks

The template class describes a `deleter` that deletes scalar objects allocated with **operator new**, suitable for use with template class `unique_ptr`. It also has the explicit specialization `default_delete<Type[]>`.

dynamic_pointer_cast

Dynamic cast to shared_ptr.

```
template <class Ty, class Other>
shared_ptr<Ty>
dynamic_pointer_cast(const shared_ptr<Other>& sp);
```

Parameters

Ty

The type controlled by the returned shared pointer.

Other

The type controlled by the argument shared pointer.

sp

The argument shared pointer.

Remarks

The template function returns an empty shared_ptr object if `dynamic_cast<Ty*>(sp.get())` returns a null pointer; otherwise it returns a [shared_ptr Class](#)<Ty> object that owns the resource that is owned by *sp*. The expression

`dynamic_cast<Ty*>(sp.get())` must be valid.

Example

```
// std__memory__dynamic_pointer_cast.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct base
{
    virtual ~base() {}
    int val;
};

struct derived
    : public base
{
};

int main()
{
    std::shared_ptr<base> sp0(new derived);
    std::shared_ptr<derived> sp1 =
        std::dynamic_pointer_cast<derived>(sp0);

    sp0->val = 3;
    std::cout << "sp1->val == " << sp1->val << std::endl;

    return (0);
}
```

```
sp1->val == 3
```

get_deleter

Get deleter from shared_ptr.

```
template <class D, class Ty>
D* get_deleter(const shared_ptr<Ty>& sp);
```

Parameters

D

The type of the deleter.

Ty

The type controlled by the shared pointer.

sp

The shared pointer.

Remarks

The template function returns a pointer to the deleter of type *D* that belongs to the [shared_ptr Class](#) object *sp*. If *sp* has no deleter or if its deleter is not of type *D* the function returns 0.

Example

```
// std__memory__get_deleter.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct base
{
    int val;
};

struct deleter
{
    void operator()(base *p)
    {
        delete p;
    }
};

int main()
{
    std::shared_ptr<base> sp0(new base);

    sp0->val = 3;
    std::cout << "get_deleter(sp0) != 0 == " << std::boolalpha
        << (std::get_deleter<deleter>(sp0) != 0) << std::endl;

    std::shared_ptr<base> sp1(new base, deleter());

    sp0->val = 3;
    std::cout << "get_deleter(sp1) != 0 == " << std::boolalpha
        << (std::get_deleter<deleter>(sp1) != 0) << std::endl;

    return (0);
}
```

```
get_deleter(sp0) != 0 == false
get_deleter(sp1) != 0 == true
```

get_pointer_safety

Returns the type of pointer safety assumed by any garbage collector.

```
pointer_safety get_pointer_safety();
```

Remarks

The function returns the type of pointer safety assumed by any automatic garbage collector.

get_temporary_buffer

Allocates temporary storage for a sequence of elements that does not exceed a specified number of elements.

```
template <class Type>
pair<Type *, ptrdiff_t> get_temporary_buffer(ptrdiff_t count);
```

Parameters

count

The maximum number of elements requested for which memory is to be allocated.

Return Value

A `pair` whose first component is a pointer to the memory that was allocated, and whose second component gives the size of the buffer, indicating the largest number of elements that it could store.

Remarks

The function makes a request for memory and it may not succeed. If no buffer is allocated, then the function returns a pair, with the second component equal to zero and the first component equal to the null pointer.

This function should only be used for memory that is temporary.

Example

```
// memory_get_temp_buf.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

using namespace std;

int main( )
{
    // Create an array of ints
    int intArray [ ] = { 10, 20, 30, 40, 100, 200, 300, 1000, 2000 };
    int count = sizeof ( intArray ) / sizeof ( int );
    cout << "The number of integers in the array is: "
         << count << "." << endl;

    pair<int *, ptrdiff_t> resultPair;
    resultPair = get_temporary_buffer<int>( count );

    cout << "The number of elements that the allocated memory\n"
         << "could store is given by: resultPair.second = "
         << resultPair.second << "." << endl;
}
```

```
The number of integers in the array is: 9.
The number of elements that the allocated memory
could store is given by: resultPair.second = 9.
```

make_shared

Creates and returns a `shared_ptr` that points to the allocated objects that are constructed from zero or more arguments by using the default allocator. Allocates and constructs both an object of the specified type and a `shared_ptr` to manage shared ownership of the object, and returns the `shared_ptr`.

```
template <class Type, class... Types>
shared_ptr<Type>
make_shared(Types&&... _Args);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Args</code>	Zero or more constructor arguments. The function infers which constructor overload to invoke based on the arguments that are provided.

Remarks

Use `make_shared` as a simple and more efficient way to create an object and a `shared_ptr` to manage shared access to the object at the same time. Semantically, these two statements are equivalent:

```
auto sp = std::shared_ptr<Example>(new Example(argument));
auto msp = std::make_shared<Example>(argument);
```

However, the first statement makes two allocations, and if the allocation of the `shared_ptr` fails after the allocation of the `Example` object has succeeded, then the unnamed `Example` object is leaked. The statement that uses `make_shared` is simpler because there's only one function call involved. It's more efficient because the library can make a single allocation for both the object and the smart pointer. This is both faster and leads to less memory fragmentation, and there is no chance of an exception on one allocation but not the other. Performance is improved by better locality for code that references the object and updates the reference counts in the smart pointer.

Consider using [make_unique](#) if you do not need shared access to the object. Use [allocate_shared](#) if you need to specify a custom allocator for the object. You can't use `make_shared` if your object requires a custom deleter, because there is no way to pass the deleter as an argument.

The following example shows how to create shared pointers to a type by invoking specific constructor overloads.

Example

```

// stl_make_shared.cpp
// Compile by using: cl /W4 /EHsc stl_make_shared.cpp
#include <iostream>
#include <string>
#include <memory>
#include <vector>

class Song {
public:
    std::wstring title_;
    std::wstring artist_;

    Song(std::wstring title, std::wstring artist) : title_(title), artist_(artist) {}
    Song(std::wstring title) : title_(title), artist_(L"Unknown") {}
};

void CreateSharedPointers() {
    // Okay, but less efficient to have separate allocations for
    // Song object and shared_ptr control block.
    auto song = new Song(L"Ode to Joy", L"Beethoven");
    std::shared_ptr<Song> sp0(song);

    // Use make_shared function when possible. Memory for control block
    // and Song object are allocated in the same call:
    auto sp1 = std::make_shared<Song>(L"Yesterday", L"The Beatles");
    auto sp2 = std::make_shared<Song>(L"Blackbird", L"The Beatles");

    // make_shared infers which constructor to use based on the arguments.
    auto sp3 = std::make_shared<Song>(L"Greensleeves");

    // The playlist vector makes copies of the shared_ptr pointers.
    std::vector<std::shared_ptr<Song>> playlist;
    playlist.push_back(sp0);
    playlist.push_back(sp1);
    playlist.push_back(sp2);
    playlist.push_back(sp3);
    playlist.push_back(sp1);
    playlist.push_back(sp2);
    for (auto&& sp : playlist) {
        std::wcout << L"Playing " << sp->title_ <<
            L" by " << sp->artist_ << L", use count: " <<
            sp.use_count() << std::endl;
    }
}

int main() {
    CreateSharedPointers();
}

```

The example produces this output:

```

Playing Ode to Joy by Beethoven, use count: 2
Playing Yesterday by The Beatles, use count: 3
Playing Blackbird by The Beatles, use count: 3
Playing Greensleeves by Unknown, use count: 2
Playing Yesterday by The Beatles, use count: 3
Playing Blackbird by The Beatles, use count: 3

```

make_unique

Creates and returns a [unique_ptr](#) to an object of the specified type, which is constructed by using the specified arguments.

```

// make_unique<T>
template <class T, class... Types>
unique_ptr<T>
make_unique(Types&&... Args)
{
    return (unique_ptr<T>(new T(forward<Types>(Args)...)));
}

// make_unique<T[]>
template <class T>
make_unique(size_t Size)
{
    return (unique_ptr<T>(new Elem[Size]()));
}

// make_unique<T[N]> disallowed
template <class T, class... Types>
typename enable_if<extent<T>::value != 0, void>::type
make_unique(Types&&...) = delete;

```

Parameters

T

The type of the object that the `unique_ptr` will point to.

Types

The types of the constructor arguments specified by *Args*.

Args

The arguments to be passed to the constructor of the object of type *T*.

Elem

An array of elements of type *T*.

Size

The number of elements to allocate space for in the new array.

Remarks

The first overload is used for single objects, the second overload is invoked for arrays, and the third overload prevents you from specifying an array size in the type argument (`make_unique<T[N]>`); this construction is not supported by the current standard. When you use `make_unique` to create a `unique_ptr` to an array, you have to initialize the array elements separately. If you are considering this overload, perhaps a better choice is to use a [std::vector](#).

Because `make_unique` is carefully implemented for exception safety, we recommend that you use `make_unique` instead of directly calling `unique_ptr` constructors.

Example

The following example shows how to use `make_unique`. For more examples, see [How to: Create and Use unique_ptr Instances](#).

```

class Animal
{
private:
    std::wstring genus;
    std::wstring species;
    int age;
    double weight;
public:
    Animal(const wstring&, const wstring&, int, double){/*...*/ }
    Animal(){}
};

void MakeAnimals()
{
    // Use the Animal default constructor.
    unique_ptr<Animal> p1 = make_unique<Animal>();

    // Use the constructor that matches these arguments
    auto p2 = make_unique<Animal>(L"Felis", L"Catus", 12, 16.5);

    // Create a unique_ptr to an array of 5 Animals
    unique_ptr<Animal[]> p3 = make_unique<Animal[]>(5);

    // Initialize the elements
    p3[0] = Animal(L"Rattus", L"norvegicus", 3, 2.1);
    p3[1] = Animal(L"Corynorhinus", L"townsendii", 4, 1.08);

    // auto p4 = p2; //C2280

    vector<unique_ptr<Animal>> vec;
    // vec.push_back(p2); //C2280
    // vector<unique_ptr<Animal>> vec2 = vec; // C2280

    // OK. p2 no longer points to anything
    vec.push_back(std::move(p2));

    // unique_ptr overloads operator bool
    wcout << boolalpha << (p2 == false) << endl; // Prints "true"

    // OK but now you have two pointers to the same memory location
    Animal* pAnimal = p2.get();

    // OK. p2 no longer points to anything
    Animal* p5 = p2.release();
}

```

When you see error C2280 in connection with a `unique_ptr`, it is almost certainly because you are attempting to invoke its copy constructor, which is a deleted function.

owner_less

Allows ownership-based mixed comparisons of shared and weak pointers. Returns **true** if the left parameter is ordered before right parameter by the member function `owner_before`.

```

template <class Type>
struct owner_less; // not defined

template <class Type>
struct owner_less<shared_ptr<Type>> {
    bool operator()(
        const shared_ptr<Type>& left,
        const shared_ptr<Type>& right);

    bool operator()(
        const shared_ptr<Type>& left,
        const weak_ptr<Type>& right);

    bool operator()(
        const weak_ptr<Type>& left,
        const shared_ptr<Type>& right);
};

template <class Type>
struct owner_less<weak_ptr<Type>>
    bool operator()(
        const weak_ptr<Type>& left,
        const weak_ptr<Type>& right);

    bool operator()(
        const weak_ptr<Type>& left,
        const shared_ptr<Type>& right);

    bool operator()(
        const shared_ptr<Type>& left,
        const weak_ptr<Type>& right);
};

```

Parameters

_left

A shared or weak pointer.

right

A shared or weak pointer.

Remarks

The template classes define all their member operators as returning `left.owner_before(right)`.

return_temporary_buffer

Deallocates the temporary memory that was allocated using the `get_temporary_buffer` template function.

```

template <class Type>
void return_temporary_buffer(Type* _Pbuf);

```

Parameters

_Pbuf

A pointer to the memory to be deallocated.

Remarks

This function should only be used for memory that is temporary.

Example

```

// memory_ret_temp_buf.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

using namespace std;

int main( )
{
    // Create an array of ints
    int intArray [ ] = { 10, 20, 30, 40, 100, 200, 300 };
    int count = sizeof ( intArray ) / sizeof ( int );
    cout << "The number of integers in the array is: "
         << count << "." << endl;

    pair<int *, ptrdiff_t> resultPair;
    resultPair = get_temporary_buffer<int>( count );

    cout << "The number of elements that the allocated memory\n"
         << " could store is given by: resultPair.second = "
         << resultPair.second << "." << endl;

    int* tempBuffer = resultPair.first;

    // Deallocates memory allocated with get_temporary_buffer
    return_temporary_buffer ( tempBuffer );
}

```

```

The number of integers in the array is: 7.
The number of elements that the allocated memory
could store is given by: resultPair.second = 7.

```

static_pointer_cast

Static cast to shared_ptr.

```

template <class Ty, class Other>
shared_ptr<Ty>
static_pointer_cast(const shared_ptr<Other>& sp);

```

Parameters

Ty

The type controlled by the returned shared pointer.

Other

The type controlled by the argument shared pointer.

Other

The argument shared pointer.

Remarks

The template function returns an empty shared_ptr object if `sp` is an empty `shared_ptr` object; otherwise it returns a `shared_ptr Class<Ty>` object that owns the resource that is owned by `sp`. The expression

```
static_cast<Ty*>(sp.get())
```

must be valid.

Example

```

// std__memory__static_pointer_cast.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct base
{
    int val;
};

struct derived
    : public base
{
};

int main()
{
    std::shared_ptr<base> sp0(new derived);
    std::shared_ptr<derived> sp1 =
        std::static_pointer_cast<derived>(sp0);

    sp0->val = 3;
    std::cout << "sp1->val == " << sp1->val << std::endl;

    return (0);
}

```

```
sp1->val == 3
```

swap (C++ Standard Library)

Swap two `shared_ptr` or `weak_ptr` objects.

```

template <class Ty, class Other>
void swap(shared_ptr<Ty>& left, shared_ptr<Other>& right);

template <class Ty, class Other>
void swap(weak_ptr<Ty>& left, weak_ptr<Other>& right);

```

Parameters

Ty

The type controlled by the left shared/weak pointer.

Other

The type controlled by the right shared/weak pointer.

left

The left shared/weak pointer.

right

The right shared/weak pointer.

Remarks

The template functions call `left.swap(right)`.

Example

```

// std_memory_swap.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct deleter
{
    void operator()(int *p)
    {
        delete p;
    }
};

int main()
{
    std::shared_ptr<int> sp1(new int(5));
    std::shared_ptr<int> sp2(new int(10));
    std::cout << "*sp1 == " << *sp1 << std::endl;

    sp1.swap(sp2);
    std::cout << "*sp1 == " << *sp1 << std::endl;

    swap(sp1, sp2);
    std::cout << "*sp1 == " << *sp1 << std::endl;
    std::cout << std::endl;

    std::weak_ptr<int> wp1(sp1);
    std::weak_ptr<int> wp2(sp2);
    std::cout << "*wp1 == " << *wp1.lock() << std::endl;

    wp1.swap(wp2);
    std::cout << "*wp1 == " << *wp1.lock() << std::endl;

    swap(wp1, wp2);
    std::cout << "*wp1 == " << *wp1.lock() << std::endl;

    return (0);
}

```

```

*sp1 == 5
*sp1 == 10
*sp1 == 5

*wp1 == 5
*wp1 == 10
*wp1 == 5

```

undeclare_no_pointers

Informs a garbage collector that the characters in the memory block defined by a base address pointer and block size may now contain traceable pointers.

```

void undeclare_no_pointers(
    char* ptr,
    size_t _Size);

```

Remarks

The function informs any garbage collector that the range of addresses `[ptr, ptr + _Size)` may now contain traceable pointers.

undeclare_reachable

Revokes a declaration of reachability for a specified memory location.

```
template <class Type>
Type *undeclare_reachable(Type* ptr);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the memory address to be declared not reachable.

Remarks

If *ptr* is not **nullptr**, the function informs any garbage collector that *ptr* is no longer reachable. It returns a safely-derived pointer that compares equal to *ptr*.

uninitialized_copy

Copies objects from a specified source range into an uninitialized destination range.

```
template <class InputIterator, class ForwardIterator>
ForwardIterator uninitialized_copy(InputIterator first, InputIterator last, ForwardIterator dest);
```

Parameters

first

An input iterator addressing the first element in the source range.

last

An input iterator addressing the last element in the source range.

dest

A forward iterator addressing the first element in the destination range.

Return Value

A forward iterator addressing the first position beyond the destination range, unless the source range was empty.

Remarks

This algorithm allows the decoupling of memory allocation from object construction.

The template function effectively executes:

```
while (first != last) {
    new (static_cast<void*>(&* dest++))
        typename iterator_traits<InputIterator>::value_type(*first++);
}
return dest;
```

unless the code throws an exception. In that case, all constructed objects are destroyed and the exception is rethrown.

Example

```

// memory_uninit_copy.cpp
// compile with: /EHsc /W3
#include <memory>
#include <iostream>

using namespace std;

class Integer
{
public:
    Integer(int x) : val(x) {}
    int get() { return val; }
private:
    int val;
};

int main()
{
    int Array[] = { 10, 20, 30, 40 };
    const int N = sizeof(Array) / sizeof(int);

    int i;
    cout << "The initialized Array contains " << N << " elements: ";
    for (i = 0; i < N; i++)
    {
        cout << " " << Array[i];
    }
    cout << endl;

    Integer* ArrayPtr = (Integer*)malloc(N * sizeof(int));
    Integer* LArrayPtr = uninitialized_copy(
        Array, Array + N, ArrayPtr); // C4996

    cout << "Address of position after the last element in the array is: "
        << &Array[0] + N << endl;
    cout << "The iterator returned by uninitialized_copy addresses: "
        << (void*)LArrayPtr << endl;
    cout << "The address just beyond the last copied element is: "
        << (void*)(ArrayPtr + N) << endl;

    if ((&Array[0] + N) == (void*)LArrayPtr)
        cout << "The return value is an iterator "
            << "pointing just beyond the original array." << endl;
    else
        cout << "The return value is an iterator "
            << "not pointing just beyond the original array." << endl;

    if ((void*)LArrayPtr == (void*)(ArrayPtr + N))
        cout << "The return value is an iterator "
            << "pointing just beyond the copied array." << endl;
    else
        cout << "The return value is an iterator "
            << "not pointing just beyond the copied array." << endl;

    free(ArrayPtr);

    cout << "Note that the exact addresses returned will vary\n"
        << "with the memory allocation in individual computers."
        << endl;
}

```

uninitialized_copy_n

Creates a copy of a specified number of elements from an input iterator. The copies are put in a forward iterator.

```
template <class InputIterator, class Size, class ForwardIterator>
ForwardIterator uninitialized_copy_n(
    InputIterator first,
    Size count,
    ForwardIterator dest);
```

Parameters

first

An input iterator that refers to the object to copy.

count

A signed or unsigned integer type specifying the number of times to copy the object.

dest

A forward iterator that refers to where the new copies go.

Return Value

A forward iterator that addresses the first position beyond the destination. If the source range was empty, the iterator addresses *first*.

Remarks

The template function effectively executes the following:

```
for (; 0 < count; --count)
    new (static_cast<void*>(&* dest++))
        typename iterator_traits<InputIterator>::value_type(*first++);
return dest;
```

unless the code throws an exception. In that case, all constructed objects are destroyed and the exception is rethrown.

uninitialized_fill

Copies objects of a specified value into an uninitialized destination range.

```
template <class ForwardIterator, class Type>
void uninitialized_fill(ForwardIterator first, ForwardIterator last, const Type& val);
```

Parameters

first

A forward iterator addressing the first element in the destination range that is to be initiated.

last

A forward iterator addressing the last element in the destination range that is to be initiated.

val

The value to be used to initialize the destination range.

Remarks

This algorithm allows the decoupling of memory allocation from object construction.

The template function effectively executes:

```

while (first != last)
    new (static_cast<void*>(&* first ++))
        typename iterator_traits<ForwardIterator>::value_type (val);

```

unless the code throws an exception. In that case, all constructed objects are destroyed and the exception is rethrown.

Example

```

// memory_uninit_fill.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

using namespace std;

class Integer {          // No default constructor
public:
    Integer( int x ) : val( x ) {}
    int get( ) { return val; }
private:
    int val;
};

int main( )
{
    const int N = 10;
    Integer val ( 25 );
    Integer* Array = ( Integer* ) malloc( N * sizeof( int ) );
    uninitialized_fill( Array, Array + N, val );
    int i;
    cout << "The initialized Array contains: ";
    for ( i = 0 ; i < N; i++ )
    {
        cout << Array [ i ].get( ) << " ";
    }
    cout << endl;
}

```

The initialized Array contains: 25 25 25 25 25 25 25 25 25 25

uninitialized_fill_n

Copies objects of a specified value into specified number of elements into an uninitialized destination range.

```

template <class FwdIt, class Size, class Type>
void uninitialized_fill_n(ForwardIterator first, Size count, const Type& val);

```

Parameters

first

A forward iterator addressing the first element in the destination range to be initiated.

count

The number of elements to be initialized.

val

The value to be used to initialize the destination range.

Remarks

This algorithm allows the decoupling of memory allocation from object construction.

The template function effectively executes:

```
while (0 < count--)
    new (static_cast<void*>(&* first++))
        typename iterator_traits<ForwardIterator>::value_type(val);
```

unless the code throws an exception. In that case, all constructed objects are destroyed and the exception is rethrown.

Example

```
// memory_uninit_fill_n.cpp
// compile with: /EHsc /W3
#include <memory>
#include <iostream>

using namespace std;

class Integer {    // No default constructor
public:
    Integer( int x ) : val( x ) {}
    int get( ) { return val; }
private:
    int val;
};

int main() {
    const int N = 10;
    Integer val ( 60 );
    Integer* Array = ( Integer* ) malloc( N * sizeof( int ) );
    uninitialized_fill_n( Array, N, val ); // C4996
    int i;
    cout << "The uninitialized Array contains: ";
    for ( i = 0 ; i < N; i++ )
        cout << Array [ i ].get( ) << " ";
}
```

<memory> operators

11/9/2018 • 4 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<<</code>	<code>operator<=</code>
<code>operator==</code>		

operator!=

Tests for inequality between objects.

```
template <class Type, class Other>
bool operator!=(
    const allocator<Type>& left,
    const allocator<Other>& right) throw();

template <class T, class Del1, class U, class Del2>
bool operator!=(
    const unique_ptr<T, Del1>& left,
    const unique_ptr<U&, Del2>& right);

template <class Ty1, class Ty2>
bool operator!=(
    const shared_ptr<Ty1>& left,
    const shared_ptr<Ty2>& right);
```

Parameters

left

One of the objects to be tested for inequality.

right

One of the objects to be tested for inequality.

Ty1

The type controlled by the left shared pointer.

Ty2

The type controlled by the right shared pointer.

Return Value

true if the objects are not equal; **false** if objects are equal.

Remarks

The first template operator returns false. (All default allocators are equal.)

The second and third template operators return `!(left == right)`.

Example

```

// memory_op_me.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    allocator<double> Alloc;
    vector <char>:: allocator_type v1Alloc;

    if ( Alloc != v1Alloc )
        cout << "The allocator objects Alloc & v1Alloc not are equal."
              << endl;
    else
        cout << "The allocator objects Alloc & v1Alloc are equal."
              << endl;
}

```

The allocator objects Alloc & v1Alloc are equal.

Example

```

// std__memory__operator_ne.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0(new int(0));
    std::shared_ptr<int> sp1(new int(0));

    std::cout << "sp0 != sp0 == " << std::boolalpha
              << (sp0 != sp0) << std::endl;
    std::cout << "sp0 != sp1 == " << std::boolalpha
              << (sp0 != sp1) << std::endl;

    return (0);
}

```

```

sp0 != sp0 == false
sp0 != sp1 == true

```

operator==

Tests for equality between objects.

```

template <class Type, class Other>
bool operator==(
    const allocator<Type>& left,
    const allocator<Other>& right) throw();

template <class Ty1, class Del1, class Ty2, class Del2>
bool operator==(
    const unique_ptr<Ty1, Del1>& left,
    const unique_ptr<Ty2, Del2>& right);

template <class Ty1, class Ty2>
bool operator==(
    const shared_ptr<Ty1>& left;,
    const shared_ptr<Ty2>& right);

```

Parameters

left

One of the objects to be tested for equality.

right

One of the objects to be tested for equality.

Ty1

The type controlled by the left shared pointer.

Ty2

The type controlled by the right shared pointer.

Return Value

true if the objects are equal, **false** if objects are not equal.

Remarks

The first template operator returns true. (All default allocators are equal.)

The second and third template operators return `left.get() == right.get()`.

Example

```

// memory_op_eq.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    allocator<char> Alloc;
    vector<int>:: allocator_type v1Alloc;

    allocator<char> cAlloc(Alloc);
    allocator<int> cv1Alloc(v1Alloc);

    if ( cv1Alloc == v1Alloc )
        cout << "The allocator objects cv1Alloc & v1Alloc are equal."
              << endl;
    else
        cout << "The allocator objects cv1Alloc & v1Alloc are not equal."
              << endl;

    if ( cAlloc == Alloc )
        cout << "The allocator objects cAlloc & Alloc are equal."
              << endl;
    else
        cout << "The allocator objects cAlloc & Alloc are not equal."
              << endl;
}

```

The allocator objects cv1Alloc & v1Alloc are equal.
The allocator objects cAlloc & Alloc are equal.

Example

```

// std_memory_operator_eq.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0(new int(0));
    std::shared_ptr<int> sp1(new int(0));

    std::cout << "sp0 == sp0 == " << std::boolalpha
              << (sp0 == sp0) << std::endl;
    std::cout << "sp0 == sp1 == " << std::boolalpha
              << (sp0 == sp1) << std::endl;

    return (0);
}

```

sp0 == sp0 == true
sp0 == sp1 == false

operator>=

Tests for one object being greater than or equal to a second object.

```

template <class T, class Del1, class U, class Del2>
bool operator>=(
    const unique_ptr<T, Del1>& left,
    const unique_ptr<U, Del2>& right);

template <class Ty1, class Ty2>
bool operator>=(
    const shared_ptr<Ty1>& left,
    const shared_ptr<Ty2>& right);

```

Parameters

left

One of the objects to be compared.

right

One of the objects to be compared.

Ty1

The type controlled by the left shared pointer.

Ty2

The type controlled by the right shared pointer.

Remarks

The template operators return `left.get() >= right.get()` .

operator<

Tests for one object being less than a second object.

```

template <class T, class Del1, class U, class Del2>
bool operator<(
    const unique_ptr<T, Del1>& left,
    const unique_ptr<U, Del2>& right);

template <class Ty1, class Ty2>
bool operator<(
    const shared_ptr<Ty1>& left,
    const shared_ptr<Ty2>& right);

```

Parameters

left

One of the objects to be compared.

right

One of the objects to be compared.

Ty1

The type controlled by the left pointer.

Ty2

The type controlled by the right pointer.

operator<=

Tests for one object being less than or equal to a second object.

```
template <class T, class Del1, class U, class Del2>
bool operator<=(
    const unique_ptr<T, Del1>& left,
    const unique_ptr<U&, Del2>& right);

template <class Ty1, class Ty2>
bool operator<=(
    const shared_ptr<Ty1>& left,
    const shared_ptr<Ty2>& right);
```

Parameters

left

One of the objects to be compared.

right

One of the objects to be compared.

Ty1

The type controlled by the left shared pointer.

Ty2

The type controlled by the right shared pointer.

Remarks

The template operators return `left.get() <= right.get()`

operator>

Tests for one object being greater than a second object.

```
template <class Ty1, class Del1, class Ty2, class Del2>
bool operator>(
    const unique_ptr<Ty1, Del1>& left,
    const unique_ptr<Ty2&, Del2>& right);

template <class Ty1, class Ty2>
bool operator>(
    const shared_ptr<Ty1>& left,
    const shared_ptr<Ty2>& right);
```

Parameters

left

One of the objects to be compared.

right

One of the objects to be compared.

Ty1

The type controlled by the left shared pointer.

Ty2

The type controlled by the right shared pointer.

operator<<

Writes the shared pointer to the stream.

```
template <class Elem, class Tr, class Ty>
std::basic_ostream<Elem, Tr>& operator<<(std::basic_ostream<Elem, Tr>& out,
    shared_ptr<Ty>& sp);
```

Parameters

Elem

The type of the stream element.

Tr

The type the stream element traits.

Ty

The type controlled by the shared pointer.

out

The output stream.

sp

The shared pointer.

Remarks

The template function returns `out << sp.get()` .

Example

```
// std__memory__operator_sl.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0(new int(5));

    std::cout << "sp0 == " << sp0 << " (varies)" << std::endl;

    return (0);
}
```

```
sp0 == 3f3040 (varies)
```

[<memory>](#)

<memory> enums

10/31/2018 • 2 minutes to read • [Edit Online](#)

`pointer_safety`

pointer_safety Enumeration

The enumeration of possible values returned by `get_pointer_safety`.

```
class pointer_safety { relaxed, preferred, strict };
```

Remarks

The scoped **enum** defines the values that can be returned by `get_pointer_safety()`:

`relaxed` -- pointers not safely derived (obviously pointers to declared or allocated objects) are treated the same as those safely derived.

`preferred` -- as before, but pointers not safely derived should not be dereferenced.

`strict` -- pointers not safely derived might be treated differently than those safely derived.

[<memory>](#)

allocator Class

11/9/2018 • 18 minutes to read • [Edit Online](#)

The template class describes an object that manages storage allocation and freeing for arrays of objects of type `Type`. An object of class `allocator` is the default allocator object specified in the constructors for several container template classes in the C++ Standard Library.

Syntax

```
template <class Type>
class allocator
```

Parameters

Type

The type of object for which storage is being allocated or deallocated.

Remarks

All the C++ Standard Library containers have a template parameter that defaults to `allocator`. Constructing a container with a custom allocator provide control over allocation and freeing of that container's elements.

For example, an allocator object might allocate storage on a private heap or in shared memory, or it might optimize for small or large object sizes. It might also specify, through the type definitions it supplies, that elements be accessed through special accessor objects that manage shared memory, or perform automatic garbage collection. Hence, a class that allocates storage using an allocator object should use these types for declaring pointer and reference objects, as the containers in the C++ Standard Library do.

(C++98/03 only) When you derive from allocator class, you have to provide a `rebind` struct, whose `_Other` typedef references your newly-derived class.

Thus, an allocator defines the following types:

- `pointer` behaves like a pointer to `Type`.
- `const_pointer` behaves like a const pointer to `Type`.
- `reference` behaves like a reference to `Type`.
- `const_reference` behaves like a const reference to `Type`.

These `Type`s specify the form that pointers and references must take for allocated elements. (`allocator::pointer` is not necessarily the same as `Type*` for all allocator objects, even though it has this obvious definition for class `allocator`.)

C++11 and later: To enable move operations in your allocator, use the minimal allocator interface and implement copy constructor, `==` and `!=` operators, `allocate` and `deallocate`. For more information and an example, see [Allocators](#)

Members

Constructors

CONSTRUCTOR	DESCRIPTION
allocator	Constructors used to create <code>allocator</code> objects.

Typedefs

TYPE NAME	DESCRIPTION
const_pointer	A type that provides a constant pointer to the type of object managed by the allocator.
const_reference	A type that provides a constant reference to type of object managed by the allocator.
difference_type	A signed integral type that can represent the difference between values of pointers to the type of object managed by the allocator.
pointer	A type that provides a pointer to the type of object managed by the allocator.
reference	A type that provides a reference to the type of object managed by the allocator.
size_type	An unsigned integral type that can represent the length of any sequence that an object of template class <code>allocator</code> can allocate.
value_type	A type that is managed by the allocator.

Member functions

MEMBER FUNCTION	DESCRIPTION
address	Finds the address of an object whose value is specified.
allocate	Allocates a block of memory large enough to store at least some specified number of elements.
construct	Constructs a specific type of object at a specified address that is initialized with a specified value.
deallocate	Frees a specified number of objects from storage beginning at a specified position.
destroy	Calls an objects destructor without deallocating the memory where the object was stored.
max_size	Returns the number of elements of type <code>Type</code> that could be allocated by an object of class <code>allocator</code> before the free memory is used up.
rebind	A structure that enables an allocator for objects of one type to allocate storage for objects of another type.

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Assigns one <code>allocator</code> object to another <code>allocator</code> object.

Requirements

Header: <memory>

Namespace: std

allocator::address

Finds the address of an object whose value is specified.

```
pointer address(reference val) const;
const_pointer address(const_reference val) const;
```

Parameters

val

The const or nonconst value of the object whose address is being searched for.

Return Value

A const or nonconst pointer to the object found of, respectively, const or nonconst value.

Remarks

The member functions return the address of *val*, in the form that pointers must take for allocated elements.

Example

```

// allocator_address.cpp
// compile with: /EHsc
#include <memory>
#include <algorithm>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    vector <int> v1;
    vector <int>::iterator v1Iter;
    vector <int>:: allocator_type v1Alloc;

    int i;
    for ( i = 1 ; i <= 7 ; i++ )
    {
        v1.push_back( 2 * i );
    }

    cout << "The original vector v1 is:\n ( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ; v1Iter++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;

    allocator<int>::const_pointer v1Ptr;
    const int k = 8;
    v1Ptr = v1Alloc.address( *find(v1.begin( ), v1.end( ), k) );
    // v1Ptr = v1Alloc.address( k );
    cout << "The integer addressed by v1Ptr has a value of: "
        << "*v1Ptr = " << *v1Ptr << "." << endl;
}

```

```

The original vector v1 is:
( 2 4 6 8 10 12 14 ).
The integer addressed by v1Ptr has a value of: *v1Ptr = 8.

```

allocator::allocate

Allocates a block of memory large enough to store at least some specified number of elements.

```

pointer allocate(size_type count, const void* _Hint);

```

Parameters

count

The number of elements for which sufficient storage is to be allocated.

_Hint

A const pointer that may assist the allocator object satisfy the request for storage by locating the address of an object allocated prior to the request.

Return Value

A pointer to the allocated object or null if memory was not allocated.

Remarks

The member function allocates storage for an array of count elements of type `Type`, by calling operator `new(count)`. It returns a pointer to the allocated object. The hint argument helps some allocators in improving

locality of reference; a valid choice is the address of an object earlier allocated by the same allocator object and not yet deallocated. To supply no hint, use a null pointer argument instead.

Example

```
// allocator_allocate.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    allocator<int> v1Alloc;
    allocator<int>::pointer v1aPtr;
    v1aPtr = v1Alloc.allocate ( 10 );

    int i;
    for ( i = 0 ; i < 10 ; i++ )
    {
        v1aPtr[ i ] = i;
    }

    for ( i = 0 ; i < 10 ; i++ )
    {
        cout << v1aPtr[ i ] << " ";
    }
    cout << endl;
    v1Alloc.deallocate( v1aPtr, 10 );
}
```

0 1 2 3 4 5 6 7 8 9

allocator::allocator

Constructors used to create allocator objects.

```
allocator();
allocator(const allocator<Type>& right);
template <class Other>
allocator(const allocator<Other>& right);
```

Parameters

right

The allocator object to be copied.

Remarks

The constructor does nothing. In general, however, an allocator object constructed from another allocator object should compare equal to it and permit intermixing of object allocation and freeing between the two allocator objects.

Example

```

// allocator_allocator.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

class Int {
public:
    Int( int i )
    {
        cout << "Constructing " << ( void* )this << endl;
        x = i;
        bIsConstructed = true;
    };
    ~Int( )
    {
        cout << "Destructing " << ( void* )this << endl;
        bIsConstructed = false;
    };
    Int &operator++( )
    {
        x++;
        return *this;
    };
    int x;
private:
    bool bIsConstructed;
};

int main( )
{
    allocator<double> Alloc;
    vector <Int>:: allocator_type v1Alloc;

    allocator<double> cAlloc(Alloc);
    allocator<Int> cv1Alloc(v1Alloc);

    if ( cv1Alloc == v1Alloc )
        cout << "The allocator objects cv1Alloc & v1Alloc are equal."
              << endl;
    else
        cout << "The allocator objects cv1Alloc & v1Alloc are not equal."
              << endl;

    if ( cAlloc == Alloc )
        cout << "The allocator objects cAlloc & Alloc are equal."
              << endl;
    else
        cout << "The allocator objects cAlloc & Alloc are not equal."
              << endl;
}

```

```

The allocator objects cv1Alloc & v1Alloc are equal.
The allocator objects cAlloc & Alloc are equal.

```

allocator::const_pointer

A type that provides a constant pointer to the type of object managed by the allocator.

```
typedef const value_type *const_pointer;
```

Remarks

The pointer type describes an object `ptr` that can designate, through the expression `*ptr`, any const object that an object of template class allocator can allocate.

Example

```
// allocator_const_ptr.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    vector <int> v1;
    vector <int>::iterator v1Iter;
    vector <int>:: allocator_type v1Alloc;

    int i;
    for ( i = 1 ; i <= 7 ; i++ )
    {
        v1.push_back( i * 2 );
    }

    cout << "The original vector v1 is:\n ( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ; v1Iter++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;

    allocator<int>::const_pointer v1Ptr;
    const int k = 10;
    v1Ptr = v1Alloc.address( k );

    cout << "The integer's address found has a value of: "
        << *v1Ptr << "." << endl;
}
```

```
The original vector v1 is:
( 2 4 6 8 10 12 14 ).
The integer's address found has a value of: 10.
```

allocator::const_reference

A type that provides a constant reference to type of object managed by the allocator.

```
typedef const value_type& const_reference;
```

Remarks

The reference type describes an object that can designate any const object that an object of template class allocator can allocate.

Example

```

// allocator_const_ref.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    vector <double> v;
    vector <double> ::iterator vIter, vfIter;
    vector <double> :: allocator_type vAlloc;

    int j;
    for ( j = 1 ; j <= 7 ; j++ )
    {
        v.push_back( 100.0 * j );
    }

    cout << "The original vector v is:\n ( " ;
    for ( vIter = v.begin( ) ; vIter != v.end( ) ; vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;

    vfIter = v.begin( );
    allocator<double>::const_reference vcref =*vfIter;
    cout << "The value of the element referred to by vref is: "
        << vcref << ",\n the first element in the vector." << endl;

    // const references can have their elements modified,
    // so the following would generate an error:
    // vcref = 150;
    // but the value of the first element could be modified through
    // its nonconst iterator and the const reference would remain valid
    *vfIter = 175;
    cout << "The value of the element referred to by vcref,"
        << "\n after nofication through its nonconst iterator, is: "
        << vcref << "." << endl;
}

```

```

The original vector v is:
( 100 200 300 400 500 600 700 ).
The value of the element referred to by vref is: 100,
the first element in the vector.
The value of the element referred to by vcref,
after nofication through its nonconst iterator, is: 175.

```

allocator::construct

Constructs a specific type of object at a specified address that is initialized with a specified value.

```

void construct(pointer ptr, const Type& val);
void construct(pointer ptr, Type&& val);
template <class _Other>
void construct(pointer ptr, _Other&&... val);

```

Parameters

ptr

A pointer to the location where the object is to be constructed.

val

The value with which the object being constructed is to be initialized.

Remarks

The first member function is equivalent to **new** ((`void *`) `ptr`) **Type** (`val`).

Example

```
// allocator_construct.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <algorithm>
#include <vector>

using namespace std;

int main( )
{
    vector <int> v1;
    vector <int>::iterator v1Iter;
    vector <int>:: allocator_type v1Alloc;

    int i;
    for ( i = 1 ; i <= 7 ; i++ )
    {
        v1.push_back( 3 * i );
    }

    cout << "The original vector v1 is:\n ( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ; v1Iter++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;

    allocator<int>::pointer v1PtrA;
    int kA = 6, kB = 7;
    v1PtrA = v1Alloc.address( *find( v1.begin( ), v1.end( ), kA ) );
    v1Alloc.destroy ( v1PtrA );
    v1Alloc.construct ( v1PtrA , kB );

    cout << "The modified vector v1 is:\n ( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ; v1Iter++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;
}
```

```
The original vector v1 is:
( 3 6 9 12 15 18 21 ).
The modified vector v1 is:
( 3 7 9 12 15 18 21 ).
```

allocator::deallocate

Frees a specified number of objects from storage beginning at a specified position.

```
void deallocate(pointer ptr, size_type count);
```

Parameters

ptr

A pointer to the first object to be deallocated from storage.

count

The number of objects to be deallocated from storage.

Remarks

The member function frees storage for the array of *count* objects of type `Type` beginning at *ptr*, by calling `operator delete(ptr)`. The pointer *ptr* must have been returned earlier by a call to [allocate](#) for an allocator object that compares equal to ***this**, allocating an array object of the same size and type. `deallocate` never throws an exception.

Example

For an example using the member function, see [allocator::allocate](#).

allocator::destroy

Calls an objects destructor without deallocating the memory where the object was stored.

```
void destroy(pointer ptr);
```

Parameters

ptr

A pointer designating the address of the object to be destroyed.

Remarks

The member function destroys the object designated by *ptr*, by calling the destructor `ptr->Type::~~Type`.

Example

```

// allocator_destroy.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <algorithm>
#include <vector>

using namespace std;

int main( )
{
    vector<int> v1;
    vector<int>::iterator v1Iter;
    vector<int>:: allocator_type v1Alloc;

    int i;
    for ( i = 1 ; i <= 7 ; i++ )
    {
        v1.push_back( 2 * i );
    }

    cout << "The original vector v1 is:\n ( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ; v1Iter++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;

    allocator<int>::pointer v1PtrA;
    int kA = 12, kB = -99;
    v1PtrA = v1Alloc.address( *find(v1.begin( ), v1.end( ), kA) );
    v1Alloc.destroy ( v1PtrA );
    v1Alloc.construct ( v1PtrA , kB );

    cout << "The modified vector v1 is:\n ( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ; v1Iter++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;
}

```

```

The original vector v1 is:
( 2 4 6 8 10 12 14 ).
The modified vector v1 is:
( 2 4 6 8 10 -99 14 ).

```

allocator::difference_type

A signed integral type that can represent the difference between values of pointers to the type of object managed by the allocator.

```
typedef ptrdiff_t difference_type;
```

Remarks

The signed integer type describes an object that can represent the difference between the addresses of any two elements in a sequence that an object of template class allocator can allocate.

Example

```

// allocator_diff_type.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    vector<int> v1;
    vector<int>::iterator v1Iter;
    vector<int>:: allocator_type v1Alloc;

    int i;
    for ( i = 0 ; i <= 7 ; i++ )
    {
        v1.push_back( i * 2 );
    }

    cout << "The original vector v1 is:\n ( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ; v1Iter++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;

    allocator<int>::const_pointer v1PtrA, v1PtrB;
    const int kA = 4, kB =12;
    v1PtrA = v1Alloc.address( kA );
    v1PtrB = v1Alloc.address( kB );
    allocator<int>::difference_type v1diff = *v1PtrB - *v1PtrA;

    cout << "Pointer v1PtrA addresses " << *v1PtrA << "." << endl;
    cout << "Pointer v1PtrB addresses " << *v1PtrB << "." << endl;
    cout << "The difference between the integer's addresses is: "
        << v1diff << "." << endl;
}

```

```

The original vector v1 is:
( 0 2 4 6 8 10 12 14 ).
Pointer v1PtrA addresses 4.
Pointer v1PtrB addresses 12.
The difference between the integer's addresses is: 8.

```

allocator::max_size

Returns the number of elements of type `Type` that could be allocated by an object of class `allocator` before the free memory is used up.

```

size_type max_size() const;

```

Return Value

The number of elements that could be allocated.

Example

```

// allocator_max_size.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    vector<int> v1;
    vector<int>::iterator v1Iter;
    vector<int>:: allocator_type v1Alloc;

    int i;
    for ( i = 1 ; i <= 7 ; i++ )
    {
        v1.push_back( i );
    }

    cout << "The original vector v1 is:\n ( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ; v1Iter++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;

    vector<double> v2;
    vector<double> ::iterator v2Iter;
    vector<double> :: allocator_type v2Alloc;
    allocator<int>::size_type v1size;
    v1size = v1Alloc.max_size( );

    cout << "The number of integers that can be allocated before\n"
        << " the free memory in the vector v1 is used up is: "
        << v1size << "." << endl;

    int ii;
    for ( ii = 1 ; ii <= 7 ; ii++ )
    {
        v2.push_back( ii * 10.0 );
    }

    cout << "The original vector v2 is:\n ( " ;
    for ( v2Iter = v2.begin( ) ; v2Iter != v2.end( ) ; v2Iter++ )
        cout << *v2Iter << " ";
    cout << ")." << endl;
    allocator<double>::size_type v2size;
    v2size = v2Alloc.max_size( );

    cout << "The number of doubles that can be allocated before\n"
        << " the free memory in the vector v2 is used up is: "
        << v2size << "." << endl;
}

```

allocator::operator=

Assigns one allocator object to another allocator object.

```

template <class Other>
allocator<Type>& operator=(const allocator<Other>& right);

```

Parameters

right

An allocator object to be assigned to another such object.

Return Value

A reference to the allocator object

Remarks

The template assignment operator does nothing. In general, however, an allocator object assigned to another allocator object should compare equal to it and permit intermixing of object allocation and freeing between the two allocator objects.

Example

```
// allocator_op_assign.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

class Int {
public:
    Int(int i)
    {
        cout << "Constructing " << ( void* )this << endl;
        x = i;
        bIsConstructed = true;
    };
    ~Int( ) {
        cout << "Destructing " << ( void* )this << endl;
        bIsConstructed = false;
    };
    Int &operator++( )
    {
        x++;
        return *this;
    };
    int x;
private:
    bool bIsConstructed;
};

int main( )
{
    allocator<Int> Alloc;
    allocator<Int> cAlloc ;
    cAlloc = Alloc;
}
```

allocator::pointer

A type that provides a pointer to the type of object managed by the allocator.

```
typedef value_type *pointer;
```

Remarks

The pointer type describes an object `ptr` that can designate, through the expression ***ptr**, any object that an object of template class allocator can allocate.

Example

```

// allocator_ptr.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    vector <int> v1;
    vector <int>::iterator v1Iter;
    vector <int>:: allocator_type v1Alloc;

    int i;
    for ( i = 1 ; i <= 7 ; i++ )
    {
        v1.push_back( 3 * i );
    }

    cout << "The original vector v1 is:\n( " ;
    for ( v1Iter = v1.begin( ) ; v1Iter != v1.end( ) ; v1Iter++ )
        cout << *v1Iter << " ";
    cout << ")." << endl;

    allocator<int>::const_pointer v1Ptr;
    const int k = 12;
    v1Ptr = v1Alloc.address( k );

    cout << "The integer addressed by v1Ptr has a value of: "
        << "*v1Ptr = " << *v1Ptr << "." << endl;
}

```

```

The original vector v1 is:
( 3 6 9 12 15 18 21 ).
The integer addressed by v1Ptr has a value of: *v1Ptr = 12.

```

allocator::rebind

A structure that enables an allocator for objects of one type to allocate storage for objects of another type.

```

struct rebind {     typedef allocator<_Other> other ;     };

```

Parameters

other

The type of element for which memory is being allocated.

Remarks

This structure is useful for allocating memory for type that differs from the element type of the container being implemented.

The member template class defines the type *other*. Its sole purpose is to provide the type name **allocator<_Other>**, given the type name **allocator< Type>**.

For example, given an allocator object `a1` of type `A`, you can allocate an object of type `_Other` with the expression:

```
A::rebind<Other>::other(al).allocate(1, (Other *)0)
```

Or, you can name its pointer type by writing the type:

```
A::rebind<Other>::other::pointer
```

Example

```
// allocator_rebind.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <algorithm>
#include <vector>

using namespace std;

typedef vector<int>::allocator_type IntAlloc;
int main( )
{
    IntAlloc v1Iter;
    vector<int> v1;

    IntAlloc::rebind<char>::other::pointer pszC =
        IntAlloc::rebind<char>::other(v1.get_allocator()).allocate(1, (void *)0);

    int * pInt = v1Iter.allocate(10);
}
```

allocator::reference

A type that provides a reference to the type of object managed by the allocator.

```
typedef value_type& reference;
```

Remarks

The reference type describes an object that can designate any object that an object of template class allocator can allocate.

Example

```

// allocator_reference.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    vector <double> v;
    vector <double> ::iterator vIter, vfIter;
    vector <double> :: allocator_type vAlloc;

    int j;
    for ( j = 1 ; j <= 7 ; j++ )
    {
        v.push_back( 100.0 * j );
    }

    cout << "The original vector v is:\n ( " ;
    for ( vIter = v.begin( ) ; vIter != v.end( ) ; vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;

    vfIter = v.begin( );
    allocator<double>::reference vref =*vfIter;
    cout << "The value of the element referred to by vref is: "
        << vref << ",\n the first element in the vector." << endl;

    // nonconst references can have their elements modified
    vref = 150;
    cout << "The element referred to by vref after being modified is: "
        << vref << "." << endl;
}

```

```

The original vector v is:
( 100 200 300 400 500 600 700 ).
The value of the element referred to by vref is: 100,
the first element in the vector.
The element referred to by vref after being modified is: 150.

```

allocator::size_type

An unsigned integral type that can represent the length of any sequence that an object of template class allocator can allocate.

```
typedef size_t size_type;
```

Example

```

// allocator_size_type.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

int main( )
{
    vector <double> v;
    vector <double> ::iterator vIter;
    vector <double> :: allocator_type vAlloc;

    int j;
    for ( j = 1 ; j <= 7 ; j++ )
    {
        v.push_back( 100.0 * j );
    }

    cout << "The original vector v is:\n ( " ;
    for ( vIter = v.begin( ) ; vIter != v.end( ) ; vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;

    allocator<double>::size_type vsize;
    vsize = vAlloc.max_size( );

    cout << "The number of doubles that can be allocated before\n"
        << " the free memory in the vector v is used up is: "
        << vsize << "." << endl;
}

```

allocator::value_type

A type that is managed by the allocator.

```
typedef Type value_type;
```

Remarks

The type is a synonym for the template parameter `Type`.

Example

```

// allocator_value_type.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>
using namespace std;

int main( )
{
    vector <double> v;
    vector <double> ::iterator vIter, vfIter;
    vector <double> :: allocator_type vAlloc;

    int j;
    for ( j = 1 ; j <= 7 ; j++ )
    {
        v.push_back( 100.0 * j );
    }

    cout << "The original vector v is:\n ( " ;
    for ( vIter = v.begin( ) ; vIter != v.end( ) ; vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;

    vfIter = v.begin( );
    allocator<double>::value_type vecVal = 150.0;
    *vfIter = vecVal;
    cout << "The value of the element addressed by vfIter is: "
        << *vfIter << ",\n the first element in the vector." << endl;

    cout << "The modified vector v is:\n ( " ;
    for ( vIter = v.begin( ) ; vIter != v.end( ) ; vIter++ )
        cout << *vIter << " ";
    cout << ")." << endl;
}

```

```

The original vector v is:
( 100 200 300 400 500 600 700 ).
The value of the element addressed by vfIter is: 150,
the first element in the vector.
The modified vector v is:
( 150 200 300 400 500 600 700 ).

```

[Thread Safety in the C++ Standard Library](#)

allocator<void> Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

A specialization of the template class `allocator` to type **void**, defining the types that make sense in this context.

Syntax

```
template <>
class allocator<void> {
    typedef void *pointer;
    typedef const void *const_pointer;
    typedef void value_type;
    template <class Other>
    struct rebind;
    allocator();
    allocator(const allocator<void>&);

    template <class Other>
    allocator(const allocator<Other>&);

    template <class Other>
    allocator<void>& operator=(const allocator<Other>&);
};
```

Remarks

The class explicitly specializes template class `allocator` for type **void**. Its constructors and assignment operator behave the same as for the template class, but it defines only the following types:

- `const_pointer`.
- `pointer`.
- `value_type`.
- `rebind`, a nested template class.

Requirements

Header: <memory>

Namespace: std

[Thread Safety in the C++ Standard Library](#)

allocator_traits Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

The template class describes an object that supplements an *allocator type*. An allocator type is any type that describes an allocator object that is used for managing allocated storage. Specifically, for any allocator type `Alloc`, you can use `allocator_traits<Alloc>` to determine all the information that is needed by an allocator-enabled container. For more information, see the default [allocator Class](#).

Syntax

```
template <class Alloc>
class allocator_traits;
```

Typedefs

NAME	DESCRIPTION
<code>allocator_traits::allocator_type</code>	This type is a synonym for the template parameter <code>Alloc</code> .
<code>allocator_traits::const_pointer</code>	This type is <code>Alloc::const_pointer</code> , if that type is well-formed; otherwise, this type is <code>pointer_traits<pointer>::rebind<const value_type></code> .
<code>allocator_traits::const_void_pointer</code>	This type is <code>Alloc::const_void_pointer</code> , if that type is well-formed; otherwise, this type is <code>pointer_traits<pointer>::rebind<const void></code> .
<code>allocator_traits::difference_type</code>	This type is <code>Alloc::difference_type</code> , if that type is well-formed; otherwise, this type is <code>pointer_traits<pointer>::difference_type</code> .
<code>allocator_traits::pointer</code>	This type is <code>Alloc::pointer</code> , if that type is well-formed; otherwise, this type is <code>value_type *</code> .
<code>allocator_traits::propagate_on_container_copy_assignment</code>	This type is <code>Alloc::propagate_on_container_copy_assignment</code> , if that type is well-formed; otherwise, this type is <code>false_type</code> .
<code>allocator_traits::propagate_on_container_move_assignment</code>	This type is <code>Alloc::propagate_on_container_move_assignment</code> , if that type is well-formed; otherwise, this type is <code>false_type</code> . If the type holds true, an allocator-enabled container copies its stored allocator on a move assignment.
<code>allocator_traits::propagate_on_container_swap</code>	This type is <code>Alloc::propagate_on_container_swap</code> , if that type is well-formed; otherwise, this type is <code>false_type</code> . If the type holds true, an allocator-enabled container swaps its stored allocator on a swap.

NAME	DESCRIPTION
<code>allocator_traits::size_type</code>	This type is <code>Alloc::size_type</code> , if that type is well-formed; otherwise, this type is <code>make_unsigned<difference_type>::type</code> .
<code>allocator_traits::value_type</code>	This type is a synonym for <code>Alloc::value_type</code> .
<code>allocator_traits::void_pointer</code>	This type is <code>Alloc::void_pointer</code> , if that type is well-formed; otherwise, this type is <code>pointer_traits<pointer>::rebind<void></code> .

Static Methods

The following static methods call the corresponding method on a given allocator parameter.

NAME	DESCRIPTION
<code>allocate</code>	Static method that allocates memory by using the given allocator parameter.
<code>construct</code>	Static method that uses a specified allocator to construct an object.
<code>deallocate</code>	Static method that uses a specified allocator to deallocate a specified number of objects.
<code>destroy</code>	Static method that uses a specified allocator to call the destructor on an object without deallocating its memory.
<code>max_size</code>	Static method that uses a specified allocator to determine the maximum number of objects that can be allocated.
<code>select_on_container_copy_construction</code>	Static method that calls <code>select_on_container_copy_construction</code> on the specified allocator.

Requirements

Header: <memory>

Namespace: std

`allocator_traits::allocate`

Static method that allocates memory by using the given allocator parameter.

```
static pointer allocate(Alloc& al, size_type count);

static pointer allocate(Alloc& al, size_type count,
    typename allocator_traits<void>::const_pointer* hint);
```

Parameters

al

An allocator object.

count

The number of elements to allocate.

hint

A `const_pointer` that might assist the allocator object in satisfying the request for storage by locating the address of an allocated object prior to the request. A null pointer is treated as no hint.

Return Value

Each method returns a pointer to the allocated object.

The first static method returns `a1.allocate(count)`.

The second method returns `a1.allocate(count, hint)`, if that expression is well formed; otherwise it returns `a1.allocate(count)`.

allocator_traits::construct

Static method that uses a specified allocator to construct an object.

```
template <class Uty, class Types>
static void construct(Alloc& al, Uty* ptr, Types&&... args);
```

Parameters

al

An allocator object.

ptr

A pointer to the location where the object is to be constructed.

args

A list of arguments that is passed to the object constructor.

Remarks

The static member function calls `a1.construct(ptr, args...)`, if that expression is well formed; otherwise it evaluates `::new (static_cast<void *>(ptr)) Uty(std::forward<Types>(args)...) .`

allocator_traits::deallocate

Static method that uses a specified allocator to deallocate a specified number of objects.

```
static void deallocate(Alloc al,
    pointer ptr,
    size_type count);
```

Parameters

al

An allocator object.

ptr

A pointer to the starting location of the objects to be deallocated.

count

The number of objects to deallocate.

Remarks

This method calls `al.deallocate(ptr, count)`.

This method throws nothing.

allocator_traits::destroy

Static method that uses a specified allocator to call the destructor on an object without deallocating its memory.

```
template <class Uty>
static void destroy(Alloc& al, Uty* ptr);
```

Parameters

al

An allocator object.

ptr

A pointer to the location of the object.

Remarks

This method calls `al.destroy(ptr)`, if that expression is well formed; otherwise it evaluates `ptr->~Uty()`.

allocator_traits::max_size

Static method that uses a specified allocator to determine the maximum number of objects that can be allocated.

```
static size_type max_size(const Alloc& al);
```

Parameters

al

An allocator object.

Remarks

This method returns `al.max_size()`, if that expression is well formed; otherwise it returns `numeric_limits<size_type>::max()`.

allocator_traits::select_on_container_copy_construction

Static method that calls `select_on_container_copy_construction` on the specified allocator.

```
static Alloc select_on_container_copy_construction(const Alloc& al);
```

Parameters

al

An allocator object.

Return Value

This method returns `al.select_on_container_copy_construction()`, if that type is well formed; otherwise it returns *al*.

Remarks

This method is used to specify an allocator when the associated container is copy-constructed.

[<memory>](#)

[pointer_traits](#) Struct

[scoped_allocator_adaptor](#) Class

auto_ptr Class

11/8/2018 • 7 minutes to read • [Edit Online](#)

Wraps a smart pointer around a resource that ensures the resource is destroyed automatically when control leaves a block.

The more capable `unique_ptr` class supersedes `auto_ptr`. For more information, see [unique_ptr Class](#).

For more information about `throw()` and exception handling, see [Exception Specifications \(throw\)](#).

Syntax

```
class auto_ptr {
public:
    typedef Type element_type;
    explicit auto_ptr(Type* ptr = 0) throw();
    auto_ptr(auto_ptr<Type>& right) throw()
        ;
    template <class Other>
    operator auto_ptr<Other>() throw();
    template <class Other>
    auto_ptr<Type>& operator=(auto_ptr<Other>& right) throw();
    template <class Other>
    auto_ptr(auto_ptr<Other>& right);
    auto_ptr<Type>& operator=(auto_ptr<Type>& right);
    ~auto_ptr();
    Type& operator*() const throw();
    Type * operator->()const throw();
    Type *get() const throw();
    Type *release()throw();
    void reset(Type* ptr = 0);
};
```

Parameters

right

The `auto_ptr` from which to get an existing resource.

ptr

The pointer specified to replace the stored pointer.

Remarks

The template class describes a smart pointer, called an `auto_ptr`, to an allocated object. The pointer must be either null or designate an object allocated by **new**. The `auto_ptr` transfers ownership if its stored value is assigned to another object. (It replaces the stored value after a transfer with a null pointer.) The destructor for `auto_ptr<Type>` deletes the allocated object. The `auto_ptr<Type>` ensures that an allocated object is automatically deleted when control leaves a block, even through a thrown exception. You should not construct two `auto_ptr<Type>` objects that own the same object.

You can pass an `auto_ptr<Type>` object by value as an argument to a function call. An `auto_ptr` cannot be an element of any Standard Library container. You cannot reliably manage a sequence of `auto_ptr<Type>` objects with a C++ Standard Library container.

Members

Constructors

CONSTRUCTOR	DESCRIPTION
<code>auto_ptr</code>	The constructor for objects of type <code>auto_ptr</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>element_type</code>	The type is a synonym for the template parameter <code>Type</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>get</code>	The member function returns the stored pointer <code>myptr</code> .
<code>release</code>	The member replaces the stored pointer <code>myptr</code> with a null pointer and returns the previously stored pointer.
<code>reset</code>	The member function evaluates the expression <code>delete myptr</code> , but only if the stored pointer value <code>myptr</code> changes as a result of function call. It then replaces the stored pointer with <i>ptr</i> .

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	An assignment operator that transfers ownership from one <code>auto_ptr</code> object to another.
<code>operator*</code>	The dereferencing operator for objects of type <code>auto_ptr</code> .
<code>operator-></code>	The operator for allowing member access.
<code>operator auto_ptr<Other></code>	Casts from one kind of <code>auto_ptr</code> to another kind of <code>auto_ptr</code> .
<code>operator auto_ptr_ref<Other></code>	Casts from an <code>auto_ptr</code> to an <code>auto_ptr_ref</code> .

Requirements

Header: `<memory>`

Namespace: `std`

`auto_ptr::auto_ptr`

The constructor for objects of type `auto_ptr`.

```
explicit auto_ptr(Type* ptr = 0) throw();

auto_ptr(auto_ptr<Type>& right) throw();

auto_ptr(auto_ptr_ref<Type> right) throw();

template <class Other>
auto_ptr(auto_ptr<Other>& right) throw();
```

Parameters

ptr

The pointer to the object that `auto_ptr` encapsulates.

right

The `auto_ptr` object to be copied by the constructor.

Remarks

The first constructor stores *ptr* in `myptr`, the stored pointer to the allocated object. The second constructor transfers ownership of the pointer stored in *right*, by storing *right.release* in `myptr`.

The third constructor behaves the same as the second, except that it stores `right.ref.release` in `myptr`, where `ref` is the reference stored in `right`.

The template constructor behaves the same as the second constructor, provided that a pointer to `Other` can be implicitly converted to a pointer to `Type`.

Example

```

// auto_ptr_auto_ptr.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

class Int
{
public:
    Int(int i)
    {
        cout << "Constructing " << ( void* )this << endl;
        x = i;
        bIsConstructed = true;
    };
    ~Int( )
    {
        cout << "Destructing " << ( void* )this << endl;
        bIsConstructed = false;
    };
    Int &operator++( )
    {
        x++;
        return *this;
    };
    int x;
private:
    bool bIsConstructed;
};

void function ( auto_ptr<Int> &pi )
{
    ++( *pi );
    auto_ptr<Int> pi2( pi );
    ++( *pi2 );
    pi = pi2;
}

int main( )
{
    auto_ptr<Int> pi ( new Int( 5 ) );
    cout << pi->x << endl;
    function( pi );
    cout << pi->x << endl;
}

```

```

Constructing 00311AF8
5
7
Destructing 00311AF8

```

auto_ptr::element_type

The type is a synonym for the template parameter `Type`.

```
typedef Type element _type;
```

auto_ptr::get

The member function returns the stored pointer `myptr`.

```
Type *get() const throw();
```

Return Value

The stored pointer `myptr`.

Example

```
// auto_ptr_get.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>
using namespace std;

class Int
{
public:
    Int(int i)
    {
        x = i;
        cout << "Constructing " << ( void* )this << " Value: " << x << endl;
    };
    ~Int( )
    {
        cout << "Destructing " << ( void* )this << " Value: " << x << endl;
    };

    int x;
};

int main( )
{
    auto_ptr<Int> pi ( new Int( 5 ) );
    pi.reset( new Int( 6 ) );
    Int* pi2 = pi.get ( );
    Int* pi3 = pi.release ( );
    if (pi2 == pi3)
        cout << "pi2 == pi3" << endl;
    delete pi3;
}
```

```
Constructing 00311AF8 Value: 5
Constructing 00311B88 Value: 6
Destructing 00311AF8 Value: 5
pi2 == pi3
Destructing 00311B88 Value: 6
```

auto_ptr::operator=

An assignment operator that transfers ownership from one `auto_ptr` object to another.

```
template <class Other>
auto_ptr<Type>& operator=(auto_ptr<Other>& right) throw();
auto_ptr<Type>& operator=(auto_ptr<Type>& right) throw();
auto_ptr<Type>& operator=(auto_ptr_ref<Type> right) throw();
```

Parameters

right

An object of type `auto_ptr`.

Return Value

A reference to an object of type `auto_ptr<Type>`.

Remarks

The assignment evaluates the expression `delete myptr`, but only if the stored pointer `myptr` changes as a result of the assignment. It then transfers ownership of the pointer stored in *right*, by storing *right.release* in `myptr`. The function returns ***this**.

Example

For an example of the use of the member operator, see [auto_ptr::auto_ptr](#).

auto_ptr::operator*

The dereferencing operator for objects of type `auto_ptr`.

```
Type& operator*() const throw();
```

Return Value

A reference to an object of type `Type` that the pointer owns.

Remarks

The indirection operator returns `*get`. Hence, the stored pointer must not be null.

Example

For an example of how to use the member function, see [auto_ptr::auto_ptr](#).

auto_ptr::operator->

The operator for allowing member access.

```
Type * operator->() const throw();
```

Return Value

A member of the object that `auto_ptr` owns.

Remarks

The selection operator returns `get ()`, so that the expression *ap*-> **member** behaves the same as (*ap*. **get**())-> **member**, where *ap* is an object of class `auto_ptr < Type>`. Hence, the stored pointer must not be null, and `Type` must be a class, struct, or union type with a `member` member.

Example

For an example of how to use the member function, see [auto_ptr::auto_ptr](#).

auto_ptr::operator auto_ptr<Other>

Casts from one kind of `auto_ptr` to another kind of `auto_ptr`.

```
template <class Other>
operator auto_ptr<Other>() throw();
```

Return Value

The type cast operator returns `auto_ptr < Other> (*this)`.

Example

```
// auto_ptr_op_auto_ptr.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;
int main()
{
    auto_ptr<int> pi ( new int( 5 ) );
    auto_ptr<const int> pc = ( auto_ptr<const int> )pi;
}
```

auto_ptr::operator auto_ptr_ref<Other>

Casts from an `auto_ptr` to an `auto_ptr_ref`.

```
template <class Other>
operator auto_ptr_ref<Other>() throw();
```

Return Value

The type cast operator returns `auto_ptr_ref< Other> (*this)`.

Example

```

// auto_ptr_op_auto_ptr_ref.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

class C {
public:
    C(int _i) : m_i(_i) {
    }
    ~C() {
        cout << "~C:  " << m_i << "\n";
    }
    C &operator =(const int &x) {
        m_i = x;
        return *this;
    }
    int m_i;
};

void f(auto_ptr<C> arg) {
};

int main()
{
    const auto_ptr<C> ciap(new C(1));
    auto_ptr<C> iap(new C(2));

    // Error: this implies transfer of ownership of iap's pointer
    // f(ciap);
    f(iap); // compiles, but gives up ownership of pointer

            // here, iap owns a destroyed pointer so the following is bad:
            // *iap = 5; // BOOM

    cout << "main exiting\n";
}

```

```

~C:  2
main exiting
~C:  1

```

auto_ptr::release

The member replaces the stored pointer `myptr` with a null pointer and returns the previously stored pointer.

```
Type *release() throw();
```

Return Value

The previously stored pointer.

Remarks

The member replaces the stored pointer `myptr` with a null pointer and returns the previously stored pointer.

Example

```

// auto_ptr_release.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>
using namespace std;

class Int
{
public:
    Int(int i)
    {
        x = i;
        cout << "Constructing " << (void*)this << " Value: " << x << endl;
    };
    ~Int() {
        cout << "Destructing " << (void*)this << " Value: " << x << endl;
    };

    int x;
};

int main()
{
    auto_ptr<Int> pi(new Int(5));
    pi.reset(new Int(6));
    Int* pi2 = pi.get();
    Int* pi3 = pi.release();
    if (pi2 == pi3)
        cout << "pi2 == pi3" << endl;
    delete pi3;
}

```

```

Constructing 00311AF8 Value: 5
Constructing 00311B88 Value: 6
Destructing 00311AF8 Value: 5
pi2 == pi3
Destructing 00311B88 Value: 6

```

auto_ptr::reset

The member function evaluates the expression `delete myptr`, but only if the stored pointer value `myptr` changes as a result of a function call. It then replaces the stored pointer with `ptr`.

```
void reset(Type* ptr = 0);
```

Parameters

ptr

The pointer specified to replace the stored pointer `myptr`.

Example

```

// auto_ptr_reset.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>
#include <vector>

using namespace std;

class Int
{
public:
    Int(int i)
    {
        x = i;
        cout << "Constructing " << (void*)this << " Value: " << x << endl;
    };
    ~Int()
    {
        cout << "Destructing " << (void*)this << " Value: " << x << endl;
    };

    int x;
};

int main()
{
    auto_ptr<Int> pi(new Int(5));
    pi.reset(new Int(6));
    Int* pi2 = pi.get();
    Int* pi3 = pi.release();
    if (pi2 == pi3)
        cout << "pi2 == pi3" << endl;
    delete pi3;
}

```

```

Constructing 00311AF8 Value: 5
Constructing 00311B88 Value: 6
Destructing 00311AF8 Value: 5
pi2 == pi3
Destructing 00311B88 Value: 6

```

[Thread Safety in the C++ Standard Library](#)

[unique_ptr Class](#)

bad_weak_ptr Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Reports bad weak_ptr exception.

Syntax

```
class bad_weak_ptr : public std::exception
{
public:
    bad_weak_ptr();
    const char *what() throw();
};
```

Remarks

The class describes an exception that can be thrown from the [shared_ptr Class](#) constructor that takes an argument of type [weak_ptr Class](#). The member function `what` returns `"bad_weak_ptr"`.

Example

```
// std__memory__bad_weak_ptr.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::weak_ptr<int> wp;

    {
        std::shared_ptr<int> sp(new int);
        wp = sp;
    }

    try
    {
        std::shared_ptr<int> sp1(wp); // weak_ptr has expired
    }
    catch (const std::bad_weak_ptr&)
    {
        std::cout << "bad weak pointer" << std::endl;
    }
    catch (...)
    {
        std::cout << "unknown exception" << std::endl;
    }

    return (0);
}
```

bad weak pointer

Requirements

Header: <memory>

Namespace: std

[weak_ptr](#) Class

enable_shared_from_this Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Helps generate a `shared_ptr`.

Syntax

```
class enable_shared_from_this {
public:
    shared_ptr<Ty>
        shared_from_this();
    shared_ptr<const Ty> shared_from_this() const;
protected:
    enable_shared_from_this();
    enable_shared_from_this(const enable_shared_from_this&);
    enable_shared_from_this& operator=(const enable_shared_from_this&);
    ~enable_shared_from_this();
};
```

Parameters

Ty

The type controlled by the shared pointer.

Remarks

Objects derived from `enable_shared_from_this` can use the `shared_from_this` methods in member functions to create `shared_ptr` owners of the instance that share ownership with existing `shared_ptr` owners. Otherwise, if you create a new `shared_ptr` by using **this**, it is distinct from existing `shared_ptr` owners, which can lead to invalid references or cause the object to be deleted more than once.

The constructors, destructor, and assignment operator are protected to help prevent accidental misuse. The template argument type *Ty* must be the type of the derived class.

For an example of usage, see [enable_shared_from_this::shared_from_this](#).

Requirements

Header: <memory>

Namespace: std

enable_shared_from_this::shared_from_this

Generates a `shared_ptr` that shares ownership of the instance with existing `shared_ptr` owners.

```
shared_ptr<T> shared_from_this();
shared_ptr<const T> shared_from_this() const;
```

Remarks

When you derive objects from the `enable_shared_from_this` base class, the `shared_from_this` template member functions return a `shared_ptr Class` object that shares ownership of this instance with existing `shared_ptr` owners.

Otherwise, if you create a new `shared_ptr` from **this**, it is distinct from existing `shared_ptr` owners, which can lead to invalid references or cause the object to be deleted more than once. The behavior is undefined if you call `shared_from_this` on an instance that is not already owned by a `shared_ptr` object.

Example

```
// std_memory_shared_from_this.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

using namespace std;

struct base : public std::enable_shared_from_this<base>
{
    int val;
    shared_ptr<base> share_more()
    {
        return shared_from_this();
    }
};

int main()
{
    auto sp1 = make_shared<base>();
    auto sp2 = sp1->share_more();

    sp1->val = 3;
    cout << "sp2->val == " << sp2->val << endl;
    return 0;
}
```

```
sp2->val == 3
```

[enable_shared_from_this::shared_from_this](#)

[shared_ptr Class](#)

pointer_traits Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

Supplies information that is needed by an object of template class `allocator_traits` to describe an allocator with pointer type `Ptr`.

Syntax

```
template <class Ptr>
struct pointer_traits;
```

Remarks

`Ptr` can be a raw pointer of type `Ty *` or a class with the following properties.

```
struct Ptr
{ // describes a pointer type usable by allocators
    typedef Ptr pointer;
    typedef T1 element_type; // optional
    typedef T2 difference_type; // optional
    template <class Other>
    using rebind = typename Ptr<Other, Rest...>; // optional
    static pointer pointer_to(element_type& obj);
    // optional
};
```

Typedefs

NAME	DESCRIPTION
<code>typedef T2 difference_type</code>	The type <code>T2</code> is <code>Ptr::difference_type</code> if that type exists, otherwise <code>ptrdiff_t</code> . If <code>Ptr</code> is a raw pointer, the type is <code>ptrdiff_t</code> .
<code>typedef T1 element_type</code>	The type <code>T1</code> is <code>Ptr::element_type</code> if that type exists, otherwise <code>Ty</code> . If <code>Ptr</code> is a raw pointer, the type is <code>Ty</code> .
<code>typedef Ptr pointer</code>	The type is <code>Ptr</code> .

Structs

NAME	DESCRIPTION
<code>pointer_traits::rebind</code>	Attempts to convert the underlying pointer type to a specified type.

Methods

NAME	DESCRIPTION
pointer_to	Converts an arbitrary reference to an object of class <code>Ptr</code> .

Requirements

Header: `<memory>`

Namespace: `std`

pointer_to

Static method that returns `Ptr::pointer_to(obj)`, if that function exists. Otherwise, it is not possible to convert an arbitrary reference to an object of class `Ptr`. If `Ptr` is a raw pointer, this method returns `addressof(obj)`.

```
static pointer pointer_to(element_type& obj);
```

See also

[<memory>](#)

[allocator_traits](#) Class

raw_storage_iterator Class

10/31/2018 • 6 minutes to read • [Edit Online](#)

An adaptor class that is provided to enable algorithms to store their results into uninitialized memory.

Syntax

```
template <class OutputIterator, class Type>
class raw_storage_iterator
```

Parameters

OutputIterator

Specifies the output iterator for the object being stored.

Type

The type of object for which storage is being allocated.

Remarks

The class describes an output iterator that constructs objects of type `Type` in the sequence it generates. An object of class `raw_storage_iterator` < **ForwardIterator**, **Type**> accesses storage through a forward iterator object, of class `ForwardIterator`, that you specify when you construct the object. For an object first of class `ForwardIterator`, the expression **&*first** must designate unconstructed storage for the next object (of type `Type`) in the generated sequence.

This adaptor class is used when it is necessary to separate memory allocation and object construction. The `raw_storage_iterator` can be used to copy objects into uninitialized storage, such as memory allocated using the `malloc` function.

Members

Constructors

CONSTRUCTOR	DESCRIPTION
<code>raw_storage_iterator</code>	Constructs a raw storage iterator with a specified underlying output iterator.

Typedefs

TYPE NAME	DESCRIPTION
<code>element_type</code>	Provides a type that describes an element to be stored a raw storage iterator.
<code>iter_type</code>	Provides a type that describes an iterator that underlies a raw storage iterator.

Operators

OPERATOR	DESCRIPTION
<code>operator*</code>	A dereferencing operator used to implement the output iterator expression <code>* ii = x</code> .
<code>operator=</code>	An assignment operator used to implement the raw storage iterator expression <code>* i = x</code> for storing in memory.
<code>operator++</code>	Preincrement and postincrement operators for raw storage iterators.

Requirements

Header: <memory>

Namespace: std

raw_storage_iterator::element_type

Provides a type that describes an element to be stored a raw storage iterator.

```
typedef Type element_type;
```

Remarks

The type is a synonym for the raw_storage_iterator class template parameter `Type`.

raw_storage_iterator::iter_type

Provides a type that describes an iterator that underlies a raw storage iterator.

```
typedef ForwardIterator iter_type;
```

Remarks

The type is a synonym for the template parameter `ForwardIterator`.

raw_storage_iterator::operator*

A dereferencing operator used to implement the raw storage iterator expression `* ii = x`.

```
raw_storage_iterator<ForwardIterator, Type>& operator*();
```

Return Value

A reference to the raw storage iterator

Remarks

The requirements for a `ForwardIterator` are that the raw storage iterator must satisfy require only the expression `* ii = t` be valid and that it says nothing about the **operator** or the `operator=` on their own. The member operators in this implementation returns ***this**, so that `operator=(constType&)` can perform the actual store in an expression, such as `* ptr = val`.

Example

```

// raw_storage_iterator_op_deref.cpp
// compile with: /EHsc
#include <iostream>
#include <iterator>
#include <memory>
#include <list>
using namespace std;

class Int
{
public:
    Int(int i)
    {
        cout << "Constructing " << i << endl;
        x = i;
        bIsConstructed = true;
    };

    Int &operator=(int i)
    {
        if (!bIsConstructed)
            cout << "Not constructed.\n";
        cout << "Copying " << i << endl;
        x = i;
        return *this;
    };

    int x;

private:
    bool bIsConstructed;
};

int main( void)
{
    Int *pInt = ( Int* ) malloc( sizeof( Int ) );
    memset( pInt, 0, sizeof( Int ) ); // Set bIsConstructed to false;
    *pInt = 5;
    raw_storage_iterator< Int*, Int > it( pInt );
    *it = 5;
}
/* Output:
Not constructed.
Copying 5
Constructing 5
*/

```

raw_storage_iterator::operator=

Assignment operator used to implement the raw storage iterator expression $*i = x$ for storing in memory.

```

raw_storage_iterator<ForwardIterator, Type>& operator=(
    const Type& val);

```

Parameters

val

The value of the object of type `Type` to be inserted into memory.

Return Value

The operator inserts `val` into memory, and then returns a reference to the raw storage iterator.

Remarks

The requirements for a `ForwardIterator` state that the raw storage iterator must satisfy require only the expression `*i = t` be valid, and that it says nothing about the **operator** or the `operator=` on their own. These member operators return ***this**.

The assignment operator constructs the next object in the output sequence using the stored iterator value first, by evaluating the placement new expression `new ((void *)&* first) Type(val)`.

Example

```
// raw_storage_iterator_op_assign.cpp
// compile with: /EHsc
#include <iostream>
#include <iterator>
#include <memory>
#include <list>
using namespace std;

class Int
{
public:
    Int( int i )
    {
        cout << "Constructing " << i << endl;
        x = i;
        bIsConstructed = true;
    };
    Int &operator=( int i )
    {
        if ( !bIsConstructed )
            cout << "Not constructed.\n";
        cout << "Copying " << i << endl; x = i;
        return *this;
    };
    int x;
private:
    bool bIsConstructed;
};

int main( void )
{
    Int *pInt = ( Int* )malloc( sizeof( Int ) );
    memset( pInt, 0, sizeof( Int ) ); // Set bIsConstructed to false;

    *pInt = 5;

    raw_storage_iterator<Int*, Int> it( pInt );
    *it = 5;
}
/* Output:
Not constructed.
Copying 5
Constructing 5
*/
```

raw_storage_iterator::operator++

Preincrement and postincrement operators for raw storage iterators.

```
raw_storage_iterator<ForwardIterator, Type>& operator++();

raw_storage_iterator<ForwardIterator, Type> operator++(int);
```

Return Value

An raw storage iterator or a reference to an raw storage iterator.

Remarks

The first operator eventually attempts to extract and store an object of type `CharType` from the associated input stream. The second operator makes a copy of the object, increments the object, and then returns the copy.

The first preincrement operator increments the stored output iterator object, and then returns ***this**.

The second postincrement operator makes a copy of ***this**, increments the stored output iterator object, and then returns the copy.

The constructor stores `first` as the output iterator object.

Example

```
// raw_storage_iterator_op_incr.cpp
// compile with: /EHsc
#include <iostream>
#include <iterator>
#include <memory>
#include <list>
using namespace std;

int main( void )
{
    int *pInt = new int[5];
    std::raw_storage_iterator<int*,int> it( pInt );
    for ( int i = 0; i < 5; i++, it++ ) {
        *it = 2 * i;
    };

    for ( int i = 0; i < 5; i++ ) cout << "array " << i << " = " << pInt[i] << endl;;

    delete[] pInt;
}
/* Output:
array 0 = 0
array 1 = 2
array 2 = 4
array 3 = 6
array 4 = 8
*/
```

raw_storage_iterator::raw_storage_iterator

Constructs a raw storage iterator with a specified underlying output iterator.

```
explicit raw_storage_iterator(ForwardIterator first);
```

Parameters

first

The forward iterator that is to underlie the `raw_storage_iterator` object being constructed.

Example

```
// raw_storage_iterator_ctor.cpp
// compile with: /EHsc /W3
#include <iostream>
#include <iterator>
#include <memory>
```

```

#include <memory>
#include <list>
using namespace std;

class Int
{
public:
    Int(int i)
    {
        cout << "Constructing " << i << endl;
        x = i;
        bIsConstructed = true;
    };
    Int &operator=( int i )
    {
        if (!bIsConstructed)
            cout << "Error! I'm not constructed!\n";
        cout << "Copying " << i << endl; x = i; return *this;
    };
    int x;
    bool bIsConstructed;
};

int main( void )
{
    std::list<int> l;
    l.push_back( 1 );
    l.push_back( 2 );
    l.push_back( 3 );
    l.push_back( 4 );

    Int *pInt = (Int*)malloc(sizeof(Int)*l.size( ));
    memset (pInt, 0, sizeof(Int)*l.size( ));
    // Hack: make sure bIsConstructed is false

    std::copy( l.begin( ), l.end( ), pInt ); // C4996
    for (unsigned int i = 0; i < l.size( ); i++)
        cout << "array " << i << " = " << pInt[i].x << endl;;

    memset (pInt, 0, sizeof(Int)*l.size( ));
    // hack: make sure bIsConstructed is false

    std::copy( l.begin( ), l.end( ),
        std::raw_storage_iterator<Int*,Int>(pInt)); // C4996
    for (unsigned int i = 0; i < l.size( ); i++ )
        cout << "array " << i << " = " << pInt[i].x << endl;

    free(pInt);
}
/* Output:
Error! I'm not constructed!
Copying 1
Error! I'm not constructed!
Copying 2
Error! I'm not constructed!
Copying 3
Error! I'm not constructed!
Copying 4
array 0 = 1
array 1 = 2
array 2 = 3
array 3 = 4
Constructing 1
Constructing 2
Constructing 3
Constructing 4
array 0 = 1
array 1 = 2
array 2 = 3

```

```
array 3 = 4  
*/
```

shared_ptr Class

11/9/2018 • 12 minutes to read • [Edit Online](#)

Wraps a reference-counted smart pointer around a dynamically allocated object.

Syntax

```
template <class T>
class shared_ptr;
```

Remarks

The `shared_ptr` class describes an object that uses reference counting to manage resources. A `shared_ptr` object effectively holds a pointer to the resource that it owns or holds a null pointer. A resource can be owned by more than one `shared_ptr` object; when the last `shared_ptr` object that owns a particular resource is destroyed, the resource is freed.

A `shared_ptr` stops owning a resource when it is reassigned or reset.

The template argument `T` might be an incomplete type except as noted for certain member functions.

When a `shared_ptr<T>` object is constructed from a resource pointer of type `G*` or from a `shared_ptr<G>`, the pointer type `G*` must be convertible to `T*`. If it is not, the code will not compile. For example:

```
#include <memory>
using namespace std;

class F {};
class G : public F {};

shared_ptr<G> sp0(new G); // okay, template parameter G and argument G*
shared_ptr<G> sp1(sp0);  // okay, template parameter G and argument shared_ptr<G>
shared_ptr<F> sp2(new G); // okay, G* convertible to F*
shared_ptr<F> sp3(sp0);  // okay, template parameter F and argument shared_ptr<G>
shared_ptr<F> sp4(sp2);  // okay, template parameter F and argument shared_ptr<F>
shared_ptr<int> sp5(new G); // error, G* not convertible to int*
shared_ptr<int> sp6(sp2);  // error, template parameter int and argument shared_ptr<F>
```

A `shared_ptr` object owns a resource:

- if it was constructed with a pointer to that resource,
- if it was constructed from a `shared_ptr` object that owns that resource,
- if it was constructed from a [weak_ptr Class](#) object that points to that resource, or
- if ownership of that resource was assigned to it, either with `shared_ptr::operator=` or by calling the member function `shared_ptr::reset`.

The `shared_ptr` objects that own a resource share a control block. The control block holds:

- the number of `shared_ptr` objects that own the resource,
- the number of `weak_ptr` objects that point to the resource,

- the deleter for that resource if it has one,
- the custom allocator for the control block if it has one.

A `shared_ptr` object that is initialized by using a null pointer has a control block and is not empty. After a `shared_ptr` object releases a resource, it no longer owns that resource. After a `weak_ptr` object releases a resource, it no longer points to that resource.

When the number of `shared_ptr` objects that own a resource becomes zero, the resource is freed, either by deleting it or by passing its address to a deleter, depending on how ownership of the resource was originally created. When the number of `shared_ptr` objects that own a resource is zero, and the number of `weak_ptr` objects that point to that resource is zero, the control block is freed, using the custom allocator for the control block if it has one.

An empty `shared_ptr` object does not own any resources and has no control block.

A deleter is a function object that has a member function `operator()`. Its type must be copy constructible, and its copy constructor and destructor must not throw exceptions. It accepts one parameter, the object to be deleted.

Some functions take an argument list that defines properties of the resulting `shared_ptr<T>` or `weak_ptr<T>` object. You can specify such an argument list in several ways:

no arguments -- the resulting object is an empty `shared_ptr` object or an empty `weak_ptr` object.

`ptr` -- a pointer of type `other*` to the resource to be managed. `T` must be a complete type. If the function fails (because the control block cannot be allocated) it evaluates the expression `delete ptr`.

`ptr, dtor` -- a pointer of type `other*` to the resource to be managed and a deleter for that resource. If the function fails (because the control block cannot be allocated), it calls `dtor(ptr)`, which must be well defined.

`ptr, dtor, alloc` -- a pointer of type `other*` to the resource to be managed, a deleter for that resource, and an allocator to manage any storage that must be allocated and freed. If the function fails (because the control block can't be allocated) it calls `dtor(ptr)`, which must be well defined.

`sp` -- a `shared_ptr<Other>` object that owns the resource to be managed.

`wp` -- a `weak_ptr<Other>` object that points to the resource to be managed.

`ap` -- an `auto_ptr<Other>` object that holds a pointer to the resource to be managed. If the function succeeds it calls `ap.release()`; otherwise it leaves `ap` unchanged.

In all cases, the pointer type `other*` must be convertible to `T*`.

Thread Safety

Multiple threads can read and write different `shared_ptr` objects at the same time, even when the objects are copies that share ownership.

Members

Constructors

CONSTRUCTOR	DESCRIPTION
<code>shared_ptr</code>	Constructs a <code>shared_ptr</code> .
<code>shared_ptr::~~shared_ptr</code>	Destroys a <code>shared_ptr</code> .

Types

TYPE NAME	DESCRIPTION
<code>element_type</code>	The type of an element.

Functions

FUNCTION	DESCRIPTION
<code>get</code>	Gets address of owned resource.
<code>owner_before</code>	Returns true if this <code>shared_ptr</code> is ordered before (or less than) the provided pointer.
<code>reset</code>	Replace owned resource.
<code>swap</code>	Swaps two <code>shared_ptr</code> objects.
<code>unique</code>	Tests if owned resource is unique.
<code>use_count</code>	Counts numbers of resource owners.

Operators

OPERATOR	DESCRIPTION
<code>shared_ptr::operator bool</code>	Tests if an owned resource exists.
<code>shared_ptr::operator*</code>	Gets the designated value.
<code>shared_ptr::operator=</code>	Replaces the owned resource.
<code>shared_ptr::operator-></code>	Gets a pointer to the designated value.

Requirements

Header: <memory>

Namespace: std

`shared_ptr::element_type`

The type of an element.

```
typedef T element_type;
```

Remarks

The type is a synonym for the template parameter `T`.

Example

```
// std__memory__shared_ptr_element_type.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0(new int(5));
    std::shared_ptr<int>::element_type val = *sp0;

    std::cout << "*sp0 == " << val << std::endl;

    return (0);
}
```

```
*sp0 == 5
```

shared_ptr::get

Gets address of owned resource.

```
T *get() const;
```

Remarks

The member function returns the address of the owned resource. If the object does not own a resource it returns 0.

Example

```
// std__memory__shared_ptr_get.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0;
    std::shared_ptr<int> sp1(new int(5));

    std::cout << "sp0.get() == 0 == " << std::boolalpha
              << (sp0.get() == 0) << std::endl;
    std::cout << "*sp1.get() == " << *sp1.get() << std::endl;

    return (0);
}
```

```
sp0.get() == 0 == true
*sp1.get() == 5
```

shared_ptr::operator bool

Tests if an owned resource exists.

```
explicit operator bool() const noexcept;
```

Remarks

The operator returns a value of **true** when `get() != nullptr`, otherwise **false**.

Example

```
// std__memory__shared_ptr_operator_bool.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0;
    std::shared_ptr<int> sp1(new int(5));

    std::cout << "(bool)sp0 == " << std::boolalpha
        << (bool)sp0 << std::endl;
    std::cout << "(bool)sp1 == " << std::boolalpha
        << (bool)sp1 << std::endl;

    return (0);
}
```

```
(bool)sp0 == false
(bool)sp1 == true
```

shared_ptr::operator*

Gets the designated value.

```
T& operator*() const;
```

Remarks

The indirection operator returns `*get()`. Hence, the stored pointer must not be null.

Example

```
// std__memory__shared_ptr_operator_st.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0(new int(5));

    std::cout << "*sp0 == " << *sp0 << std::endl;

    return (0);
}
```

```
*sp0 == 5
```

shared_ptr::operator=

Replaces the owned resource.

```

shared_ptr& operator=(const shared_ptr& sp);

template <class Other>
shared_ptr& operator=(const shared_ptr<Other>& sp);

template <class Other>
shared_ptr& operator=(auto_ptr<Other>& ap);

template <class Other>
shared_ptr& operator=(auto_ptr<Other>& ap);

template <class Other>
shared_ptr& operator=(auto_ptr<Other>&& ap);

template <class Other, class Deletor>
shared_ptr& operator=(unique_ptr<Other, Deletor>&& ap);

```

Parameters

sp

The shared pointer to copy.

ap

The auto pointer to copy.

Remarks

The operators all decrement the reference count for the resource currently owned by `*this` and assign ownership of the resource named by the operand sequence to `*this`. If the reference count falls to zero, the resource is released. If an operator fails it leaves `*this` unchanged.

Example

```

// std__memory__shared_ptr_operator_as.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0;
    std::shared_ptr<int> sp1(new int(5));
    std::auto_ptr<int> ap(new int(10));

    sp0 = sp1;
    std::cout << "sp0 == " << *sp0 << std::endl;

    sp0 = ap;
    std::cout << "sp0 == " << *sp0 << std::endl;

    return (0);
}

```

```

*sp0 == 5
*sp0 == 10

```

shared_ptr::operator->

Gets a pointer to the designated value.

```
T * operator->() const;
```

Remarks

The selection operator returns `get()`, so that the expression `sp->member` behaves the same as `(sp.get())->member` where `sp` is an object of class `shared_ptr<T>`. Hence, the stored pointer must not be null, and `T` must be a class, structure, or union type with a member `member`.

Example

```
// std__memory__shared_ptr_operator_ar.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

typedef std::pair<int, int> Mypair;
int main()
{
    std::shared_ptr<Mypair> sp0(new Mypair(1, 2));

    std::cout << "sp0->first == " << sp0->first << std::endl;
    std::cout << "sp0->second == " << sp0->second << std::endl;

    return (0);
}
```

```
sp0->first == 1
sp0->second == 2
```

shared_ptr::owner_before

Returns true if this `shared_ptr` is ordered before (or less than) the provided pointer.

```
template <class Other>
bool owner_before(const shared_ptr<Other>& ptr);

template <class Other>
bool owner_before(const weak_ptr<Other>& ptr);
```

Parameters

ptr

An `lvalue` reference to either a `shared_ptr` or a `weak_ptr`.

Remarks

The template member function returns true if `*this` is ordered before `ptr`.

shared_ptr::reset

Replace owned resource.

```
void reset();

template <class Other>
void reset(Other *ptr);

template <class Other, class D>
void reset(Other *ptr, D dtor);

template <class Other, class D, class A>
void reset(Other *ptr, D dtor, A alloc);
```

Parameters

Other

The type controlled by the argument pointer.

D

The type of the deleter.

ptr

The pointer to copy.

dtor

The deleter to copy.

A

The type of the allocator.

alloc

The allocator to copy.

Remarks

The operators all decrement the reference count for the resource currently owned by `*this` and assign ownership of the resource named by the operand sequence to `*this`. If the reference count falls to zero, the resource is released. If an operator fails it leaves `*this` unchanged.

Example

```

// std__memory__shared_ptr_reset.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct deleter
{
    void operator()(int *p)
    {
        delete p;
    }
};

int main()
{
    std::shared_ptr<int> sp(new int(5));

    std::cout << "*sp == " << std::boolalpha
        << *sp << std::endl;

    sp.reset();
    std::cout << "(bool)sp == " << std::boolalpha
        << (bool)sp << std::endl;

    sp.reset(new int(10));
    std::cout << "*sp == " << std::boolalpha
        << *sp << std::endl;

    sp.reset(new int(15), deleter());
    std::cout << "*sp == " << std::boolalpha
        << *sp << std::endl;

    return (0);
}

```

```

*sp == 5
(bool)sp == false
*sp == 10
*sp == 15

```

shared_ptr::shared_ptr

Constructs a `shared_ptr` .

```

shared_ptr();

shared_ptr(nullptr_t);

shared_ptr(const shared_ptr& sp);

shared_ptr(shared_ptr&& sp);

template <class Other>
explicit shared_ptr(Other* ptr);

template <class Other, class D>
shared_ptr(Other* ptr, D dtor);

template <class D>
shared_ptr(nullptr_t ptr, D dtor);

template <class Other, class D, class A>
shared_ptr(Other* ptr, D dtor, A alloc);

template <class D, class A>
shared_ptr(nullptr_t ptr, D dtor, A alloc);

template <class Other>
shared_ptr(const shared_ptr<Other>& sp);

template <class Other>
shared_ptr(const weak_ptr<Other>& wp);

template <class >
shared_ptr(std::auto_ptr<Other>& ap);

template <class >
shared_ptr(std::auto_ptr<Other>&& ap);

template <class Other, class D>
shared_ptr(unique_ptr<Other, D>&& up);

template <class Other>
shared_ptr(const shared_ptr<Other>& sp, T* ptr);

template <class Other, class D>
shared_ptr(const unique_ptr<Other, D>& up) = delete;

```

Parameters

Other

The type controlled by the argument pointer.

ptr

The pointer to copy.

D

The type of the deleter.

A

The type of the allocator.

dtor

The deleter.

ator

The allocator.

sp

The smart pointer to copy.

wp

The weak pointer.

ap

The auto pointer to copy.

Remarks

The constructors each construct an object that owns the resource named by the operand sequence. The constructor `shared_ptr(const weak_ptr<Other>& wp)` throws an exception object of type [bad_weak_ptr Class](#) if `wp.expired()` .

Example

```
// std__memory__shared_ptr_construct.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct deleter
{
    void operator()(int *p)
    {
        delete p;
    }
};

int main()
{
    std::shared_ptr<int> sp0;
    std::cout << "(bool)sp0 == " << std::boolalpha
        << (bool)sp0 << std::endl;

    std::shared_ptr<int> sp1(new int(5));
    std::cout << "*sp1 == " << *sp1 << std::endl;

    std::shared_ptr<int> sp2(new int(10), deleter());
    std::cout << "*sp2 == " << *sp2 << std::endl;

    std::shared_ptr<int> sp3(sp2);
    std::cout << "*sp3 == " << *sp3 << std::endl;

    std::weak_ptr<int> wp(sp3);
    std::shared_ptr<int> sp4(wp);
    std::cout << "*sp4 == " << *sp4 << std::endl;

    std::auto_ptr<int> ap(new int(15));
    std::shared_ptr<int> sp5(ap);
    std::cout << "*sp5 == " << *sp5 << std::endl;

    return (0);
}
```

```
(bool)sp0 == false
*sp1 == 5
*sp2 == 10
*sp3 == 10
*sp4 == 10
*sp5 == 15
```

shared_ptr::~~shared_ptr

Destroys a `shared_ptr`.

```
~shared_ptr();
```

Remarks

The destructor decrements the reference count for the resource currently owned by `*this`. If the reference count falls to zero, the resource is released.

Example

```
// std__memory__shared_ptr_destroy.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct deleter
{
    void operator()(int *p)
    {
        delete p;
    }
};

int main()
{
    std::shared_ptr<int> sp1(new int(5));
    std::cout << "*sp1 == " << *sp1 << std::endl;
    std::cout << "use count == " << sp1.use_count() << std::endl;

    {
        std::shared_ptr<int> sp2(sp1);
        std::cout << "*sp2 == " << *sp2 << std::endl;
        std::cout << "use count == " << sp1.use_count() << std::endl;
    }

    // check use count after sp2 is destroyed
    std::cout << "use count == " << sp1.use_count() << std::endl;

    return (0);
}
```

```
*sp1 == 5
use count == 1
*sp2 == 5
use count == 2
use count == 1
```

shared_ptr::swap

Swaps two `shared_ptr` objects.

```
void swap(shared_ptr& sp);
```

Parameters

sp

The shared pointer to swap with.

Remarks

The member function leaves the resource originally owned by `*this` subsequently owned by `sp`, and the resource originally owned by `sp` subsequently owned by `*this`. The function does not change the reference counts for the two resources and it does not throw any exceptions.

Example

```
// std__memory__shared_ptr_swap.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct deleter
{
    void operator()(int *p)
    {
        delete p;
    }
};

int main()
{
    std::shared_ptr<int> sp1(new int(5));
    std::shared_ptr<int> sp2(new int(10));
    std::cout << "*sp1 == " << *sp1 << std::endl;

    sp1.swap(sp2);
    std::cout << "*sp1 == " << *sp1 << std::endl;

    swap(sp1, sp2);
    std::cout << "*sp1 == " << *sp1 << std::endl;
    std::cout << std::endl;

    std::weak_ptr<int> wp1(sp1);
    std::weak_ptr<int> wp2(sp2);
    std::cout << "*wp1 == " << *wp1.lock() << std::endl;

    wp1.swap(wp2);
    std::cout << "*wp1 == " << *wp1.lock() << std::endl;

    swap(wp1, wp2);
    std::cout << "*wp1 == " << *wp1.lock() << std::endl;

    return (0);
}
```

```
*sp1 == 5
*sp1 == 10
*sp1 == 5

*wp1 == 5
*wp1 == 10
*wp1 == 5
```

shared_ptr::unique

Tests if owned resource is unique.

```
bool unique() const;
```

Remarks

The member function returns **true** if no other `shared_ptr` object owns the resource that is owned by `*this`, otherwise **false**.

Example

```
// std__memory__shared_ptr_unique.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct deleter
{
    void operator()(int *p)
    {
        delete p;
    }
};

int main()
{
    std::shared_ptr<int> sp1(new int(5));
    std::cout << "sp1.unique() == " << std::boolalpha
              << sp1.unique() << std::endl;

    std::shared_ptr<int> sp2(sp1);
    std::cout << "sp1.unique() == " << std::boolalpha
              << sp1.unique() << std::endl;

    return (0);
}
```

```
sp1.unique() == true
sp1.unique() == false
```

shared_ptr::use_count

Counts numbers of resource owners.

```
long use_count() const;
```

Remarks

The member function returns the number of `shared_ptr` objects that own the resource that is owned by `*this`.

Example

```
// std__memory__shared_ptr_use_count.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp1(new int(5));
    std::cout << "sp1.use_count() == "
              << sp1.use_count() << std::endl;

    std::shared_ptr<int> sp2(sp1);
    std::cout << "sp1.use_count() == "
              << sp1.use_count() << std::endl;

    return (0);
}
```

```
sp1.use_count() == 1
sp1.use_count() == 2
```

unique_ptr Class

11/9/2018 • 6 minutes to read • [Edit Online](#)

Stores a pointer to an owned object or array. The object/array is owned by no other `unique_ptr`. The object/array is destroyed when the `unique_ptr` is destroyed.

Syntax

```

class unique_ptr {
public:
    unique_ptr();
    unique_ptr(nullptr_t Nptr);
    explicit unique_ptr(pointer Ptr);
    unique_ptr(pointer Ptr,
        typename conditional<is_reference<Del>::value, Del,
        typename add_reference<const Del>::type>::type Deleter);
    unique_ptr(pointer Ptr,
        typename remove_reference<Del>::type&& Deleter);
    unique_ptr(unique_ptr&& Right);
    template <class T2, Class Del2>
    unique_ptr(unique_ptr<T2, Del2>&& Right);
    unique_ptr(const unique_ptr& Right) = delete;
    unique_ptr& operator=(const unique_ptr& Right) = delete;
};

//Specialization for arrays:
template <class T, class D>
class unique_ptr<T[], D> {
public:
    typedef pointer;
    typedef T element_type;
    typedef D deleter_type;
    constexpr unique_ptr() noexcept;
    template <class U>
    explicit unique_ptr(U p) noexcept;
    template <class U>
    unique_ptr(U p, see below d) noexcept;
    template <class U>
    unique_ptr(U p, see below d) noexcept;
    unique_ptr(unique_ptr&& u) noexcept;
    constexpr unique_ptr(nullptr_t) noexcept : unique_ptr() { }      template <class U, class E>
        unique_ptr(unique_ptr<U, E>&& u) noexcept;
    ~unique_ptr();
    unique_ptr& operator=(unique_ptr&& u) noexcept;
    template <class U, class E>
    unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
    unique_ptr& operator=(nullptr_t) noexcept;
    T& operator[](size_t i) const;

    pointer get() const noexcept;
    deleter_type& get_deleter() noexcept;
    const deleter_type& get_deleter() const noexcept;
    explicit operator bool() const noexcept;
    pointer release() noexcept;
    void reset(pointer p = pointer()) noexcept;
    void reset(nullptr_t = nullptr) noexcept;
    template <class U>
    void reset(U p) noexcept = delete;
    void swap(unique_ptr& u) noexcept; // disable copy from lvalue unique_ptr(const unique_ptr&) = delete;
    unique_ptr& operator=(const unique_ptr&) = delete;
};

```

Parameters

Right

A `unique_ptr` .

Nptr

An `rvalue` of type `std::nullptr_t` .

Ptr

A `pointer` .

Deleter

A `deleter` function that is bound to a `unique_ptr`.

Exceptions

No exceptions are generated by `unique_ptr`.

Remarks

The `unique_ptr` class supersedes `auto_ptr`, and can be used as an element of C++ Standard Library containers.

Use the [make_unique](#) helper function to efficiently create new instances of `unique_ptr`.

`unique_ptr` uniquely manages a resource. Each `unique_ptr` object stores a pointer to the object that it owns or stores a null pointer. A resource can be owned by no more than one `unique_ptr` object; when a `unique_ptr` object that owns a particular resource is destroyed, the resource is freed. A `unique_ptr` object may be moved, but not copied; for more information, see [Rvalue Reference Declarator: &&](#).

The resource is freed by calling a stored `deleter` object of type `De1` that knows how resources are allocated for a particular `unique_ptr`. The default `deleter` `default_delete<T>` assumes that the resource pointed to by `ptr` is allocated with `new`, and that it can be freed by calling `delete_ptr`. (A partial specialization `unique_ptr<T[]>` manages array objects allocated with `new[]`, and has the default `deleter` `default_delete<T[]>`, specialized to call `delete[] ptr`.)

The stored pointer to an owned resource, `stored_ptr` has type `pointer`. It is `De1::pointer` if defined, and `T *` if not. The stored `deleter` object `stored_deleter` occupies no space in the object if the `deleter` is stateless. Note that `De1` can be a reference type.

Members

Constructors

CONSTRUCTOR	DESCRIPTION
unique_ptr	There are seven constructors for <code>unique_ptr</code> .

Typedefs

TYPE NAME	DESCRIPTION
deleter_type	A synonym for the template parameter <code>De1</code> .
element_type	A synonym for the template parameter <code>T</code> .
pointer	A synonym for <code>De1::pointer</code> if defined, otherwise <code>T *</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
get	Returns <code>stored_ptr</code> .
get_deleter	Returns a reference to <code>stored_deleter</code> .

MEMBER FUNCTION	DESCRIPTION
<code>release</code>	stores <code>pointer()</code> in <code>stored_ptr</code> and returns its previous contents.
<code>reset</code>	Releases the currently owned resource and accepts a new resource.
<code>swap</code>	Exchanges resource and <code>deleter</code> with the provided <code>unique_ptr</code> .

Operators

OPERATOR	DESCRIPTION
<code>operator bool</code>	The operator returns a value of a type that is convertible to <code>bool</code> . The result of the conversion to <code>bool</code> is <code>true</code> when <code>get() != pointer()</code> , otherwise <code>false</code> .
<code>operator-></code>	The member function returns <code>stored_ptr</code> .
<code>operator*</code>	The member function returns <code>*stored_ptr</code> .
<code>unique_ptr operator=</code>	Assigns the value of a <code>unique_ptr</code> (or a <code>pointer-type</code>) to the current <code>unique_ptr</code> .

Requirements

Header: `<memory>`

Namespace: `std`

`deleter_type`

The type is a synonym for the template parameter `Del`.

```
typedef Del deleter_type;
```

Remarks

The type is a synonym for the template parameter `Del`.

`element_type`

The type is a synonym for the template parameter `Type`.

```
typedef Type element_type;
```

Remarks

The type is a synonym for the template parameter `Ty`.

`unique_ptr::get`

Returns `stored_ptr` .

```
pointer get() const;
```

Remarks

The member function returns `stored_ptr` .

unique_ptr::get_deleter

Returns a reference to `stored_deleter` .

```
Del& get_deleter();  
  
const Del& get_deleter() const;
```

Remarks

The member function returns a reference to `stored_deleter` .

unique_ptr operator=

Assigns the address of the provided `unique_ptr` to the current one.

```
unique_ptr& operator=(unique_ptr&& right);  
template <class U, Class Del2>  
unique_ptr& operator=(unique_ptr<Type, Del>&& right);  
unique_ptr& operator=(pointer-type);
```

Parameters

A `unique_ptr` reference used to assign the value of to the current `unique_ptr` .

Remarks

The member functions call `reset(right.release())` and move `right.stored_deleter` to `stored_deleter` , then return `*this` .

pointer

A synonym for `Del::pointer` if defined, otherwise `Type *` .

```
typedef T1 pointer;
```

Remarks

The type is a synonym for `Del::pointer` if defined, otherwise `Type *` .

unique_ptr::release

Releases ownership of the returned stored pointer to the caller and sets the stored pointer value to **nullptr**.

```
pointer release();
```

Remarks

Use `release` to take over ownership of the raw pointer stored by the `unique_ptr`. The caller is responsible for deletion of the returned pointer. The `unique_ptr` is set to the empty default-constructed state. You can assign another pointer of compatible type to the `unique_ptr` after the call to `release`.

Example

This example shows how the caller of `release` is responsible for the object returned:

```
// stl_release_unique.cpp
// Compile by using: cl /W4 /EHsc stl_release_unique.cpp
#include <iostream>
#include <memory>

struct Sample {
    int content_;
    Sample(int content) : content_(content) {
        std::cout << "Constructing Sample(" << content_ << ")" << std::endl;
    }
    ~Sample() {
        std::cout << "Deleting Sample(" << content_ << ")" << std::endl;
    }
};

void ReleaseUniquePointer() {
    // Use make_unique function when possible.
    auto up1 = std::make_unique<Sample>(3);
    auto up2 = std::make_unique<Sample>(42);

    // Take over ownership from the unique_ptr up2 by using release
    auto ptr = up2.release();
    if (up2) {
        // This statement does not execute, because up2 is empty.
        std::cout << "up2 is not empty." << std::endl;
    }
    // We are now responsible for deletion of ptr.
    delete ptr;
    // up1 deletes its stored pointer when it goes out of scope.
}

int main() {
    ReleaseUniquePointer();
}
```

Computer output:

```
Constructing Sample(3)
Constructing Sample(42)
Deleting Sample(42)
Deleting Sample(3)
```

unique_ptr::reset

Takes ownership of the pointer parameter, and then deletes the original stored pointer. If the new pointer is the same as the original stored pointer, `reset` deletes the pointer and sets the stored pointer to **nullptr**.

```
void reset(pointer ptr = pointer());
void reset(nullptr_t ptr);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the resource to take ownership of.

Remarks

Use `reset` to change the stored [pointer](#) owned by the `unique_ptr` to *ptr* and then delete the original stored pointer. If the `unique_ptr` was not empty, `reset` invokes the deleter function returned by [get_deleter](#) on the original stored pointer.

Because `reset` first stores the new pointer *ptr*, and then deletes the original stored pointer, it's possible for `reset` to immediately delete *ptr* if it is the same as the original stored pointer.

unique_ptr::swap

Exchanges pointers between two `unique_ptr` objects.

```
void swap(unique_ptr& right);
```

Parameters

right

A `unique_ptr` used to swap pointers.

Remarks

The member function swaps `stored_ptr` with `right.stored_ptr` and `stored_deleter` with `right.stored_deleter`.

unique_ptr::unique_ptr

There are seven constructors for `unique_ptr`.

```
unique_ptr();

unique_ptr(nullptr_t);
explicit unique_ptr(pointer ptr);

unique_ptr(
    Type* ptr,
    typename conditional<
        is_reference<Del>::value,
        Del,
        typename add_reference<const Del>::type::type _Deleter);

unique_ptr(pointer ptr, typename remove_reference<Del>::type&& _Deleter);
unique_ptr(unique_ptr&& right);
template <class Ty2, Class Del2>
unique_ptr(unique_ptr<Ty2, Del2>&& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>ptr</i>	A pointer to the resource to be assigned to a <code>unique_ptr</code> .
<i>_Deleter</i>	A <code>deleter</code> to be assigned to a <code>unique_ptr</code> .

PARAMETER	DESCRIPTION
<i>right</i>	An rvalue reference to a <code>unique_ptr</code> from which <code>unique_ptr</code> fields are move assigned to the newly constructed <code>unique_ptr</code> .

Remarks

The first two constructors construct an object that manages no resource. The third constructor stores *ptr* in `stored_ptr`. The fourth constructor stores *ptr* in `stored_ptr` and `deleter` in `stored_deleter`.

The fifth constructor stores *ptr* in `stored_ptr` and moves `deleter` into `stored_deleter`. The sixth and seventh constructors store `right.release()` in `stored_ptr` and moves `right.get_deleter()` into `stored_deleter`.

unique_ptr ~unique_ptr

The destructor for `unique_ptr`, destroys a `unique_ptr` object.

```
~unique_ptr();
```

Remarks

The destructor calls `get_deleter()(stored_ptr)`.

[<memory>](#)

weak_ptr Class

11/9/2018 • 7 minutes to read • [Edit Online](#)

Wraps a weakly linked pointer.

Syntax

```
template<class _Ty>
    class weak_ptr {
public:
    typedef Ty element_type;
    weak_ptr();
    weak_ptr(const weak_ptr&);
    template <class Other>
        weak_ptr(const weak_ptr<Other>&);
    template <class Other>
        weak_ptr(const shared_ptr<Other>&);
    weak_ptr& operator=(const weak_ptr&);
    template <class Other>
        weak_ptr& operator=(const weak_ptr<Other>&);
    template <class Other>
        weak_ptr& operator=(shared_ptr<Other>&);
    void swap(weak_ptr&);
    void reset();
    long use_count() const;
    bool expired() const;
    shared_ptr<Ty> lock() const;
};
```

Parameters

Ty

The type controlled by the weak pointer.

Remarks

The template class describes an object that points to a resource that is managed by one or more [shared_ptr Class](#) objects. The `weak_ptr` objects that point to a resource do not affect the resource's reference count. Thus, when the last `shared_ptr` object that manages that resource is destroyed the resource will be freed, even if there are `weak_ptr` objects pointing to that resource. This is essential for avoiding cycles in data structures.

A `weak_ptr` object points to a resource if it was constructed from a `shared_ptr` object that owns that resource, if it was constructed from a `weak_ptr` object that points to that resource, or if that resource was assigned to it with `operator=`. A `weak_ptr` object does not provide direct access to the resource that it points to. Code that needs to use the resource does so through a `shared_ptr` object that owns that resource, created by calling the member function `lock`. A `weak_ptr` object has expired when the resource that it points to has been freed because all of the `shared_ptr` objects that own the resource have been destroyed. Calling `lock` on a `weak_ptr` object that has expired creates an empty `shared_ptr` object.

An empty `weak_ptr` object does not point to any resources and has no control block. Its member function `lock` returns an empty `shared_ptr` object.

A cycle occurs when two or more resources controlled by `shared_ptr` objects hold mutually referencing `shared_ptr` objects. For example, a circular linked list with three elements has a head node `NO`; that node holds a

`shared_ptr` object that owns the next node, `N1`; that node holds a `shared_ptr` object that owns the next node, `N2`; that node, in turn, holds a `shared_ptr` object that owns the head node, `N0`, closing the cycle. In this situation, none of the reference counts will ever become zero, and the nodes in the cycle will not be freed. To eliminate the cycle, the last node `N2` should hold a `weak_ptr` object pointing to `N0` instead of a `shared_ptr` object. Since the `weak_ptr` object does not own `N0` it doesn't affect `N0`'s reference count, and when the program's last reference to the head node is destroyed the nodes in the list will also be destroyed.

Members

Constructors

CONSTRUCTOR	DESCRIPTION
<code>weak_ptr</code>	Constructs a <code>weak_ptr</code> .

Methods

<code>element_type</code>	The type of the element.
<code>expired</code>	Tests if ownership has expired.
<code>lock</code>	Obtains exclusive ownership of a resource.
<code>owner_before</code>	Returns true if this <code>weak_ptr</code> is ordered before (or less than) the provided pointer.
<code>reset</code>	Releases owned resource.
<code>swap</code>	Swaps two <code>weak_ptr</code> objects.
<code>use_count</code>	Counts number of designated <code>shared_ptr</code> objects.

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Replaces owned resource.

Requirements

Header: <memory>

Namespace: std

element_type

The type of the element.

```
typedef Ty element_type;
```

Remarks

The type is a synonym for the template parameter `Ty`.

Example

```
// std_memory_weak_ptr_element_type.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0(new int(5));
    std::weak_ptr<int> wp0(sp0);
    std::weak_ptr<int>::element_type val = *wp0.lock();

    std::cout << "*wp0.lock() == " << val << std::endl;

    return (0);
}
```

```
*wp0.lock() == 5
```

expired

Tests if ownership has expired.

```
bool expired() const;
```

Remarks

The member function returns **true** if `*this` has expired, otherwise **false**.

Example

```

// std_memory_weak_ptr_expired.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct deleter
{
    void operator()(int *p)
    {
        delete p;
    }
};

int main()
{
    std::weak_ptr<int> wp;

    {
        std::shared_ptr<int> sp(new int(10));
        wp = sp;
        std::cout << "wp.expired() == " << std::boolalpha
            << wp.expired() << std::endl;
        std::cout << "wp.lock() == " << *wp.lock() << std::endl;
    }

    // check expired after sp is destroyed
    std::cout << "wp.expired() == " << std::boolalpha
        << wp.expired() << std::endl;
    std::cout << "(bool)wp.lock() == " << std::boolalpha
        << (bool)wp.lock() << std::endl;

    return (0);
}

```

```

wp.expired() == false
*wp.lock() == 10
wp.expired() == true
(bool)wp.lock() == false

```

lock

Obtains exclusive ownership of a resource.

```
shared_ptr<Ty> lock() const;
```

Remarks

The member function returns an empty `shared_ptr` object if `*this` has expired; otherwise it returns a `shared_ptr` `Class<Ty>` object that owns the resource that `*this` points to.

Example

```

// std_memory_weak_ptr_lock.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct deleter
{
    void operator()(int *p)
    {
        delete p;
    }
};

int main()
{
    std::weak_ptr<int> wp;

    {
        std::shared_ptr<int> sp(new int(10));
        wp = sp;
        std::cout << "wp.expired() == " << std::boolalpha
            << wp.expired() << std::endl;
        std::cout << "*wp.lock() == " << *wp.lock() << std::endl;
    }

    // check expired after sp is destroyed
    std::cout << "wp.expired() == " << std::boolalpha
        << wp.expired() << std::endl;
    std::cout << "(bool)wp.lock() == " << std::boolalpha
        << (bool)wp.lock() << std::endl;

    return (0);
}

```

```

wp.expired() == false
*wp.lock() == 10
wp.expired() == true
(bool)wp.lock() == false

```

operator=

Replaces owned resource.

```

weak_ptr& operator=(const weak_ptr& wp);

template <class Other>
weak_ptr& operator=(const weak_ptr<Other>& wp);

template <class Other>
weak_ptr& operator=(const shared_ptr<Other>& sp);

```

Parameters

Other

The type controlled by the argument shared/weak pointer.

wp

The weak pointer to copy.

sp

The shared pointer to copy.

Remarks

The operators all release the resource currently pointed to by `*this` and assign ownership of the resource named by the operand sequence to `*this`. If an operator fails it leaves `*this` unchanged.

Example

```
// std_memory_weak_ptr_operator_as.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp0(new int(5));
    std::weak_ptr<int> wp0(sp0);
    std::cout << "*wp0.lock() == " << *wp0.lock() << std::endl;

    std::shared_ptr<int> sp1(new int(10));
    wp0 = sp1;
    std::cout << "*wp0.lock() == " << *wp0.lock() << std::endl;

    std::weak_ptr<int> wp1;
    wp1 = wp0;
    std::cout << "*wp1.lock() == " << *wp1.lock() << std::endl;

    return (0);
}
```

```
*wp0.lock() == 5
*wp0.lock() == 10
*wp1.lock() == 10
```

owner_before

Returns **true** if this `weak_ptr` is ordered before (or less than) the provided pointer.

```
template <class Other>
bool owner_before(const shared_ptr<Other>& ptr);

template <class Other>
bool owner_before(const weak_ptr<Other>& ptr);
```

Parameters

ptr

An `lvalue` reference to either a `shared_ptr` or a `weak_ptr`.

Remarks

The template member function returns **true** if `*this` is ordered before `ptr`.

reset

Releases owned resource.

```
void reset();
```

Remarks

The member function releases the resource pointed to by `*this` and converts `*this` to an empty `weak_ptr` object.

Example

```
// std_memory_weak_ptr_reset.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp(new int(5));
    std::weak_ptr<int> wp(sp);
    std::cout << "*wp.lock() == " << *wp.lock() << std::endl;
    std::cout << "wp.expired() == " << std::boolalpha
        << wp.expired() << std::endl;

    wp.reset();
    std::cout << "wp.expired() == " << std::boolalpha
        << wp.expired() << std::endl;

    return (0);
}
```

```
*wp.lock() == 5
wp.expired() == false
wp.expired() == true
```

swap

Swaps two `weak_ptr` objects.

```
void swap(weak_ptr& wp);
```

Parameters

wp

The weak pointer to swap with.

Remarks

The member function leaves the resource originally pointed to by `*this` subsequently pointed to by *wp*, and the resource originally pointed to by *wp* subsequently pointed to by `*this`. The function does not change the reference counts for the two resources and it does not throw any exceptions.

Example

```

// std_memory_weak_ptr_swap.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

struct deleter
{
    void operator()(int *p)
    {
        delete p;
    }
};

int main()
{
    std::shared_ptr<int> sp1(new int(5));
    std::shared_ptr<int> sp2(new int(10));
    std::cout << "*sp1 == " << *sp1 << std::endl;

    sp1.swap(sp2);
    std::cout << "*sp1 == " << *sp1 << std::endl;

    swap(sp1, sp2);
    std::cout << "*sp1 == " << *sp1 << std::endl;
    std::cout << std::endl;

    std::weak_ptr<int> wp1(sp1);
    std::weak_ptr<int> wp2(sp2);
    std::cout << "*wp1 == " << *wp1.lock() << std::endl;

    wp1.swap(wp2);
    std::cout << "*wp1 == " << *wp1.lock() << std::endl;

    swap(wp1, wp2);
    std::cout << "*wp1 == " << *wp1.lock() << std::endl;

    return (0);
}

```

```

*sp1 == 5
*sp1 == 10
*sp1 == 5

*wp1 == 5
*wp1 == 10
*wp1 == 5

```

use_count

Counts number of designated `shared_ptr` objects.

```
long use_count() const;
```

Remarks

The member function returns the number of `shared_ptr` objects that own the resource pointed to by `*this`.

Example

```
// std_memory__weak_ptr_use_count.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::shared_ptr<int> sp1(new int(5));
    std::weak_ptr<int> wp(sp1);
    std::cout << "wp.use_count() == "
        << wp.use_count() << std::endl;

    std::shared_ptr<int> sp2(sp1);
    std::cout << "wp.use_count() == "
        << wp.use_count() << std::endl;

    return (0);
}
```

```
wp.use_count() == 1
wp.use_count() == 2
```

weak_ptr

Constructs a `weak_ptr`.

```
weak_ptr();

weak_ptr(const weak_ptr& wp);

template <class Other>
weak_ptr(const weak_ptr<Other>& wp);

template <class Other>
weak_ptr(const shared_ptr<Other>& sp);
```

Parameters

Other

The type controlled by the argument shared/weak pointer.

wp

The weak pointer to copy.

sp

The shared pointer to copy.

Remarks

The constructors each construct an object that points to the resource named by the operand sequence.

Example

```

// std__memory__weak_ptr_construct.cpp
// compile with: /EHsc
#include <memory>
#include <iostream>

int main()
{
    std::weak_ptr<int> wp0;
    std::cout << "wp0.expired() == " << std::boolalpha
        << wp0.expired() << std::endl;

    std::shared_ptr<int> sp1(new int(5));
    std::weak_ptr<int> wp1(sp1);
    std::cout << "*wp1.lock() == "
        << *wp1.lock() << std::endl;

    std::weak_ptr<int> wp2(wp1);
    std::cout << "*wp2.lock() == "
        << *wp2.lock() << std::endl;

    return (0);
}

```

```

wp0.expired() == true
*wp1.lock() == 5
*wp2.lock() == 5

```

[shared_ptr Class](#)

<mutex>

10/31/2018 • 4 minutes to read • [Edit Online](#)

Include the standard header <mutex> to define the classes `mutex`, `recursive_mutex`, `timed_mutex`, and `recursive_timed_mutex`; the templates `lock_guard` and `unique_lock`; and supporting types and functions that define mutual-exclusion code regions.

WARNING

Beginning in Visual Studio 2015, the C++ Standard Library synchronization types are based on Windows synchronization primitives and no longer use ConCRT (except when the target platform is Windows XP). The types defined in <mutex> should not be used with any ConCRT types or functions.

Syntax

```
#include <mutex>
```

Remarks

NOTE

In code that is compiled by using `/clr`, this header is blocked.

The classes `mutex` and `recursive_mutex` are *mutex types*. A mutex type has a default constructor and a destructor that does not throw exceptions. These objects have methods that provide mutual exclusion when multiple threads try to lock the same object. Specifically, a mutex type contains the methods `lock`, `try_lock`, and `unlock`:

- The `lock` method blocks the calling thread until the thread obtains ownership of the mutex. Its return value is ignored.
- The `try_lock` method tries to obtain ownership of the mutex without blocking. Its return type is convertible to **bool** and is **true** if the method obtains ownership, but is otherwise **false**.
- The `unlock` method releases the ownership of the mutex from the calling thread.

You can use mutex types as type arguments to instantiate the templates `lock_guard` and `unique_lock`. You can use objects of these types as the `Lock` argument to the wait member functions in the template [condition_variable_any](#).

A *timed mutex type* satisfies the requirements for a mutex type. In addition, it has the `try_lock_for` and `try_lock_until` methods that must be callable by using one argument and must return a type that is convertible to **bool**. A timed mutex type can define these functions by using additional arguments, provided that those additional arguments all have default values.

- The `try_lock_for` method must be callable by using one argument, `Rel_time`, whose type is an instantiation of [chrono::duration](#). The method tries to obtain ownership of the mutex, but returns within the time that is designated by `Rel_time`, regardless of success. The return value converts to **true** if the method obtains ownership; otherwise, the return value converts to **false**.

- The `try_lock_until` method must be callable by using one argument, `Abs_time`, whose type is an instantiation of `chrono::time_point`. The method tries to obtain ownership of the mutex, but returns no later than the time that is designated by `Abs_time`, regardless of success. The return value converts to **true** if the method obtains ownership; otherwise, the return value converts to **false**.

A mutex type is also known as a *lockable type*. If it does not provide the member function `try_lock`, it is a *basic lockable type*. A timed mutex type is also known as a *timed lockable type*.

Classes

NAME	DESCRIPTION
lock_guard Class	Represents a template that can be instantiated to create an object whose destructor unlocks a <code>mutex</code> .
mutex Class (C++ Standard Library)	Represents a mutex type. Use objects of this type to enforce mutual exclusion within a program.
recursive_mutex Class	Represents a mutex type. In contrast to the <code>mutex</code> class, the behavior of calling locking methods for objects that are already locked is well-defined.
recursive_timed_mutex Class	Represents a timed mutex type. Use objects of this type to enforce mutual exclusion that has time-limited blocking within a program. Unlike objects of type <code>timed_mutex</code> , the effect of calling locking methods for <code>recursive_timed_mutex</code> objects is well-defined.
timed_mutex Class	Represents a timed mutex type. Use objects of this type to enforce mutual exclusion that has time-limited blocking within a program.
unique_lock Class	Represents a template that can be instantiated to create objects that manage the locking and unlocking of a <code>mutex</code> .

Functions

NAME	DESCRIPTION
call_once	Provides a mechanism for calling a specified callable object exactly once during execution.
lock	Attempts to lock all arguments without deadlock.

Structs

NAME	DESCRIPTION
adopt_lock_t Structure	Represents a type that is used to define an <code>adopt_lock</code> .
defer_lock_t Structure	Represents a type that defines a <code>defer_lock</code> object that is used to select one of the overloaded constructors of <code>unique_lock</code> .

NAME	DESCRIPTION
once_flag Structure	Represents a struct that is used with the template function <code>call_once</code> to ensure that initialization code is called only once, even in the presence of multiple threads of execution.
try_to_lock_t Structure	Represents a struct that defines a <code>try_to_lock</code> object and is used to select one of the overloaded constructors of <code>unique_lock</code> .

Variables

NAME	DESCRIPTION
adopt_lock	Represents an object that can be passed to constructors for <code>lock_guard</code> and <code>unique_lock</code> to indicate that the mutex object that is also being passed to the constructor is locked.
defer_lock	Represents an object that can be passed to the constructor for <code>unique_lock</code> , to indicate that the constructor should not lock the mutex object that is also being passed to it.
try_to_lock	Represents an object that can be passed to the constructor for <code>unique_lock</code> to indicate that the constructor should try to unlock the <code>mutex</code> that is also being passed to it without blocking.

[Header Files Reference](#)

<mutex> functions and variables

10/31/2018 • 2 minutes to read • [Edit Online](#)

adopt_lock	call_once	defer_lock
lock	try_to_lock	

adopt_lock Variable

Represents an object that can be passed to constructors for [lock_guard](#) and [unique_lock](#) to indicate that the mutex object that is also being passed to the constructor is locked.

```
const adopt_lock_t adopt_lock;
```

call_once

Provides a mechanism for calling a specified callable object exactly once during execution.

```
template <class Callable, class... Args>
void call_once(once_flag& Flag,
               Callable F&&, Args&&... A);
```

Parameters

Flag

A [once_flag](#) object that ensures that the callable object is only called once.

F

A callable object.

A

An argument list.

Remarks

If *Flag* is not valid, the function throws a [system_error](#) that has an error code of `invalid_argument`. Otherwise, the template function uses its *Flag* argument to ensure that it calls `F(A...)` successfully exactly once, regardless of how many times the template function is called. If `F(A...)` exits by throwing an exception, the call was not successful.

defer_lock Variable

Represents an object that can be passed to the constructor for [unique_lock](#). This indicates that the constructor should not lock the mutex object that's also being passed to it.

```
const defer_lock_t defer_lock;
```

lock

Attempts to lock all arguments without deadlock.

```
template <class L1, class L2, class... L3>
void lock(L1&, L2&, L3&...);
```

Remarks

The arguments to the template function must be *mutex types*, except that calls to `try_lock` might throw exceptions.

The function locks all of its arguments without deadlock by calls to `lock`, `try_lock`, and `unlock`. If a call to `lock` or `try_lock` throws an exception, the function calls `unlock` on any of the mutex objects that were successfully locked before rethrowing the exception.

try_to_lock Variable

Represents an object that can be passed to the constructor for [unique_lock](#) to indicate that the constructor should try to unlock the `mutex` that is also being passed to it without blocking.

```
const try_to_lock_t try_to_lock;
```

See also

<[mutex](#)>

adopt_lock_t Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a type that is used to define an [adopt_lock](#).

Syntax

```
struct adopt_lock_t;
```

Requirements

Header: <mutex>

Namespace: std

See also

[Header Files Reference](#)

[<mutex>](#)

defer_lock_t Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a type that defines a [defer_lock](#) object that is used to select one of the overloaded constructors of [unique_lock](#).

Syntax

```
struct defer_lock_t;
```

Requirements

Header: <mutex>

Namespace: std

See also

[Header Files Reference](#)

[<mutex>](#)

lock_guard Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a template that can be instantiated to create an object whose destructor unlocks a `mutex`.

Syntax

```
template <class Mutex>
class lock_guard;
```

Remarks

The template argument `Mutex` must name a *mutex type*.

Members

Public Typedefs

NAME	DESCRIPTION
<code>lock_guard::mutex_type</code>	Synonym for the template argument <code>Mutex</code> .

Public Constructors

NAME	DESCRIPTION
<code>lock_guard</code>	Constructs a <code>lock_guard</code> object.
<code>lock_guard::~lock_guard</code> Destructor	Unlocks the <code>mutex</code> that was passed to the constructor.

Requirements

Header: `<mutex>`

Namespace: `std`

lock_guard::lock_guard Constructor

Constructs a `lock_guard` object.

```
explicit lock_guard(mutex_type& Mtx);

lock_guard(mutex_type& Mtx, adopt_lock_t);
```

Parameters

Mtx

A *mutex type* object.

Remarks

The first constructor constructs an object of type `lock_guard` and locks *Mtx*. If *Mtx* is not a recursive mutex, it must be unlocked when this constructor is called.

The second constructor does not lock *Mtx*. *Mtx* must be locked when this constructor is called. The constructor throws no exceptions.

lock_guard::~lock_guard Destructor

Unlocks the `mutex` that was passed to the constructor.

```
~lock_guard() noexcept;
```

Remarks

If the `mutex` does not exist when the destructor runs, the behavior is undefined.

[Header Files Reference](#)

[<mutex>](#)

mutex Class (C++ Standard Library)

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a *mutex type*. Objects of this type can be used to enforce mutual exclusion within a program.

Syntax

```
class mutex;
```

Members

Public Constructors

NAME	DESCRIPTION
mutex	Constructs a <code>mutex</code> object.
mutex::~mutex Destructor	Releases any resources that were used by the <code>mutex</code> object.

Public Methods

NAME	DESCRIPTION
lock	Blocks the calling thread until the thread obtains ownership of the <code>mutex</code> .
native_handle	Returns the implementation-specific type that represents the mutex handle.
try_lock	Attempts to obtain ownership of the <code>mutex</code> without blocking.
unlock	Releases ownership of the <code>mutex</code> .

Requirements

Header: <mutex>

Namespace: std

mutex::lock

Blocks the calling thread until the thread obtains ownership of the `mutex`.

```
void lock();
```

Remarks

If the calling thread already owns the `mutex`, the behavior is undefined.

mutex::mutex Constructor

Constructs a `mutex` object that is not locked.

```
constexpr mutex() noexcept;
```

mutex::~mutex Destructor

Releases any resources that are used by the `mutex` object.

```
~mutex();
```

Remarks

If the object is locked when the destructor runs, the behavior is undefined.

mutex::native_handle

Returns the implementation-specific type that represents the mutex handle. The mutex handle can be used in implementation-specific ways.

```
native_handle_type native_handle();
```

Return Value

`native_handle_type` is defined as a `Concurrency::critical_section *` that's cast as `void *`.

mutex::try_lock

Attempts to obtain ownership of the `mutex` without blocking.

```
bool try_lock();
```

Return Value

true if the method successfully obtains ownership of the `mutex`; otherwise, **false**.

Remarks

If the calling thread already owns the `mutex`, the behavior is undefined.

mutex::unlock

Releases ownership of the `mutex`.

```
void unlock();
```

Remarks

If the calling thread does not own the `mutex`, the behavior is undefined.

See also

[Header Files Reference](#)

<mutex>

once_flag Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a **struct** that is used with the template function [call_once](#) to ensure that initialization code is called only once, even in the presence of multiple threads of execution.

Syntax

```
struct once_flag { constexpr once_flag() noexcept; };
```

Remarks

The `once_flag` **struct** has only a default constructor.

Objects of type `once_flag` can be created, but they cannot be copied.

Requirements

Header: <mutex>

Namespace: std

See also

[Header Files Reference](#)

[<mutex>](#)

recursive_mutex Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a *mutex type*. In contrast to [mutex](#), the behavior of calls to locking methods for objects that are already locked is well-defined.

Syntax

```
class recursive_mutex;
```

Members

Public Constructors

NAME	DESCRIPTION
recursive_mutex	Constructs a <code>recursive_mutex</code> object.
~recursive_mutex Destructor	Releases any resources that are used by the <code>recursive_mutex</code> object.

Public Methods

NAME	DESCRIPTION
lock	Blocks the calling thread until the thread obtains ownership of the mutex.
try_lock	Attempts to obtain ownership of the mutex without blocking.
unlock	Releases ownership of the mutex.

Requirements

Header: <mutex>

Namespace: std

lock

Blocks the calling thread until the thread obtains ownership of the `mutex`.

```
void lock();
```

Remarks

If the calling thread already owns the `mutex`, the method returns immediately, and the previous lock remains in effect.

recursive_mutex

Constructs a `recursive_mutex` object that is not locked.

```
recursive_mutex();
```

~recursive_mutex

Releases any resources that are used by the object.

```
~recursive_mutex();
```

Remarks

If the object is locked when the destructor runs, the behavior is undefined.

try_lock

Attempts to obtain ownership of the `mutex` without blocking.

```
bool try_lock() noexcept;
```

Return Value

true if the method successfully obtains ownership of the `mutex` or if the calling thread already owns the `mutex`; otherwise, **false**.

Remarks

If the calling thread already owns the `mutex`, the function immediately returns **true**, and the previous lock remains in effect.

unlock

Releases ownership of the mutex.

```
void unlock();
```

Remarks

This method releases ownership of the `mutex` only after it is called as many times as `lock` and `try_lock` have been called successfully on the `recursive_mutex` object.

If the calling thread does not own the `mutex`, the behavior is undefined.

[Header Files Reference](#)

[<mutex>](#)

recursive_timed_mutex Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a *timed mutex type*. Objects of this type are used to enforce mutual exclusion by using time-limited blocking within a program. Unlike objects of type [timed_mutex](#), the effect of calling locking methods for `recursive_timed_mutex` objects is well-defined.

Syntax

```
class recursive_timed_mutex;
```

Members

Public Constructors

NAME	DESCRIPTION
recursive_timed_mutex	Constructs a <code>recursive_timed_mutex</code> object that's not locked.
~recursive_timed_mutex Destructor	Releases any resources that are used by the <code>recursive_timed_mutex</code> object.

Public Methods

NAME	DESCRIPTION
lock	Blocks the calling thread until the thread obtains ownership of the <code>mutex</code> .
try_lock	Attempts to obtain ownership of the <code>mutex</code> without blocking.
try_lock_for	Attempts to obtain ownership of the <code>mutex</code> for a specified time interval.
try_lock_until	Attempts to obtain ownership of the <code>mutex</code> until a specified time.
unlock	Releases ownership of the <code>mutex</code> .

Requirements

Header: <mutex>

Namespace: std

lock

Blocks the calling thread until the thread obtains ownership of the `mutex` .

```
void lock();
```

Remarks

If the calling thread already owns the `mutex` , the method returns immediately, and the previous lock remains in effect.

recursive_timed_mutex Constructor

Constructs a `recursive_timed_mutex` object that is not locked.

```
recursive_timed_mutex();
```

~recursive_timed_mutex Destructor

Releases any resources that are used by the `recursive_timed_mutex` object.

```
~recursive_timed_mutex();
```

Remarks

If the object is locked when the destructor runs, the behavior is undefined.

try_lock

Attempts to obtain ownership of the `mutex` without blocking.

```
bool try_lock() noexcept;
```

Return Value

true if the method successfully obtained ownership of the `mutex` or if the calling thread already owns the `mutex` ; otherwise, **false**.

Remarks

If the calling thread already owns the `mutex` , the function immediately returns **true**, and the previous lock remains in effect.

try_lock_for

Attempts to obtain ownership of the `mutex` without blocking.

```
template <class Rep, class Period>  
bool try_lock_for(const chrono::duration<Rep, Period>& Rel_time);
```

Parameters

Rel_time

A `chrono::duration` object that specifies the maximum amount of time that the method attempts to obtain ownership of the `mutex` .

Return Value

true if the method successfully obtains ownership of the `mutex` or if the calling thread already owns the `mutex`; otherwise, **false**.

Remarks

If the calling thread already owns the `mutex`, the method immediately returns **true**, and the previous lock remains in effect.

try_lock_until

Attempts to obtain ownership of the `mutex` without blocking.

```
template <class Clock, class Duration>
bool try_lock_for(const chrono::time_point<Clock, Duration>& Abs_time);

bool try_lock_until(const xtime* Abs_time);
```

Parameters

Abs_time

A point in time that specifies the threshold after which the method no longer attempts to obtain ownership of the `mutex`.

Return Value

true if the method successfully obtains ownership of the `mutex` or if the calling thread already owns the `mutex`; otherwise, **false**.

Remarks

If the calling thread already owns the `mutex`, the method immediately returns **true**, and the previous lock remains in effect.

unlock

Releases ownership of the `mutex`.

```
void unlock();
```

Remarks

This method releases ownership of the `mutex` only after it is called as many times as [lock](#), [try_lock](#), [try_lock_for](#), and [try_lock_until](#) have been called successfully on the `recursive_timed_mutex` object.

If the calling thread does not own the `mutex`, the behavior is undefined.

timed_mutex Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a *timed mutex type*. Objects of this type are used to enforce mutual exclusion through time-limited blocking within a program.

Syntax

```
class timed_mutex;
```

Members

Public Constructors

NAME	DESCRIPTION
timed_mutex	Constructs a <code>timed_mutex</code> object that's not locked.
timed_mutex::~timed_mutex Destructor	Releases any resources that are used by the <code>timed_mutex</code> object.

Public Methods

NAME	DESCRIPTION
lock	Blocks the calling thread until the thread obtains ownership of the <code>mutex</code> .
try_lock	Attempts to obtain ownership of the <code>mutex</code> without blocking.
try_lock_for	Attempts to obtain ownership of the <code>mutex</code> for a specified time interval.
try_lock_until	Attempts to obtain ownership of the <code>mutex</code> until a specified time.
unlock	Releases ownership of the <code>mutex</code> .

Requirements

Header: <mutex>

Namespace: std

timed_mutex::lock

Blocks the calling thread until the thread obtains ownership of the `mutex`.

```
void lock();
```

Remarks

If the calling thread already owns the `mutex`, the behavior is undefined.

timed_mutex::timed_mutex Constructor

Constructs a `timed_mutex` object that is not locked.

```
timed_mutex();
```

timed_mutex::~~timed_mutex Destructor

Releases any resources that are used by the `mutex` object.

```
~timed_mutex();
```

Remarks

If the object is locked when the destructor runs, the behavior is undefined.

timed_mutex::try_lock

Attempts to obtain ownership of the `mutex` without blocking.

```
bool try_lock();
```

Return Value

true if the method successfully obtains ownership of the `mutex`; otherwise, **false**.

Remarks

If the calling thread already owns the `mutex`, the behavior is undefined.

timed_mutex::try_lock_for

Attempts to obtain ownership of the `mutex` without blocking.

```
template <class Rep, class Period>  
bool try_lock_for(const chrono::duration<Rep, Period>& Rel_time);
```

Parameters

Rel_time

A [chrono::duration](#) object that specifies the maximum amount of time that the method attempts to obtain ownership of the `mutex`.

Return Value

true if the method successfully obtains ownership of the `mutex`; otherwise, **false**.

Remarks

If the calling thread already owns the `mutex`, the behavior is undefined.

timed_mutex::try_lock_until

Attempts to obtain ownership of the `mutex` without blocking.

```
template <class Clock, class Duration>
bool try_lock_for(const chrono::time_point<Clock, Duration>& Abs_time);

bool try_lock_until(const xtime* Abs_time);
```

Parameters

Abs_time

A point in time that specifies the threshold after which the method no longer attempts to obtain ownership of the `mutex`.

Return Value

true if the method successfully obtains ownership of the `mutex`; otherwise, **false**.

Remarks

If the calling thread already owns the `mutex`, the behavior is undefined.

timed_mutex::unlock

Releases ownership of the `mutex`.

```
void unlock();
```

Remarks

If the calling thread does not own the `mutex`, the behavior is undefined.

[<mutex>](#)

unique_lock Class

10/31/2018 • 5 minutes to read • [Edit Online](#)

Represents a template that can be instantiated to create objects that manage the locking and unlocking of a `mutex`.

Syntax

```
template <class Mutex>
class unique_lock;
```

Remarks

The template argument `Mutex` must name a *mutex type*.

Internally, a `unique_lock` stores a pointer to an associated `mutex` object and a **bool** that indicates whether the current thread owns the `mutex`.

Members

Public Typedefs

NAME	DESCRIPTION
<code>mutex_type</code>	Synonym for the template argument <code>Mutex</code> .

Public Constructors

NAME	DESCRIPTION
<code>unique_lock</code>	Constructs a <code>unique_lock</code> object.
<code>~unique_lock</code> Destructor	Releases any resources that are associated with the <code>unique_lock</code> object.

Public Methods

NAME	DESCRIPTION
<code>lock</code>	Blocks the calling thread until the thread obtains ownership of the associated <code>mutex</code> .
<code>mutex</code>	Retrieves the stored pointer to the associated <code>mutex</code> .
<code>owns_lock</code>	Specifies whether the calling thread owns the associated <code>mutex</code> .
<code>release</code>	Disassociates the <code>unique_lock</code> object from the associated <code>mutex</code> object.

NAME	DESCRIPTION
swap	Swaps the associated <code>mutex</code> and ownership status with that of a specified object.
try_lock	Attempts to obtain ownership of the associated <code>mutex</code> without blocking.
try_lock_for	Attempts to obtain ownership of the associated <code>mutex</code> without blocking.
try_lock_until	Attempts to obtain ownership of the associated <code>mutex</code> without blocking.
unlock	Releases ownership of the associated <code>mutex</code> .

Public Operators

NAME	DESCRIPTION
operator bool	Specifies whether the calling thread has ownership of the associated <code>mutex</code> .
operator=	Copies the stored <code>mutex</code> pointer and associated ownership status from a specified object.

Inheritance Hierarchy

unique_lock

Requirements

Header: <mutex>

Namespace: std

lock

Blocks the calling thread until the thread obtains ownership of the associated `mutex` .

```
void lock();
```

Remarks

If the stored `mutex` pointer is NULL, this method throws a [system_error](#) that has an error code of `operation_not_permitted` .

If the calling thread already owns the associated `mutex` , this method throws a `system_error` that has an error code of `resource_deadlock_would_occur` .

Otherwise, this method calls `lock` on the associated `mutex` and sets the internal thread ownership flag to **true**.

mutex

Retrieves the stored pointer to the associated `mutex` .

```
mutex_type *mutex() const noexcept;
```

operator bool

Specifies whether the calling thread has ownership of the associated mutex.

```
explicit operator bool() noexcept
```

Return Value

true if the thread owns the mutex; otherwise **false**.

operator=

Copies the stored `mutex` pointer and associated ownership status from a specified object.

```
unique_lock& operator=(unique_lock&& Other) noexcept;
```

Parameters

Other

A `unique_lock` object.

Return Value

`*this`

Remarks

If the calling thread owns the previously associated `mutex` , before this method calls `unlock` on the `mutex` , it assigns the new values.

After the copy, this method sets *Other* to a default-constructed state.

owns_lock

Specifies whether the calling thread owns the associated `mutex` .

```
bool owns_lock() const noexcept;
```

Return Value

true if the thread owns the `mutex` ; otherwise, **false**.

release

Disassociates the `unique_lock` object from the associated `mutex` object.

```
mutex_type *release() noexcept;
```

Return Value

The previous value of the stored `mutex` pointer.

Remarks

This method sets the value of the stored `mutex` pointer to 0 and sets the internal `mutex` ownership flag to **false**.

swap

Swaps the associated `mutex` and ownership status with that of a specified object.

```
void swap(unique_lock& Other) noexcept;
```

Parameters

Other

A `unique_lock` object.

try_lock

Attempts to obtain ownership of the associated `mutex` without blocking.

```
bool try_lock() noexcept;
```

Return Value

true if the method successfully obtains ownership of the `mutex`; otherwise, **false**.

Remarks

If the stored `mutex` pointer is NULL, the method throws a [system_error](#) that has an error code of `operation_not_permitted`.

If the calling thread already owns the `mutex`, the method throws a `system_error` that has an error code of `resource_deadlock_would_occur`.

try_lock_for

Attempts to obtain ownership of the associated `mutex` without blocking.

```
template <class Rep, class Period>
bool try_lock_for(
    const chrono::duration<Rep, Period>& Rel_time);
```

Parameters

Rel_time

A [chrono::duration](#) object that specifies the maximum amount of time that the method attempts to obtain ownership of the `mutex`.

Return Value

true if the method successfully obtains ownership of the `mutex`; otherwise, **false**.

Remarks

If the stored `mutex` pointer is NULL, the method throws a [system_error](#) that has an error code of `operation_not_permitted`.

If the calling thread already owns the `mutex`, the method throws a `system_error` that has an error code of `resource_deadlock_would_occur`.

try_lock_until

Attempts to obtain ownership of the associated `mutex` without blocking.

```
template <class Clock, class Duration>
bool try_lock_until(const chrono::time_point<Clock, Duration>& Abs_time);

bool try_lock_until(const xtime* Abs_time);
```

Parameters

Abs_time

A point in time that specifies the threshold after which the method no longer attempts to obtain ownership of the `mutex`.

Return Value

true if the method successfully obtains ownership of the `mutex`; otherwise, **false**.

Remarks

If the stored `mutex` pointer is NULL, the method throws a [system_error](#) that has an error code of `operation_not_permitted`.

If the calling thread already owns the `mutex`, the method throws a `system_error` that has an error code of `resource_deadlock_would_occur`.

unique_lock Constructor

Constructs a `unique_lock` object.

```
unique_lock() noexcept;
unique_lock(unique_lock&& Other) noexcept;
explicit unique_lock(mutex_type& Mtx);

unique_lock(mutex_type& Mtx, adopt_lock_t Adopt);

unique_lock(mutex_type& Mtx, defer_lock_t Defer) noexcept;
unique_lock(mutex_type& Mtx, try_to_lock_t Try);

template <class Rep, class Period>
unique_lock(mutex_type& Mtx,
    const chrono::duration<Rep, Period>
    Rel_time);

template <class Clock, class Duration>
unique_lock(mutex_type& Mtx,
    const chrono::time_point<Clock, Duration>
    Abs_time);

unique_lock(mutex_type& Mtx,
    const xtime* Abs_time) noexcept;
```

Parameters

Mtx

A mutex type object.

Rel_time

A [chrono::duration](#) object that specifies the maximum amount of time that the method attempts to obtain ownership of the `mutex`.

Abs_time

A point in time that specifies the threshold after which the method no longer attempts to obtain ownership of the `mutex` .

Other

A `unique_lock` object.

Remarks

The first constructor constructs an object that has an associated mutex pointer value of 0.

The second constructor moves the associated mutex status from *Other*. After the move, *Other* is no longer associated with a mutex.

The remaining constructors store & *Mtx* as the stored `mutex` pointer. Ownership of the `mutex` is determined by the second argument, if it exists.

No argument	Ownership is obtained by calling the <code>lock</code> method on the associated <code>mutex</code> object.
Adopt	Ownership is assumed. <code>Mtx</code> must be locked when the constructor is called.
Defer	The calling thread is assumed not to own the <code>mutex</code> object. <code>Mtx</code> must not be locked when the constructor is called.
Try	Ownership is determined by calling <code>try_lock</code> on the associated <code>mutex</code> object. The constructor throws nothing.
Rel_time	Ownership is determined by calling <code>try_lock_for(Rel_time)</code> .
Abs_time	Ownership is determined by calling <code>try_lock_until(Abs_time)</code> .

~unique_lock Destructor

Releases any resources that are associated with the `unique_lock` object.

```
~unique_lock() noexcept;
```

Remarks

If the calling thread owns the associated `mutex` , the destructor releases ownership by calling `unlock` on the `mutex` object.

unlock

Releases ownership of the associated `mutex` .

```
void unlock();
```

Remarks

If the calling thread doesn't own the associated `mutex`, this method throws a [system_error](#) that has an error code of `operation_not_permitted`.

Otherwise, this method calls `unlock` on the associated `mutex` and sets the internal thread ownership flag to **false**.

[Header Files Reference](#)

[<mutex>](#)

<new>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines several types and functions that control the allocation and freeing of storage under program control. It also defines components for reporting on storage management errors.

Syntax

```
#include <new>
```

Remarks

Some of the functions declared in this header are replaceable. The implementation supplies a default version, whose behavior is described in this document. A program can, however, define a function with the same signature to replace the default version at link time. The replacement version must satisfy the requirements described in this document.

Objects

nothrow	Provides an object to be used as an argument for the nothrow versions of new and delete .

Typedefs

TYPE NAME	DESCRIPTION
new_handler	A type that points to a function suitable for use as a new handler.

Functions

FUNCTION	DESCRIPTION
set_new_handler	Installs a user function that is called when new fails in its attempt to allocate memory.

Operators

OPERATOR	DESCRIPTION
operator delete	The function called by a delete expression to deallocate storage for individual of objects.
operator delete[]	The function called by a delete expression to deallocate storage for an array of objects.
operator new	The function called by a new expression to allocate storage for individual objects.

OPERATOR	DESCRIPTION
operator new[]	The function called by a new expression to allocate storage for an array of objects.

Classes

CLASS	DESCRIPTION
bad_alloc Class	The class describes an exception thrown to indicate that an allocation request did not succeed.
nothrow_t Class	The class is used as a function parameter to operator new to indicate that the function should return a null pointer to report an allocation failure, rather than throw an exception.

<new> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

[nothrow](#)

[set_new_handler](#)

nothrow

Provides an object to be used as an argument for the **nothrow** versions of **new** and **delete**.

```
extern const std::nothrow_t nothrow;
```

Remarks

The object is used as a function argument to match the parameter type [std::nothrow_t](#).

Example

See [operator new](#) and [operator new\[\]](#) for examples of how `std::nothrow_t` is used as a function parameter.

set_new_handler

Installs a user function that is to be called when **operator new** fails in its attempt to allocate memory.

```
new_handler set_new_handler(new_handler Pnew) throw();
```

Parameters

Pnew

The `new_handler` to be installed.

Return Value

0 on the first call and the previous `new_handler` on subsequent calls.

Remarks

The function stores *Pnew* in a static [new handler](#) pointer that it maintains, then returns the value previously stored in the pointer. The new handler is used by [operator new](#)(**size_t**).

Example

```

// new_set_new_handler.cpp
// compile with: /EHsc
#include<new>
#include<iostream>

using namespace std;
void __cdecl newhandler( )
{
    cout << "The new_handler is called:" << endl;
    throw bad_alloc( );
    return;
}

int main( )
{
    set_new_handler (newhandler);
    try
    {
        while ( 1 )
        {
            new int[5000000];
            cout << "Allocating 5000000 ints." << endl;
        }
    }
    catch ( exception e )
    {
        cout << e.what( ) << endl;
    }
}

```

```

`new_handler`

`new_handler`

The type points to a function suitable for use as a new handler.

```
typedef void (*new_handler)();
```

Remarks

This type of handler function is called by **operator new** or `operator new[]` when they cannot satisfy a request for additional storage.

Example

See [set_new_handler](#) for an example using `new_handler` as a return value.

See also

[<new>](#)

<new> operators

10/31/2018 • 8 minutes to read • [Edit Online](#)

operator delete	operator delete[]	operator new
operator new[]		

operator delete

The function called by a delete expression to deallocate storage for individual of objects.

```
void operator delete(void* ptr) throw();

void operator delete(void *,
    void*) throw();

void operator delete(void* ptr,
    const std::nothrow_t&) throw();
```

Parameters

ptr

The pointer whose value is to be rendered invalid by the deletion.

Remarks

The first function is called by a delete expression to render the value of *ptr* invalid. The program can define a function with this function signature that replaces the default version defined by the C++ Standard Library. The required behavior is to accept a value of *ptr* that is null or that was returned by an earlier call to [operator new\(size_t\)](#).

The default behavior for a null value of *ptr* is to do nothing. Any other value of *ptr* must be a value returned earlier by a call as previously described. The default behavior for such a nonnull value of *ptr* is to reclaim storage allocated by the earlier call. It is unspecified under what conditions part or all of such reclaimed storage is allocated by a subsequent call to `operator new(size_t)`, or to any of `calloc(size_t)`, `malloc(size_t)`, or `realloc(void*, size_t)`.

The second function is called by a placement delete expression corresponding to a new expression of the form **new(std::size_t)**. It does nothing.

The third function is called by a placement delete expression corresponding to a new expression of the form **new(std::size_t, const std::nothrow_t&)**. The program can define a function with this function signature that replaces the default version defined by the C++ Standard Library. The required behavior is to accept a value of `ptr` that is null or that was returned by an earlier call to `operator new(size_t)`. The default behavior is to evaluate **delete(ptr)**.

Example

See [operator new](#) for an example that use **operator delete**.

operator delete[]

The function called by a delete expression to deallocate storage for an array of objects.

```

void operator delete[](void* ptr) throw();

void operator delete[](void *,
    void*) throw();

void operator delete[](void* ptr,
    const std::nothrow_t&) throw();

```

Parameters

ptr

The pointer whose value is to be rendered invalid by the deletion.

Remarks

The first function is called by an `delete[]` expression to render the value of *ptr* invalid. The function is replaceable because the program can define a function with this function signature that replaces the default version defined by the C++ Standard Library. The required behavior is to accept a value of *ptr* that is null or that was returned by an earlier call to [operator new\[\]\(**size_t**\)](#). The default behavior for a null value of *ptr* is to do nothing. Any other value of *ptr* must be a value returned earlier by a call as previously described. The default behavior for such a non-null value of *ptr* is to reclaim storage allocated by the earlier call. It is unspecified under what conditions part or all of such reclaimed storage is allocated by a subsequent call to [operator new\(**size_t**\)](#), or to any of `calloc(size_t)`, `malloc(size_t)`, or `realloc(void*, size_t)`.

The second function is called by a placement `delete[]` expression corresponding to a `new[]` expression of the form `new[](std::size_t)`. It does nothing.

The third function is called by a placement delete expression corresponding to a `new[]` expression of the form `new[](std::size_t, const std::nothrow_t&)`. The program can define a function with this function signature that replaces the default version defined by the C++ Standard Library. The required behavior is to accept a value of *ptr* that is null or that was returned by an earlier call to [operator new\[\]\(**size_t**\)](#). The default behavior is to evaluate `delete[](ptr)`.

Example

See [operator new\[\]](#) for examples of the use of `operator delete[]`.

operator new

The function called by a new-expression to allocate storage for individual objects.

```

void* operator new(std::size_t count) throw(bad_alloc);

void* operator new(std::size_t count,
    const std::nothrow_t&) throw();

void* operator new(std::size_t count,
    void* ptr) throw();

```

Parameters

count

The number of bytes of storage to be allocated.

ptr

The pointer to be returned.

Return Value

A pointer to the lowest byte address of the newly-allocated storage. Or *ptr*.

Remarks

The first function is called by a new expression to allocate `count` bytes of storage suitably aligned to represent any object of that size. The program can define an alternate function with this function signature that replaces the default version defined by the C++ Standard Library and so is replaceable.

The required behavior is to return a nonnull pointer only if storage can be allocated as requested. Each such allocation yields a pointer to storage disjoint from any other allocated storage. The order and contiguity of storage allocated by successive calls is unspecified. The initial stored value is unspecified. The returned pointer points to the start (lowest byte address) of the allocated storage. If `count` is zero, the value returned does not compare equal to any other value returned by the function.

The default behavior is to execute a loop. Within the loop, the function first attempts to allocate the requested storage. Whether the attempt involves a call to `malloc (size_t)` is unspecified. If the attempt is successful, the function returns a pointer to the allocated storage. Otherwise, the function calls the designated [new handler](#). If the called function returns, the loop repeats. The loop terminates when an attempt to allocate the requested storage is successful or when a called function does not return.

The required behavior of a new handler is to perform one of the following operations:

- Make more storage available for allocation and then return.
- Call either **abort** or **exit**(`int`).
- Throw an object of type **bad_alloc**.

The default behavior of a [new handler](#) is to throw an object of type `bad_alloc`. A null pointer designates the default new handler.

The order and contiguity of storage allocated by successive calls to `operator new (size_t)` is unspecified, as are the initial values stored there.

The second function is called by a placement new expression to allocate `count` bytes of storage suitably aligned to represent any object of that size. The program can define an alternate function with this function signature that replaces the default version defined by the C++ Standard Library and so is replaceable.

The default behavior is to return `operator new (count)` if that function succeeds. Otherwise, it returns a null pointer.

The third function is called by a placement **new** expression, of the form **new** (*args*) *T*. Here, *args* consists of a single object pointer. This can be useful for constructing an object at a known address. The function returns *ptr*.

To free storage allocated by **operator new**, call [operator delete](#).

For information on throwing or nonthrowing behavior of new, see [The new and delete Operators](#).

Example

```

// new_op_new.cpp
// compile with: /EHsc
#include<new>
#include<iostream>

using namespace std;

class MyClass
{
public:
    MyClass( )
    {
        cout << "Construction MyClass." << this << endl;
    };

    ~MyClass( )
    {
        imember = 0; cout << "Destructing MyClass." << this << endl;
    };
    int imember;
};

int main( )
{
    // The first form of new delete
    MyClass* fPtr = new MyClass;
    delete fPtr;

    // The second form of new delete
    MyClass* fPtr2 = new( nothrow ) MyClass;
    delete fPtr2;

    // The third form of new delete
    char x[sizeof( MyClass )];
    MyClass* fPtr3 = new( &x[0] ) MyClass;
    fPtr3 -> ~MyClass();
    cout << "The address of x[0] is : " << ( void* )&x[0] << endl;
}

```

operator new[]

The allocation function called by a new expression to allocate storage for an array of objects.

```

void* operator new[](std::size_t count) throw(std::bad_alloc);

void* operator new[](std::size_t count,
    const std::nothrow_t&) throw();

void* operator new[](std::size_t count,
    void* ptr) throw();

```

Parameters

count

The number of bytes of storage to be allocated for the array object.

ptr

The pointer to be returned.

Return Value

A pointer to the lowest byte address of the newly-allocated storage. Or *ptr*.

Remarks

The first function is called by a `new[]` expression to allocate `count` bytes of storage suitably aligned to represent any array object of that size or smaller. The program can define a function with this function signature that replaces the default version defined by the C++ Standard Library. The required behavior is the same as for [operator new\(size_t\)](#). The default behavior is to return `operator new (count)`.

The second function is called by a placement `new[]` expression to allocate `count` bytes of storage suitably aligned to represent any array object of that size. The program can define a function with this function signature that replaces the default version defined by the C++ Standard Library. The default behavior is to return **`operatornew(count)`** if that function succeeds. Otherwise, it returns a null pointer.

The third function is called by a placement `new[]` expression, of the form **`new (args) T[N]`**. Here, *args* consists of a single object pointer. The function returns `ptr`.

To free storage allocated by `operator new[]`, call [operator delete\[\]](#).

For information on throwing or nonthrowing behavior of new, see [The new and delete Operators](#).

Example

```
// new_op_alloc.cpp
// compile with: /EHsc
#include <new>
#include <iostream>

using namespace std;

class MyClass {
public:
    MyClass() {
        cout << "Construction MyClass." << this << endl;
    };

    ~MyClass() {
        imember = 0; cout << "Destructing MyClass." << this << endl;
    };
    int imember;
};

int main() {
    // The first form of new delete
    MyClass* fPtr = new MyClass[2];
    delete[ ] fPtr;

    // The second form of new delete
    char x[2 * sizeof( MyClass ) + sizeof(int)];

    MyClass* fPtr2 = new( &x[0] ) MyClass[2];
    fPtr2[1].~MyClass();
    fPtr2[0].~MyClass();
    cout << "The address of x[0] is : " << ( void* )&x[0] << endl;

    // The third form of new delete
    MyClass* fPtr3 = new( nothrow ) MyClass[2];
    delete[ ] fPtr3;
}
```

See also

[<new>](#)

bad_alloc Class

3/11/2019 • 2 minutes to read • [Edit Online](#)

The class describes an exception thrown to indicate that an allocation request did not succeed.

Syntax

```
class bad_alloc : public exception {  
    bad_alloc();  
    virtual ~bad_alloc();  
  
};
```

Remarks

The value returned by `what` is an implementation-defined C string. None of the member functions throw any exceptions.

Requirements

Header: <new>

Namespace: std

Example

```
// bad_alloc.cpp  
// compile with: /EHsc  
#include<new>  
#include<iostream>  
using namespace std;  
  
int main() {  
    char* ptr;  
    try {  
        ptr = new char[(~unsigned int((int)0)/2) - 1];  
        delete[] ptr;  
    }  
    catch( bad_alloc &ba) {  
        cout << ba.what( ) << endl;  
    }  
}
```

Sample Output

```
bad allocation
```

Requirements

Header: <new>

See also

[exception Class](#)

[Thread Safety in the C++ Standard Library](#)

nothrow_t Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

The struct is used as a function parameter to operator new to indicate that the function should return a null pointer to report an allocation failure, rather than throw an exception.

Syntax

```
struct std::nothrow_t {};
```

Remarks

The struct helps the compiler to select the correct version of the constructor. [nothrow](#) is a synonym for objects of type `std::nothrow_t`.

Example

See [operator new](#) and [operator new\[\]](#) for examples of how `std::nothrow_t` is used as a function parameter.

Requirements

Header: <new>

Namespace: std

See also

[Thread Safety in the C++ Standard Library](#)

<numeric>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines container template functions that perform algorithms for numerical processing.

Syntax

```
#include <numeric>
```

Remarks

The numeric algorithms resemble the C++ Standard Library algorithms in [<algorithm>](#), and can operate on a variety of data structures. These include standard library container classes—for example, [vector](#) and [list](#), and program-defined data structures and arrays of elements that satisfy the requirements of a particular algorithm. The algorithms achieve this level of generality by accessing and traversing the elements of a container indirectly through iterators. The algorithms process iterator ranges that are typically specified by their beginning or ending positions. The ranges referred to must be valid in the sense that all pointers in the ranges must be dereferenceable and within the sequences of each range, and the last position must be reachable from the first by means of incrementation.

The algorithms extend the actions that are supported by the operations and member functions of each of the C++ Standard Library containers and enable interaction with different types of container objects at the same time.

Functions

FUNCTION	DESCRIPTION
accumulate	Computes the sum of all elements in a specified range—including some initial value—by computing successive partial sums, or computes the result of successive partial results that are obtained by using a specified binary operation instead of the sum operation.
adjacent_difference	Computes the successive differences between each element and its predecessor in an input range and outputs the results to a destination range, or computes the result of a generalized procedure where the difference operation is replaced by another specified binary operation.
inner_product	Computes the sum of the element-wise product of two ranges and adds it to a specified initial value, or computes the result of a generalized procedure where the sum and product operations are replaced by other specified binary operations.
iota	Stores a starting value, beginning with the first element and filling with successive increments of the value (<code>value++</code>) in each of the elements in the interval <code>[first, last)</code> .

FUNCTION	DESCRIPTION
partial_sum	Computes a series of sums in an input range from the first element through the <i>i</i> th element and stores the result of each sum in the <i>i</i> th element of a destination range, or computes the result of a generalized procedure where the sum operation is replaced by another specified binary operation.

[C++ Standard Library Reference](#)

<numeric> functions

10/31/2018 • 14 minutes to read • [Edit Online](#)

accumulate	adjacent_difference	inner_product
iota	partial_sum	

accumulate

Computes the sum of all the elements in a specified range including some initial value by computing successive partial sums or computes the result of successive partial results similarly obtained from using a specified binary operation other than the sum.

```
template <class InputIterator, class Type>
Type accumulate(InputIterator first, InputIterator last, Type val);

template <class InputIterator, class Type, class BinaryOperation>
Type accumulate(
    InputIterator first,
    InputIterator last,
    Type val,
    BinaryOperation binary_op);
```

Parameters

first

An input iterator addressing the first element in the range to be summed or combined according to a specified binary operation.

last

An input iterator addressing the last element in the range to be summed or combined according to a specified binary operation that is one position beyond the final element actually included in the iterated accumulation.

val

An initial value to which each element is in turn added or combined with according to a specified binary operation.

binary_op

The binary operation that is to be applied to the each element in the specified range and the result of its previous applications.

Return Value

The sum of *val* and all the elements in the specified range for the first template function, or, for the second template function, the result of applying the binary operation specified, instead of the sum operation, to (*PartialResult*, **Iter*), where *PartialResult* is the result of previous applications of the operation and `Iter` is an iterator pointing to an element in the range.

Remarks

The initial value insures that there will be a well-defined result when the range is empty, in which case *val* is returned. The binary operation does not need to be associative or commutative. The result is initialized to the initial value *val* and then *result* = `binary_op (result, *Iter)` is calculated iteratively through the range, where `Iter` is an iterator pointing to successive element in the range. The range must be valid and the complexity is linear with the

size of the range. The return type of the binary operator must be convertible to **Type** to ensure closure during the iteration.

Example

```
// numeric_accum.cpp
// compile with: /EHsc
#include <vector>
#include <numeric>
#include <functional>
#include <iostream>

int main( )
{
    using namespace std;

    vector<int> v1, v2(20);
    vector<int>::iterator iter1, iter2;

    int i;
    for (i = 1; i < 21; i++)
    {
        v1.push_back(i);
    }

    cout << "The original vector v1 is:\n ( " ;
    for (iter1 = v1.begin(); iter1 != v1.end(); iter1++)
        cout << *iter1 << " ";
    cout << ")." << endl;

    // The first member function for the accumulated sum
    int total;
    total = accumulate(v1.begin(), v1.end(), 0);

    cout << "The sum of the integers from 1 to 20 is: "
        << total << "." << endl;

    // Constructing a vector of partial sums
    int j = 0, parttotal;
    for (iter1 = v1.begin(); iter1 != v1.end(); iter1++)
    {
        parttotal = accumulate(v1.begin(), iter1 + 1, 0);
        v2[j] = parttotal;
        j++;
    }

    cout << "The vector of partial sums is:\n ( " ;
    for (iter2 = v2.begin(); iter2 != v2.end(); iter2++)
        cout << *iter2 << " ";
    cout << ")." << endl << endl;

    // The second member function for the accumulated product
    vector<int> v3, v4(10);
    vector<int>::iterator iter3, iter4;

    int s;
    for (s = 1; s < 11; s++)
    {
        v3.push_back(s);
    }

    cout << "The original vector v3 is:\n ( " ;
    for (iter3 = v3.begin(); iter3 != v3.end(); iter3++)
        cout << *iter3 << " ";
    cout << ")." << endl;

    int ptotal;
    ptotal = accumulate(v3.begin(), v3.end(), 1, multiplies<int>());
```

```

    ptotal = accumulate(v3.begin(), v3.end(), 1, multiplies<int>());

    cout << "The product of the integers from 1 to 10 is: "
          << ptotal << "." << endl;

    // Constructing a vector of partial products
    int k = 0, ppartotal;
    for (iter3 = v3.begin(); iter3 != v3.end(); iter3++) {
        ppartotal = accumulate(v3.begin(), iter3 + 1, 1, multiplies<int>());
        v4[k] = ppartotal;
        k++;
    }

    cout << "The vector of partial products is:\n ( " ;
    for (iter4 = v4.begin(); iter4 != v4.end(); iter4++)
        cout << *iter4 << " ";
    cout << ")." << endl;
}

```

```

The original vector v1 is:
( 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 ).
The sum of the integers from 1 to 20 is: 210.
The vector of partial sums is:
( 1 3 6 10 15 21 28 36 45 55 66 78 91 105 120 136 153 171 190 210 ).

The original vector v3 is:
( 1 2 3 4 5 6 7 8 9 10 ).
The product of the integers from 1 to 10 is: 3628800.
The vector of partial products is:
( 1 2 6 24 120 720 5040 40320 362880 3628800 ).

```

adjacent_difference

Computes the successive differences between each element and its predecessor in an input range and outputs the results to a destination range or computes the result of a generalized procedure where the difference operation is replaced by another, specified binary operation.

```

template <class InputIterator, class OutIterator>
OutputIterator adjacent_difference(
    InputIterator first,
    InputIterator last,
    OutputIterator result);

template <class InputIterator, class OutIterator, class BinaryOperation>
OutputIterator adjacent_difference(
    InputIterator first,
    InputIterator last,
    OutputIterator result,
    BinaryOperation binary_op);

```

Parameters

first

An input iterator addressing the first element in the input range whose elements are to be differenced with their respective predecessors or where the pair of values is to be operated on by another specified binary operation.

last

An input iterator addressing the last element in the input range whose elements are to be differenced with their respective predecessors or where the pair of values is to be operated on by another specified binary operation.

result

An output iterator addressing the first element a destination range where the series of differences or the results of the specified operation is to be stored.

binary_op

The binary operation that is to be applied in the generalized operation replacing the operation of subtraction in the differencing procedure.

Return Value

An output iterator addressing the end of the destination range: `result` + (`last` - `first`).

Remarks

The output iterator `_result` is allowed to be the same iterator as the input iterator `* first`,* so that `adjacent_difference`s may be computed in place.

For a sequence of values a_1, a_2, a_3 , in an input range, the first template function stores successive `partial_difference`s $a_1, a_2 - a_1, a_3 - a_2$, in the destination range.

For a sequence of values a_1, a_2, a_3 , in an input range, the second template function stores successive `partial_difference`s $a_1, a_2 \text{ } binary_op \text{ } a_1, a_3 \text{ } binary_op \text{ } a_2$, in the destination range.

The binary operation `binary_op` is not required to be either associative or commutative, because the order of operations applies is completely specified.

Example

```

// numeric_adj_diff.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <numeric>
#include <functional>
#include <iostream>

int main( )
{
    using namespace std;

    vector<int> V1( 10 ), V2( 10 );
    vector<int>::iterator VIter1, VIter2, VIterend, VIterend2;

    list<int> L1;
    list<int>::iterator LIter1, LIterend, LIterend2;

    int t;
    for ( t = 1 ; t <= 10 ; t++ )
    {
        L1.push_back( t * t );
    }

    cout << "The input list L1 is:\n ( " ;
    for ( LIter1 = L1.begin( ) ; LIter1 != L1.end( ) ; LIter1++ )
        cout << *LIter1 << " ";
    cout << ")." << endl;

    // The first member function for the adjacent_differences of
    // elements in a list output to a vector
    VIterend = adjacent_difference ( L1.begin ( ) , L1.end ( ) ,
        V1.begin ( ) );

    cout << "Output vector containing adjacent_differences is:\n ( " ;
    for ( VIter1 = V1.begin( ) ; VIter1 != VIterend ; VIter1++ )
        cout << *VIter1 << " ";
    cout << ")." << endl;

    // The second member function used to compute
    // the adjacent products of the elements in a list
    VIterend2 = adjacent_difference ( L1.begin ( ) , L1.end ( ) , V2.begin ( ) ,
        multiplies<int>( ) );

    cout << "The output vector with the adjacent products is:\n ( " ;
    for ( VIter2 = V2.begin( ) ; VIter2 != VIterend2 ; VIter2++ )
        cout << *VIter2 << " ";
    cout << ")." << endl;

    // Computation of adjacent_differences in place
    LIterend2 = adjacent_difference ( L1.begin ( ) , L1.end ( ) , L1.begin ( ) );
    cout << "In place output adjacent_differences in list L1 is:\n ( " ;
    for ( LIter1 = L1.begin( ) ; LIter1 != LIterend2 ; LIter1++ )
        cout << *LIter1 << " ";
    cout << ")." << endl;
}

```

inner_product

Computes the sum of the element-wise product of two ranges and adds it to a specified initial value or computes the result of a generalized procedure where the sum and product binary operations are replaced by other specified binary operations.

```

template <class InputIterator1, class InputIterator2, class Type>
Type inner_product(
    InputIterator1    first1,
    InputIterator1    last1,
    InputIterator2    first2,
    Type              val);

template <class InputIterator1, class InputIterator2, class Type, class BinaryOperation1, class
BinaryOperation2>
Type inner_product(
    InputIterator1    first1,
    InputIterator1    last1,
    InputIterator2    first2,
    Type              val,
    BinaryOperation1  binary_op1,
    BinaryOperation2  binary_op2);

```

Parameters

first1

An input iterator addressing the first element in the first range whose inner product or generalized inner product with the second range is to be computed.

last1

An input iterator addressing the last element in the first range whose inner product or generalized inner product with the second range is to be computed.

first2

An input iterator addressing the first element in the second range whose inner product or generalized inner product with the first range is to be computed.

val

An initial value to which the inner product or generalized inner product between the ranges is to be added.

binary_op1

The binary operation that replaces the inner product operation of sum applied to the element-wise products in the generalization of the inner product.

binary_op2

The binary operation that replaces the inner product element-wise operation of multiply in the generalization of the inner product.

Return Value

The first member function returns the sum of the element-wise products and adds to it the specified initial value. So for ranges of values a_i and b_i , it returns:

$$val + (a_1 * b_1) + (a_2 * b_2) + \dots + (a_n * b_n)$$

by iteratively replacing *val* with $val + (a_i * b_i)$.

The second member function returns:

$$val \text{ binary_op1 } (a_1 \text{ binary_op2 } b_1) \text{ binary_op1 } (a_2 \text{ binary_op2 } b_2) \text{ binary_op1 } \dots \text{ binary_op1 } (a_n \text{ binary_op2 } b_n)$$

by iteratively replacing *val* with $val \text{ binary_op1 } (a_i \text{ binary_op2 } b_i)$.

Remarks

The initial value ensures that there will be a well-defined result when the range is empty, in which case *val* is returned. The binary operations do not need to be associative or commutative. The range must be valid and the

complexity is linear with the size of the range. The return type of the binary operator must be convertible to **Type** to ensure closure during the iteration.

Example

```
// numeric_inner_prod.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <numeric>
#include <functional>
#include <iostream>

int main()
{
    using namespace std;

    vector<int> v1, v2(7), v3(7);
    vector<int>::iterator iter1, iter2, iter3;

    int i;
    for (i = 1; i <= 7; i++)
    {
        v1.push_back(i);
    }

    cout << "The original vector v1 is:\n ( " ;
    for (iter1 = v1.begin(); iter1 != v1.end(); iter1++)
        cout << *iter1 << " ";
    cout << ")." << endl;

    list<int> l1, l2(7);
    list<int>::iterator lIter1, lIter2;

    int t;
    for (t = 1; t <= 7; t++)
    {
        l1.push_back(t);
    }

    cout << "The original list l1 is:\n ( " ;
    for (lIter1 = l1.begin(); lIter1 != l1.end(); lIter1++)
        cout << *lIter1 << " ";
    cout << ")." << endl;

    // The first member function for the inner product
    int inprod;
    inprod = inner_product(v1.begin(), v1.end(), l1.begin(), 0);

    cout << "The inner_product of the vector v1 and the list l1 is: "
        << inprod << "." << endl;

    // Constructing a vector of partial inner_products between v1 & l1
    int j = 0, parinprod;
    for (iter1 = v1.begin(); iter1 != v1.end(); iter1++) {
        parinprod = inner_product(v1.begin(), iter1 + 1, l1.begin(), 0);
        v2[j] = parinprod;
        j++;
    }

    cout << "Vector of partial inner_products between v1 & l1 is:\n ( " ;
    for (iter2 = v2.begin(); iter2 != v2.end(); iter2++)
        cout << *iter2 << " ";
    cout << ")." << endl << endl;

    // The second member function used to compute
    // the product of the element-wise sums
    int inprod2;
```

```

inprod2 = inner_product (v1.begin(), v1.end(),
    l1.begin(), 1, multiplies<int>(), plus<int>());

cout << "The sum of the element-wise products of v1 and l1 is: "
    << inprod2 << "." << endl;

// Constructing a vector of partial sums of element-wise products
int k = 0, parinprod2;
for (iter1 = v1.begin(); iter1 != v1.end(); iter1++)
{
    parinprod2 =
        inner_product(v1.begin(), iter1 + 1, l1.begin(), 1,
            multiplies<int>(), plus<int>());
    v3[k] = parinprod2;
    k++;
}

cout << "Vector of partial sums of element-wise products is:\n ( " ;
for (iter3 = v3.begin(); iter3 != v3.end(); iter3++)
    cout << *iter3 << " ";
cout << ")." << endl << endl;
}

```

iota

Stores a starting value, beginning with the first element and filling with successive increments of that value (`value++`) in each of the elements in the interval `[first, last)` .

```

template <class ForwardIterator, class Type>
void iota(ForwardIterator first, ForwardIterator last, Type value);

```

Parameters

first

An input iterator that addresses the first element in the range to be filled.

last

An input iterator that addresses the last element in the range to be filled.

value

The starting value to store in the first element and to successively increment for subsequent elements.

Remarks

Example

The following example demonstrates some uses for the `iota` function by filling a [list](#) of integers and then filling a [vector](#) with the `list` so that the [random_shuffle](#) function can be used.

```

// compile by using: cl /EHsc /nologo /W4 /MTd
#include <algorithm>
#include <numeric>
#include <list>
#include <vector>
#include <iostream>

using namespace std;

int main(void)
{
    list<int> intList(10);
    vector<list<int>::iterator> intVec(intList.size());

    // Fill the list
    iota(intList.begin(), intList.end(), 0);

    // Fill the vector with the list so we can shuffle it
    iota(intVec.begin(), intVec.end(), intList.begin());

    random_shuffle(intVec.begin(), intVec.end());

    // Output results
    cout << "Contents of the integer list: " << endl;
    for (auto i: intList) {
        cout << i << ' ';
    }
    cout << endl << endl;

    cout << "Contents of the integer list, shuffled by using a vector: " << endl;
    for (auto i: intVec) {
        cout << *i << ' ';
    }
    cout << endl;
}

```

partial_sum

Computes a series of sums in an input range from the first element through the *i*th element and stores the result of each such sum in the *i*th element of a destination range or computes the result of a generalized procedure where the sum operation is replaced by another specified binary operation.

```

template <class InputIterator, class OutIt>
OutputIterator partial_sum(
    InputIterator first,
    InputIterator last,
    OutputIterator result);

template <class InputIterator, class OutIt, class Fn2>
OutputIterator partial_sum(
    InputIterator first,
    InputIterator last,
    OutputIterator result,
    BinaryOperation binary_op);

```

Parameters

first

An input iterator addressing the first element in the range to be partially summed or combined according to a specified binary operation.

last

An input iterator addressing the last element in the range to be partially summed or combined according to a specified binary operation that is one position beyond the final element actually included in the iterated accumulation.

result

An output iterator addressing the first element a destination range where the series of partial sums or the results of the specified operation is to be stored.

binary_op

The binary operation that is to be applied in the generalized operation replacing the operation of sum in the partial sum procedure.

Return Value

An output iterator addressing the end of the destination range: `result + (last - first)`,

Remarks

The output iterator *result* is allowed to be the same iterator as the input iterator *first*, so that partial sums may be computed in place.

For a sequence of values a_1, a_2, a_3 , in an input range, the first template function stores successive partial sums in the destination range, where the i th element is given by $((a_1 + a_2) + a_3) a_i$.

For a sequence of values a_1, a_2, a_3 , in an input range, the second template function stores successive partial sums in the destination range, where the i th element is given by $((a_1 \text{ `binary_op` } a_2) \text{ `binary_op` } a_3) a_i$.

The binary operation *binary_op* is not required to be either associative or commutative, because the order of operations applies is completely specified.

Example

```

// numeric_partial_sum.cpp
// compile with: /EHsc
#include <vector>
#include <list>
#include <numeric>
#include <functional>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> V1( 10 ), V2( 10 );
    vector<int>::iterator VIter1, VIter2, VIterend, VIterend2;

    list<int> L1;
    list<int>::iterator LIter1, LIterend;

    int t;
    for ( t = 1 ; t <= 10 ; t++ )
    {
        L1.push_back( t );
    }

    cout << "The input list L1 is:\n ( " ;
    for ( LIter1 = L1.begin( ) ; LIter1 != L1.end( ) ; LIter1++ )
        cout << *LIter1 << " ";
    cout << ")." << endl;

    // The first member function for the partial sums of
    // elements in a list output to a vector
    VIterend = partial_sum ( L1.begin ( ) , L1.end ( ) ,
        V1.begin ( ) );

    cout << "The output vector containing the partial sums is:\n ( " ;
    for ( VIter1 = V1.begin( ) ; VIter1 != VIterend ; VIter1++ )
        cout << *VIter1 << " ";
    cout << ")." << endl;

    // The second member function used to compute
    // the partial product of the elements in a list
    VIterend2 = partial_sum ( L1.begin ( ) , L1.end ( ) , V2.begin ( ) ,
        multiplies<int>( ) );

    cout << "The output vector with the partial products is:\n ( " ;
    for ( VIter2 = V2.begin( ) ; VIter2 != VIterend2 ; VIter2++ )
        cout << *VIter2 << " ";
    cout << ")." << endl;

    // Computation of partial sums in place
    LIterend = partial_sum ( L1.begin ( ) , L1.end ( ) , L1.begin ( ) );
    cout << "The in place output partial_sum list L1 is:\n ( " ;
    for ( LIter1 = L1.begin( ) ; LIter1 != LIterend ; LIter1++ )
        cout << *LIter1 << " ";
    cout << ")." << endl;
}

```

[<numeric>](#)

<ostream>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines the template class `basic_ostream`, which mediates insertions for the iostreams. The header also defines several related manipulators. (This header is typically included for you by another of the iostreams headers. You rarely need to include it directly.)

Syntax

```
#include <ostream>
```

Typedefs

TYPE NAME	DESCRIPTION
<code>ostream</code>	Creates a type from <code>basic_ostream</code> that is specialized on char and <code>char_traits</code> specialized on char .
<code>wostream</code>	Creates a type from <code>basic_ostream</code> that is specialized on wchar_t and <code>char_traits</code> specialized on wchar_t .

Manipulators

<code>endl</code>	Terminates a line and flushes the buffer.
<code>ends</code>	Terminates a string.
<code>flush</code>	Flushes the buffer.
<code>swap</code>	Exchanges the values of the left <code>basic_ostream</code> object parameter for those of the right <code>basic_ostream</code> object parameter.

Operators

OPERATOR	DESCRIPTION
<code>operator<<</code>	Writes various types to the stream.

Classes

CLASS	DESCRIPTION
<code>basic_ostream</code>	The template class describes an object that controls insertion of elements and encoded objects into a stream buffer.

[iostreams Conventions](#)

basic_ostream Class

3/28/2019 • 7 minutes to read • [Edit Online](#)

This template class describes an object that controls insertion of elements and encoded objects into a stream buffer with elements of type `Elem`, also known as `char_type`, whose character traits are determined by the class `Tr`, also known as `traits_type`.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>>
class basic_ostream : virtual public basic_ios<Elem, Tr>
```

Parameters

Elem

A `char_type`.

Tr

The character `traits_type`.

Remarks

Most of the member functions that overload `operator<<` are formatted output functions. They follow the pattern:

```
iostate state = goodbit;
const sentry ok(*this);

if (ok)
{try
<convert and insert elements
accumulate flags in state> }
catch (...)}
{try
{setstate(badbit);

}
catch (...)}
{}
if ((exceptions() & badbit) != 0)
throw; }}
width(0);
// Except for operator<<(Elem)
setstate(state);

return (*this);
```

Two other member functions are unformatted output functions. They follow the pattern:

```

iostate state = goodbit;
const sentry ok(*this);

if (!ok)
    state |= badbit;
else
{try
{<obtain and insert elements
    accumulate flags in state> }
    catch (...)}
{try
{setstate(badbit);

}
    catch (...)}
{
    if ((exceptions() & badbit) != 0)
        throw; }}
setstate(state);

return (*this);

```

Both groups of functions call [setstate\(badbit\)](#) if they encounter a failure while inserting elements.

An object of class `basic_istream< Elem, Tr>` stores only a virtual public base object of class `basic_ios<Elem, Tr>`.

Example

See the example for [basic_ofstream Class](#) to learn more about output streams.

Constructors

CONSTRUCTOR	DESCRIPTION
basic_ostream	Constructs a <code>basic_ostream</code> object.

Member functions

MEMBER FUNCTION	DESCRIPTION
flush	Flushes the buffer.
put	Puts a character in a stream.
seekp	Resets position in output stream.
sentry	The nested class describes an object whose declaration structures the formatted output functions and the unformatted output functions.
swap	Exchanges the values of this <code>basic_ostream</code> object for those of the provided <code>basic_ostream</code> object.
tellp	Reports position in output stream.
write	Puts characters in a stream.

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Assigns the value of the provided <code>basic_ostream</code> object parameter to this object.
<code>operator<<</code>	Writes to the stream.

Requirements

Header: `<ostream>`

Namespace: `std`

`basic_ostream::basic_ostream`

Constructs a `basic_ostream` object.

```
explicit basic_ostream(  
    basic_streambuf<Elem, Tr>* strbuf,  
    bool _Isstd = false);  
  
basic_ostream(basic_ostream&& right);
```

Parameters

strbuf

An object of type `basic_streambuf`.

_Isstd

true if this is a standard stream; otherwise, **false**.

right

An rvalue reference to an object of type `basic_ostream`.

Remarks

The first constructor initializes the base class by calling `init(strbuf)`. The second constructor initializes the base class by calling `basic_ios::move(right)`.

Example

See the example for `basic_ofstream::basic_ofstream` to learn more about output streams.

`basic_ostream::flush`

Flushes the buffer.

```
basic_ostream<Elem, Tr>& flush();
```

Return Value

A reference to the `basic_ostream` object.

Remarks

If `rdbuf` is not a null pointer, the function calls `rdbuf->pubsync`. If that returns `-1`, the function calls `setstate(badbit)`. It returns ***this**.

Example

```
// basic_ostream_flush.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    cout << "test";
    cout.flush();
}
```

```
test
```

basic_ostream::operator<<

Writes to the stream.

```
basic_ostream<Elem, Tr>& operator<<(
    basic_ostream<Elem, Tr>& (* Pfn)(basic_ostream<Elem, Tr>&));

basic_ostream<Elem, Tr>& operator<<(
    ios_base& (* Pfn)(ios_base&));

basic_ostream<Elem, Tr>& operator<<(
    basic_ios<Elem, Tr>& (* Pfn)(basic_ios<Elem, Tr>&));

basic_ostream<Elem, Tr>& operator<<(basic_streambuf<Elem, Tr>* strbuf);
basic_ostream<Elem, Tr>& operator<<(bool val);
basic_ostream<Elem, Tr>& operator<<(short val);
basic_ostream<Elem, Tr>& operator<<(unsigned short val);
basic_ostream<Elem, Tr>& operator<<(int __w64 val);
basic_ostream<Elem, Tr>& operator<<(unsigned int __w64 val);
basic_ostream<Elem, Tr>& operator<<(long val);
basic_ostream<Elem, Tr>& operator<<(unsigned long __w64 val);
basic_ostream<Elem, Tr>& operator<<(long long val);
basic_ostream<Elem, Tr>& operator<<(unsigned long long val);
basic_ostream<Elem, Tr>& operator<<(float val);
basic_ostream<Elem, Tr>& operator<<(double val);
basic_ostream<Elem, Tr>& operator<<(long double val);
basic_ostream<Elem, Tr>& operator<<(const void* val);
```

Parameters

Pfn

A function pointer.

strbuf

A pointer to a `stream_buf` object.

val

An element to write to the stream.

Return Value

A reference to the `basic_ostream` object.

Remarks

The `<ostream>` header also defines several global insertion operators. For more information, see [operator<<](#).

The first member function ensures that an expression of the form `ostr << endl` calls `endl(ostr)`, and then returns `*this`. The second and third functions ensure that other manipulators, such as `hex`, behave similarly. The remaining functions are all formatted output functions.

The function

```
basic_ostream<Elem, Tr>& operator<<(basic_streambuf<Elem, Tr>* strbuf);
```

extracts elements from *strbuf*, if *strbuf* is not a null pointer, and inserts them. Extraction stops on end of file, or if an extraction throws an exception (which is rethrown). It also stops, without extracting the element in question, if an insertion fails. If the function inserts no elements, or if an extraction throws an exception, the function calls `setstate(failbit)`. In any case, the function returns `*this`.

The function

```
basic_ostream<Elem, Tr>& operator<<(bool val);
```

converts `_val` to a Boolean field and inserts it by calling `use_facet<num_put<Elem, OutIt>> (getloc)`. `put(OutIt(rdbuf), *this, getloc, val)`. Here, `OutIt` is defined as `ostreambuf_iterator<Elem, Tr>`. The function returns `*this`.

The functions

```
basic_ostream<Elem, Tr>& operator<<(short val);
basic_ostream<Elem, Tr>& operator<<(unsigned short val);
basic_ostream<Elem, Tr>& operator<<(int val);
basic_ostream<Elem, Tr>& operator<<(unsigned int __w64 val);
basic_ostream<Elem, Tr>& operator<<(long val);
basic_ostream<Elem, Tr>& operator<<(unsigned long val);
basic_ostream<Elem, Tr>& operator<<(long long val);
basic_ostream<Elem, Tr>& operator<<(unsigned long long val);
basic_ostream<Elem, Tr>& operator<<(const void* val);
```

each convert *val* to a numeric field and insert it by calling `use_facet<num_put<Elem, OutIt>> (getloc)`. `put(OutIt(rdbuf), *this, getloc, val)`. Here, `OutIt` is defined as `ostreambuf_iterator<Elem, Tr>`. The function returns `*this`.

The functions

```
basic_ostream<Elem, Tr>& operator<<(float val);
basic_ostream<Elem, Tr>& operator<<(double val);
basic_ostream<Elem, Tr>& operator<<(long double val);
```

each convert *val* to a numeric field and insert it by calling `use_facet<num_put<Elem, OutIt>> (getloc)`. `put(OutIt(rdbuf), *this, getloc, val)`. Here, `OutIt` is defined as `ostreambuf_iterator<Elem, Tr>`. The function returns `*this`.

Example

```

// basic_ostream_op_write.cpp
// compile with: /EHsc
#include <iostream>
#include <string.h>

using namespace std;

ios_base& hex2( ios_base& ib )
{
    ib.unsetf( ios_base::dec );
    ib.setf( ios_base::hex );
    return ib;
}

basic_ostream<char, char_traits<char> >& somefunc(basic_ostream<char, char_traits<char> > &i)
{
    if (i == cout)
    {
        i << "i is cout" << endl;
    }
    return i;
}

class CTxtStreambuf : public basic_streambuf< char, char_traits< char > >
{
public:
    CTxtStreambuf(char *_pszText)
    {
        pszText = _pszText;
        setg(pszText, pszText, pszText + strlen(pszText));
    };
    char *pszText;
};

int main()
{
    cout << somefunc;
    cout << 21 << endl;

    hex2(cout);
    cout << 21 << endl;

    CTxtStreambuf f("text in streambuf");
    cout << &f << endl;
}

```

basic_ostream::operator=

Assigns values for the provided `basic_ostream` object parameter to this object.

```
basic_ostream& operator=(basic_ostream&& right);
```

Parameters

right

An `rvalue` reference to a `basic_ostream` object.

Remarks

The member operator calls swap `(right)`.

basic_ostream::put

Puts a character in a stream.

```
basic_ostream<Elem, Tr>& put(char_type _Ch);
```

Parameters

_Ch

A character.

Return Value

A reference to the `basic_ostream` object.

Remarks

The unformatted output function inserts the element *_Ch*. It returns ***this**.

Example

```
// basic_ostream_put.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    cout.put( 'v' );
    cout << endl;
    wcout.put( L'l' );
}
```

```
v
l
```

basic_ostream::seekp

Reset position in output stream.

```
basic_ostream<Elem, Tr>& seekp(pos_type _Pos);

basic_ostream<Elem, Tr>& seekp(off_type _Off, ios_base::seekdir _Way);
```

Parameters

_Pos

The position in the stream.

_Off

The offset relative to *_Way*.

_Way

One of the `ios_base::seekdir` enumerations.

Return Value

A reference to the `basic_ostream` object.

Remarks

If `fail` is **false**, the first member function calls `newpos = rdbuf->pubseekpos(_Pos)`, for some `pos_type`

temporary object `newpos`. If `fail` is false, the second function calls **`newpos = rdbuf->pubseekoff(_Off, _Way)`**. In either case, if `(off_type)newpos == (off_type)(-1)` (the positioning operation fails), then the function calls **`istr.setstate(failbit)`**. Both functions return **`*this`**.

Example

```
// basic_ostream_seekp.cpp
// compile with: /EHsc
#include <fstream>
#include <iostream>

int main()
{
    using namespace std;
    ofstream x("basic_ostream_seekp.txt");
    streamoff i = x.tellp();
    cout << i << endl;
    x << "testing";
    i = x.tellp();
    cout << i << endl;
    x.seekp(2); // Put char in third char position in file
    x << " ";

    x.seekp(2, ios::end); // Put char two after end of file
    x << "z";
}
```

```
0
7
```

basic_ostream::sentry

The nested class describes an object whose declaration structures the formatted output functions and the unformatted output functions.

```
class sentry { public: explicit sentry(basic_ostream<Elem, Tr>& _Ostr); operator bool() const; ~sentry(); ;
```

Remarks

The nested class describes an object whose declaration structures the formatted output functions and the unformatted output functions. If **`ostr.good`** is **true** and **`ostr.tie`** is not a null pointer, the constructor calls **`ostr.tie->flush`**. The constructor then stores the value returned by `ostr.good` in `status`. A later call to `operator bool` delivers this stored value.

If `uncaught_exception` returns **false** and **`flags & unitbuf`** is nonzero, the destructor calls **`flush`**.

basic_ostream::swap

Exchanges the values of this `basic_ostream` object for the values of the provided `basic_ostream`.

```
void swap(basic_ostream& right);
```

Parameters

right

A reference to a `basic_ostream` object.

Remarks

The member function calls `basic_ios::swap` (right) to exchange the contents of this object for the contents of *right*.

basic_ostream::tellp

Report position in output stream.

```
pos_type tellp();
```

Return Value

Position in output stream.

Remarks

If `fail` is **false**, the member function returns `rdbuf->pubseekoff(0, cur, in)`. Otherwise, it returns `pos_type` (-1).

Example

See [seekp](#) for an example using `tellp`.

basic_ostream::write

Put characters in a stream.

```
basic_ostream<Elem, Tr>& write(const char_type* str, streamsize count);
```

Parameters

count

Count of characters to put into the stream.

str

Characters to put into the stream.

Return Value

A reference to the `basic_ostream` object.

Remarks

The [unformatted output function](#) inserts the sequence of *count* elements beginning at *str*.

Example

See [streamsize](#) for an example using `write`.

<ostream> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

These are the global template functions defined in <ostream>. For member functions, see the [basic_ostream Class](#) documentation.

endl	ends	flush
swap		

endl

Terminates a line and flushes the buffer.

```
template class<Elem, Tr>
basic_ostream<Elem, Tr>& endl(
    basic_ostream<Elem, Tr>& Ostr);
```

Parameters

Elem

The element type.

Ostr

An object of type **basic_ostream**.

Tr

Character traits.

Return Value

An object of type **basic_ostream**.

Remarks

The manipulator calls *Ostr.put(Ostr.widen('\n'))*, and then calls *Ostr.flush*. It returns *Ostr*.

Example

```
// ostream_endl.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    cout << "testing" << endl;
}
```

```
testing
```

ends

Terminates a string.

```
template class<Elem, Tr>
basic_ostream<Elem, Tr>& ends(
    basic_ostream<Elem, Tr>& Ostr);
```

Parameters

Elem

The element type.

Ostr

An object of type `basic_ostream`.

Tr

Character traits.

Return Value

An object of type `basic_ostream`.

Remarks

The manipulator calls `Ostr.put(Elem('\\0'))`. It returns *Ostr*.

Example

```
// ostream_ends.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    cout << "a";
    cout << "b" << ends;
    cout << "c" << endl;
}
```

```
ab c
```

flush

Flushes the buffer.

```
template class<Elem, Tr>
basic_ostream<Elem, Tr>& flush(
    basic_ostream<Elem, Tr>& Ostr);
```

Parameters

Elem

The element type.

Ostr

An object of type `basic_ostream`.

Tr

Character traits.

Return Value

An object of type `basic_ostream`.

Remarks

The manipulator calls `Ostr.flush`. It returns `Ostr`.

Example

```
// ostream_flush.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    cout << "testing" << flush;
}
```

```
testing
```

swap

Exchanges the values of two `basic_ostream` objects.

```
template <class Elem, class Tr>
void swap(
    basic_ostream<Elem, Tr>& left,
    basic_ostream<Elem, Tr>& right);
```

Parameters

Elem

The element type.

Tr

Character traits.

left

An lvalue reference to a `basic_ostream` object.

right

An lvalue reference to a `basic_ostream` object.

Remarks

The template function `swap` executes `left.swap(right)`.

[<ostream>](#)

<ostream> operators

10/31/2018 • 3 minutes to read • [Edit Online](#)

operator<<

operator<<

Writes various types to the stream.

```

template <class _Elem, class _Tr>
basic_ostream<_Elem, _Tr>& operator<<(
    basic_ostream<_Elem, _Tr>& _Ostr,
    const Elem* str);

template <class _Elem, class _Tr>
basic_ostream<_Elem, _Tr>& operator<<(
    basic_ostream<_Elem, _Tr>& _Ostr,
    Elem _Ch);

template <class _Elem, class _Tr>
basic_ostream<_Elem, _Tr>& operator<<(
    basic_ostream<_Elem, _Tr>& _Ostr,
    const char* str);

template <class _Elem, class _Tr>
basic_ostream<_Elem, _Tr>& operator<<(
    basic_ostream<_Elem, _Tr>& _Ostr,
    char _Ch);

template <class _Tr>
basic_ostream<char, _Tr>& operator<<(
    basic_ostream<char, _Tr>& _Ostr,
    const char* str);

template <class _Tr>
basic_ostream<char, _Tr>& operator<<(
    basic_ostream<char, _Tr>& _ostr,
    char _Ch);

template <class _Tr>
basic_ostream<char, _Tr>& operator<<(
    basic_ostream<char, _Tr>& _Ostr,
    const signed char* str);

template <class _Tr>
basic_ostream<char, _Tr>& operator<<(
    basic_ostream<char, _Tr>& _Ostr,
    signed char _Ch);

template <class _Tr>
basic_ostream<char, _Tr>& operator<<(
    basic_ostream<char, _Tr>& _Ostr,
    const unsigned char* str);

template <class _Tr>
basic_ostream<char, _Tr>& operator<<(
    basic_ostream<char, _Tr>& _Ostr,
    unsigned char _Ch);

template <class _Elem, class _Tr, class T>
basic_ostream<_Elem, _Tr>& operator<<(
    basic_ostream<_Elem, _Tr>&& _Ostr,
    Ty val);

```

Parameters

_Ch

A character.

_Elem

The element type.

_Ostr

A `basic_ostream` object.

str

A character string.

_Tr

Character traits.

val

The type

Return Value

The stream.

Remarks

The `basic_ostream` class also defines several insertion operators. For more information, see [basic_ostream::operator<<](#).

The template function

```
template <class _Elem, class _Tr>
basic_ostream<Elem, _Tr>& operator<<(
    basic_ostream<Elem, _Tr>& _ostr,
    const Elem *str);
```

determines the length $N = \text{traits_type::length}(\text{str})$ of the sequence beginning at *str*, and inserts the sequence. If $N < _ostr.\text{width}$, then the function also inserts a repetition of $_ostr.\text{width} - N$ fill characters. The repetition precedes the sequence if $(_ostr.\text{flags} \& \text{adjustfield} \neq \text{left})$. Otherwise, the repetition follows the sequence. The function returns *_Ostr*.

The template function

```
template <class _Elem, class _Tr>
basic_ostream<Elem, _Tr>& operator<<(
    basic_ostream<Elem, _Tr>& _Ostr,
    Elem _Ch);
```

inserts the element `_Ch`. If $1 < _Ostr.\text{width}$, then the function also inserts a repetition of $_Ostr.\text{width} - 1$ fill characters. The repetition precedes the sequence if $_Ostr.\text{flags} \& \text{adjustfield} \neq \text{left}$. Otherwise, the repetition follows the sequence. It returns *_Ostr*.

The template function

```
template <class _Elem, class _Tr>
basic_ostream<Elem, _Tr>& operator<<(
    basic_ostream<Elem, _Tr>& _Ostr,
    const char *str);
```

behaves the same as

```
template <class _Elem, class _Tr>
basic_ostream<Elem, _Tr>& operator<<(
    basic_ostream<Elem, _Tr>& _Ostr,
    const Elem *str);
```

except that each element *_Ch* of the sequence beginning at *str* is converted to an object of type `Elem` by calling `_Ostr.put(_Ostr.widen(_Ch))`.

The template function

```
template <class _Elem, class _Tr>
basic_ostream<Elem, _Tr>& operator<<(  
    basic_ostream<Elem, _Tr>& _Ostr,  
    char _Ch);
```

behaves the same as

```
template <class _Elem, class _Tr>
basic_ostream<Elem, _Tr>& operator<<(  
    basic_ostream<Elem, _Tr>& _Ostr,  
    Elem _Ch);
```

except that *_Ch* is converted to an object of type `Elem` by calling `_Ostr.put (_Ostr.widen (_Ch))`.

The template function

```
template <class _Tr>
basic_ostream<char, _Tr>& operator<<(  
    basic_ostream<char, _Tr>& _Ostr,  
    const char *str);
```

behaves the same as

```
template <class _Elem, class _Tr>
basic_ostream<Elem, _Tr>& operator<<(  
    basic_ostream<Elem, _Tr>& _Ostr,  
    const Elem *str);
```

(It does not have to widen the elements before inserting them.)

The template function

```
template <class _Tr>
basic_ostream<char, Tr>& operator<<(  
    basic_ostream<char, _Tr>& _Ostr,  
    char _Ch);
```

behaves the same as

```
template <class _Elem, class _Tr>
basic_ostream<Elem, _Tr>& operator<<(  
    basic_ostream<Elem, _Tr>& _Ostr,  
    Elem _Ch);
```

(It does not have to widen *_Ch* before inserting it.)

The template function

```
template <class _Tr>
basic_ostream<char, _Tr>& operator<<(  
    basic_ostream<char, _Tr>& _Ostr,  
    const signed char *str);
```

returns `_Ostr << (const char *) str`.

The template function

```
template <class _Tr>
basic_ostream<char, _Tr>& operator<<(
    basic_ostream<char, _Tr>& _Ostr,
    signed char _Ch);
```

returns `_Ostr << (char) _Ch`.

The template function:

```
template <class _Tr>
basic_ostream<char, _Tr>& operator<<(
    basic_ostream<char, _Tr>& _Ostr,
    const unsigned char *str);
```

returns `_Ostr << (const char *) str`.

The template function:

```
template <class _Tr>
basic_ostream<char, _Tr>& operator<<(
    basic_ostream<char, _Tr>& _Ostr,
    unsigned char _Ch);
```

returns `_Ostr << (char) _Ch`.

The template function:

```
template <class _Elem, class _Tr, class T>
basic_ostream<_Elem, _Tr>& operator<<(
    basic_ostream<char, _Tr>&& _Ostr,
    T val);
```

returns `_Ostr << val` (and converts a [RValue Reference](#) to `_Ostr` to an lvalue in the process).

Example

See [flush](#) for an example using `operator<<`.

See also

[<ostream>](#)

<ostream> typedefs

10/31/2018 • 2 minutes to read • [Edit Online](#)

ostream	wostream
---------	----------

ostream

Creates a type from `basic_ostream` that is specialized on **char** and `char_traits` specialized on **char**.

```
typedef basic_ostream<char, char_traits<char>> ostream;
```

Remarks

The type is a synonym for template class `basic_ostream`, specialized for elements of type **char** with default character traits.

wostream

Creates a type from `basic_ostream` that is specialized on **wchar_t** and `char_traits` specialized on **wchar_t**.

```
typedef basic_ostream<wchar_t, char_traits<wchar_t>> wostream;
```

Remarks

The type is a synonym for template class `basic_ostream`, specialized for elements of type **wchar_t** with default character traits.

See also

[<ostream>](#)

<queue>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines the template classes `priority_queue` and `queue` and several supporting templates.

Syntax

```
#include <queue>
```

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests if the queue object on the left side of the operator is not equal to the queue object on the right side.
<code>operator<</code>	Tests if the queue object on the left side of the operator is less than the queue object on the right side.
<code>operator<=</code>	Tests if the queue object on the left side of the operator is less than or equal to the queue object on the right side.
<code>operator==</code>	Tests if the queue object on the left side of the operator is equal to the queue object on the right side.
<code>operator></code>	Tests if the queue object on the left side of the operator is greater than the queue object on the right side.
<code>operator>=</code>	Tests if the queue object on the left side of the operator is greater than or equal to the queue object on the right side.

Classes

CLASS	DESCRIPTION
<code>queue Class</code>	A template container adaptor class that provides a restriction of functionality limiting access to the front and back elements of some underlying container type.
<code>priority_queue Class</code>	A template container adaptor class that provides a restriction of functionality limiting access to the top element of some underlying container type, which is always the largest.

[C++ Standard Library Reference](#)

<queue> operators

10/31/2018 • 7 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<=</code>	<code>operator==</code>

operator!=

Tests if the queue object on the left side of the operator is not equal to the queue object on the right side.

```
bool operator!=(const queue <Type, Container>& left, const queue <Type, Container>& right,);
```

Parameters

left

An object of type `queue`.

right

An object of type `queue`.

Return Value

true if the queues are not equal; **false** if queues are equal.

Remarks

The comparison between queue objects is based on a pairwise comparison of their elements. Two queues are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```

// queue_op_ne.cpp
// compile with: /EHsc
#include <queue>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares queues with list base containers
    queue <int, list<int> > q1, q2, q3;

    // The following line would have caused an error because vector
    // does not support pop_front( ) and so cannot be adapted
    // by queue as a base container
    // queue <int, vector<int> > q1, q2, q3;

    q1.push( 1 );
    q2.push( 1 );
    q2.push( 2 );
    q3.push( 1 );

    if ( q1 != q2 )
        cout << "The queues q1 and q2 are not equal." << endl;
    else
        cout << "The queues q1 and q2 are equal." << endl;

    if ( q1 != q3 )
        cout << "The queues q1 and q3 are not equal." << endl;
    else
        cout << "The queues q1 and q3 are equal." << endl;
}

```

The queues q1 and q2 are not equal.
The queues q1 and q3 are equal.

operator<

Tests if the queue object on the left side of the operator is less than the queue object on the right side.

```
bool operator<(const queue <Type, Container>& left, const queue <Type, Container>& right,);
```

Parameters

left

An object of type `queue`.

right

An object of type `queue`.

Return Value

true if the queue on the left side of the operator is less than and not equal to the queue on the right side of the operator; otherwise **false**.

Remarks

The comparison between queue objects is based on a pairwise comparison of their elements. The less-than relationship between two queue objects is based on a comparison of the first pair of unequal elements.

Example

```
// queue_op_lt.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares queues with default deque base container
    queue <int> q1, q2, q3;

    q1.push( 1 );
    q1.push( 2 );
    q2.push( 5 );
    q2.push( 10 );
    q3.push( 1 );
    q3.push( 2 );

    if ( q1 < q2 )
        cout << "The queue q1 is less than the queue q2." << endl;
    else
        cout << "The queue q1 is not less than the queue q2." << endl;

    if ( q1 < q3 )
        cout << "The queue q1 is less than the queue q3." << endl;
    else
        cout << "The queue q1 is not less than the queue q3." << endl;
}
```

The queue q1 is less than the queue q2.
The queue q1 is not less than the queue q3.

operator<=

Tests if the queue object on the left side of the operator is less than or equal to the queue object on the right side.

```
bool operator<=(const queue <Type, Container>& left, const queue <Type, Container>& right,);
```

Parameters

left

An object of type `queue`.

right

An object of type `queue`.

Return Value

true if the queue on the left side of the operator is strictly less than the queue on the right side of the operator; otherwise **false**.

Remarks

The comparison between queue objects is based on a pairwise comparison of their elements. The less than or equal to relationship between two queue objects is based on a comparison of the first pair of unequal elements.

Example

```

// queue_op_le.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    queue <int> q1, q2, q3;

    q1.push( 5 );
    q1.push( 10 );
    q2.push( 1 );
    q2.push( 2 );
    q3.push( 5 );
    q3.push( 10 );

    if ( q1 <= q2 )
        cout << "The queue q1 is less than or equal to "
              << "the queue q2." << endl;
    else
        cout << "The queue q1 is greater than "
              << "the queue q2." << endl;

    if ( q1 <= q3 )
        cout << "The queue q1 is less than or equal to "
              << "the queue q3." << endl;
    else
        cout << "The queue q1 is greater than "
              << "the queue q3." << endl;
}

```

The queue q1 is greater than the queue q2.
The queue q1 is less than or equal to the queue q3.

operator==

Tests if the queue object on the left side of the operator is equal to queue object on the right side.

```
bool operator==(const queue <Type, Container>& left, const queue <Type, Container>& right,);
```

Parameters

left

An object of type `queue`.

right

An object of type `queue`.

Return Value

true if the queues are not equal; **false** if queues are equal.

Remarks

The comparison between queue objects is based on a pairwise comparison of their elements. Two queues are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```

// queue_op_eq.cpp
// compile with: /EHsc
#include <queue>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares queues with list base containers
    queue <int, list<int> > q1, q2, q3;

    // The following line would have caused an error because vector
    // does not support pop_front( ) and so cannot be adapted
    // by queue as a base container
    // queue <int, vector<int> > q1, q2, q3;

    q1.push( 1 );
    q2.push( 2 );
    q3.push( 1 );

    if ( q1 != q2 )
        cout << "The queues q1 and q2 are not equal." << endl;
    else
        cout << "The queues q1 and q2 are equal." << endl;

    if ( q1 != q3 )
        cout << "The queues q1 and q3 are not equal." << endl;
    else
        cout << "The queues q1 and q3 are equal." << endl;
}

```

```

The queues q1 and q2 are not equal.
The queues q1 and q3 are equal.

```

operator>

Tests if the queue object on the left side of the operator is greater than the queue object on the right side.

```
bool operator>(const queue <Type, Container>& left, const queue <Type, Container>& right,);
```

Parameters

left

An object of type `queue`.

right

An object of type `queue`.

Return Value

true if the queue on the left side of the operator is strictly less than the queue on the right side of the operator; otherwise **false**.

Remarks

The comparison between queue objects is based on a pairwise comparison of their elements. The greater-than relationship between two queue objects is based on a comparison of the first pair of unequal elements.

Example

```
// queue_op_gt.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    queue <int> q1, q2, q3;

    q1.push( 1 );
    q1.push( 2 );
    q1.push( 3 );
    q2.push( 5 );
    q2.push( 10 );
    q3.push( 1 );
    q3.push( 2 );

    if ( q1 > q2 )
        cout << "The queue q1 is greater than "
              << "the queue q2." << endl;
    else
        cout << "The queue q1 is not greater than "
              << "the queue q2." << endl;

    if ( q1 > q3 )
        cout << "The queue q1 is greater than "
              << "the queue q3." << endl;
    else
        cout << "The queue q1 is not greater than "
              << "the queue q3." << endl;
}
```

The queue q1 is not greater than the queue q2.
The queue q1 is greater than the queue q3.

operator>=

Tests if the queue object on the left side of the operator is greater than or equal to the queue object on the right side.

```
bool operator>=(const queue <Type, Container>& left, const queue <Type, Container>& right,);
```

Parameters

left

An object of type `queue`.

right

An object of type `queue`.

Return Value

true if the queue on the left side of the operator is strictly less than the queue on the right side of the operator; otherwise **false**.

Remarks

The comparison between queue objects is based on a pairwise comparison of their elements. Two queues are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// queue_op_ge.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    queue <int> q1, q2, q3;

    q1.push( 1 );
    q1.push( 2 );
    q2.push( 5 );
    q2.push( 10 );
    q3.push( 1 );
    q3.push( 2 );

    if ( q1 >= q2 )
        cout << "The queue q1 is greater than or equal to "
              << "the queue q2." << endl;
    else
        cout << "The queue q1 is less than "
              << "the queue q2." << endl;

    if ( q1 >= q3 )
        cout << "The queue q1 is greater than or equal to "
              << "the queue q3." << endl;
    else
        cout << "The queue q1 is less than "
              << "the queue q3." << endl;
}
```

The queue q1 is less than the queue q2.
The queue q1 is greater than or equal to the queue q3.

[<queue>](#)

priority_queue Class

11/8/2018 • 11 minutes to read • [Edit Online](#)

A template container adaptor class that provides a restriction of functionality limiting access to the top element of some underlying container type, which is always the largest or of the highest priority. New elements can be added to the priority_queue and the top element of the priority_queue can be inspected or removed.

Syntax

```
template <class Type, class Container= vector <Type>, class Compare= less <typename Container ::value_type>>
class priority_queue
```

Parameters

Type

The element data type to be stored in the priority_queue.

Container

The type of the underlying container used to implement the priority_queue.

Compare

The type that provides a function object that can compare two element values as sort keys to determine their relative order in the priority_queue. This argument is optional and the binary predicate

`less<typename Container::value_type>` is the default value.

Remarks

The elements of class `Type` stipulated in the first template parameter of a queue object are synonymous with `value_type` and must match the type of element in the underlying container class `Container` stipulated by the second template parameter. The `Type` must be assignable, so that it is possible to copy objects of that type and to assign values to variables of that type.

The priority_queue orders the sequence it controls by calling a stored function object of class `Traits`. In general, the elements need be merely less than comparable to establish this order: so that, given any two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. On a more technical note, the comparison function is a binary predicate that induces a strict weak ordering in the standard mathematical sense.

Suitable underlying container classes for priority_queue include `deque Class` and the default `vector Class` or any other sequence container that supports the operations of `front`, `push_back`, and `pop_back` and a random-access iterator. The underlying container class is encapsulated within the container adaptor, which exposes only the limited set of the sequence container member functions as a public interface.

Adding elements to and removing elements from a `priority_queue` both have logarithmic complexity. Accessing elements in a `priority_queue` has constant complexity.

There are three types of container adaptors defined by the C++ Standard Library: `stack`, `queue`, and `priority_queue`. Each restricts the functionality of some underlying container class to provide a precisely controlled interface to a standard data structure.

- The `stack Class` supports a last-in, first-out (LIFO) data structure. A good analogue to keep in mind would be a stack of plates. Elements (plates) may be inserted, inspected, or removed only from the top of the

stack, which is the last element at the end of the base container. The restriction to accessing only the top element is the reason for using the stack class.

- The [queue Class](#) supports a first-in, first-out (FIFO) data structure. A good analogue to keep in mind would be people lining up for a bank teller. Elements (people) may be added to the back of the line and are removed from the front of the line. Both the front and the back of a line may be inspected. The restriction to accessing only the front and back elements in this way is the reason for using the queue class.
- The `priority_queue` class orders its elements so that the largest element is always at the top position. It supports insertion of an element and the inspection and removal of the top element. A good analogue to keep in mind would be people lining up where they are arranged by age, height, or some other criterion.

Constructors

CONSTRUCTOR	DESCRIPTION
priority_queue	Constructs a <code>priority_queue</code> that is empty or that is a copy of a range of a base container object or of other <code>priority_queue</code> .

Typedefs

TYPE NAME	DESCRIPTION
container_type	A type that provides the base container to be adapted by a <code>priority_queue</code> .
size_type	An unsigned integer type that can represent the number of elements in a <code>priority_queue</code> .
value_type	A type that represents the type of object stored as an element in a <code>priority_queue</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
empty	Tests if the <code>priority_queue</code> is empty.
pop	Removes the largest element of the <code>priority_queue</code> from the top position.
push	Adds an element to the priority queue based on the priority of the element from operator<.
size	Returns the number of elements in the <code>priority_queue</code> .
top	Returns a const reference to the largest element at the top of the <code>priority_queue</code> .

Requirements

Header: <queue>

Namespace: std

priority_queue::container_type

A type that provides the base container to be adapted.

```
typedef Container container_type;
```

Remarks

The type is a synonym for the template parameter `Container`. The C++ Standard Library sequence container class `deque` and the default class `vector` meet the requirements to be used as the base container for a `priority_queue` object. User-defined types satisfying the requirements may also be used.

For more information on `Container`, see the Remarks section of the [priority_queue Class](#) topic.

Example

See the example for [priority_queue](#) for an example of how to declare and use `container_type`.

priority_queue::empty

Tests if a `priority_queue` is empty.

```
bool empty() const;
```

Return Value

true if the `priority_queue` is empty; **false** if the `priority_queue` is nonempty.

Example

```
// pqueue_empty.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares priority_queues with default deque base container
    priority_queue<int> q1, s2;

    q1.push( 1 );

    if ( q1.empty( ) )
        cout << "The priority_queue q1 is empty." << endl;
    else
        cout << "The priority_queue q1 is not empty." << endl;

    if ( s2.empty( ) )
        cout << "The priority_queue s2 is empty." << endl;
    else
        cout << "The priority_queue s2 is not empty." << endl;
}
```

```
The priority_queue q1 is not empty.
The priority_queue s2 is empty.
```

priority_queue::pop

Removes the largest element of the priority_queue from the top position.

```
void pop();
```

Remarks

The priority_queue must be nonempty to apply the member function. The top of the priority_queue is always occupied by the largest element in the container.

Example

```
// pqueue_pop.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    priority_queue <int> q1, s2;

    q1.push( 10 );
    q1.push( 20 );
    q1.push( 30 );

    priority_queue <int>::size_type i, iii;
    i = q1.size( );
    cout << "The priority_queue length is " << i << "." << endl;

    const int& ii = q1.top( );
    cout << "The element at the top of the priority_queue is "
         << ii << "." << endl;

    q1.pop( );

    iii = q1.size( );
    cout << "After a pop, the priority_queue length is "
         << iii << "." << endl;

    const int& iv = q1.top( );
    cout << "After a pop, the element at the top of the "
         << "priority_queue is " << iv << "." << endl;
}
```

```
The priority_queue length is 3.
The element at the top of the priority_queue is 30.
After a pop, the priority_queue length is 2.
After a pop, the element at the top of the priority_queue is 20.
```

priority_queue::priority_queue

Constructs a priority_queue that is empty or that is a copy of a range of a base container object or of another priority_queue.

```

priority_queue();

explicit priority_queue(const Traits& _comp);

priority_queue(const Traits& _comp, const container_type& _Cont);

priority_queue(const priority_queue& right);

template <class InputIterator>
priority_queue(InputIterator first, InputIterator last);

template <class InputIterator>
priority_queue(InputIterator first, InputIterator last, const Traits& _comp);

template <class InputIterator>
priority_queue(InputIterator first, InputIterator last, const Traits& _comp, const container_type& _Cont);

```

Parameters

_comp

The comparison function of type **const Traits** used to order the elements in the priority_queue, which defaults to compare function of the base container.

_Cont

The base container of which the constructed priority_queue is to be a copy.

right

The priority_queue of which the constructed set is to be a copy.

first

The position of the first element in the range of elements to be copied.

last

The position of the first element beyond the range of elements to be copied.

Remarks

Each of the first three constructors specifies an empty initial priority_queue, the second also specifying the type of comparison function (`comp`) to be used in establishing the order of the elements and the third explicitly specifying the `container_type` (`_Cont`) to be used. The keyword **explicit** suppresses certain kinds of automatic type conversion.

The fourth constructor specifies a copy of the priority_queue *right*.

The last three constructors copy the range [*first*, *last*) of some container and use the values to initialize a priority_queue with increasing explicitness in specifying the type of comparison function of class `Traits` and `container_type`.

Example

```

// pqueue_ctor.cpp
// compile with: /EHsc
#include <queue>
#include <vector>
#include <deque>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function declares priority_queue

```

```

// with a default vector base container
priority_queue<int> q1;
cout << "q1 = ( ";
while ( !q1.empty( ) )
{
    cout << q1.top( ) << " ";
    q1.pop( );
}
cout << ")" << endl;

// Explicitly declares a priority_queue with nondefault
// deque base container
priority_queue<int, deque<int> > q2;
q2.push( 5 );
q2.push( 15 );
q2.push( 10 );
cout << "q2 = ( ";
while ( !q2.empty( ) )
{
    cout << q2.top( ) << " ";
    q2.pop( );
}
cout << ")" << endl;

// This method of printing out the elements of a priority_queue
// removes the elements from the priority queue, leaving it empty
cout << "After printing, q2 has " << q2.size( ) << " elements." << endl;

// The third member function declares a priority_queue
// with a vector base container and specifies that the comparison
// function greater is to be used for ordering elements
priority_queue<int, vector<int>, greater<int> > q3;
q3.push( 2 );
q3.push( 1 );
q3.push( 3 );
cout << "q3 = ( ";
while ( !q3.empty( ) )
{
    cout << q3.top( ) << " ";
    q3.pop( );
}
cout << ")" << endl;

// The fourth member function declares a priority_queue and
// initializes it with elements copied from another container:
// first, inserting elements into q1, then copying q1 elements into q4
q1.push( 100 );
q1.push( 200 );
priority_queue<int> q4( q1 );
cout << "q4 = ( ";
while ( !q4.empty( ) )
{
    cout << q4.top( ) << " ";
    q4.pop( );
}
cout << ")" << endl;

// Creates an auxiliary vector object v5 to be used to initialize q5
vector<int> v5;
vector<int>::iterator v5_Iter;
v5.push_back( 10 );
v5.push_back( 30 );
v5.push_back( 20 );
cout << "v5 = ( " ;
for ( v5_Iter = v5.begin( ) ; v5_Iter != v5.end( ) ; v5_Iter++ )
    cout << *v5_Iter << " ";
cout << ")" << endl;

// The fifth member function declares and

```

```

// initializes a priority_queue q5 by copying the
// range v5[ first, last) from vector v5
priority_queue<int> q5( v5.begin( ), v5.begin( ) + 2 );
cout << "q5 = ( ";
while ( !q5.empty( ) )
{
    cout << q5.top( ) << " ";
    q5.pop( );
}
cout << ")" << endl;

// The sixth member function declares a priority_queue q6
// with a comparison function greater and initializes q6
// by copying the range v5[ first, last) from vector v5
priority_queue<int, vector<int>, greater<int> >
    q6( v5.begin( ), v5.begin( ) + 2 );
cout << "q6 = ( ";
while ( !q6.empty( ) )
{
    cout << q6.top( ) << " ";
    q6.pop( );
}
cout << ")" << endl;
}

```

priority_queue::push

Adds an element to the priority queue based on the priority of the element from operator<.

```
void push(const Type& val);
```

Parameters

val

The element added to the top of the priority_queue.

Remarks

The top of the priority_queue is the position occupied by the largest element in the container.

Example

```
// pqueue_push.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    priority_queue<int> q1;

    q1.push( 10 );
    q1.push( 30 );
    q1.push( 20 );

    priority_queue<int>::size_type i;
    i = q1.size( );
    cout << "The priority_queue length is " << i << "." << endl;

    const int& ii = q1.top( );
    cout << "The element at the top of the priority_queue is "
        << ii << "." << endl;
}
```

```
The priority_queue length is 3.
The element at the top of the priority_queue is 30.
```

priority_queue::size

Returns the number of elements in the priority_queue.

```
size_type size() const;
```

Return Value

The current length of the priority_queue.

Example

```
// pqueue_size.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    priority_queue <int> q1, q2;
    priority_queue <int>::size_type i;

    q1.push( 1 );
    i = q1.size( );
    cout << "The priority_queue length is " << i << "." << endl;

    q1.push( 2 );
    i = q1.size( );
    cout << "The priority_queue length is now " << i << "." << endl;
}
```

```
The priority_queue length is 1.
The priority_queue length is now 2.
```

priority_queue::size_type

An unsigned integer type that can represent the number of elements in a priority_queue.

```
typedef typename Container::size_type size_type;
```

Remarks

The type is a synonym for the `size_type` of the base container adapted by the priority_queue.

Example

See the example for [size](#) for an example of how to declare and use `size_type`.

priority_queue::top

Returns a const reference to the largest element at the top of the priority_queue.

```
const_reference top() const;
```

Return Value

A reference to the largest element, as determined by the `Traits` function, object of the priority_queue.

Remarks

The priority_queue must be nonempty to apply the member function.

Example

```
// pqueue_top.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    priority_queue<int> q1;

    q1.push( 10 );
    q1.push( 30 );
    q1.push( 20 );

    priority_queue<int>::size_type i;
    i = q1.size( );
    cout << "The priority_queue length is " << i << "." << endl;

    const int& ii = q1.top( );
    cout << "The element at the top of the priority_queue is "
        << ii << "." << endl;
}
```

```
The priority_queue length is 3.
The element at the top of the priority_queue is 30.
```

priority_queue::value_type

A type that represents the type of object stored as an element in a priority_queue.

```
typedef typename Container::value_type value_type;
```

Remarks

The type is a synonym for the `value_type` of the base container adapted by the priority_queue.

Example

```
// pqueue_value_type.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares priority_queues with default deque base container
    priority_queue<int>::value_type AnInt;

    AnInt = 69;
    cout << "The value_type is AnInt = " << AnInt << endl;

    priority_queue<int> q1;
    q1.push( AnInt );
    cout << "The element at the top of the priority_queue is "
        << q1.top( ) << "." << endl;
}
```

```
The value_type is AnInt = 69
The element at the top of the priority_queue is 69.
```

queue Class

10/31/2018 • 10 minutes to read • [Edit Online](#)

A template container adaptor class that provides a restriction of functionality for some underlying container type, limiting access to the front and back elements. Elements can be added at the back or removed from the front, and elements can be inspected at either end of the queue.

Syntax

```
template <class Type, class Container = deque <Type>>
class queue
```

Parameters

Type

The element data type to be stored in the queue

Container

The type of the underlying container used to implement the queue.

Remarks

The elements of class `Type` stipulated in the first template parameter of a queue object are synonymous with [value_type](#) and must match the type of element in the underlying container class `Container` stipulated by the second template parameter. The `Type` must be assignable, so that it is possible to copy objects of that type and to assign values to variables of that type.

Suitable underlying container classes for queue include [deque](#) and [list](#), or any other sequence container that supports the operations of `front`, `back`, `push_back`, and `pop_front`. The underlying container class is encapsulated within the container adaptor, which exposes only the limited set of the sequence container member functions as a public interface.

The queue objects are equality comparable if and only if the elements of class `Type` are equality comparable, and are less-than comparable if and only if the elements of class `Type` are less-than comparable.

There are three types of container adaptors defined by the C++ Standard Library: `stack`, `queue`, and `priority_queue`. Each restricts the functionality of some underlying container class to provide a precisely controlled interface to a standard data structure.

- The [stack class](#) supports a last-in, first-out (LIFO) data structure. A good analogue to keep in mind would be a stack of plates. Elements (plates) may be inserted, inspected, or removed only from the top of the stack, which is the last element at the end of the base container. The restriction to accessing only the top element is the reason for using the stack class.
- The queue class supports a first-in, first-out (FIFO) data structure. A good analogue to keep in mind would be people lining up for a bank teller. Elements (people) may be added to the back of the line and are removed from the front of the line. Both the front and the back of a line may be inspected. The restriction to accessing only the front and back elements in this way is the reason for using the queue class.
- The [priority_queue class](#) orders its elements so that the largest element is always at the top position. It supports insertion of an element and the inspection and removal of the top element. A good analogue to keep in mind would be people lining up where they are arranged by age, height, or some other criterion.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>queue</code>	Constructs a <code>queue</code> that is empty or that is a copy of a base container object.

Typedefs

TYPE NAME	DESCRIPTION
<code>container_type</code>	A type that provides the base container to be adapted by the <code>queue</code> .
<code>size_type</code>	An unsigned integer type that can represent the number of elements in a <code>queue</code> .
<code>value_type</code>	A type that represents the type of object stored as an element in a <code>queue</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>back</code>	Returns a reference to the last and most recently added element at the back of the <code>queue</code> .
<code>empty</code>	Tests if the <code>queue</code> is empty.
<code>front</code>	Returns a reference to the first element at the front of the <code>queue</code> .
<code>pop</code>	Removes an element from the front of the <code>queue</code> .
<code>push</code>	Adds an element to the back of the <code>queue</code> .
<code>size</code>	Returns the number of elements in the <code>queue</code> .

Requirements

Header: `<queue>`

Namespace: `std`

`queue::back`

Returns a reference to the last and most recently added element at the back of the queue.

```
reference back();

const_reference back() const;
```

Return Value

The last element of the queue. If the queue is empty, the return value is undefined.

Remarks

If the return value of `back` is assigned to a `const_reference`, the queue object cannot be modified. If the return value of `back` is assigned to a `reference`, the queue object can be modified.

When compiled by using `_ITERATOR_DEBUG_LEVEL` defined as 1 or 2, a runtime error will occur if you attempt to access an element in an empty queue. See [Checked Iterators](#) for more information.

Example

```
// queue_back.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    queue <int> q1;

    q1.push( 10 );
    q1.push( 11 );

    int& i = q1.back( );
    const int& ii = q1.front( );

    cout << "The integer at the back of queue q1 is " << i
         << "." << endl;
    cout << "The integer at the front of queue q1 is " << ii
         << "." << endl;
}
```

queue::container_type

A type that provides the base container to be adapted.

```
typedef Container container_type;
```

Remarks

The type is a synonym for the template parameter `Container`. Two C++ Standard Library sequence container classes — the list class and the default deque class — meet the requirements to be used as the base container for a queue object. User-defined types satisfying the requirements may also be used.

For more information on `Container`, see the Remarks section of the [queue Class](#) topic.

Example

See the example for [queue](#) for an example of how to declare and use `container_type`.

queue::empty

Tests if a queue is empty.

```
bool empty() const;
```

Return Value

true if the queue is empty; **false** if the queue is nonempty.

Example

```
// queue_empty.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares queues with default deque base container
    queue<int> q1, q2;

    q1.push( 1 );

    if ( q1.empty( ) )
        cout << "The queue q1 is empty." << endl;
    else
        cout << "The queue q1 is not empty." << endl;

    if ( q2.empty( ) )
        cout << "The queue q2 is empty." << endl;
    else
        cout << "The queue q2 is not empty." << endl;
}
```

```
The queue q1 is not empty.
The queue q2 is empty.
```

queue::front

Returns a reference to the first element at the front of the queue.

```
reference front();

const_reference front() const;
```

Return Value

The first element of the queue. If the queue is empty, the return value is undefined.

Remarks

If the return value of `front` is assigned to a `const_reference`, the queue object cannot be modified. If the return value of `front` is assigned to a `reference`, the queue object can be modified.

The member function returns a `reference` to the first element of the controlled sequence, which must be nonempty.

When compiled by using `_ITERATOR_DEBUG_LEVEL` defined as 1 or 2, a runtime error will occur if you attempt to access an element in an empty queue. See [Checked Iterators](#) for more information.

Example

```

// queue_front.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main() {
    using namespace std;
    queue <int> q1;

    q1.push( 10 );
    q1.push( 20 );
    q1.push( 30 );

    queue <int>::size_type i;
    i = q1.size( );
    cout << "The queue length is " << i << "." << endl;

    int& ii = q1.back( );
    int& iii = q1.front( );

    cout << "The integer at the back of queue q1 is " << ii
        << "." << endl;
    cout << "The integer at the front of queue q1 is " << iii
        << "." << endl;
}

```

queue::pop

Removes an element from the front of the queue.

```
void pop();
```

Remarks

The queue must be nonempty to apply the member function. The top of the queue is the position occupied by the most recently added element and is the last element at the end of the container.

Example

```

// queue_pop.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    queue <int> q1, s2;

    q1.push( 10 );
    q1.push( 20 );
    q1.push( 30 );

    queue <int>::size_type i;
    i = q1.size( );
    cout << "The queue length is " << i << "." << endl;

    i = q1.front( );
    cout << "The element at the front of the queue is "
        << i << "." << endl;

    q1.pop( );

    i = q1.size( );
    cout << "After a pop the queue length is "
        << i << "." << endl;

    i = q1.front( );
    cout << "After a pop, the element at the front of the queue is "
        << i << "." << endl;
}

```

```

The queue length is 3.
The element at the front of the queue is 10.
After a pop the queue length is 2.
After a pop, the element at the front of the queue is 20.

```

queue::push

Adds an element to the back of the queue.

```
void push(const Type& val);
```

Parameters

val

The element added to the back of the queue.

Remarks

The back of the queue is the position occupied by the most recently added element and is the last element at the end of the container.

Example

```
// queue_push.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    queue <int> q1;

    q1.push( 10 );
    q1.push( 20 );
    q1.push( 30 );

    queue <int>::size_type i;
    i = q1.size( );
    cout << "The queue length is " << i << "." << endl;

    i = q1.front( );
    cout << "The element at the front of the queue is "
        << i << "." << endl;
}
```

```
The queue length is 3.
The element at the front of the queue is 10.
```

queue::queue

Constructs a queue that is empty or that is a copy of a base container object.

```
queue();

explicit queue(const container_type& right);
```

Parameters

right

The **const** container of which the constructed queue is to be a copy.

Remarks

The default base container for queue is deque. You can also specify list as a base container, but you cannot specify vector, because it lacks the required `pop_front` member function.

Example

```

// queue_queue.cpp
// compile with: /EHsc
#include <queue>
#include <vector>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares queue with default deque base container
    queue <char> q1;

    // Explicitly declares a queue with deque base container
    queue <char, deque<char> > q2;

    // These lines don't cause an error, even though they
    // declares a queue with a vector base container
    queue <int, vector<int> > q3;
    q3.push( 10 );
    // but the following would cause an error because vector has
    // no pop_front member function
    // q3.pop( );

    // Declares a queue with list base container
    queue <int, list<int> > q4;

    // The second member function copies elements from a container
    list<int> li1;
    li1.push_back( 1 );
    li1.push_back( 2 );
    queue <int, list<int> > q5( li1 );
    cout << "The element at the front of queue q5 is "
         << q5.front( ) << "." << endl;
    cout << "The element at the back of queue q5 is "
         << q5.back( ) << "." << endl;
}

```

```

The element at the front of queue q5 is 1.
The element at the back of queue q5 is 2.

```

queue::size

Returns the number of elements in the queue.

```

size_type size() const;

```

Return Value

The current length of the queue.

Example

```
// queue_size.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;
    queue <int> q1, q2;
    queue <int>::size_type i;

    q1.push( 1 );
    i = q1.size( );
    cout << "The queue length is " << i << "." << endl;

    q1.push( 2 );
    i = q1.size( );
    cout << "The queue length is now " << i << "." << endl;
}
```

```
The queue length is 1.
The queue length is now 2.
```

queue::size_type

An unsigned integer type that can represent the number of elements in a queue.

```
typedef typename Container::size_type size_type;
```

Remarks

The type is a synonym for the `size_type` of the base container adapted by the queue.

Example

See the example for [queue::front](#) for an example of how to declare and use `size_type`.

queue::value_type

A type that represents the type of object stored as an element in a queue.

```
typedef typename Container::value_type value_type;
```

Remarks

The type is a synonym for the `value_type` of the base container adapted by the queue.

Example

```
// queue_value_type.cpp
// compile with: /EHsc
#include <queue>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares queues with default deque base container
    queue<int>::value_type AnInt;

    AnInt = 69;
    cout << "The value_type is AnInt = " << AnInt << endl;

    queue<int> q1;
    q1.push(AnInt);
    cout << "The element at the front of the queue is "
        << q1.front( ) << "." << endl;
}
```

```
The value_type is AnInt = 69
The element at the front of the queue is 69.
```

[C++ Standard Library Reference](#)

<random>

10/31/2018 • 15 minutes to read • [Edit Online](#)

Defines facilities for random number generation, allowing creation of uniformly distributed random numbers.

Syntax

```
#include <random>
```

Summary

A *random number generator* is an object that produces a sequence of pseudo-random values. A generator that produces values that are uniformly distributed in a specified range is a *Uniform Random Number Generator* (URNG). A template class designed to function as a URNG is referred to as an *engine* if that class has certain common traits, which are discussed later in this article. A URNG can be—and usually is—combined with a *distribution* by passing the URNG as an argument to the distribution's `operator()` to produce values that are distributed in a manner that is defined by the distribution.

These links jump to the major sections of this article:

- [Examples](#)
- [Categorized Listing](#)
- [Engines and Distributions](#)
- [Remarks](#)

Quick Tips

Here are some tips to keep in mind when using <random>:

- For most purposes, URNGs produce raw bits that must be shaped by distributions. (A notable exception to this is `std::shuffle()` because it uses a URNG directly.)
- A single instantiation of a URNG or distribution cannot safely be called concurrently because running a URNG or distribution is a modifying operation. For more information, see [Thread Safety in the C++ Standard Library](#).
- [Predefined typedefs](#) of several engines are provided; this is the preferred way to create a URNG if an engine is being used.
- The most useful pairing for most applications is the `mt19937` engine with `uniform_int_distribution`, as shown in the [code example](#) later in this article.

There are many options to choose from in the <random> header, and any of them is preferable to the outdated C Runtime function `rand()`. For information about what's wrong with `rand()` and how <random> addresses these shortcomings, see [this video](#).

Examples

The following code example shows how to generate some random numbers in this case five of them using a generator created with non-deterministic seed.

```
#include <random>
#include <iostream>

using namespace std;

int main()
{
    random_device rd;    // non-deterministic generator
    mt19937 gen(rd());    // to seed mersenne twister.
                        // replace the call to rd() with a
                        // constant value to get repeatable
                        // results.

    for (int i = 0; i < 5; ++i) {
        cout << gen() << " "; // print the raw output of the generator.
    }
    cout << endl;
}
```

```
2430338871 3531691818 2723770500 3252414483 3632920437
```

While these are high quality random numbers and different every time this program is run, they are not necessarily in a useful range. To control the range, use a uniform distribution as shown in the following code:

```
#include <random>
#include <iostream>

using namespace std;

int main()
{
    random_device rd;    // non-deterministic generator
    mt19937 gen(rd());    // to seed mersenne twister.
    uniform_int_distribution<> dist(1,6); // distribute results between 1 and 6 inclusive.

    for (int i = 0; i < 5; ++i) {
        cout << dist(gen) << " "; // pass the generator to the distribution.
    }
    cout << endl;
}
```

```
5 1 6 1 2
```

The next code example shows a more realistic set of use cases with uniformly distributed random number generators shuffling the contents of a vector and an array.

```
// cl.exe /EHsc /nologo /W4 /MTd
#include <algorithm>
#include <array>
#include <iostream>
#include <random>
#include <string>
#include <vector>
#include <functional> // ref()
```

```

using namespace std;

template <typename C> void print(const C& c) {
    for (const auto& e : c) {
        cout << e << " ";
    }

    cout << endl;
}

template <class URNG>
void test(URNG& urng) {

    // Uniform distribution used with a vector
    // Distribution is [-5, 5] inclusive
    uniform_int_distribution<int> dist(-5, 5);
    vector<int> v;

    for (int i = 0; i < 20; ++i) {
        v.push_back(dist(urng));
    }

    cout << "Randomized vector: ";
    print(v);

    // Shuffle an array
    // (Notice that shuffle() takes a URNG, not a distribution)
    array<string, 26> arr = { { "H", "He", "Li", "Be", "B", "C", "N", "O", "F",
        "Ne", "Na", "Mg", "Al", "Si", "P", "S", "Cl", "Ar", "K", "Ca", "Sc",
        "Ti", "V", "Cr", "Mn", "Fe" } };

    shuffle(arr.begin(), arr.end(), urng);

    cout << "Randomized array: ";
    print(arr);
    cout << "--" << endl;
}

int main()
{
    // First run: non-seedable, non-deterministic URNG random_device
    // Slower but crypto-secure and non-repeatable.
    random_device rd;
    cout << "Using random_device URNG:" << endl;
    test(rd);

    // Second run: simple integer seed, repeatable results
    cout << "Using constant-seed mersenne twister URNG:" << endl;
    mt19937 engine1(12345);
    test(engine1);

    // Third run: random_device as a seed, different each run
    // (Desirable for most purposes)
    cout << "Using non-deterministic-seed mersenne twister URNG:" << endl;
    mt19937 engine2(rd());
    test(engine2);

    // Fourth run: "warm-up" sequence as a seed, different each run
    // (Advanced uses, allows more than 32 bits of randomness)
    cout << "Using non-deterministic-seed \"warm-up\" sequence mersenne twister URNG:" << endl;
    array<unsigned int, mt19937::state_size> seed_data;
    generate_n(seed_data.begin(), seed_data.size(), ref(rd));
    seed_seq seq(begin(seed_data), end(seed_data));
    mt19937 engine3(seq);
    test(engine3);
}

```

```

Using random_device URNG:
Randomized vector: 5 -4 2 3 0 5 -2 0 4 2 -1 2 -4 -3 1 4 4 1 2 -2
Randomized array: O Li V K C Ti N Mg Ne Sc Cl B Cr Mn Ca Al F P Na Be Si Ar Fe S He H
--
Using constant-seed mersenne twister URNG:
Randomized vector: 3 -1 -5 0 0 5 3 -4 -3 -4 1 -3 0 -3 -2 -4 5 1 -1 -1
Randomized array: Al O Ne Si Na Be C N Cr Mn H V F Sc Mg Fe K Ca S Ti B P Ar Cl Li He
--
Using non-deterministic-seed mersenne twister URNG:
Randomized vector: 5 -4 0 2 1 -2 4 4 -4 0 0 4 -5 4 -5 -1 -3 0 0 3
Randomized array: Si Fe Al Ar Na P B Sc H F Mg Li C Ti He N Mn Be O Ca Cr V K Ne Cl S
--
Using non-deterministic-seed "warm-up" sequence mersenne twister URNG:
Randomized vector: -1 3 -2 4 1 3 0 -5 5 -5 0 0 5 0 -3 3 -4 2 5 0
Randomized array: Si C Sc H Na O S Cr K Li Al Ti Cl B Mn He Fe Ne Be Ar V P Ca N Mg F
--

```

This code demonstrates two different randomizations—randomize a vector of integers and shuffle an array of indexed data—with a test template function. The first call to the test function uses the cryptographically secure, non-deterministic, not-seedable, non-repeatable URNG `random_device`. The second test run uses `mersenne_twister_engine` as URNG, with a deterministic 32-bit constant seed, which means the results are repeatable. The third test run seeds `mersenne_twister_engine` with a 32-bit non-deterministic result from `random_device`. The fourth test run expands on this by using a [seed sequence](#) filled with `random_device` results, which effectively gives more than 32-bit non-deterministic randomness (but still not crypto-secure). For more information, read on.

Categorized Listing

Uniform Random Number Generators

URNGs are often described in terms of these properties:

1. **Period length:** How many iterations it takes to repeat the sequence of numbers generated. The longer the better.
2. **Performance:** How quickly numbers can be generated and how much memory it takes. The smaller the better.
3. **Quality:** How close to true random numbers the generated sequence is. This is often called "*randomness*".

The following sections list the uniform random number generators (URNGs) provided in the `<random>` header.

Non-Deterministic Generator

random_device Class	Generates a non-deterministic, cryptographically secure random sequence by using an external device. Usually used to seed an engine. Low performance, very high quality. For more information, see Remarks .
-------------------------------------	--

Engine Typedefs with Predefined Parameters

For instantiating engines and engine adaptors. For more information, see [Engines and Distributions](#).

- `default_random_engine` The default engine.

```
typedef mt19937 default_random_engine;
```

- `knuth_b` Knuth engine.

```
typedef shuffle_order_engine<minstd_rand0, 256> knuth_b;
```

- `minstd_rand0` 1988 minimal standard engine (Lewis, Goodman, and Miller, 1969).

```
typedef linear_congruential_engine<unsigned int, 16807, 0, 2147483647> minstd_rand0;
```

- `minstd_rand` Updated minimal standard engine `minstd_rand0` (Park, Miller, and Stockmeyer, 1993).

```
typedef linear_congruential_engine<unsigned int, 48271, 0, 2147483647> minstd_rand;
```

- `mt19937` 32-bit Mersenne twister engine (Matsumoto and Nishimura, 1998).

```
typedef mersenne_twister_engine<
    unsigned int, 32, 624, 397,
    31, 0x9908b0df,
    11, 0xffffffff,
    7, 0x9d2c5680,
    15, 0xefc60000,
    18, 1812433253> mt19937;
```

- `mt19937_64` 64-bit Mersenne twister engine (Matsumoto and Nishimura, 2000).

```
typedef mersenne_twister_engine<
    unsigned long long, 64, 312, 156,
    31, 0xb5026f5aa96619e9ULL,
    29, 0x5555555555555555ULL,
    17, 0x71d67ffeda60000ULL,
    37, 0xfff7eee000000000ULL,
    43, 6364136223846793005ULL> mt19937_64;
```

- `ranlux24` 24-bit RANLUX engine (Martin Lüscher and Fred James, 1994).

```
typedef discard_block_engine<ranlux24_base, 223, 23> ranlux24;
```

- `ranlux24_base` Used as a base for `ranlux24`.

```
typedef subtract_with_carry_engine<unsigned int, 24, 10, 24> ranlux24_base;
```

- `ranlux48` 48-bit RANLUX engine (Martin Lüscher and Fred James, 1994).

```
typedef discard_block_engine<ranlux48_base, 389, 11> ranlux48;
```

- `ranlux48_base` Used as a base for `ranlux48`.

```
typedef subtract_with_carry_engine<unsigned long long, 48, 5, 12> ranlux48_base;
```

Engine Templates

Engine templates are used as standalone URNGs or as base engines passed to [engine adaptors](#).

Usually these are instantiated with a [predefined engine typedef](#) and passed to a [distribution](#). For more information, see the [Engines and Distributions](#) section.

linear_congruential_engine Class	Generates a random sequence by using the linear congruential algorithm. Most simplistic and lowest quality.
mersenne_twister_engine Class	Generates a random sequence by using the Mersenne twister algorithm. Most complex, and is highest quality except for the random_device class. Very fast performance.
subtract_with_carry_engine Class	Generates a random sequence by using the subtract-with-carry algorithm. An improvement on <code>linear_congruential_engine</code> , but much lower quality and performance than <code>mersenne_twister_engine</code> .

Engine Adaptor Templates

Engine adaptors are templates that adapt other (base) engines. Usually these are instantiated with a [predefined engine typedef](#) and passed to a [distribution](#). For more information, see the [Engines and Distributions](#) section.

discard_block_engine Class	Generates a random sequence by discarding values returned by its base engine.
independent_bits_engine Class	Generates a random sequence with a specified number of bits by repacking bits from the values returned by its base engine.
shuffle_order_engine Class	Generates a random sequence by reordering the values returned from its base engine.

[[Engine Templates](#)]

Random Number Distributions

The following sections list the distributions provided in the `<random>` header. Distributions are a post-processing mechanism, usually using URNG output as input and distributing the output by a defined statistical probability density function. For more information, see the [Engines and Distributions](#) section.

Uniform Distributions

uniform_int_distribution Class	Produces a uniform integer value distribution across a range in the closed interval [a, b] (inclusive-inclusive).
uniform_real_distribution Class	Produces a uniform real (floating-point) value distribution across a range in the half-open interval [a, b) (inclusive-exclusive).
generate_canonical	Produces an even distribution of real (floating point) values of a given precision across [0, 1) (inclusive-exclusive).

[Random Number Distributions]

Bernoulli Distributions

bernoulli_distribution Class	Produces a Bernoulli distribution of bool values.
binomial_distribution Class	Produces a binomial distribution of integer values.
geometric_distribution Class	Produces a geometric distribution of integer values.
negative_binomial_distribution Class	Produces a negative binomial distribution of integer values.

[Random Number Distributions]

Normal Distributions

cauchy_distribution Class	Produces a Cauchy distribution of real (floating point) values.
chi_squared_distribution Class	Produces a chi-squared distribution of real (floating point) values.
fisher_f_distribution Class	Produces an F-distribution (also known as Snedecor's F distribution or the Fisher-Snedecor distribution) of real (floating point) values.
lognormal_distribution Class	Produces a log-normal distribution of real (floating point) values.
normal_distribution Class	Produces a normal (Gaussian) distribution of real (floating point) values.
student_t_distribution Class	Produces a Student's <i>t</i> -distribution of real (floating point) values.

[Random Number Distributions]

Poisson Distributions

exponential_distribution Class	Produces an exponential distribution of real (floating point) values.
extreme_value_distribution Class	Produces an extreme value distribution of real (floating point) values.
gamma_distribution Class	Produces a gamma distribution of real (floating point) values.
poisson_distribution Class	Produces a Poisson distribution of integer values.
weibull_distribution Class	Produces a Weibull distribution of real (floating point) values.

[\[Random Number Distributions\]](#)

Sampling Distributions

discrete_distribution Class	Produces a discrete integer distribution.
piecewise_constant_distribution Class	Produces a piecewise constant distribution of real (floating point) values.
piecewise_linear_distribution Class	Produces a piecewise linear distribution of real (floating point) values.

[\[Random Number Distributions\]](#)

Utility Functions

This section lists the general utility functions provided in the `<random>` header.

seed_seq Class	Generates a non-biased scrambled seed sequence. Used to avoid replication of random variate streams. Useful when many URNGs are instantiated from engines.

Operators

This section lists the operators provided in the `<random>` header.

<code>operator==</code>	Tests whether the URNG on the left side of the operator is equal to the engine on the right side.
<code>operator!=</code>	Tests whether the URNG on the left side of the operator is not equal to the engine on the right side.
<code>operator<<</code>	Writes state information to a stream.
<code>operator>></code>	Extracts state information from a stream.

Engines and Distributions

Refer to the following sections for information about each of these template class categories defined in `<random>`. Both of these template class categories take a type as an argument and use shared template parameter names to describe the properties of the type that are permitted as an actual argument type, as follows:

- `IntType` indicates a **short**, **int**, **long**, **long long**, **unsigned short**, **unsigned int**, **unsigned long**, or **unsigned long long**.
- `UIntType` indicates **unsigned short**, **unsigned int**, **unsigned long**, or **unsigned long long**.
- `RealType` indicates a **float**, **double**, or **long double**.

Engines

[Engine Templates](#) and [Engine Adaptor Templates](#) are templates whose parameters customize the generator created.

An *engine* is a class or template class whose instances (generators) act as a source of random numbers uniformly distributed between a minimum and maximum value. An *engine adaptor* delivers a sequence of values that have different randomness properties by taking values produced by some other random number engine and applying an algorithm of some kind to those values.

Every engine and engine adaptor has the following members:

- `typedef numeric_type result_type` is the type that is returned by the generator's `operator()`. The `numeric_type` is passed as a template parameter on instantiation.
- `result_type operator()` returns values that are uniformly distributed between `min()` and `max()`.
- `result_type min()` returns the minimum value that is returned by the generator's `operator()`. Engine adaptors use the base engine's `min()` result.
- `result_type max()` returns the maximum value that is returned by the generator's `operator()`. When `result_type` is an integral (integer-valued) type, `max()` is the maximum value that can actually be returned (inclusive); when `result_type` is a floating-point (real-valued) type, `max()` is the smallest value greater than all values that can be returned (non-inclusive). Engine adaptors use the base engine's `max()` result.
- `void seed(result_type s)` seeds the generator with seed value `s`. For engines, the signature is `void seed(result_type s = default_seed)` for default parameter support (engine adaptors define a separate `void seed()`, see next subsection).
- `template <class Seq> void seed(Seq& q)` seeds the generator by using a `seed_seq` `Seq`.
- An explicit constructor with argument `result_type x` that creates a generator seeded as if by calling `seed(x)`.
- An explicit constructor with argument `seed_seq& seq` that creates a generator seeded as if by calling `seed(seq)`.
- `void discard(unsigned long long count)` effectively calls `operator()` `count` times and discards each value.

Engine adaptors additionally support these members (`Engine` is the first template parameter of an engine adaptor, designating the base engine's type):

- A default constructor to initialize the generator as if from the base engine's default constructor.
- An explicit constructor with argument `const Engine& eng`. This is to support copy construction using the base engine.
- An explicit constructor with argument `Engine&& eng`. This is to support move construction using the base engine.
- `void seed()` that initializes the generator with the base engine's default seed value.
- `const Engine& base()` property function that returns the base engine that was used to construct the generator.

Every engine maintains a *state* that determines the sequence of values that will be generated by subsequent calls to `operator()`. The states of two generators instantiated from engines of the same type can be compared by using `operator==` and `operator!=`. If the two states compare as equal, they will generate the same sequence of values. The state of an object can be saved to a stream as a sequence of 32-bit unsigned values by using the `operator<<` of the generator. The state is not

changed by saving it. A saved state can be read into generator instantiated from an engine of the same type by using `operator>>`.

Distributions

A [Random Number Distributions](#) is a class or template class whose instances transform a stream of uniformly distributed random numbers obtained from an engine into a stream of random numbers that have a particular distribution. Every distribution has the following members:

- `typedef numeric_type result_type` is the type that is returned by the distribution's `operator()`. The `numeric_type` is passed as a template parameter on instantiation.
- `template <class URNG> result_type operator()(URNG& gen)` returns values that are distributed according to the distribution's definition, by using `gen` as a source of uniformly distributed random values and the stored *parameters of the distribution*.
- `template <class URNG> result_type operator()(URNG& gen, param_type p)` returns values distributed in accordance with the distribution's definition, using `gen` as a source of uniformly distributed random values and the parameters structure `p`.
- `typedef unspecified_type param_type` is the package of parameters optionally passed to `operator()` and is used in place of the stored parameters to generate its return value.
- A `const param&` constructor initializes the stored parameters from its argument.
- `param_type param() const` gets the stored parameters.
- `void param(const param_type&)` sets the stored parameters from its argument.
- `result_type min()` returns the minimum value that is returned by the distribution's `operator()`.
- `result_type max()` returns the maximum value that is returned by the distribution's `operator()`. When `result_type` is an integral (integer-valued) type, `max()` is the maximum value that can actually be returned (inclusive); when `result_type` is a floating-point (real-valued) type, `max()` is the smallest value greater than all values that can be returned (non-inclusive).
- `void reset()` discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

A parameter structure is an object that stores all of the parameters needed for a distribution. It contains:

- `typedef distribution_type distribution_type`, which is the type of its distribution.
- One or more constructors that take the same parameter lists as the distribution constructors take.
- The same parameter-access functions as the distribution.
- Equality and inequality comparison operators.

For more information, see the reference subtopics below this one, linked previously in this article.

Remarks

There are two highly useful URNGs in Visual Studio—`mt19937` and `random_device`—as shown in this comparison table:

URNG	FAST	CRYPTO-SECURE	SEEDABLE	DETERMINISTIC
<code>mt19937</code>	Yes	No	Yes	Yes*
<code>random_device</code>	No	Yes	No	No

* When provided with a known seed.

Although the ISO C++ Standard does not require `random_device` to be cryptographically secure, in Visual Studio it is implemented to be cryptographically secure. (The term "cryptographically secure" does not imply guarantees, but refers to a minimum level of entropy—and therefore, the level of predictability—a given randomization algorithm provides. For more information, see the Wikipedia article [Cryptographically secure pseudorandom number generator](#).) Because the ISO C++ Standard does not require this, other platforms may implement `random_device` as a simple pseudo-random number generator (not cryptographically secure) and may only be suitable as a seed source for another generator. Check the documentation for those platforms when using `random_device` in cross-platform code.

By definition, `random_device` results are not reproducible, and a side-effect is that it may run significantly slower than other URNGs. Most applications that are not required to be cryptographically secure use `mt19937` or a similar engine, although you may want to seed it with a call to `random_device`, as shown in the [code example](#).

[Header Files Reference](#)

<random> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

generate_canonical

Returns a floating-point value from a random sequence.

NOTE

The ISO C++ Standard states that this function should return values in the range [0, 1). Visual Studio is not yet compliant with this constraint. As a workaround to generate values in this range, use [uniform_real_distribution](#).

```
template <class RealType, size_t Bits, class Generator>
RealType generate_canonical(Generator& Gen);
```

Parameters

RealType

The floating point integral type. For possible types, see [<random>](#).

Bits

The random number generator.

Gen

The random number generator.

Remarks

The template function calls `operator()` of *Gen* repeatedly and packs the returned values into a floating-point value `x` of type *RealType* until it has gathered the specified number of mantissa bits in `x`. The specified number is the smaller of *Bits* (which must be nonzero) and the full number of mantissa bits in *RealType*. The first call supplies the lowest-order bits. The function returns `x`.

[<random>](#)

bernoulli_distribution Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Generates a Bernoulli distribution.

Syntax

```
class bernoulli_distribution
{
public:
    // types
    typedef bool result_type;
    struct param_type;

    // constructors and reset functions
    explicit bernoulli_distribution(double p = 0.5);
    explicit bernoulli_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    double p() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

URNG

The uniform random number generator engine. For possible types, see [<random>](#).

Remarks

The class describes a distribution that produces values of type **bool**, distributed according to the Bernoulli distribution discrete probability function. The following table links to articles about individual members.

bernoulli_distribution	<code>bernoulli_distribution::p</code>	<code>bernoulli_distribution::param</code>
<code>bernoulli_distribution::operator()</code>		param_type

The property member `p()` returns the currently stored distribution parameter value `p`.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the Bernoulli distribution discrete probability function, see the Wolfram MathWorld article [Bernoulli Distribution](#).

Example

```
// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double p, const int s) {

    // uncomment to use a non-deterministic seed
    // std::random_device rd;
    // std::mt19937 gen(rd());
    std::mt19937 gen(1729);

    std::bernoulli_distribution distr(p);

    std::cout << "p == " << distr.p() << std::endl;

    // generate the distribution as a histogram
    std::map<bool, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Histogram for " << s << " samples:" << std::endl;
    for (const auto& elem : histogram) {
        std::cout << std::boolalpha << std::setw(5) << elem.first << ' ' << std::string(elem.second, ':') <<
std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    double p_dist = 0.5;
    int samples = 100;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter a double value for p distribution (where 0.0 <= p <= 1.0): ";
    std::cin >> p_dist;
    std::cout << "Enter an integer value for a sample count: ";
    std::cin >> samples;

    test(p_dist, samples);
}
```

```
Use CTRL-Z to bypass data entry and run using default values.
Enter a double value for p distribution (where 0.0 <= p <= 1.0): .45
Enter an integer value for a sample count: 100
p == 0.45
Histogram for 100 samples:
false ::::::::::::::::::::::::::::::::::::::::::::::::::::::::::::
true  ::::::::::::::::::::::::::::::::::::::::::::::::::::::::::::
```

Requirements

Header: <random>

Namespace: std

bernoulli_distribution::bernoulli_distribution

Constructs the distribution.

```
explicit bernoulli_distribution(double p = 0.5);
explicit bernoulli_distribution(const param_type& parm);
```

Parameters

p

The stored `p` distribution parameter.

parm

The `param_type` structure used to construct the distribution.

Remarks

Precondition: $0.0 \leq p \leq 1.0$

The first constructor constructs an object whose stored `p` value holds the value *p*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

bernoulli_distribution::param_type

Contains the parameters of the distribution.

```
struct param_type { typedef bernoulli_distribution distribution_type; param_type(double p = 0.5); double p() const;
bool operator==(const param_type& right) const; bool operator!=(const param_type& right) const; };
```

Parameters

p

The stored `p` distribution parameter.

Remarks

Precondition: $0.0 \leq p \leq 1.0$

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

[<random>](#)

binomial_distribution Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

Generates a binomial distribution.

Syntax

```
template<class IntType = int>
class binomial_distribution
{
public:
    // types
    typedef IntType result_type;
    struct param_type;

    // constructors and reset functions
    explicit binomial_distribution(result_type t = 1, double p = 0.5);
    explicit binomial_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type t() const;
    double p() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

IntType

The integer result type, defaults to **int**. For possible types, see [<random>](#).

URNG

The uniform random number generator engine. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified integral type, or type **int** if none is provided, distributed according to the Binomial Distribution discrete probability function. The following table links to articles about individual members.

binomial_distribution	<code>binomial_distribution::t</code>	<code>binomial_distribution::param</code>
<code>binomial_distribution::operator()</code>	<code>binomial_distribution::p</code>	param_type

The property members `t()` and `p()` return the currently stored distribution parameter values *t* and *p*

respectively.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the binomial distribution discrete probability function, see the Wolfram MathWorld article [Binomial Distribution](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const int t, const double p, const int& s) {

    // uncomment to use a non-deterministic seed
    // std::random_device rd;
    // std::mt19937 gen(rd());
    std::mt19937 gen(1729);

    std::binomial_distribution<> distr(t, p);

    std::cout << std::endl;
    std::cout << "p == " << distr.p() << std::endl;
    std::cout << "t == " << distr.t() << std::endl;

    // generate the distribution as a histogram
    std::map<int, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Histogram for " << s << " samples:" << std::endl;
    for (const auto& elem : histogram) {
        std::cout << std::setw(5) << elem.first << ' ' << std::string(elem.second, ':') << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    int t_dist = 1;
    double p_dist = 0.5;
    int samples = 100;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter an integer value for t distribution (where 0 <= t): ";
    std::cin >> t_dist;
    std::cout << "Enter a double value for p distribution (where 0.0 <= p <= 1.0): ";
    std::cin >> p_dist;
    std::cout << "Enter an integer value for a sample count: ";
    std::cin >> samples;

    test(t_dist, p_dist, samples);
}

```

First run:

```
Use CTRL-Z to bypass data entry and run using default values.
Enter an integer value for t distribution (where  $0 \leq t$ ): 22
Enter a double value for p distribution (where  $0.0 \leq p \leq 1.0$ ): .25
Enter an integer value for a sample count: 100
```

```
p == 0.25
t == 22
Histogram for 100 samples:

 5 ::::::::::::::::::::::
 6 ::::::::::::::
 7 :::::::::::
 8 ::::::
 9 ::::::
11 :
12 :
```

Second run:

```
Use CTRL-Z to bypass data entry and run using default values.
Enter an integer value for t distribution (where  $0 \leq t$ ): 22
Enter a double value for p distribution (where  $0.0 \leq p \leq 1.0$ ): .5
Enter an integer value for a sample count: 100
```

```
p == 0.5
t == 22
Histogram for 100 samples:
 6 :
 7 ::
 8 :::::::::::
 9 :::::::::::
10 ::::::::::::::
11 ::::::::::::::
12 :::::::::::
13 :::::::::::
14 :::::::::::
15 ::
16 ::
```

Third run:

```
Use CTRL-Z to bypass data entry and run using default values.
Enter an integer value for t distribution (where  $0 \leq t$ ): 22
Enter a double value for p distribution (where  $0.0 \leq p \leq 1.0$ ): .75
Enter an integer value for a sample count: 100
```

```
p == 0.75
t == 22
Histogram for 100 samples:
13 :::
14 :::::::::::
15 ::::::::::::::
16 ::::::::::::::
17 :::::::::::
18 :::::::::::
19 :::::::::::
20 ::::::
21 :
```

Requirements

Header: <random>

Namespace: std

binomial_distribution::binomial_distribution

Constructs the distribution.

```
explicit binomial_distribution(result_type t = 1, double p = 0.5);
explicit binomial_distribution(const param_type& parm);
```

Parameters

t

The `t` distribution parameter.

p

The `p` distribution parameter.

parm

The `param_type` structure used to construct the distribution.

Remarks

Precondition: $0 \leq t$ and $0.0 \leq p \leq 1.0$

The first constructor constructs an object whose stored *p* value holds the value *p* and whose stored *t* value holds the value *t*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

binomial_distribution::param_type

Stores all the parameters of the distribution.

```
struct param_type {
    typedef binomial_distribution<result_type> distribution_type;
    param_type(result_type t = 1, double p = 0.5);
    result_type t() const;
    double p() const;
    .....
    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

t

The `t` distribution parameter.

p

The `p` distribution parameter.

right

The `param_type` object to compare to this.

Remarks

Precondition: $0 \leq t$ and $0.0 \leq p \leq 1.0$

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

cauchy_distribution Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

Generates a Cauchy distribution.

Syntax

```
template<class RealType = double>
class cauchy_distribution {
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructor and reset functions
    explicit cauchy_distribution(result_type a = 0.0, result_type b = 1.0);
    explicit cauchy_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type a() const;
    result_type b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

URNG

The uniform random number generator engine. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified floating-point type, or type **double** if none is provided, distributed according to the Cauchy Distribution. The following table links to articles about individual members.

cauchy_distribution	<code>cauchy_distribution::a</code>	<code>cauchy_distribution::param</code>
<code>cauchy_distribution::operator()</code>	<code>cauchy_distribution::b</code>	param_type

The property functions `a()` and `b()` return their respective values for stored distribution parameters `a` and `b`.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the cauchy distribution, see the Wolfram MathWorld article [Cauchy Distribution](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double a, const double b, const int s) {

    // uncomment to use a non-deterministic generator
    // std::random_device gen;

    std::mt19937 gen(1701);

    std::cauchy_distribution<> distr(a, b);

    std::cout << std::endl;
    std::cout << "min() == " << distr.min() << std::endl;
    std::cout << "max() == " << distr.max() << std::endl;
    std::cout << "a() == " << std::fixed << std::setw(11) << std::setprecision(10) << distr.a() << std::endl;
    std::cout << "b() == " << std::fixed << std::setw(11) << std::setprecision(10) << distr.b() << std::endl;

    // generate the distribution as a histogram
    std::map<double, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results

```

Requirements

Header: <random>

Namespace: std

cauchy_distribution::cauchy_distribution

Constructs the distribution.

```
explicit cauchy_distribution(result_type a = 0.0, result_type b = 1.0);
explicit cauchy_distribution(const param_type& parm);
```

Parameters

a

The `a` distribution parameter.

b

The `b` distribution parameter.

parm

The `param_type` structure used to construct the distribution.

Remarks

Precondition: $0.0 < b$

The first constructor constructs an object whose stored `a` value holds the value *a* and whose stored `b` value holds the value *b*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

cauchy_distribution::param_type

Stores all the parameters of the distribution.

```
struct param_type {
    typedef cauchy_distribution<result_type> distribution_type;
    param_type(result_type a = 0.0, result_type b = 1.0);
    result_type a() const;
    result_type b() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

a

The `a` distribution parameter.

b

The `b` distribution parameter.

right

The `param_type` object to compare to this.

Remarks

Precondition: `0.0 < b`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

chi_squared_distribution Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

Generates a chi-squared distribution.

Syntax

```
template<class RealType = double>
class chi_squared_distribution {
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructor and reset functions
    explicit chi_squared_distribution(RealType n = 1);
    explicit chi_squared_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    RealType n() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

URNG

The uniform random number generator engine. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified floating-point type, or type **double** if none is provided, distributed according to the Chi-Squared Distribution. The following table links to articles about individual members.

chi_squared_distribution	<code>chi_squared_distribution::n</code>	<code>chi_squared_distribution::param</code>
<code>chi_squared_distribution::operator()</code>		param_type

The property function `n()` returns the value for the stored distribution parameter `n`.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the chi-squared distribution, see the Wolfram MathWorld article [Chi-Squared Distribution](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double n, const int s) {

    // uncomment to use a non-deterministic generator
    // std::random_device gen;
    std::mt19937 gen(1701);

    std::chi_squared_distribution<> distr(n);

    std::cout << std::endl;

Requirements

Header: <random>

Namespace: std

chi_squared_distribution::chi_squared_distribution

Constructs the distribution.

```
explicit chi_squared_distribution(result_type n = 1.0);
explicit chi_squared_distribution(const param_type& parm);
```

Parameters

n

The `n` distribution parameter.

parm

The parameter structure used to construct the distribution.

Remarks

Precondition: `0.0 < n`

The first constructor constructs an object whose stored `n` value holds the value *n*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

chi_squared_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type {
    typedef chi_squared_distribution<result_type> distribution_type;
    param_type(result_type n = 1.0);
    result_type n() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

n

The `n` distribution parameter.

right

The `param_type` object to compare to this.

Remarks

Precondition: `0.0 < n`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

[<random>](#)

discard_block_engine Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Generates a random sequence by discarding values returned by its base engine.

Syntax

```
template <class Engine, size_t P, size_t R>
class discard_block_engine;
```

Parameters

Engine

The base engine type.

P

Block size. The number of values in each block.

R

Used block. The number of values in each block that are used. The rest are discarded ($P - R$). **Precondition:**

$0 < R \leq P$

Members

<code>discard_block_engine::discard_block_engine</code>	<code>discard_block_engine::base</code>	<code>discard_block_engine::discard</code>
<code>discard_block_engine::operator()</code>	<code>discard_block_engine::base_type</code>	<code>discard_block_engine::seed</code>

For more information about engine members, see [<random>](#).

Remarks

This template class describes an engine adaptor that produces values by discarding some of the values returned by its base engine.

Requirements

Header: `<random>`

Namespace: `std`

[<random>](#)

discrete_distribution Class

11/15/2018 • 5 minutes to read • [Edit Online](#)

Generates a discrete integer distribution that has uniform-width intervals with uniform probability in each interval.

Syntax

```
template<class IntType = int>
class discrete_distribution
{
public:
    // types
    typedef IntType result_type;
    struct param_type;

    // constructor and reset functions
    discrete_distribution();
    template <class InputIterator>
    discrete_distribution(InputIterator firstW, InputIterator lastW);
    discrete_distribution(initializer_list<double> weightlist);
    template <class UnaryOperation>
    discrete_distribution(size_t count, double xmin, double xmax, UnaryOperation funcweight);
    explicit discrete_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    vector<double> probabilities() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

IntType

The integer result type, defaults to **int**. For possible types, see [<random>](#).

Remarks

This sampling distribution has uniform-width intervals with uniform probability in each interval. For information about other sampling distributions, see [piecewise_linear_distribution Class](#) and [piecewise_constant_distribution Class](#).

The following table links to articles about individual members:

discrete_distribution	<code>discrete_distribution::param</code>
---------------------------------------	---

<code>discrete_distribution::operator()</code>	<code>param_type</code>

The property function `vector<double> probabilities()` returns the individual probabilities for each integer generated.

For more information about distribution classes and their members, see [<random>](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

using namespace std;

void test(const int s) {

    // uncomment to use a non-deterministic generator
    // random_device rd;
    // mt19937 gen(rd());
    mt19937 gen(1701);

    discrete_distribution<> distr({ 1, 2, 3, 4, 5 });

    cout << endl;
    cout << "min() == " << distr.min() << endl;
    cout << "max() == " << distr.max() << endl;
    cout << "probabilities (value: probability):" << endl;
    vector<double> p = distr.probabilities();
    int counter = 0;
    for (const auto& n : p) {
        cout << fixed << setw(11) << counter << ": " << setw(14) << setprecision(10) << n << endl;
        ++counter;
    }
    cout << endl;

    // generate the distribution as a histogram
    map<int, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    cout << "Distribution for " << s << " samples:" << endl;
    for (const auto& elem : histogram) {
        cout << setw(5) << elem.first << ' ' << string(elem.second, ':') << endl;
    }
    cout << endl;
}

int main()
{
    int samples = 100;

    cout << "Use CTRL-Z to bypass data entry and run using default values." << endl;
    cout << "Enter an integer value for the sample count: ";
    cin >> samples;

    test(samples);
}

```

Use CTRL-Z to bypass data entry and run using default values.

Enter an integer value for the sample count: 100

min() == 0

max() == 4

probabilities (value: probability):

0:	0.0666666667
1:	0.1333333333
2:	0.2000000000
3:	0.2666666667
4:	0.3333333333

Distribution for 100 samples:

0	:::
1	::::::::::::::
2	::::::::::::::
3	::::::::::::::::::::::
4	::::::::::::::::::::::

Requirements

Header: <random>

Namespace: std

discrete_distribution::discrete_distribution

Constructs the distribution.

```
// default constructor
discrete_distribution();

// construct using a range of weights, [firstW, lastW)
template <class InputIterator>
discrete_distribution(InputIterator firstW, InputIterator lastW);

// construct using an initializer list for range of weights
discrete_distribution(initializer_list<double> weightlist);

// construct using unary operation function
template <class UnaryOperation>
discrete_distribution(size_t count, double low, double high, UnaryOperation weightfunc);

// construct from an existing param_type structure
explicit discrete_distribution(const param_type& parm);
```

Parameters

firstW

The first iterator in the list from which to construct the distribution.

lastW

The last iterator in the list from which to construct the distribution (non-inclusive because iterators use an empty element for the end).

weightlist

The [initializer_list](#) from which to construct the distribution.

count

The number of elements in the distribution range. If `count==0`, equivalent to the default constructor (always generates zero).

low

The lowest value in the distribution range.

high

The highest value in the distribution range.

weightfunc

The object representing the probability function for the distribution. Both the parameter and the return value must be convertible to **double**.

parm

The `param_type` structure used to construct the distribution.

Remarks

The default constructor constructs an object whose stored probability value has one element with value 1. This will result in a distribution that always generates a zero.

The iterator range constructor that has parameters *firstW* and *lastW* constructs a distribution object by using weight values taken from the iterators over the interval sequence [*firstW*, *lastW*).

The initializer list constructor that has a *weightlist* parameter constructs a distribution object with weights from the initializer list *weightlist*.

The constructor that has *count*, *low*, *high*, and *weightfunc* parameters constructs a distribution object initialized based on these rules:

- If *count* < 1, **n** = 1, and as such is equivalent to the default constructor, always generating zero.
- If *count* > 0, **n** = *count*. Provided **d** = (*high* - *low*) / **n** is greater than zero, using **d** uniform subranges, each weight is assigned as follows: `weight[k] = weightfunc(x)`, where **x** = *low* + **k** * **d** + **d** / 2, for **k** = 0, ..., **n** - 1.

The constructor that has a `param_type` parameter *parm* constructs a distribution object using *parm* as the stored parameter structure.

discrete_distribution::param_type

Stores all the parameters of the distribution.

```
struct param_type {
    typedef discrete_distribution<result_type> distribution_type;
    param_type();

    // construct using a range of weights, [firstW, lastW)
    template <class InputIterator>
    param_type(InputIterator firstW, InputIterator lastW);

    // construct using an initializer list for range of weights
    param_type(initializer_list<double> weightlist);

    // construct using unary operation function
    template <class UnaryOperation>
    param_type(size_t count, double low, double high, UnaryOperation weightfunc);

    std::vector<double> probabilities() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

firstW

The first iterator in the list from which to construct the distribution.

lastW

The last iterator in the list from which to construct the distribution (non-inclusive because iterators use an empty element for the end).

weightlist

The [initializer_list](#) from which to construct the distribution.

count

The number of elements in the distribution range. If *count* is 0, this is equivalent to the default constructor (always generates zero).

low

The lowest value in the distribution range.

high

The highest value in the distribution range.

weightfunc

The object representing the probability function for the distribution. Both the parameter and the return value must be convertible to **double**.

right

The `param_type` object to compare to this.

Remarks

This parameter package can be passed to `operator()` to generate the return value.

[<random>](#)

exponential_distribution Class

11/9/2018 • 3 minutes to read • [Edit Online](#)

Generates an exponential distribution.

Syntax

```
template<class RealType = double>
class exponential_distribution
{
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructors and reset functions
    explicit exponential_distribution(result_type lambda = 1.0);
    explicit exponential_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type lambda() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

URNG

The random number generator engine. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified integral type, or type **double** if none is provided, distributed according to the Exponential Distribution. The following table links to articles about individual members.

exponential_distribution	<code>exponential_distribution::lambda</code>	<code>exponential_distribution::param</code>
<code>exponential_distribution::operator()</code>		param_type

The property member function `lambda()` returns the value for the stored distribution parameter `lambda`.

The property member function `param()` sets or returns the `param_type` stored distribution parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the exponential distribution, see the Wolfram MathWorld article [Exponential Distribution](#).

Example

```
// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double l, const int s) {

    // uncomment to use a non-deterministic generator
    // std::random_device gen;
    std::mt19937 gen(1701);

    std::exponential_distribution<> distr(l);

    std::cout << std::endl;
    std::cout << "min() == " << distr.min() << std::endl;
    std::cout << "max() == " << distr.max() << std::endl;
    std::cout << "lambda() == " << std::fixed << std::setw(11) << distr.lambda() <<
    std::endl;

    // generate the distribution as a histogram
    std::map<double, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Distribution for " << s << " samples:" << std::endl;
    int counter = 0;
    for (const auto& elem : histogram) {
        std::cout << std::fixed << std::setw(11) << ++counter << ": "
            << std::setw(14) << std::setprecision(10) << elem.first << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    double l_dist = 0.5;
    int samples = 10;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter a floating point value for the 'lambda' distribution parameter (must be greater than
zero): ";
    std::cin >> l_dist;
    std::cout << "Enter an integer value for the sample count: ";
    std::cin >> samples;

    test(l_dist, samples);
}
```

```
Use CTRL-Z to bypass data entry and run using default values.  
Enter a floating point value for the 'lambda' distribution parameter (must be greater than zero): 1  
Enter an integer value for the sample count: 10
```

```
min() == 0  
max() == 1.79769e+308  
lambda() == 1.0000000000  
Distribution for 10 samples:  
1: 0.0936880533  
2: 0.1225944894  
3: 0.6443593183  
4: 0.6551171649  
5: 0.7313457551  
6: 0.7313557977  
7: 0.7590097389  
8: 1.4466885214  
9: 1.6434088411  
10: 2.1201210996
```

Requirements

Header: <random>

Namespace: std

exponential_distribution::exponential_distribution

Constructs the distribution.

```
explicit exponential_distribution(result_type lambda = 1.0);  
explicit exponential_distribution(const param_type& parm);
```

Parameters

lambda

The `lambda` distribution parameter.

parm

The parameter package used to construct the distribution.

Remarks

Precondition: `0.0 < lambda`

The first constructor constructs an object whose stored `lambda` value holds the value *lambda*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

exponential_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type {
    typedef exponential_distribution<result_type> distribution_type;
    param_type(result_type lambda = 1.0);
    result_type lambda() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

lambda

The `lambda` distribution parameter.

right

The `param_type` object to compare to this.

Remarks

Precondition: `0.0 < lambda`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

extreme_value_distribution Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Generates an extreme value distribution.

Syntax

```
template<class RealType = double>
class extreme_value_distribution
{
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructor and reset functions
    explicit extreme_value_distribution(result_type a = 0.0, result_type b = 1.0);
    explicit extreme_value_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type a() const;
    result_type b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

URNG

The random number generator engine. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified floating-point type, or type **double** if none is provided, distributed according to the Extreme Value Distribution. The following table links to articles about individual members.

extreme_value_distribution	<code>extreme_value_distribution::a</code>	<code>extreme_value_distribution::param</code>
<code>extreme_value_distribution::operator()</code>	<code>extreme_value_distribution::b</code>	param_type

The property functions `a()` and `b()` return their respective values for stored distribution parameters `a` and `b`.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the extreme value distribution, see the Wolfram MathWorld article [Extreme Value Distribution](#).

Example

```
// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double a, const double b, const int s) {

    // uncomment to use a non-deterministic generator
    // std::random_device gen;

    std::mt19937 gen(1701);

10: 2.0568757061
```

Requirements

Header: <random>

Namespace: std

extreme_value_distribution::extreme_value_distribution

Constructs the distribution.

```
explicit extreme_value_distribution(result_type a_value = 0.0, result_type b_value = 1.0);
explicit extreme_value_distribution(const param_type& parm);
```

Parameters

a_value

The `a` distribution parameter.

b_value

The `b` distribution parameter.

parm

The `param_type` structure used to construct the distribution.

Remarks

Precondition: $0.0 < b$

The first constructor constructs an object whose stored `a` value holds the value *a_value* and whose stored `b` value holds the value *b_value*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

extreme_value_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type {
    typedef extreme_value_distribution<result_type> distribution_type;
    param_type(result_type a_value = 0.0, result_type b_value = 1.0);
    result_type a() const;
    result_type b() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

a_value

The `a` distribution parameter.

b_value

The `b` distribution parameter.

right

The `param_type` object to compare to this.

Remarks

Precondition: `0.0 < b`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

fisher_f_distribution Class

11/9/2018 • 4 minutes to read • [Edit Online](#)

Generates a Fisher F distribution.

Syntax

```
template<class RealType = double>
class fisher_f_distribution
{
public:
    // types
    typedef RealType result_type;
    struct param_type; // constructor and reset functions
    explicit fisher_f_distribution(result_type m = 1.0, result_type n = 1.0);
    explicit fisher_f_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type m() const;
    result_type n() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

URNG

The uniform random number generator engine. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified floating-point type, or type **double** if none is provided, distributed according to the Fisher's F-Distribution. The following table links to articles about individual members.

fisher_f_distribution	<code>fisher_f_distribution::m</code>	<code>fisher_f_distribution::param</code>
<code>fisher_f_distribution::operator()</code>	<code>fisher_f_distribution::n</code>	param_type

The property functions `m()` and `n()` return the values for the stored distribution parameters `m` and `n` respectively.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the F-distribution, see the Wolfram MathWorld article [F-Distribution](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double m, const double n, const int s) {

    // uncomment to use a non-deterministic seed
    // std::random_device rd;
    // std::mt19937 gen(rd());
    std::mt19937 gen(1701);

    std::fisher_f_distribution<> distr(m, n);

    std::cout << std::endl;
    std::cout << "min() == " << distr.min() << std::endl;
    std::cout << "max() == " << distr.max() << std::endl;
    std::cout << "m() == " << std::fixed << std::setw(11) << std::setprecision(10) << distr.m() << std::endl;
    std::cout << "n() == " << std::fixed << std::setw(11) << std::setprecision(10) << distr.n() << std::endl;

    // generate the distribution as a histogram
    std::map<double, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Distribution for " << s << " samples:" << std::endl;
    int counter = 0;
    for (const auto& elem : histogram) {
        std::cout << std::fixed << std::setw(11) << ++counter << ": "
            << std::setw(14) << std::setprecision(10) << elem.first << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    double m_dist = 1;
    double n_dist = 1;
    int samples = 10;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter a floating point value for the \'m\' distribution parameter (must be greater than
zero): ";
    std::cin >> m_dist;
    std::cout << "Enter a floating point value for the \'n\' distribution parameter (must be greater than
zero): ";
    std::cin >> n_dist;
    std::cout << "Enter an integer value for the sample count: ";
    std::cin >> samples;

    test(m_dist, n_dist, samples);
}

```

Output

First run:

```
Enter a floating point value for the 'm' distribution parameter (must be greater than zero): 1
Enter a floating point value for the 'n' distribution parameter (must be greater than zero): 1
Enter an integer value for the sample count: 10
```

```
min() == 0
max() == 1.79769e+308

Requirements

Header: <random>

Namespace: std

fisher_f_distribution::fisher_f_distribution

Constructs the distribution.

```
explicit fisher_f_distribution(result_type m = 1.0, result_type n = 1.0);
explicit fisher_f_distribution(const param_type& parm);
```

Parameters

m

The `m` distribution parameter.

n

The `n` distribution parameter.

parm

The `param_type` structure used to construct the distribution.

Remarks

Precondition: $0.0 < m$ and $0.0 < n$

The first constructor constructs an object whose stored `m` value holds the value *m* and whose stored `n` value holds the value *n*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

fisher_f_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type {
    typedef fisher_f_distribution<result_type> distribution_type;
    param_type(result_type m = 1.0, result_type n = 1.0);
    result_type m() const;
    result_type n() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

m

The `m` distribution parameter.

n

The `n` distribution parameter.

right

The `param_type` object to compare to this.

Remarks

Precondition: $0.0 < m$ and $0.0 < n$

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

gamma_distribution Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

Generates a gamma distribution.

Syntax

```
template<class RealType = double>
class gamma_distribution {
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructors and reset functions
    explicit gamma_distribution(result_type alpha = 1.0, result_type beta = 1.0);
    explicit gamma_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type alpha() const;
    result_type beta() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

URNG

The uniform random number generator engine. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified floating-point type, or type **double** if none is provided, distributed according to the Gamma Distribution. The following table links to articles about individual members.

gamma_distribution	<code>gamma_distribution::alpha</code>	<code>gamma_distribution::param</code>
<code>gamma_distribution::operator()</code>	<code>gamma_distribution::beta</code>	param_type

The property functions `alpha()` and `beta()` return their respective values for stored distribution parameters *alpha* and *beta*.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the gamma distribution, see the Wolfram MathWorld article [Gamma Distribution](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double a, const double b, const int s) {

    // uncomment to use a non-deterministic generator
    // std::random_device gen;

    std::mt19937 gen(1701);

    std::gamma_distribution<> distr(a, b);

    std::cout << std::endl;
    std::cout << "min() == " << distr.min() << std::endl;
    std::cout << "max() == " << distr.max() << std::endl;
    std::cout << "alpha() == " << std::fixed << std::setw(11) << distr.alpha() <<
std::endl;
    std::cout << "beta() == " << std::fixed << std::setw(11) << distr.beta() <<
std::endl;

    // generate the distribution as a histogram
    std::map<double, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Distribution for " << s << " samples:" << std::endl;
    int counter = 0;
    for (const auto& elem : histogram) {
        std::cout << std::fixed << std::setw(11) << ++counter << ": "
            << std::setw(14) << std::setprecision(10) << elem.first << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    double a_dist = 0.0;
    double b_dist = 1;

    int samples = 10;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter a floating point value for the 'alpha' distribution parameter (must be greater than
zero): ";
    std::cin >> a_dist;
    std::cout << "Enter a floating point value for the 'beta' distribution parameter (must be greater than
zero): ";
    std::cin >> b_dist;
    std::cout << "Enter an integer value for the sample count: ";
    std::cin >> samples;

    test(a_dist, b_dist, samples);
}

```

Use CTRL-Z to bypass data entry and run using default values.

Enter a floating point value for the 'alpha' distribution parameter (must be greater than zero): 1

Enter a floating point value for the 'beta' distribution parameter (must be greater than zero): 1

Enter an integer value for the sample count: 10

```
min() == 4.94066e-324

```

```
10: 2.1201210996
```

Requirements

Header: <random>

Namespace: std

gamma_distribution::gamma_distribution

Constructs the distribution.

```
explicit gamma_distribution(result_type alpha = 1.0, result_type beta = 1.0);
explicit gamma_distribution(const param_type& parm);
```

Parameters

alpha

The `alpha` distribution parameter.

beta

The `beta` distribution parameter.

parm

The parameter structure used to construct the distribution.

Remarks

Precondition: `0.0 < alpha` and `0.0 < beta`

The first constructor constructs an object whose stored `alpha` value holds the value *alpha* and whose stored `beta` value holds the value *beta*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

gamma_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type {
    typedef gamma_distribution<result_type> distribution_type;
    param_type(result_type alpha = 1.0, result_type beta 1.0);
    result_type alpha() const;
    result_type beta() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

alpha

The `alpha` distribution parameter.

beta

The `beta` distribution parameter.

right

The `param_type` instance to compare this to.

Remarks

Precondition: `0.0 < alpha` and `0.0 < beta`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

geometric_distribution Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Generates a geometric distribution.

Syntax

```
template<class IntType = int>
class geometric_distribution {
public:
    // types
    typedef IntType result_type;
    struct param_type;

    // constructors and reset functions
    explicit geometric_distribution(double p = 0.5);
    explicit geometric_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    double p() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

IntType

The integer result type, defaults to **int**. For possible types, see [<random>](#).

URNG

The uniform random number generator engine. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified integral type with a geometric distribution. The following table links to articles about individual members.

geometric_distribution	<code>geometric_distribution::p</code>	<code>geometric_distribution::param</code>
<code>geometric_distribution::operator()</code>		param_type

The property function `p()` returns the value for stored distribution parameter `p`.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the chi-squared distribution, see the Wolfram MathWorld article [Geometric Distribution](#).

Example

```
// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double p, const int s) {

    // uncomment to use a non-deterministic generator
    // std::random_device gen;
    std::mt19937 gen(1701);

    std::geometric_distribution<> distr(p);

    std::cout << std::endl;
    std::cout << "min() == " << distr.min() << std::endl;
    std::cout << "max() == " << distr.max() << std::endl;
    std::cout << "p() == " << std::fixed << std::setw(11) << std::setprecision(10) << distr.p() << std::endl;

    // generate the distribution as a histogram
    std::map<int, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Distribution for " << s << " samples:" << std::endl;
    for (const auto& elem : histogram) {
        std::cout << std::setw(5) << elem.first << ' ' << std::string(elem.second, ':') << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    double p_dist = 0.5;

    int samples = 100;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter a floating point value for the \'p\' distribution parameter: ";
    std::cin >> p_dist;
    std::cout << "Enter an integer value for the sample count: ";
    std::cin >> samples;

    test(p_dist, samples);
}
```

First test:

```
Use CTRL-Z to bypass data entry and run using default values.  
Enter a floating point value for the 'p' distribution parameter: .5  
Enter an integer value for the sample count: 100
```

```

Requirements

Header: <random>

Namespace: std

geometric_distribution::geometric_distribution

Constructs the distribution.

```
explicit geometric_distribution(double p = 0.5);
explicit geometric_distribution(const param_type& parm);
```

Parameters

p

The `p` distribution parameter.

parm

The parameter structure used to construct the distribution.

Remarks

Precondition: `0.0 < p && p < 1.0`

The first constructor constructs an object whose stored `p` value holds the value *p*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

geometric_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type {
    typedef geometric_distribution<result_type> distribution_type;
    param_type(double p = 0.5);
    double p() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

p

The `p` distribution parameter.

right

The `param_type` instance to compare this to.

Remarks

Precondition: `0.0 < p && p < 1.0`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

See also

[<random>](#)

independent_bits_engine Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Generates a random sequence of numbers with a specified number of bits by repacking bits from the values returned by its base engine.

Syntax

```
template <class Engine, size_t W, class UIntType>
class independent_bits_engine;
```

Parameters

Engine

The base engine type.

W

Word size. Size, in bits, of each number generated. **Precondition:** $0 < W \leq \text{numeric_limits}<\text{UIntType}>::\text{digits}$

UIntType

The unsigned integer result type. For possible types, see [<random>](#).

Members

<code>independent_bits_engine::independent_b</code>	<code>independent_bits_engine::base</code>	<code>independent_bits_engine::discard</code>
<code>independent_bits_engine::operator()</code>	<code>independent_bits_engine::base_type</code>	<code>independent_bits_engine::seed</code>

For more information about engine members, see [<random>](#).

Remarks

This template class describes an *engine adaptor* that produces values by repacking bits from the values returned by its base engine, resulting in *W*-bit values.

Requirements

linear_congruential_engine Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Generates a random sequence by the linear congruential algorithm.

Syntax

```
class linear_congruential_engine{
public: // types
typedef UIntType result_type;
// engine characteristics
static constexpr result_type multiplier = a;
static constexpr result_type increment = c;
static constexpr result_type modulus = m;
static constexpr result_type min() { return c == 0u ? 0u : 0u; }
static constexpr result_type max() { return m - 1u; }
static constexpr result_type default_seed = 1u;
// constructors and seeding functions
explicit linear_congruential_engine(result_type s = default_seed);
template <class Sseq>
explicit linear_congruential_engine(Sseq& q);
void seed(result_type s = default_seed);
template <class Sseq>
void seed(Sseq& q);
// generating functions
result_type operator()();
void discard(unsigned long long z);
};
```

Parameters

UIntType

The unsigned integer result type. For possible types, see [<random>](#).

A

Multiplier. Precondition: See Remarks section.

C

Increment. Precondition: See Remarks section.

M

Modulus. Precondition: See remarks.

Members

<code>linear_congruential_engine::linear_con</code>	<code>linear_congruential_engine::min</code>	<code>linear_congruential_engine::discard</code>
<code>linear_congruential_engine::operator()</code>	<code>linear_congruential_engine::max</code>	<code>linear_congruential_engine::seed</code>

`default_seed` is a member constant, defined as `1u`, used as the default parameter value for `linear_congruential_engine::seed` and the single value constructor.

For more information about engine members, see [<random>](#).

Remarks

The `linear_congruential_engine` template class is the simplest generator engine, but not the fastest or highest quality. An improvement over this engine is the [subtract_with_carry_engine](#). Neither of these engines is as fast or with as high quality results as the [mersenne_twister_engine](#).

This engine produces values of a user-specified unsigned integral type using the recurrence relation (*period*)

```
x(i) = (A * x(i-1) + C) mod M.
```

If M is zero, the value used for this modulus operation is `numeric_limits<result_type>::max() + 1`. The engine's state is the last value returned, or the seed value if no call has been made to `operator()`.

If M is not zero, the values of the template arguments A and C must be less than M .

Although you can construct a generator from this engine directly, you can also use one of these predefined typedefs.

`minstd_rand0`: 1988 minimal standard engine (Lewis, Goodman, and Miller, 1969).

```
typedef linear_congruential_engine<unsigned int, 16807, 0, 2147483647> minstd_rand0;
```

`minstd_rand`: Updated minimal standard engine `minstd_rand0` (Park, Miller, and Stockmeyer, 1993).

```
typedef linear_congruential_engine<unsigned int, 48271, 0, 2147483647> minstd_rand;
```

For detailed information about the linear congruential engine algorithm, see the Wikipedia article [Linear congruential generator](#).

Requirements

Header: `<random>`

Namespace: `std`

[<random>](#)

lognormal_distribution Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

Generates a log normal distribution.

Syntax

```
template <class RealType = double>
class lognormal_distribution
{
public:
    // types
    typedef RealType result_type;
    struct param_type;
    // constructor and reset functions
    explicit lognormal_distribution(result_type m = 0.0, result_type s = 1.0);
    explicit lognormal_distribution(const param_type& parm);
    void reset();
    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);
    // property functions
    result_type m() const;
    result_type s() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified integral type, or type **double** if none is provided, distributed according to the Log Normal Distribution. The following table links to articles about individual members.

lognormal_distribution	<code>lognormal_distribution::m</code>	<code>lognormal_distribution::param</code>
<code>lognormal_distribution::operator()</code>	<code>lognormal_distribution::s</code>	param_type

The property functions `m()` and `s()` return the values for the stored distribution parameters *m* and *s*, respectively.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the LogNormal distribution, see the Wolfram MathWorld article [LogNormal Distribution](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

using namespace std;

void test(const double m, const double s, const int samples) {

    // uncomment to use a non-deterministic seed
    // random_device gen;
    // mt19937 gen(rd());
    mt19937 gen(1701);

    lognormal_distribution<> distr(m, s);

    cout << endl;
    cout << "min() == " << distr.min() << endl;
    cout << "max() == " << distr.max() << endl;
    cout << "m() == " << fixed << setw(11) << setprecision(10) << distr.m() << endl;
    cout << "s() == " << fixed << setw(11) << setprecision(10) << distr.s() << endl;

    // generate the distribution as a histogram
    map<double, int> histogram;
    for (int i = 0; i < samples; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    cout << "Distribution for " << samples << " samples:" << endl;
    int counter = 0;
    for (const auto& elem : histogram) {
        cout << fixed << setw(11) << ++counter << ": "
            << setw(14) << setprecision(10) << elem.first << endl;
    }
    cout << endl;
}

int main()
{
    double m_dist = 1;
    double s_dist = 1;
    int samples = 10;

    cout << "Use CTRL-Z to bypass data entry and run using default values." << endl;
    cout << "Enter a floating point value for the 'm' distribution parameter: ";
    cin >> m_dist;
    cout << "Enter a floating point value for the 's' distribution parameter (must be greater than zero): ";
    cin >> s_dist;
    cout << "Enter an integer value for the sample count: ";
    cin >> samples;

    test(m_dist, s_dist, samples);
}

```

```
Use CTRL-Z to bypass data entry and run using default values.
Enter a floating point value for the 'm' distribution parameter: 0
Enter a floating point value for the 's' distribution parameter (must be greater than zero): 1
Enter an integer value for the sample count: 10
```

```
min() == -1.79769e+308
max() == 1.79769e+308
m() == 0.0000000000
s() == 1.0000000000
Distribution for 10 samples:
 1: 0.3862809339
 2: 0.4128865601
 3: 0.4490576787
 4: 0.4862035428
 5: 0.5930607126
 6: 0.8190778771
 7: 0.8902379317
 8: 2.8332911667
 9: 5.1359445565
10: 5.4406507912
```

Requirements

Header: <random>

Namespace: std

lognormal_distribution::lognormal_distribution

Constructs the distribution.

```
explicit lognormal_distribution(RealType m = 0.0, RealType s = 1.0);
explicit lognormal_distribution(const param_type& parm);
```

Parameters

m

The `m` distribution parameter.

s

The `s` distribution parameter.

parm

The `param_type` structure used to construct the distribution.

Remarks

Precondition: $0.0 < s$

The first constructor constructs an object whose stored `m` value holds the value *m* and whose stored `s` value holds the value *s*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

lognormal_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type {
    typedef lognormal_distribution<result_type> distribution_type;
    param_type(result_type m = 0.0, result_type s = 1.0);
    result_type m() const;
    result_type s() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

m

The `m` distribution parameter.

s

The `s` distribution parameter.

right

The `param_type` structure used to compare.

Remarks

Precondition: `0.0 < s`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

[<random>](#)

mersenne_twister_engine Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Generates a high quality random sequence of integers based on the Mersenne twister algorithm.

Syntax

```
template <class UIntType,
    size_t W, size_t N, size_t M, size_t R,
    UIntType A, size_t U, UIntType D, size_t S,
    UIntType B, size_t T, UIntType C, size_t L, UIntType F>
class mersenne_twister_engine;
```

Parameters

UIntType

The unsigned integer result type. For possible types, see [<random>](#).

W

Word size. Size of each word, in bits, of the state sequence. **Precondition:**

$2u < W \leq \text{numeric_limits}<\text{UIntType}>::\text{digits}$

N

State size. The number of elements (values) in the state sequence.

M

Shift size. The number of elements to skip during each twist. **Precondition:** $0 < M \leq N$

R

Mask bits. Precondition: $R \leq W$

A

XOR mask. Precondition: $A \leq (1u << W) - 1u$

U, S, T, L

Tempering shift parameters. Used as shift values during scrambling (tempering). Precondition: $U, S, T, L \leq W$

D, B, C

Tempering bit mask parameters. Used as bit mask values during scrambling (tempering). Precondition:

$D, B, C \leq (1u << W) - 1u$

F

Initialization multiplier. Used to help with initialization of the sequence. Precondition: $F \leq (1u << W) - 1u$

Members

<code>mersenne_twister_engine::mersenne_twis</code>	<code>mersenne_twister_engine::min</code>	<code>mersenne_twister_engine::discard</code>
<code>mersenne_twister_engine::operator()</code>	<code>mersenne_twister_engine::max</code>	<code>mersenne_twister_engine::seed</code>

`default_seed` is a member constant, defined as `5489u`, used as the default parameter value for

`mersenne_twister_engine::seed` and the single value constructor.

For more information about engine members, see [<random>](#).

Remarks

This template class describes a random number engine, returning values on the closed interval $[0, 2^W - 1]$. It holds a large integral value with $W * (N - 1) + R$ bits. It extracts W bits at a time from this large value, and when it has used all the bits it twists the large value by shifting and mixing the bits so that it has a new set of bits to extract from. The engine's state is the last N W -bit values used if `operator()` has been called at least N times, otherwise the M W -bit values that have been used and the last $N - M$ values of the seed.

The generator twists the large value that it holds by using a twisted generalized feedback shift register defined by shift values N and M , a twist value R , and a conditional XOR-mask A . Additionally, the bits of the raw shift register are scrambled (tempered) according to a bit-scrambling matrix defined by values U, D, S, B, T, C , and L .

The template argument `UIntType` must be large enough to hold values up to $2^W - 1$. The values of the other template arguments must satisfy the following requirements:

```
2u < W, 0 < M, M ≤ N, R ≤ W, U ≤ W, S ≤ W, T ≤ W, L ≤ W, W ≤ numeric_limits<UIntType>::digits, A ≤ (1u<<W) - 1u, B ≤ (1u<<W) - 1u, C ≤ (1u<<W) - 1u, D ≤ (1u<<W) - 1u, and F ≤ (1u<<W) - 1u
```

.

Although you can construct a generator from this engine directly, it is recommended you use one of these predefined typedefs:

`mt19937`: 32-bit Mersenne twister engine (Matsumoto and Nishimura, 1998).

```
typedef mersenne_twister_engine<unsigned int, 32, 624, 397,
    31, 0x9908b0df,
    11, 0xffffffff,
    7, 0x9d2c5680,
    15, 0xefc60000,
    18, 1812433253> mt19937;
```

`mt19937_64`: 64-bit Mersenne twister engine (Matsumoto and Nishimura, 2000).

```
typedef mersenne_twister_engine<unsigned long long, 64, 312, 156,
    31, 0xb5026f5aa96619e9ULL,
    29, 0x5555555555555555ULL,
    17, 0x71d67fffed60000ULL,
    37, 0xfff7eee000000000ULL,
    43, 6364136223846793005ULL> mt19937_64;
```

For detailed information about the Mersenne twister algorithm, see the Wikipedia article [Mersenne twister](#).

Example

For a code example, see [<random>](#).

negative_binomial_distribution Class

11/9/2018 • 4 minutes to read • [Edit Online](#)

Generates a negative binomial distribution.

Syntax

```
template<class IntType = int>
class negative_binomial_distribution
{
public:
    // types
    typedef IntType result_type;
    struct param_type;

    // constructor and reset functions
    explicit negative_binomial_distribution(result_type k = 1, double p = 0.5);
    explicit negative_binomial_distribution(const param_type& parm);
    void reset();

    // generating functions
    template `<`class URNG>
    result_type operator()(URNG& gen);
    template `<`class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type k() const;
    double p() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

IntType

The integer result type, defaults to **int**. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified integral type, or type **int** if none is provided, distributed according to the Negative Binomial Distribution discrete probability function. The following table links to articles about individual members.

negative_binomial_distribution	<code>negative_binomial_distribution::k</code>	<code>negative_binomial_distribution::param</code>
<code>negative_binomial_distribution::operator</code>	<code>negative_binomial_distribution::p</code>	param_type

The property members `k()` and `p()` return the currently stored distribution parameter values *k* and *p* respectively.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the negative binomial distribution discrete probability function, see the Wolfram MathWorld article [Negative Binomial Distribution](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const int k, const double p, const int& s) {

    // uncomment to use a non-deterministic seed
    // std::random_device rd;
    // std::mt19937 gen(rd());
    std::mt19937 gen(1729);

    std::negative_binomial_distribution<> distr(k, p);

    std::cout << std::endl;
    std::cout << "k == " << distr.k() << std::endl;
    std::cout << "p == " << distr.p() << std::endl;

    // generate the distribution as a histogram
    std::map<int, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Histogram for " << s << " samples:" << std::endl;
    for (const auto& elem : histogram) {
        std::cout << std::setw(5) << elem.first << ' ' << std::string(elem.second, ':') << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    int k_dist = 1;
    double p_dist = 0.5;
    int samples = 100;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter an integer value for k distribution (where 0 < k): ";
    std::cin >> k_dist;
    std::cout << "Enter a double value for p distribution (where 0.0 < p <= 1.0): ";
    std::cin >> p_dist;
    std::cout << "Enter an integer value for a sample count: ";
    std::cin >> samples;

    test(k_dist, p_dist, samples);
}

```

First run:

```
Use CTRL-Z to bypass data entry and run using default values.
Enter an integer value for k distribution (where 0 <= k): 1
Enter a double value for p distribution (where 0.0 <= p <= 1.0): .5
Enter an integer value for a sample count: 100
```

```

Requirements

Header: <random>

Namespace: std

negative_binomial_distribution::negative_binomial_distribution

Constructs the distribution.

```
explicit negative_binomial_distribution(result_type k = 1, double p = 0.5);
explicit negative_binomial_distribution(const param_type& parm);
```

Parameters

k

The `k` distribution parameter.

p

The `p` distribution parameter.

parm

The parameter structure used to construct the distribution.

Remarks

Precondition: $0.0 < k$ and $0.0 < p \leq 1.0$

The first constructor constructs an object whose stored `p` value holds the value p and whose stored `k` value holds the value k .

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

negative_binomial_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type { typedef negative_binomial_distribution< result_type> distribution_type;
param_type(result_type k = 1, double p = 0.5); result_type k() const; double p() const;

bool operator==(const param_type& right) const; bool operator!=(const param_type& right) const; };
```

Parameters

k

The `k` distribution parameter.

p

The `p` distribution parameter.

right

The `param_type` structure used to compare.

Remarks

Precondition: $0.0 < k$ and $0.0 < p \leq 1.0$

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

[<random>](#)

normal_distribution Class

3/11/2019 • 4 minutes to read • [Edit Online](#)

Generates a normal distribution.

Syntax

```
template<class RealType = double>
class normal_distribution
{
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructors and reset functions
    explicit normal_distribution(result_type mean = 0.0, result_type stddev = 1.0);
    explicit normal_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type mean() const;
    result_type stddev() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified integral type, or type **double** if none is provided, distributed according to the Normal Distribution. The following table links to articles about individual members.

normal_distribution	<code>normal_distribution::mean</code>	<code>normal_distribution::param</code>
<code>normal_distribution::operator()</code>	<code>normal_distribution::stddev</code>	param_type

The property functions `mean()` and `stddev()` return the values for the stored distribution parameters *mean* and *stddev* respectively.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the Normal distribution, see the Wolfram MathWorld article [Normal Distribution](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

using namespace std;

void test(const double m, const double s, const int samples) {

    // uncomment to use a non-deterministic seed
    // random_device gen;
    // mt19937 gen(rd());
    mt19937 gen(1701);

    normal_distribution<> distr(m, s);

    cout << endl;
    cout << "min() == " << distr.min() << endl;
    cout << "max() == " << distr.max() << endl;
    cout << "m() == " << fixed << setw(11) << setprecision(10) << distr.mean() << endl;
    cout << "s() == " << fixed << setw(11) << setprecision(10) << distr.stddev() << endl;

    // generate the distribution as a histogram
    map<double, int> histogram;
    for (int i = 0; i < samples; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    cout << "Distribution for " << samples << " samples:" << endl;
    int counter = 0;
    for (const auto& elem : histogram) {
        cout << fixed << setw(11) << ++counter << ": "
            << setw(14) << setprecision(10) << elem.first << endl;
    }
    cout << endl;
}

int main()
{
    double m_dist = 1;
    double s_dist = 1;
    int samples = 10;

    cout << "Use CTRL-Z to bypass data entry and run using default values." << endl;
    cout << "Enter a floating point value for the 'mean' distribution parameter: ";
    cin >> m_dist;
    cout << "Enter a floating point value for the 'stddev' distribution parameter (must be greater than zero): ";
    cin >> s_dist;
    cout << "Enter an integer value for the sample count: ";
    cin >> samples;

    test(m_dist, s_dist, samples);
}

```

```
Use CTRL-Z to bypass data entry and run using default values.
Enter a floating point value for the 'mean' distribution parameter: 0
Enter a floating point value for the 'stddev' distribution parameter (must be greater than zero): 1
Enter an integer value for the sample count: 10
```

```
min() == -1.79769e+308
max() == 1.79769e+308

```

Requirements

Header: <random>

Namespace: std

normal_distribution::normal_distribution

Constructs the distribution.

```
explicit normal_distribution(result_type mean = 0.0, result_type stddev = 1.0);
explicit normal_distribution(const param_type& parm);
```

Parameters

mean

The `mean` distribution parameter.

stddev

The `stddev` distribution parameter.

parm

The parameter structure used to construct the distribution.

Remarks

Precondition: `0.0 < stddev`

The first constructor constructs an object whose stored `mean` value holds the value *mean* and whose stored `stddev` value holds the value *stddev*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

normal_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type {
    typedef normal_distribution<result_type> distribution_type;
    param_type(result_type mean = 0.0, result_type stddev = 1.0);
    result_type mean() const;
    result_type stddev() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

mean

The `mean` distribution parameter.

stddev

The `stddev` distribution parameter.

right

The `param_type` structure used to compare.

Remarks

Precondition: `0.0 < stddev`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

piecewise_constant_distribution Class

11/15/2018 • 5 minutes to read • [Edit Online](#)

Generates a piecewise constant distribution that has varying-width intervals with uniform probability in each interval.

Syntax

```
template<class RealType = double>
class piecewise_constant_distribution
{
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructor and reset functions
    piecewise_constant_distribution();
    template <class InputIteratorI, class InputIteratorW>
    piecewise_constant_distribution(
        InputIteratorI firstI, InputIteratorI lastI, InputIteratorW firstW);
    template <class UnaryOperation>
    piecewise_constant_distribution(
        initializer_list<result_type> intervals, UnaryOperation weightfunc);
    template <class UnaryOperation>
    piecewise_constant_distribution(
        size_t count, result_type xmin, result_type xmax, UnaryOperation weightfunc);
    explicit piecewise_constant_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    vector<result_type> intervals() const;
    vector<result_type> densities() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating point result type, defaults to **double**. For possible types, see [<random>](#).

Remarks

This sampling distribution has varying-width intervals with uniform probability in each interval. For information about other sampling distributions, see [piecewise_linear_distribution Class](#) and [discrete_distribution](#).

The following table links to articles about individual members:

<code>piecewise_constant_distribution</code>	<code>piecewise_constant_distribution::inter</code>	<code>piecewise_constant_distribution::param</code>
<code>piecewise_constant_distribution::opera</code>	<code>piecewise_constant_distribution::densi</code>	<code>param_type</code>

The property function `intervals()` returns a `vector<result_type>` with the set of stored intervals of the distribution.

The property function `densities()` returns a `vector<result_type>` with the stored densities for each interval set, which are calculated according to the weights provided in the constructor parameters.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

Example

```
// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

using namespace std;

void test(const int s) {

    // uncomment to use a non-deterministic generator
    // random_device rd;
    // mt19937 gen(rd());
    mt19937 gen(1701);

    // Three intervals, non-uniform: 0 to 1, 1 to 6, and 6 to 15
    vector<double> intervals{ 0, 1, 6, 15 };
    // weights determine the densities used by the distribution
    vector<double> weights{ 1, 5, 10 };

    piecewise_constant_distribution<double> distr(intervals.begin(), intervals.end(), weights.begin());

    cout << endl;
    cout << "min() == " << distr.min() << endl;
    cout << "max() == " << distr.max() << endl;
    cout << "intervals (index: interval):" << endl;
    vector<double> i = distr.intervals();
    int counter = 0;
    for (const auto& n : i) {
        cout << fixed << setw(11) << counter << ": " << setw(14) << setprecision(10) << n << endl;
        ++counter;
    }
    cout << endl;
    cout << "densities (index: density):" << endl;
    vector<double> d = distr.densities();
```

```

counter = 0;
for (const auto& n : d) {
    cout << fixed << setw(11) << counter << ": " << setw(14) << setprecision(10) << n << endl;
    ++counter;
}
cout << endl;

// generate the distribution as a histogram
map<int, int> histogram;
for (int i = 0; i < s; ++i) {
    ++histogram[distr(gen)];
}

// print results
cout << "Distribution for " << s << " samples:" << endl;
for (const auto& elem : histogram) {
    cout << setw(5) << elem.first << '-' << elem.first+1 << ' ' << string(elem.second, ':') << endl;
}
cout << endl;
}

int main()
{
    int samples = 100;

    cout << "Use CTRL-Z to bypass data entry and run using default values." << endl;
    cout << "Enter an integer value for the sample count: ";
    cin >> samples;

    test(samples);
}

```

Use CTRL-Z to bypass data entry and run using default values.

Enter an integer value for the sample count: 100

min() == 0

max() == 15

intervals (index: interval):

piecewise_constant_distribution::piecewise_constant_distribution

Constructs the distribution.

```
// default constructor
piecewise_constant_distribution();

// constructs using a range of intervals, [firstI, lastI), with
// matching weights starting at firstW
template <class InputIteratorI, class InputIteratorW>
piecewise_constant_distribution(InputIteratorI firstI, InputIteratorI lastI, InputIteratorW firstW);

// constructs using an initializer list for range of intervals,
// with weights generated by function weightfunc
template <class UnaryOperation>
piecewise_constant_distribution(initializer_list<RealType>
intervals, UnaryOperation weightfunc);

// constructs using an initializer list for range of count intervals,
// distributed uniformly over [xmin,xmax] with weights generated by function weightfunc
template <class UnaryOperation>
piecewise_constant_distribution(size_t count, RealType xmin, RealType xmax, UnaryOperation weightfunc);

// constructs from an existing param_type structure
explicit piecewise_constant_distribution(const param_type& parm);
```

Parameters

firstI

An input iterator of the first element in the distribution range.

lastI

An input iterator of the last element in the distribution range.

firstW

An input iterator of the first element in the weights range.

intervals

An [initializer_list](#) with the intervals of the distribution.

count

The number of elements in the distribution range.

xmin

The lowest value in the distribution range.

xmax

The highest value in the distribution range. Must be greater than *xmin*.

weightfunc

The object representing the probability function for the distribution. Both the parameter and the return value must be convertible to **double**.

parm

The parameter structure used to construct the distribution.

Remarks

The default constructor sets the stored parameters such that there is one interval, 0 to 1, with a probability density of 1.

The iterator range constructor

```
template <class InputIteratorI, class InputIteratorW>
piecewise_constant_distribution(InputIteratorI firstI, InputIteratorI lastI,
                               InputIteratorW firstW);
```

constructs a distribution object with intervals from iterators over the sequence [`firstI`, `lastI`) and a matching weight sequence starting at `firstW`.

The initializer list constructor

```
template <class UnaryOperation>
piecewise_constant_distribution(initializer_list<result_type>
                               intervals,
                               UnaryOperation weightfunc);
```

constructs a distribution object with intervals from the initializer list *intervals* and weights generated from the function *weightfunc*.

The constructor defined as

```
template <class UnaryOperation>
piecewise_constant_distribution(size_t count, result_type xmin, result_type xmax,
                               UnaryOperation weightfunc);
```

constructs a distribution object with *count* intervals distributed uniformly over [`xmin`, `xmax`], assigning each interval weights according to the function *weightfunc*, and *weightfunc* must accept one parameter and have a return value, both of which are convertible to `double`. **Precondition:** `xmin < xmax`

The constructor defined as

```
explicit piecewise_constant_distribution(const param_type& parm);
```

constructs a distribution object using *parm* as the stored parameter structure.

piecewise_constant_distribution::param_type

Stores all the parameters of the distribution.

```
struct param_type {
    typedef piecewise_constant_distribution<result_type> distribution_type;
    param_type();
    template <class IterI, class IterW>
    param_type(IterI firstI, IterI lastI, IterW firstW);
    template <class UnaryOperation>
    param_type(size_t count, result_type xmin, result_type xmax, UnaryOperation weightfunc);
    std::vector<result_type> densities() const;
    std::vector<result_type> intervals() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

See the constructor parameters for the [piecewise_constant_distribution](#).

Remarks

Precondition: `xmin < xmax`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

[piecewise_linear_distribution](#)

piecewise_linear_distribution Class

11/15/2018 • 5 minutes to read • [Edit Online](#)

Generates a piecewise linear distribution that has varying-width intervals with linearly varying probability in each interval.

Syntax

```
template<class RealType = double>
class piecewise_linear_distribution
{
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructor and reset functions
    piecewise_linear_distribution();
    template <class InputIteratorI, class InputIteratorW>
    piecewise_linear_distribution(
        InputIteratorI firstI, InputIteratorI lastI, InputIteratorW firstW);
    template <class UnaryOperation>
    piecewise_linear_distribution(
        initializer_list<result_type> intervals, UnaryOperation weightfunc);
    template <class UnaryOperation>
    piecewise_linear_distribution(
        size_t count, result_type xmin, result_type xmax, UnaryOperation weightfunc);
    explicit piecewise_linear_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    vector<result_type> intervals() const;
    vector<result_type> densities() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating point result type, defaults to **double**. For possible types, see [<random>](#).

Remarks

This sampling distribution has varying-width intervals with linearly varying probability in each interval. For information about other sampling distributions, see [piecewise_linear_distribution](#) and [discrete_distribution](#).

The following table links to articles about individual members:

piecewise_linear_distribution	piecewise_linear_distribution::interval	piecewise_linear_distribution::param
piecewise_linear_distribution::operator	piecewise_linear_distribution::densities	param_type

The property function `intervals()` returns a `vector<result_type>` with the set of stored intervals of the distribution.

The property function `densities()` returns a `vector<result_type>` with the stored densities for each interval set, which are calculated according to the weights provided in the constructor parameters.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

Example

```
// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

using namespace std;

void test(const int s) {

    // uncomment to use a non-deterministic generator
    // random_device rd;
    // mt19937 gen(rd());
    mt19937 gen(1701);

    // Three intervals, non-uniform: 0 to 1, 1 to 6, and 6 to 15
    vector<double> intervals{ 0, 1, 6, 15 };
    // weights determine the densities used by the distribution
    vector<double> weights{ 1, 5, 5, 10 };

    piecewise_linear_distribution<double> distr(intervals.begin(), intervals.end(), weights.begin());

    cout << endl;
    cout << "min() == " << distr.min() << endl;
    cout << "max() == " << distr.max() << endl;
    cout << "intervals (index: interval):" << endl;
    vector<double> i = distr.intervals();
    int counter = 0;
    for (const auto& n : i) {
        cout << fixed << setw(11) << counter << ": " << setw(14) << setprecision(10) << n << endl;
        ++counter;
    }
    cout << endl;
    cout << "densities (index: density):" << endl;
    vector<double> d = distr.densities();
```

```

counter = 0;
for (const auto& n : d) {
    cout << fixed << setw(11) << counter << ": " << setw(14) << setprecision(10) << n << endl;
    ++counter;
}
cout << endl;

// generate the distribution as a histogram
map<int, int> histogram;
for (int i = 0; i < s; ++i) {
    ++histogram[distr(gen)];
}

// print results
cout << "Distribution for " << s << " samples:" << endl;
for (const auto& elem : histogram) {
    cout << setw(5) << elem.first << '-' << elem.first + 1 << ' ' << string(elem.second, ':') << endl;
}
cout << endl;
}

int main()
{
    int samples = 100;

    cout << "Use CTRL-Z to bypass data entry and run using default values." << endl;
    cout << "Enter an integer value for the sample count: ";
    cin >> samples;

    test(samples);
}

```

Use CTRL-Z to bypass data entry and run using default values.

Enter an integer value for the sample count: 100

min() == 0

max() == 15

piecewise_linear_distribution::piecewise_linear_distribution

Constructs the distribution.

```
// default constructor
piecewise_linear_distribution();

// constructs using a range of intervals, [firstI, lastI), with
// matching weights starting at firstW
template <class InputIteratorI, class InputIteratorW>
piecewise_linear_distribution(InputIteratorI firstI, InputIteratorI lastI, InputIteratorW firstW);

// constructs using an initializer list for range of intervals,
// with weights generated by function weightfunc
template <class UnaryOperation>
piecewise_linear_distribution(initializer_list<RealType>
intervals, UnaryOperation weightfunc);

// constructs using an initializer list for range of count intervals,
// distributed uniformly over [xmin,xmax] with weights generated by function weightfunc
template <class UnaryOperation>
piecewise_linear_distribution(size_t count, RealType xmin, RealType xmax, UnaryOperation weightfunc);

// constructs from an existing param_type structure
explicit piecewise_linear_distribution(const param_type& parm);
```

Parameters

firstI

An input iterator of the first element in the distribution range.

lastI

An input iterator of the last element in the distribution range.

firstW

An input iterator of the first element in the weights range.

intervals

An [initializer_list](#) with the intervals of the distribution.

count

The number of elements in the distribution range.

xmin

The lowest value in the distribution range.

xmax

The highest value in the distribution range. Must be greater than *xmin*.

weightfunc

The object representing the probability function for the distribution. Both the parameter and the return value must be convertible to **double**.

parm

The parameter structure used to construct the distribution.

Remarks

The default constructor sets the stored parameters such that there is one interval, 0 to 1, with a probability density of 1.

The iterator range constructor

```
template <class InputIteratorI, class InputIteratorW>
piecewise_linear_distribution(
    InputIteratorI firstI,
    InputIteratorI lastI,
    InputIteratorW firstW);
```

constructs a distribution object with intervals from iterators over the sequence [`firstI` , `lastI`) and a matching weight sequence starting at *firstW*.

The initializer list constructor

```
template <class UnaryOperation>
piecewise_linear_distribution(
    initializer_list<result_type> intervals,
    UnaryOperation weightfunc);
```

constructs a distribution object with intervals from the initializer list *intervals* and weights generated from the function *weightfunc*.

The constructor defined as

```
template <class UnaryOperation>
piecewise_linear_distribution(
    size_t count,
    result_type xmin,
    result_type xmax,
    UnaryOperation weightfunc);
```

constructs a distribution object with *count* intervals distributed uniformly over [`xmin`, `xmax`], assigning each interval weights according to the function *weightfunc*, and *weightfunc* must accept one parameter and have a return value, both of which are convertible to `double`. **Precondition:** `xmin < xmax`.

The constructor defined as

```
explicit piecewise_linear_distribution(const param_type& parm);
```

constructs a distribution object using *parm* as the stored parameter structure.

piecewise_linear_distribution::param_type

Stores all the parameters of the distribution.

```

struct param_type {
    typedef piecewise_linear_distribution<result_type> distribution_type;
    param_type();
    template <class IterI, class IterW>
    param_type(
        IterI firstI, IterI lastI, IterW firstW);
    template <class UnaryOperation>
    param_type(
        size_t count, result_type xmin, result_type xmax, UnaryOperation weightfunc);
    std::vector<result_type> densities() const;
    std::vector<result_type> intervals() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};

```

Parameters

See constructor parameters for [piecewise_linear_distribution](#).

Remarks

Precondition: `xmin < xmax`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

[<random>](#)

poisson_distribution Class

11/9/2018 • 3 minutes to read • [Edit Online](#)

Generates a Poisson distribution.

Syntax

```
template<class IntType = int>
class poisson_distribution
{
public:
    // types
    typedef IntType result_type;
    struct param_type;

    // constructors and reset functions
    explicit poisson_distribution(double mean = 1.0);
    explicit poisson_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    double mean() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

IntType

The integer result type, defaults to **int**. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified integral type with a Poisson distribution. The following table links to articles about individual members.

poisson_distribution	<code>poisson_distribution::mean</code>	<code>poisson_distribution::param</code>
<code>poisson_distribution::operator()</code>		param_type

The property function `mean()` returns the value for stored distribution parameter *mean*.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the Poisson distribution, see the Wolfram MathWorld article [Poisson Distribution](#).

Example

```
// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double p, const int s) {

    // uncomment to use a non-deterministic generator
    // std::random_device gen;
    std::mt19937 gen(1701);

    std::poisson_distribution<> distr(p);

    std::cout << std::endl;
    std::cout << "min() == " << distr.min() << std::endl;
    std::cout << "max() == " << distr.max() << std::endl;
    std::cout << "p() == " << std::fixed << std::setw(11) << std::setprecision(10) << distr.mean() <<
    std::endl;

    // generate the distribution as a histogram
    std::map<int, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Distribution for " << s << " samples:" << std::endl;
    for (const auto& elem : histogram) {
        std::cout << std::setw(5) << elem.first << ' ' << std::string(elem.second, ':') << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    double p_dist = 1.0;

    int samples = 100;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter a floating point value for the 'mean' distribution parameter (must be greater than
zero): ";
    std::cin >> p_dist;
    std::cout << "Enter an integer value for the sample count: ";
    std::cin >> samples;

    test(p_dist, samples);
}
```

First test:

```

Use CTRL-Z to bypass data entry and run using default values.
Enter a floating point value for the 'mean' distribution parameter (must be greater than zero): 1
Enter an integer value for the sample count: 100
min() == 0
max() == 2147483647
p() == 1.0000000000
Distribution for 100 samples:
 0 ::::::::::::::::::::::::::::
 1 ::::::::::::::::::::::::::::::
 2 ::::::::::::::::::::::::::::
 3 ::::::::::
 5 :

```

Second test:

```

Use CTRL-Z to bypass data entry and run using default values.
Enter a floating point value for the 'mean' distribution parameter (must be greater than zero): 10
Enter an integer value for the sample count: 100
min() == 0
max() == 2147483647
p() == 10.0000000000
Distribution for 100 samples:
 3 :
 4 ::
 5 ::
 6 ::::::::::
 7 ::::
 8 ::::::::::
 9 ::::::::::::::
10 ::::::::::::::
11 ::::::::::::::

13 ::::::::::
14 ::::::
15 :
16 ::
17 :

```

Requirements

Header: <random>

Namespace: std

poisson_distribution::poisson_distribution

Constructs the distribution.

```

explicit poisson_distribution(RealType mean = 1.0);
explicit binomial_distribution(const param_type& parm);

```

Parameters

mean

The `mean` distribution parameter.

parm

The parameter structure used to construct the distribution.

Remarks

Precondition: `0.0 < mean`

The first constructor constructs an object whose stored `mean` value holds the value *mean*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

poisson_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type {
    typedef poisson_distribution<IntType> distribution_type;
    param_type(double mean = 1.0);
    double mean() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

See constructor parameters for [poisson_distribution](#).

Remarks

Precondition: `0.0 < mean`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

[<random>](#)

random_device Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Generates a random sequence from an external device.

Syntax

```
class random_device {
public:
    typedef unsigned int result_type;

    // constructor
    explicit random_device(const std::string& token = "");

    // properties
    static result_type min();
    static result_type max();
    double entropy() const;

    // generate
    result_type operator()();

    // no-copy functions
    random_device(const random_device&) = delete;
    void operator=(const random_device&) = delete;
};
```

Members

random_device	entropy
random_device::operator()	

Remarks

The class describes a source of random numbers, and is allowed but not required to be non-deterministic or cryptographically secure by the ISO C++ Standard. In the Visual Studio implementation the values produced are non-deterministic and cryptographically secure, but runs more slowly than generators created from engines and engine adaptors (such as [mersenne_twister_engine](#), the high quality and fast engine of choice for most applications).

`random_device` results are uniformly distributed in the closed range [`0`, `232`).

`random_device` is not guaranteed to result in a non-blocking call.

Generally, `random_device` is used to seed other generators created with engines or engine adaptors. For more information, see [<random>](#).

Example

The following code demonstrates basic functionality of this class and example results. Because of the non-

deterministic nature of `random_device`, the random values shown in the **Output** section will not match your results. This is normal and expected.

```
// random_device_engine.cpp
// cl.exe /W4 /nologo /EHsc /MTd
#include <random>
#include <iostream>
using namespace std;

int main()
{
    random_device gen;

    cout << "entropy == " << gen.entropy() << endl;
    cout << "min == " << gen.min() << endl;
    cout << "max == " << gen.max() << endl;

    cout << "a random value == " << gen() << endl;
    cout << "a random value == " << gen() << endl;
    cout << "a random value == " << gen() << endl;
}
```

```
entropy == 32
min == 0
max == 4294967295
a random value == 2378414971
a random value == 3633694716
a random value == 213725214
```

This example is simplistic and not representative of the general use-case for this generator. For a more representative code example, see [<random>](#).

Requirements

Header: `<random>`

Namespace: `std`

`random_device::random_device`

Constructs the generator.

```
random_device(const std::string& = "");
```

Remarks

The constructor initializes the generator as needed, ignoring the string parameter. Throws a value of an implementation-defined type derived from [exception](#) if the `random_device` could not be initialized.

`random_device::entropy`

Estimates the randomness of the source.

```
double entropy() const noexcept;
```

Remarks

The member function returns an estimate of the randomness of the source, as measured in bits.

random_device::operator()

Returns a random value.

```
result_type operator()();
```

Remarks

Returns values uniformly distributed in the closed interval [`min`, `max`] as determined by member functions `min()` and `max()`. Throws a value of an implementation-defined type derived from [exception](#) if a random number could not be obtained.

[<random>](#)

seed_seq Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Stores a vector of unsigned integer values that can supply a randomized seed for a random-number engine.

Syntax

```
class seed_seq
{
public:
    // types
    typedef unsigned int result_type;

    // constructors
    seed_seq();
    template <class T>
        seed_seq(initializer_list<T> initlist);
    template <class InputIterator>
        seed_seq(InputIterator begin, InputIterator end);

    // generating functions
    template <class RandomAccessIterator>
        void generate(RandomAccessIterator begin, RandomAccessIterator end);

    // property functions
    size_t size() const;
    template <class OutputIterator>
        void param(OutputIterator dest) const;

    // no copy functions
    seed_seq(const seed_seq&) = delete;
    void operator=(const seed_seq&) = delete;
};
```

Types

```
typedef unsigned int result_type;
```

The type of the elements of the seed sequence. A 32-bit unsigned integer type.

Constructors

```
seed_seq();
```

Default constructor, initializes to have an empty internal sequence.

```
template<class T>
seed_seq(initializer_list<T> initlist);
```

Uses `initlist` to set the internal sequence. `T` must be an integer type.

```
template<class InputIterator>
seed_seq(InputIterator begin, InputIterator end);
```

Initializes the internal sequence using all elements in the input iterator range provided.

`iterator_traits<InputIterator>::value_type` must be an integer type.

Members

Generating Functions

```
template<class RandomAccessIterator>
void generate(RandomAccessIterator begin,
             RandomAccessIterator end);
```

Populates the elements of the provided sequence using an internal algorithm. This algorithm is affected by the internal sequence with which `seed_seq` was initialized. Does nothing if `begin == end`.

Property Functions

```
size_t size() const;
```

Returns the number of elements in the `seed_seq`.

```
template<class OutputIterator>
void param(OutputIterator dest) const;
```

Copies the internal sequence into the output iterator `dest`.

Example

The following code example exercises the three constructors and generates output from the resulting `seed_seq` instances when assigned to an array. For an example that uses `seed_seq` with a random number generator, see [<random>](#).

```

#include <iostream>
#include <random>
#include <string>
#include <array>

using namespace std;

void test(const seed_seq& sseq) {
    cout << endl << "seed_seq::size(): " << sseq.size() << endl;

    cout << "seed_seq::param(): ";
    ostream_iterator<unsigned int> out(cout, " ");
    sseq.param(out);
    cout << endl;

    cout << "Generating a sequence of 5 elements into an array: " << endl;
    array<unsigned int, 5> seq;
    sseq.generate(seq.begin(), seq.end());
    for (unsigned x : seq) { cout << x << endl; }
}

int main()
{
    seed_seq seed1;
    test(seed1);

    seed_seq seed2 = { 1701, 1729, 1791 };
    test(seed2);

    string sstr = "A B C D"; // seed string
    seed_seq seed3(sstr.begin(), sstr.end());
    test(seed3);
}

```

```

seed_seq::size(): 0
seed_seq::param():
Generating a sequence of 5 elements into an array:
505382999
163489202
3932644188
763126080
73937346

seed_seq::size(): 3
seed_seq::param(): 1701 1729 1791
Generating a sequence of 5 elements into an array:
1730669648
1954224479
2809786021
1172893117
2393473414

seed_seq::size(): 7
seed_seq::param(): 65 32 66 32 67 32 68
Generating a sequence of 5 elements into an array:
3139879222
3775111734
1084804564
2485037668
1985355432

```

Remarks

Member functions of this class do not throw exceptions.

Requirements

Header: <random>

Namespace: std

See also

[<random>](#)

shuffle_order_engine Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Generates a random sequence by reordering the values returned from its base engine.

Syntax

```
template <class Engine, size_t K>
class shuffle_order_engine;
```

Parameters

Engine

The base engine type.

K

Table size. Number of elements in the buffer (table). **Precondition:** $0 < K$

Members

<code>shuffle_order_engine::shuffle_order_engine</code>	<code>shuffle_order_engine::base</code>	<code>shuffle_order_engine::discard</code>
<code>shuffle_order_engine::operator()</code>	<code>shuffle_order_engine::base_type</code>	<code>shuffle_order_engine::seed</code>

For more information about engine members, see [<random>](#).

Remarks

This template class describes an *engine adaptor* that produces values by reordering the values returned by its base engine. Each constructor fills the internal table with *K* values returned by the base engine, and a random element is selected from the table when a value is requested.

Requirements

Header: `<random>`

Namespace: `std`

[<random>](#)

student_t_distribution Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Generates a Student's t -distribution.

Syntax

```
template<class RealType = double>
class student_t_distribution {
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructor and reset functions
    explicit student_t_distribution(result_type n = 1.0);
    explicit student_t_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
    result_type operator()(URNG& gen);
    template <class URNG>
    result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type n() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified integral type, or type **double** if none is provided, distributed according to the Student's t -Distribution. The following table links to articles about individual members.

student_t_distribution	<code>student_t_distribution::n</code>	<code>student_t_distribution::param</code>
<code>student_t_distribution::operator()</code>		param_type

The property function `n()` returns the value for the stored distribution parameter `n`.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the Student's t -distribution, see the Wolfram MathWorld article [Students \$t\$ -Distribution](#).

Example

```
// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double n, const int s) {

    // uncomment to use a non-deterministic generator
    // std::random_device gen;
    std::mt19937 gen(1701);

    std::student_t_distribution<> distr(n);

    std::cout << std::endl;
    std::cout << "min() == " << distr.min() << std::endl;
    std::cout << "max() == " << distr.max() << std::endl;
    std::cout << "n() == " << std::fixed << std::setw(11) << std::setprecision(10) << distr.n() << std::endl;

    // generate the distribution as a histogram
    std::map<double, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Distribution for " << s << " samples:" << std::endl;
    int counter = 0;
    for (const auto& elem : histogram) {
        std::cout << std::fixed << std::setw(11) << ++counter << ": "
            << std::setw(14) << std::setprecision(10) << elem.first << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    double n_dist = 0.5;
    int samples = 10;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter a floating point value for the 'n' distribution parameter (must be greater than zero): ";
    std::cin >> n_dist;
    std::cout << "Enter an integer value for the sample count: ";
    std::cin >> samples;

    test(n_dist, samples);
}
```

```
Use CTRL-Z to bypass data entry and run using default values.  
Enter a floating point value for the 'n' distribution parameter (must be greater than zero): 1  
Enter an integer value for the sample count: 10
```

```
min() == -1.79769e+308  
max() == 1.79769e+308  
n() == 1.0000000000  
Distribution for 10 samples:  
1: -1.3084956212  
2: -1.0899518684  
3: -0.9568771388  
4: -0.9372088821  
5: -0.7381334669  
6: -0.2488074854  
7: -0.2028714601  
8: 1.4013074495  
9: 5.3244792236  
10: 92.7084335614
```

Requirements

Header: <random>

Namespace: std

student_t_distribution::student_t_distribution

Constructs the distribution.

```
explicit student_t_distribution(RealType n = 1.0);  
explicit student_t_distribution(const param_type& parm);
```

Parameters

n

The `n` distribution parameter.

parm

The parameter package used to construct the distribution.

Remarks

Precondition: $0.0 < n$

The first constructor constructs an object whose stored `n` value holds the value *n*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

student_t_distribution::param_type

Stores all the parameters of the distribution.

```
struct param_type {
    typedef student_t_distribution<result_type> distribution_type;
    param_type(result_type n = 1.0);
    result_type n() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

n

The `n` distribution parameter.

right

The `param_type` object to compare to this.

Remarks

Precondition: `0.0 < n`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

See also

[<random>](#)

subtract_with_carry_engine Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Generates a random sequence by the subtract-with-carry (lagged Fibonacci) algorithm.

Syntax

```
template <class UIntType, size_t W, size_t S, size_t R>
class subtract_with_carry_engine;
```

Parameters

UIntType

The unsigned integer result type. For possible types, see [<random>](#).

W

Word size. Size of each word, in bits, of the state sequence. **Precondition:**

$0 < W \leq \text{numeric_limits}\langle \text{UIntType} \rangle::\text{digits}$

S

Short lag. Number of integer values. **Precondition:** $0 < S < R$

R

Long lag. Determines recurrence in the series generated.

Members

<code>subtract_with_carry_engine::subtract_w</code>	<code>subtract_with_carry_engine::min</code>	<code>subtract_with_carry_engine::discard</code>
<code>subtract_with_carry_engine::operator()</code>	<code>subtract_with_carry_engine::max</code>	<code>subtract_with_carry_engine::seed</code>
<code>default_seed</code> is a member constant, defined as <code>19780503u</code> , used as the default parameter value for <code>subtract_with_carry_engine::seed</code> and the single value constructor.		

For more information about engine members, see [<random>](#).

Remarks

The `subtract_with_carry_engine` template class is an improvement over the [linear_congruential_engine](#). Neither for these engines is as fast or with as high quality results as the [mersenne_twister_engine](#).

This engine produces values of a user-specified unsigned integral type using the recurrence relation (*period*)

$x(i) = (x(i - R) - x(i - S) - cy(i - 1)) \bmod M$, where `cy(i)` has the value `1` if $x(i - S) - x(i - R) - cy(i - 1) < 0$, otherwise `0`, and `M` has the value 2^W . The engine's state is a carry indicator plus *R* values. These values consist of the last *R* values returned if `operator()` has been called at least *R* times, otherwise the `N` values that have been returned and the last `R - N` values of the seed.

The template argument `UIntType` must be large enough to hold values up to `M - 1`.

Although you can construct a generator from this engine directly, you can also use one of these predefined typedefs:

`ranlux24_base` : Used as a base for `ranlux24` .

```
typedef subtract_with_carry_engine<unsigned int, 24, 10, 24> ranlux24_base;
```

`ranlux48_base` : Used as a base for `ranlux48` .

```
typedef subtract_with_carry_engine<unsigned long long, 48, 5, 12> ranlux48_base;
```

For detailed information about the subtract with carry engine algorithm, see the Wikipedia article [Lagged Fibonacci generator](#).

Requirements

Header: `<random>`

Namespace: `std`

[<random>](#)

uniform_int_distribution Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Generates a uniform (every value is equally probable) integer distribution within an output range that is inclusive-inclusive.

Syntax

```
template<class IntType = int>
    class uniform_int_distribution {
public:
    // types
    typedef IntType result_type;
    struct param_type;

    // constructors and reset functions
    explicit uniform_int_distribution(
        result_type a = 0, result_type b = numeric_limits<result_type>::max());
    explicit uniform_int_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
        result_type operator()(URNG& gen);
    template <class URNG>
        result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type a() const;
    result_type b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

IntType

The integer result type, defaults to **int**. For possible types, see [<random>](#).

Remarks

The template class describes an inclusive-inclusive distribution that produces values of a user-specified integral type with a distribution so that every value is equally probable. The following table links to articles about individual members.

uniform_int_distribution	<code>uniform_int_distribution::a</code>	<code>uniform_int_distribution::param</code>
<code>uniform_int_distribution::operator()</code>	<code>uniform_int_distribution::b</code>	param_type

The property member `a()` returns the currently stored minimum bound of the distribution, while `b()` returns the currently stored maximum bound. For this distribution class, these minimum and maximum values are the same as those returned by the common property functions `min()` and `max()`.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const int a, const int b, const int s) {

    // uncomment to use a non-deterministic seed
    // std::random_device rd;
    // std::mt19937 gen(rd());
    std::mt19937 gen(1729);

    std::uniform_int_distribution<> distr(a, b);

    std::cout << "lower bound == " << distr.a() << std::endl;
    std::cout << "upper bound == " << distr.b() << std::endl;

    // generate the distribution as a histogram
    std::map<int, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Distribution for " << s << " samples:" << std::endl;
    for (const auto& elem : histogram) {
        std::cout << std::setw(5) << elem.first << ' ' << std::string(elem.second, ':') << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    int a_dist = 1;
    int b_dist = 10;

    int samples = 100;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter an integer value for the lower bound of the distribution: ";
    std::cin >> a_dist;
    std::cout << "Enter an integer value for the upper bound of the distribution: ";
    std::cin >> b_dist;
    std::cout << "Enter an integer value for the sample count: ";
    std::cin >> samples;

    test(a_dist, b_dist, samples);
}

```

```
Use CTRL-Z to bypass data entry and run using default values.
Enter an integer value for the lower bound of the distribution: 0
Enter an integer value for the upper bound of the distribution: 12
Enter an integer value for the sample count: 200
lower bound == 0
upper bound == 12
Distribution for 200 samples:
 0 :::::::::::::::
 1 :::::::::::::::
 2 :::::::::::::::
 3 :::::::::::::::
 4 :::::::::::::::
 5 :::::::::::::::
 6 :::::::::::::::
 7 :::::::::::::::
 8 :::::::::::::::
 9 :::::::::::::::
10 :::::::::::::::
11 :::::::::::::::
12 :::::::::::::::
```

Requirements

Header: <random>

Namespace: std

uniform_int_distribution::uniform_int_distribution

Constructs the distribution.

```
explicit uniform_int_distribution(
    result_type a = 0, result_type b = std::numeric_limits<result_type>::max());
explicit uniform_int_distribution(const param_type& parm);
```

Parameters

a

The lower bound for random values, inclusive.

b

The upper bound for random values, inclusive.

parm

The `param_type` structure used to construct the distribution.

Remarks

Precondition: $a \leq b$

The first constructor constructs an object whose stored *a* value holds the value *a* and whose stored *b* value holds the value *b*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

uniform_int_distribution::param_type

Stores the parameters of the distribution.

```

struct param_type {
    typedef uniform_int_distribution<result_type> distribution_type;
    param_type(
        result_type a = 0, result_type b = std::numeric_limits<result_type>::max());
    result_type a() const;
    result_type b() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};

```

Parameters

a

The lower bound for random values, inclusive.

b

The upper bound for random values, inclusive.

right

The `param_type` object to compare to this.

Remarks

Precondition: `a ≤ b`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

uniform_real_distribution Class

11/9/2018 • 4 minutes to read • [Edit Online](#)

Generates a uniform (every value is equally probable) floating-point distribution within an output range that is inclusive-exclusive.

Syntax

```
template<class RealType = double>
    class uniform_real_distribution {
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructors and reset functions
    explicit uniform_real_distribution(
        result_type a = 0.0, result_type b = 1.0);
    explicit uniform_real_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
        result_type operator()(URNG& gen);
    template <class URNG>
        result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type a() const;
    result_type b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

Remarks

The template class describes an inclusive-exclusive distribution that produces values of a user-specified integral floating point type with a distribution so that every value is equally probable. The following table links to articles about individual members.

uniform_real_distribution	<code>uniform_real_distribution::a</code>	<code>uniform_real_distribution::param</code>
<code>uniform_real_distribution::operator()</code>	<code>uniform_real_distribution::b</code>	param_type

The property member `a()` returns the currently stored minimum bound of the distribution, while `b()` returns the currently stored maximum bound. For this distribution class, these minimum and maximum values are the same as those returned by the common property functions `min()` and `max()` described in the [<random>](#) topic.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result, respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double a, const double b, const int s) {

    // uncomment to use a non-deterministic seed
    // std::random_device rd;
    // std::mt19937 gen(rd());
    std::mt19937 gen(1729);

    std::uniform_real_distribution<> distr(a,b);

    std::cout << "lower bound == " << distr.a() << std::endl;
    std::cout << "upper bound == " << distr.b() << std::endl;

    // generate the distribution as a histogram
    std::map<double, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Distribution for " << s << " samples:" << std::endl;
    int counter = 0;
    for (const auto& elem : histogram) {
        std::cout << std::fixed << std::setw(11) << ++counter << ": "
            << std::setprecision(10) << elem.first << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    double a_dist = 1.0;
    double b_dist = 1.5;

    int samples = 10;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter a floating point value for the lower bound of the distribution: ";
    std::cin >> a_dist;
    std::cout << "Enter a floating point value for the upper bound of the distribution: ";
    std::cin >> b_dist;
    std::cout << "Enter an integer value for the sample count: ";
    std::cin >> samples;

    test(a_dist, b_dist, samples);
}

```

```
Use CTRL-Z to bypass data entry and run using default values.
Enter a floating point value for the lower bound of the distribution: 0
Enter a floating point value for the upper bound of the distribution: 1
Enter an integer value for the sample count: 10
lower bound == 0
upper bound == 1
Distribution for 10 samples:
  1: 0.0288609485
  2: 0.2007994386
  3: 0.3027480117
  4: 0.4124758695
  5: 0.4413777133
  6: 0.4846447405
  7: 0.6225745916
  8: 0.6880935217
  9: 0.7541936723
 10: 0.8795716566
```

Requirements

Header: <random>

Namespace: std

uniform_real_distribution::uniform_real_distribution

Constructs the distribution.

```
explicit uniform_real_distribution(result_type a = 0.0, result_type b = 1.0);
explicit uniform_real_distribution(const param_type& parm);
```

Parameters

a

The lower bound for random values, inclusive.

b

The upper bound for random values, exclusive.

parm

The `param_type` structure used to construct the distribution.

Remarks

Precondition: `a < b`

The first constructor constructs an object whose stored *a* value holds the value *a* and whose stored *b* value holds the value *b*.

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

uniform_real_distribution::param_type

Stores all the parameters of the distribution.

```
struct param_type {
    typedef uniform_real_distribution<result_type> distribution_type;
    param_type(result_type a = 0.0, result_type b = 1.0);
    result_type a() const;
    result_type b() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

a

The lower bound for random values, inclusive.

b

The upper bound for random values, exclusive.

right

The `param_type` object to compare to this.

Remarks

Precondition: `a < b`

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

weibull_distribution Class

11/9/2018 • 4 minutes to read • [Edit Online](#)

Generates a Weibull distribution.

Syntax

```
class weibull_distribution
{
public:
    // types
    typedef RealType result_type;
    struct param_type;

    // constructor and reset functions
    explicit weibull_distribution(result_type a = 1.0, result_type b = 1.0);
    explicit weibull_distribution(const param_type& parm);
    void reset();

    // generating functions
    template <class URNG>
        result_type operator()(URNG& gen);
    template <class URNG>
        result_type operator()(URNG& gen, const param_type& parm);

    // property functions
    result_type a() const;
    result_type b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Parameters

RealType

The floating-point result type, defaults to **double**. For possible types, see [<random>](#).

Remarks

The template class describes a distribution that produces values of a user-specified floating point type, or type **double** if none is provided, distributed according to the Weibull Distribution. The following table links to articles about individual members.

weibull_distribution	<code>weibull_distribution::a</code>	<code>weibull_distribution::param</code>
<code>weibull_distribution::operator()</code>	<code>weibull_distribution::b</code>	param_type

The property functions `a()` and `b()` return their respective values for stored distribution parameters *a* and *b*.

The property member `param()` sets or returns the `param_type` stored distribution parameter package.

The `min()` and `max()` member functions return the smallest possible result and largest possible result,

respectively.

The `reset()` member function discards any cached values, so that the result of the next call to `operator()` does not depend on any values obtained from the engine before the call.

The `operator()` member functions return the next generated value based on the URNG engine, either from the current parameter package, or the specified parameter package.

For more information about distribution classes and their members, see [<random>](#).

For detailed information about the Weibull distribution, see the Wolfram MathWorld article [Weibull Distribution](#).

Example

```

// compile with: /EHsc /W4
#include <random>
#include <iostream>
#include <iomanip>
#include <string>
#include <map>

void test(const double a, const double b, const int s) {

    // uncomment to use a non-deterministic generator
    // std::random_device gen;
    std::mt19937 gen(1701);

    std::weibull_distribution<> distr(a, b);

    std::cout << std::endl;
    std::cout << "min() == " << distr.min() << std::endl;
    std::cout << "max() == " << distr.max() << std::endl;
    std::cout << "a() == " << std::fixed << std::setw(11) << std::setprecision(10) << distr.a() << std::endl;
    std::cout << "b() == " << std::fixed << std::setw(11) << std::setprecision(10) << distr.b() << std::endl;

    // generate the distribution as a histogram
    std::map<double, int> histogram;
    for (int i = 0; i < s; ++i) {
        ++histogram[distr(gen)];
    }

    // print results
    std::cout << "Distribution for " << s << " samples:" << std::endl;
    int counter = 0;
    for (const auto& elem : histogram) {
        std::cout << std::fixed << std::setw(11) << ++counter << ": "
            << std::setw(14) << std::setprecision(10) << elem.first << std::endl;
    }
    std::cout << std::endl;
}

int main()
{
    double a_dist = 0.0;
    double b_dist = 1;

    int samples = 10;

    std::cout << "Use CTRL-Z to bypass data entry and run using default values." << std::endl;
    std::cout << "Enter a floating point value for the 'a' distribution parameter (must be greater than zero):";
    std::cin >> a_dist;
    std::cout << "Enter a floating point value for the 'b' distribution parameter (must be greater than zero):";
    std::cin >> b_dist;
    std::cout << "Enter an integer value for the sample count: ";
    std::cin >> samples;

    test(a_dist, b_dist, samples);
}

```

Output

First run:

```
Use CTRL-Z to bypass data entry and run using default values.
Enter a floating point value for the 'a' distribution parameter (must be greater than zero): 1
Enter a floating point value for the 'b' distribution parameter (must be greater than zero): 1
Enter an integer value for the sample count: 10
```

```
min() == 0
max() == 1.79769e+308
a() == 1.0000000000
b() == 1.0000000000
Distribution for 10 samples:
1: 0.0936880533
2: 0.1225944894
3: 0.6443593183
4: 0.6551171649
5: 0.7313457551
6: 0.7313557977
7: 0.7590097389
8: 1.4466885214
9: 1.6434088411
10: 2.1201210996
```

Second run:

```
Use CTRL-Z to bypass data entry and run using default values.
Enter a floating point value for the 'a' distribution parameter (must be greater than zero): .5
Enter a floating point value for the 'b' distribution parameter (must be greater than zero): 5.5
Enter an integer value for the sample count: 10
```

```
min() == 0
max() == 1.79769e+308
a() == 0.5000000000
b() == 5.5000000000
Distribution for 10 samples:
1: 0.0482759823
2: 0.0826617486
3: 2.2835941207
4: 2.3604817485
5: 2.9417663742
6: 2.9418471657
7: 3.1685268104
8: 11.5109922290
9: 14.8543594043
10: 24.7220241239
```

Requirements

Header: <random>

Namespace: std

weibull_distribution::weibull_distribution

```
explicit weibull_distribution(result_type a = 1.0, result_type b = 1.0);
explicit weibull_distribution(const param_type& parm);
```

Parameters

a

The `a` distribution parameter.

b

The `b` distribution parameter.

parm

The `param_type` structure used to construct the distribution.

Remarks

Precondition: $0.0 < a$ and $0.0 < b$

The first constructor constructs an object whose stored `a` value holds the value a and whose stored `b` value holds the value b .

The second constructor constructs an object whose stored parameters are initialized from *parm*. You can obtain and set the current parameters of an existing distribution by calling the `param()` member function.

weibull_distribution::param_type

Stores the parameters of the distribution.

```
struct param_type {
    typedef weibull_distribution<result_type> distribution_type;
    param_type(result_type a = 1.0, result_type b = 1.0);
    result_type a() const;
    result_type b() const;

    bool operator==(const param_type& right) const;
    bool operator!=(const param_type& right) const;
};
```

Parameters

a

The `a` distribution parameter.

b

The `b` distribution parameter.

right

The `param_type` object to compare to this.

Remarks

Precondition: $0.0 < a$ and $0.0 < b$

This structure can be passed to the distribution's class constructor at instantiation, to the `param()` member function to set the stored parameters of an existing distribution, and to `operator()` to be used in place of the stored parameters.

[<random>](#)

<ratio>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Include the standard header <ratio> to define constants and templates that are used to store and manipulate rational numbers at compile time.

Syntax

```
#include <ratio>
```

ratio Template

```
template<std::intmax_t Numerator, std::intmax_t Denominator = 1>
struct ratio // holds the ratio of Numerator to Denominator
{
    static constexpr std::intmax_t num;
    static constexpr std::intmax_t den;
    typedef ratio<num, den> type;
}
```

The template `ratio` defines the static constants `num` and `den` such that `num / den == Numerator / Denominator` and `num` and `den` have no common factors. `num / den` is the value that is represented by the template class. Therefore, `type` designates the instantiation `ratio<num, den>`.

Specializations

<ratio> also defines specializations of `ratio` that have the following form.

```
template <class R1, class R2> struct ratio_specialization
```

Each specialization takes two template parameters that must also be specializations of `ratio`. The value of `type` is determined by an associated logical operation.

NAME	TYPE VALUE
<code>ratio_add</code>	<code>R1 + R2</code>
<code>ratio_divide</code>	<code>R1 / R2</code>
<code>ratio_equal</code>	<code>R1 == R2</code>
<code>ratio_greater</code>	<code>R1 > R2</code>
<code>ratio_greater_equal</code>	<code>R1 >= R2</code>
<code>ratio_less</code>	<code>R1 < R2</code>
<code>ratio_less_equal</code>	<code>R1 <= R2</code>
<code>ratio_multiply</code>	<code>R1 * R2</code>

NAME	TYPEVALUE
ratio_not_equal	!(R1 == R2)
ratio_subtract	R1 - R2

typedefs

For convenience, the header defines ratios for the standard SI prefixes:

```
typedef ratio<1, 1000000000000000> atto;
typedef ratio<1, 100000000000000> femto;
typedef ratio<1, 100000000000> pico;
typedef ratio<1, 100000000> nano;
typedef ratio<1, 100000> micro;
typedef ratio<1, 1000> milli;
typedef ratio<1, 100> centi;
typedef ratio<1, 10> deci;
typedef ratio<10, 1> deca;
typedef ratio<100, 1> hecto;
typedef ratio<1000, 1> kilo;
typedef ratio<1000000, 1> mega;
typedef ratio<1000000000, 1> giga;
typedef ratio<1000000000000, 1> tera;
typedef ratio<1000000000000000, 1> peta;
typedef ratio<1000000000000000000, 1> exa;
```

[Header Files Reference](#)

<regex>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines a template class to parse [Regular Expressions \(C++\)](#), and several template classes and functions to search text for matches to a regular expression object.

Syntax

```
#include <regex>
```

Remarks

To create a regular expression object, use the template class [basic_regex Class](#) or one of its specializations, [regex](#) and [wregex](#), together with the syntax flags of type [regex_constants::syntax_option_type](#).

To search text for matches to a regular expression object, use the template functions [regex_match](#) and [regex_search](#), together with the match flags of type [regex_constants::match_flag_type](#). These functions return results by using the template class [match_results Class](#) and its specializations, [cmatch](#), [wcmatch](#), [smatch](#), and [wsmatch](#), together with the template class [sub_match Class](#) and its specializations, [csub_match](#), [wsub_match](#), [ssub_match](#), and [wssub_match](#).

To replace text that matches a regular expression object, use the template function [regex_replace](#), together with the match flags of type [regex_constants::match_flag_type](#).

To iterate through multiple matches of a regular expression object, use the template classes [regex_iterator Class](#) and [regex_token_iterator Class](#) or one of their specializations, [cregex_iterator](#), [sregex_iterator](#), [wcregex_iterator](#), [wsregex_iterator](#), [cregex_token_iterator](#), [sregex_token_iterator](#), [wcregex_token_iterator](#), or [wsregex_token_iterator](#), together with the match flags of type [regex_constants::match_flag_type](#).

To modify the details of the grammar of regular expressions, write a class that implements the regular expression traits.

Classes

CLASS	DESCRIPTION
basic_regex	Wraps a regular expression.
match_results	Holds a sequence of submatches.
regex_constants	Holds assorted constants.
regex_error	Reports a bad regular expression.
regex_iterator	Iterates through match results.
regex_traits	Describes characteristics of elements for matching.
regex_traits<char>	Describes characteristics of char for matching.

CLASS	DESCRIPTION
<code>regex_traits<wchar_t></code>	Describes characteristics of wchar_t for matching.
<code>regex_token_iterator</code>	Iterates through submatches.
<code>sub_match</code>	Describes a submatch.

Type Definitions

<code>cmatch</code>	Type definition for char <code>match_results</code> .
<code>cregex_iterator</code>	Type definition for char <code>regex_iterator</code> .
<code>cregex_token_iterator</code>	Type definition for char <code>regex_token_iterator</code> .
<code>csub_match</code>	Type definition for char <code>sub_match</code> .
<code>regex</code>	Type definition for char <code>basic_regex</code> .
<code>smatch</code>	Type definition for <code>string</code> <code>match_results</code> .
<code>sregex_iterator</code>	Type definition for <code>string</code> <code>regex_iterator</code> .
<code>sregex_token_iterator</code>	Type definition for <code>string</code> <code>regex_token_iterator</code> .
<code>ssub_match</code>	Type definition for <code>string</code> <code>sub_match</code> .
<code>wcmatch</code>	Type definition for wchar_t <code>match_results</code> .
<code>wcregex_iterator</code>	Type definition for wchar_t <code>regex_iterator</code> .
<code>wcregex_token_iterator</code>	Type definition for wchar_t <code>regex_token_iterator</code> .
<code>wcsub_match</code>	Type definition for wchar_t <code>sub_match</code> .
<code>wregex</code>	Type definition for wchar_t <code>basic_regex</code> .
<code>wsmatch</code>	Type definition for <code>wstring</code> <code>match_results</code> .
<code>wsregex_iterator</code>	Type definition for <code>wstring</code> <code>regex_iterator</code> .
<code>wsregex_token_iterator</code>	Type definition for <code>wstring</code> <code>regex_token_iterator</code> .
<code>wssub_match</code>	Type definition for <code>wstring</code> <code>sub_match</code> .

Functions

FUNCTION	DESCRIPTION
regex_match	Exactly matches a regular expression.
regex_replace	Replaces matched regular expressions.
regex_search	Searches for a regular expression match.
swap	Swaps <code>basic_regex</code> or <code>match_results</code> objects.

Operators

OPERATOR	DESCRIPTION
operator==	Comparison of various objects, equal.
operator!=	Comparison of various objects, not equal.
operator<	Comparison of various objects, less than.
operator<=	Comparison of various objects, less than or equal.
operator>	Comparison of various objects, greater than.
operator>=	Comparison of various objects, greater than or equal.
operator<<	Inserts a <code>sub_match</code> in a stream.

<code>regex_match</code>	Tests whether a regular expression matches the entire target string.
<code>regex_replace</code>	Replaces matched regular expressions.
<code>regex_search</code>	Searches for a regular expression match.
<code>swap</code>	Swaps two <code>basic_regex</code> or <code>match_results</code> objects.

regex_match

Tests whether a regular expression matches the entire target string.

```

// (1)
template <class BidIt, class Alloc, class Elem, class RXtraits, class Alloc2>
bool regex_match(
    BidIt first,
    BidIt last,
    match_results<BidIt, Alloc>& match,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

// (2)
template <class BidIt, class Elem, class RXtraits, class Alloc2>
bool regex_match(
    BidIt first,
    BidIt last,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

// (3)
template <class Elem, class Alloc, class RXtraits, class Alloc2>
bool regex_match(
    const Elem *ptr,
    match_results<const Elem*, Alloc>& match,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

// (4)
template <class Elem, class RXtraits, class Alloc2>
bool regex_match(
    const Elem *ptr,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

// (5)
template <class IOtraits, class IOalloc, class Alloc, class Elem, class RXtraits, class Alloc2>
bool regex_match(
    const basic_string<Elem, IOtraits, IOalloc>& str,
    match_results<typename basic_string<Elem, IOtraits, IOalloc>::const_iterator, Alloc>& match,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

// (6)
template <class IOtraits, class IOalloc, class Elem, class RXtraits, class Alloc2>
bool regex_match(
    const basic_string<Elem, IOtraits, IOalloc>& str,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

```

Parameters

BidIt

The iterator type for submatches. For common cases this one of `string::const_iterator`, `wstring::const_iterator`, `const char*` or `const wchar_t*`.

Alloc

The match results allocator class.

Elem

The type of elements to match. For common cases this is `string`, `wstring`, `char*` or `wchar_t*`.

RXtraits

Traits class for elements.

Alloc2

The regular expression allocator class.

IOtraits

The string traits class.

IOalloc

The string allocator class.

flags

Flags for matches.

first

Beginning of sequence to match.

last

End of sequence to match.

match

The match results. Corresponds to Elem type: [smatch](#) for `string`, [wsmatch](#) for `wstring`, [cmatch](#) for `char*` or [wcmatch](#) for `wchar_t*`.

ptr

Pointer to beginning of sequence to match. If *ptr* is `char*`, then use `cmatch` and `regex`. If *ptr* is `wchar_t*` then use `wcmatch` and `wregex`.

re

The regular expression to match. Type `regex` for `string` and `char*`, or `wregex` for `wstring` and `wchar_t*`.

str

String to match. Corresponds to the type of *Elem*.

Remarks

Each template function returns true only if the entire operand sequence *str* exactly matches the regular expression argument *re*. Use [regex_search](#) to match a substring within a target sequence and `regex_iterator` to find multiple matches. The functions that take a `match_results` object set its members to reflect whether the match succeeded and if so what the various capture groups in the regular expression captured.

The functions that take a `match_results` object set its members to reflect whether the match succeeded and if so what the various capture groups in the regular expression captured.

Example

```

// std__regex__regex_match.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

using namespace std;

int main()
{
    // (1) with char*
    // Note how const char* requires cmatch and regex
    const char *first = "abc";
    const char *last = first + strlen(first);
    cmatch narrowMatch;
    regex rx("a(b)c");

    bool found = regex_match(first, last, narrowMatch, rx);
    if (found)
        wcout << L"Regex found in abc" << endl;

    // (2) with std::wstring
    // Note how wstring requires wsmatch and wregex.
    // Note use of const iterators cbegin() and cend().
    wstring target(L"Hello");
    wsmatch wideMatch;
    wregex wrx(L"He(l+)o");

    if (regex_match(target.cbegin(), target.cend(), wideMatch, wrx))
        wcout << L"The matching text is:" << wideMatch.str() << endl;

    // (3) with std::string
    string target2("Drizzle");
    regex rx2(R"(D\w+e)"); // no double backslashes with raw string literal

    found = regex_match(target2.cbegin(), target2.cend(), rx2);
    if (found)
        wcout << L"Regex found in Drizzle" << endl;

    // (4) with wchar_t*
    const wchar_t* target3 = L"2014-04-02";
    wcmatch wideMatch2;

    // LR"(...)" is a raw wide-string literal. Open and close parens
    // are delimiters, not string elements.
    wregex wrx2(LR"(\d{4}(-|/)\d{2}(-|/)\d{2})");
    if (regex_match(target3, wideMatch2, wrx2))
    {
        wcout << L"Matching text: " << wideMatch2.str() << endl;
    }

    return 0;
}

```

```

Regex found in abc
The matching text is: Hello
Regex found in Drizzle
The matching text is: 2014-04-02

```

regex_replace

Replaces matched regular expressions.

```

template <class OutIt, class BidIt, class RXtraits, class Alloc, class Elem>
OutIt regex_replace(
    OutIt out,
    BidIt first,
    BidIt last,
    const basic_regex<Elem, RXtraits, Alloc>& re,
    const basic_string<Elem>& fmt,
    match_flag_type flags = match_default);

template <class RXtraits, class Alloc, class Elem>
basic_string<Elem> regex_replace(
    const basic_string<Elem>& str,
    const basic_regex<Elem, RXtraits, Alloc>& re,
    const basic_string<Elem>& fmt,
    match_flag_type flags = match_default);

```

Parameters

OutIt

The iterator type for replacements.

BidIt

The iterator type for submatches.

RXtraits

Traits class for elements.

Alloc

The regular expression allocator class.

Elem

The type of elements to match.

flags

Flags for matches.

first

Beginning of sequence to match.

fmt

The format for replacements.

last

End of sequence to match.

out

The output iterator.

re

The regular expression to match.

str

String to match.

Remarks

The first function constructs a [regex_iterator Class](#) object `iter(first, last, re, flags)` and uses it to split its input range `[first, last)` into a series of subsequences `T0 M0 T1 M1...TN-1 MN-1 TN`, where `Mn` is the *n*th match detected by the iterator. If no matches are found, `T0` is the entire input range and `N` is zero. If `(flags & format_first_only) != 0` only the first match is used, `T1` is all of the input text that follows the match, and `N` is 1. For each `i` in the range `[0, N)`, if `(flags & format_no_copy) == 0` it copies the text in the range `Ti`

to the iterator `out`. It then calls `m.format(out, fmt, flags)`, where `m` is the `match_results` object returned by the iterator object `iter` for the subsequence `Mi`. Finally, if `(flags & format_no_copy) == 0` it copies the text in the range `TN` to the iterator `out`. The function returns `out`.

The second function constructs a local variable `result` of type `basic_string<charT>` and calls `regex_replace(back_inserter(result), str.begin(), str.end(), re, fmt, flags)`. It returns `result`.

Example

```
// std__regex__regex_replace.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

int main()
{
    char buf[20];
    const char *first = "axayaz";
    const char *last = first + strlen(first);
    std::regex rx("a");
    std::string fmt("A");
    std::regex_constants::match_flag_type fonly =
        std::regex_constants::format_first_only;

    *std::regex_replace(&buf[0], first, last, rx, fmt) = '\0';
    std::cout << "replacement == " << &buf[0] << std::endl;

    *std::regex_replace(&buf[0], first, last, rx, fmt, fonly) = '\0';
    std::cout << "replacement == " << &buf[0] << std::endl;

    std::string str("adaeaf");
    std::cout << "replacement == "
        << std::regex_replace(str, rx, fmt) << std::endl;

    std::cout << "replacement == "
        << std::regex_replace(str, rx, fmt, fonly) << std::endl;

    return (0);
}
```

```
replacement == AxAyAz
replacement == Axayaz
replacement == AdAeAf
replacement == Adaeaf
```

regex_search

Searches for a regular expression match.

```

template <class BidIt, class Alloc, class Elem, class RXtraits, class Alloc2>
bool regex_search(
    BidIt first,
    Bidit last,
    match_results<BidIt, Alloc>& match,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

template <class BidIt, class Elem, class RXtraits, class Alloc2>
bool regex_search(
    BidIt first,
    Bidit last,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

template <class Elem, class Alloc, class RXtraits, class Alloc2>
bool regex_search(
    const Elem* ptr,
    match_results<const Elem*, Alloc>& match,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

template <class Elem, class RXtraits, class Alloc2>
bool regex_search(
    const Elem* ptr,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

template <class IOtraits, class IOalloc, class Alloc, class Elem, class RXtraits, class Alloc2>
bool regex_search(
    const basic_string<Elem, IOtraits, IOalloc>& str,
    match_results<typename basic_string<Elem, IOtraits, IOalloc>::const_iterator, Alloc>& match,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

template <class IOtraits, class IOalloc, class Elem, class RXtraits, class Alloc2>
bool regex_search(
    const basic_string<Elem, IOtraits, IOalloc>& str,
    const basic_regex<Elem, RXtraits, Alloc2>& re,
    match_flag_type flags = match_default);

```

Parameters

BidIt

The iterator type for submatches.

Alloc

The match results allocator class.

Elem

The type of elements to match.

RXtraits

Traits class for elements.

Alloc2

The regular expression allocator class.

IOtraits

The string traits class.

IOalloc

The string allocator class.

flags

Flags for matches.

first

Beginning of sequence to match.

last

End of sequence to match.

match

The match results.

ptr

Pointer to beginning of sequence to match.

re

The regular expression to match.

str

String to match.

Remarks

Each template function returns true only if a search for its regular expression argument *re* in its operand sequence succeeds. The functions that take a `match_results` object set its members to reflect whether the search succeeded and if so what the various capture groups in the regular expression captured.

Example

```

// std__regex__regex_search.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

int main()
{
    const char *first = "abcd";
    const char *last = first + strlen(first);
    std::cmatch mr;
    std::regex rx("abc");
    std::regex_constants::match_flag_type fl =
        std::regex_constants::match_default;

    std::cout << "search(f, f+1, \"abc\") == " << std::boolalpha
        << regex_search(first, first + 1, rx, fl) << std::endl;

    std::cout << "search(f, l, \"abc\") == " << std::boolalpha
        << regex_search(first, last, mr, rx) << std::endl;
    std::cout << "    matched: \"" << mr.str() << "\"" << std::endl;

    std::cout << "search(\"a\", \"abc\") == " << std::boolalpha
        << regex_search("a", rx) << std::endl;

    std::cout << "search(\"xabcd\", \"abc\") == " << std::boolalpha
        << regex_search("xabcd", mr, rx) << std::endl;
    std::cout << "    matched: \"" << mr.str() << "\"" << std::endl;

    std::cout << "search(string, \"abc\") == " << std::boolalpha
        << regex_search(std::string("a"), rx) << std::endl;

    std::string str("abcabc");
    std::match_results<std::string::const_iterator> mr2;
    std::cout << "search(string, \"abc\") == " << std::boolalpha
        << regex_search(str, mr2, rx) << std::endl;
    std::cout << "    matched: \"" << mr2.str() << "\"" << std::endl;

    return (0);
}

```

```

search(f, f+1, "abc") == false
search(f, l, "abc") == true
    matched: "abc"
search("a", "abc") == false
search("xabcd", "abc") == true
    matched: "abc"
search(string, "abc") == false
search(string, "abc") == true
    matched: "abc"

```

swap

Swaps two `basic_regex` or `match_results` objects.

```

template <class Elem, class RXtraits>
void swap(
    basic_regex<Elem, RXtraits, Alloc>& left,
    basic_regex<Elem, RXtraits>& right) noexcept;

template <class Elem, class IOtraits, class BidIt, class Alloc>
void swap(
    match_results<BidIt, Alloc>& left,
    match_results<BidIt, Alloc>& right) noexcept;

```

Parameters

Elem

The type of elements to match.

RXtraits

Traits class for elements.

Remarks

The template functions swap the contents of their respective arguments in constant time and do not throw exceptions.

Example

```

// std__regex__swap.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

int main()
{
    std::regex rx0("c(a*)|(b)");
    std::regex rx1;
    std::cmatch mr0;
    std::cmatch mr1;

    swap(rx0, rx1);
    std::regex_search("xcaaay", mr1, rx1);
    swap(mr0, mr1);

    std::csub_match sub = mr0[1];
    std::cout << "matched == " << std::boolalpha
        << sub.matched << std::endl;
    std::cout << "length == " << sub.length() << std::endl;
    std::cout << "string == " << sub << std::endl;

    return (0);
}

```

```

matched == true
length == 3
string == aaa

```

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<<</code>	<code>operator<=</code>
<code>operator==</code>		

operator!=

Not equal comparison for various objects.

```
template <class BidIt>
bool operator!=(const sub_match<BidIt>& left,
               const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator!=(
    const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& left,
    const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator!=(const sub_match<BidIt>& left,
               const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& right);

template <class BidIt>
bool operator!=(const typename iterator_traits<BidIt>::value_type *left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator!=(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type *right);

template <class BidIt>
bool operator!=(const typename iterator_traits<BidIt>::value_type& left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator!=(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type& right);

template <class BidIt, class Alloc>
bool operator!=(const match_results<BidIt, Alloc>& left,
               const match_results<BidIt, Alloc>& right);
```

Parameters

BidIt

The iterator type.

IOtraits

The string traits class.

Alloc

The allocator class.

left

The left object to compare.

right

The right object to compare.

Remarks

Each template operator returns `!(left == right)`.

Example

```
// std__regex__operator_ne.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

typedef std::cmatch::string_type Mystr;
int main()
{
    std::regex rx("c(a*)|(b)");
    std::cmatch mr;

    std::regex_search("xcaaay", mr, rx);

    std::csub_match sub = mr[1];
    std::cout << "match == " << mr.str() << std::endl;
    std::cout << "sub == " << sub << std::endl;
    std::cout << std::endl;

    std::cout << "match != match == " << std::boolalpha
        << (mr != mr) << std::endl;
    std::cout << "sub != sub == " << std::boolalpha
        << (sub != sub) << std::endl;

    std::cout << "string(\"aab\") != sub == " << std::boolalpha
        << (Mystr("aab") != sub) << std::endl;
    std::cout << "sub != string(\"aab\") == " << std::boolalpha
        << (sub != Mystr("aab")) << std::endl;

    std::cout << "\"aab\" != sub == " << std::boolalpha
        << ("aab" != sub) << std::endl;
    std::cout << "sub != \"aab\" == " << std::boolalpha
        << (sub != "aab") << std::endl;

    std::cout << "'a' != sub == " << std::boolalpha
        << ('a' != sub) << std::endl;
    std::cout << "sub != 'a' == " << std::boolalpha
        << (sub != 'a') << std::endl;

    return (0);
}
```

```

match == caaa
sub == aaa

match != match == false
sub != sub == false
string("aab") != sub == true
sub != string("aab") == true
"aab" != sub == true
sub != "aab" == true
'a' != sub == true
sub != 'a' == true

```

operator<

Less than comparison for various objects.

```

template <class BidIt>
bool operator<(const sub_match<BidIt>& left,
               const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator<(
    const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& left,
    const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator<(const sub_match<BidIt>& left,
               const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& right);

template <class BidIt>
bool operator<(const typename iterator_traits<BidIt>::value_type *left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator<(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type *right);

template <class BidIt>
bool operator<(const typename iterator_traits<BidIt>::value_type& left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator<(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type& right);

```

Parameters

BidIt

The iterator type.

IOtraits

The string traits class.

Alloc

The allocator class.

left

The left object to compare.

right

The right object to compare.

Remarks

Each template operator converts its arguments to a string type and returns true only if the converted value of *left* compares less than the converted value of *right*.

Example

```
// std_regex_operator_lt.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

typedef std::cmatch::string_type Mystr;
int main()
{
    std::regex rx("c(a*)|(b)");
    std::cmatch mr;

    std::regex_search("xcaaay", mr, rx);

    std::csub_match sub = mr[1];
    std::cout << "sub == " << sub << std::endl;
    std::cout << std::endl;

    std::cout << "sub < sub == " << std::boolalpha
        << (sub < sub) << std::endl;

    std::cout << "string(\"aab\") < sub == " << std::boolalpha
        << (Mystr("aab") < sub) << std::endl;
    std::cout << "sub < string(\"aab\") == " << std::boolalpha
        << (sub < Mystr("aab")) << std::endl;

    std::cout << "\"aab\" < sub == " << std::boolalpha
        << ("aab" < sub) << std::endl;
    std::cout << "sub < \"aab\" == " << std::boolalpha
        << (sub < "aab") << std::endl;

    std::cout << "'a' < sub == " << std::boolalpha
        << ('a' < sub) << std::endl;
    std::cout << "sub < 'a' == " << std::boolalpha
        << (sub < 'a') << std::endl;

    return (0);
}
```

```
sub == aaa

sub < sub == false
string("aab") < sub == false
sub < string("aab") == true
"aab" < sub == false
sub < "aab" == true
'a' < sub == true
sub < 'a' == false
```

operator<<

Inserts a sub_match in a stream.

```
template <class Elem, class IOtraits, class Alloc, class BidIt>
basic_ostream<Elem, IOtraits>& operator<<(basic_ostream<Elem, IOtraits>& os,
    const sub_match<BidIt>& right);
```

Parameters

Elem

The element type.

IOtraits

The string traits class.

Alloc

The allocator class.

BidIt

The iterator type.

os

The output stream.

right

The object to insert.

Remarks

The template operator returns `os << right.str()`.

Example

```
// std__regex_operator_ins.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

int main()
{
    std::regex rx("c(a*)|(b)");
    std::cmatch mr;

    std::regex_search("xcaaay", mr, rx);

    std::csub_match sub = mr[0];
    std::cout << "whole match: " << sub << std::endl;

    return (0);
}
```

```
whole match: caaa
```

operator<=

Less than or equal comparison for various objects.

```

template <class BidIt>
bool operator<=(const sub_match<BidIt>& left,
               const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator<=(
    const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& left,
    const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator<=(const sub_match<BidIt>& left,
               const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& right);

template <class BidIt>
bool operator<=(const typename iterator_traits<BidIt>::value_type *left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator<=(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type *right);

template <class BidIt>
bool operator<=(const typename iterator_traits<BidIt>::value_type& left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator<=(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type& right);

```

Parameters

BidIt

The iterator type.

IOtraits

The string traits class.

Alloc

The allocator class.

left

The left object to compare.

right

The right object to compare.

Remarks

Each template operator returns `!(right < left)`.

Example

```

// std__regex__operator_le.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

typedef std::cmatch::string_type Mystr;
int main()
{
    std::regex rx("c(a*)|(b)");
    std::cmatch mr;

    std::regex_search("xcaaay", mr, rx);

    std::csub_match sub = mr[1];
    std::cout << "sub == " << sub << std::endl;
    std::cout << std::endl;

    std::cout << "sub <= sub == " << std::boolalpha
        << (sub <= sub) << std::endl;

    std::cout << "string(\"aab\") <= sub == " << std::boolalpha
        << (Mystr("aab") <= sub) << std::endl;
    std::cout << "sub <= string(\"aab\") == " << std::boolalpha
        << (sub <= Mystr("aab")) << std::endl;

    std::cout << "\"aab\" <= sub == " << std::boolalpha
        << ("aab" <= sub) << std::endl;
    std::cout << "sub <= \"aab\" == " << std::boolalpha
        << (sub <= "aab") << std::endl;

    std::cout << "'a' <= sub == " << std::boolalpha
        << ('a' <= sub) << std::endl;
    std::cout << "sub <= 'a' == " << std::boolalpha
        << (sub <= 'a') << std::endl;

    return (0);
}

```

```

sub == aaa

sub <= sub == true
string("aab") <= sub == false
sub <= string("aab") == true
"aab" <= sub == false
sub <= "aab" == true
'a' <= sub == true
sub <= 'a' == false

```

operator==

Equal comparison for various objects.

```

template <class BidIt>
bool operator==(const sub_match<BidIt>& left,
               const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator==(
    const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& left,
    const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator==(const sub_match<BidIt>& left,
               const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& right);

template <class BidIt>
bool operator==(const typename iterator_traits<BidIt>::value_type* left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator==(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type* right);

template <class BidIt>
bool operator==(const typename iterator_traits<BidIt>::value_type& left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator==(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type& right);

template <class BidIt, class Alloc>
bool operator==(const match_results<BidIt, Alloc>& left,
               const match_results<BidIt, Alloc>& right);

```

Parameters

BidIt

The iterator type.

IOtraits

The string traits class.

Alloc

The allocator class.

left

The left object to compare.

right

The right object to compare.

Remarks

Each template operator converts each of its arguments to a string type and returns the result of comparing the converted objects for equality.

When a template operator converts its arguments to a string type it uses the first of the following transformations that applies:

arguments whose types are a specialization of template class `match_results` or `sub_match` are converted by calling the `str` member function;

arguments whose types are a specialization of the template class `basic_string` are unchanged;

all other argument types are converted by passing the argument value to the constructor for an appropriate

specialization of the template class `basic_string` .

Example

```
// std__regex__operator_eq.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

typedef std::cmatch::string_type Mystr;
int main()
{
    std::regex rx("c(a*)|(b)");
    std::cmatch mr;

    std::regex_search("xcaaay", mr, rx);

    std::csub_match sub = mr[1];
    std::cout << "match == " << mr.str() << std::endl;
    std::cout << "sub == " << sub << std::endl;
    std::cout << std::endl;

    std::cout << "match == match == " << std::boolalpha
        << (mr == mr) << std::endl;
    std::cout << "sub == sub == " << std::boolalpha
        << (sub == sub) << std::endl;

    std::cout << "string(\"aab\") == sub == " << std::boolalpha
        << (Mystr("aab") == sub) << std::endl;
    std::cout << "sub == string(\"aab\") == " << std::boolalpha
        << (sub == Mystr("aab")) << std::endl;

    std::cout << "\"aab\" == sub == " << std::boolalpha
        << ("aab" == sub) << std::endl;
    std::cout << "sub == \"aab\" == " << std::boolalpha
        << (sub == "aab") << std::endl;

    std::cout << "'a' == sub == " << std::boolalpha
        << ('a' == sub) << std::endl;
    std::cout << "sub == 'a' == " << std::boolalpha
        << (sub == 'a') << std::endl;

    return (0);
}
```

```
match == caaa
sub == aaa

match == match == true
sub == sub == true
string("aab") == sub == false
sub == string("aab") == false
"aab" == sub == false
sub == "aab" == false
'a' == sub == false
sub == 'a' == false
```

operator>

Greater than comparison for various objects.

```

template <class BidIt>
bool operator>(const sub_match<BidIt>& left,
               const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator>(
    const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& left,
    const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator>(const sub_match<BidIt>& left,
               const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& right);

template <class BidIt>
bool operator>(const typename iterator_traits<BidIt>::value_type *left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator>(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type *right);

template <class BidIt>
bool operator>(const typename iterator_traits<BidIt>::value_type& left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator>(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type& right);

```

Parameters

BidIt

The iterator type.

IOtraits

The string traits class.

Alloc

The allocator class.

left

The left object to compare.

right

The right object to compare.

Remarks

Each template operator returns `right < left`.

Example

```

// std_regex_operator_gt.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

typedef std::cmatch::string_type Mystr;
int main()
{
    std::regex rx("c(a*)|(b)");
    std::cmatch mr;

    std::regex_search("xcaaay", mr, rx);

    std::csub_match sub = mr[1];
    std::cout << "sub == " << sub << std::endl;
    std::cout << std::endl;

    std::cout << "sub > sub == " << std::boolalpha
        << (sub > sub) << std::endl;

    std::cout << "string(\"aab\") > sub == " << std::boolalpha
        << (Mystr("aab") > sub) << std::endl;
    std::cout << "sub > string(\"aab\") == " << std::boolalpha
        << (sub > Mystr("aab")) << std::endl;

    std::cout << "\"aab\" > sub == " << std::boolalpha
        << ("aab" > sub) << std::endl;
    std::cout << "sub > \"aab\" == " << std::boolalpha
        << (sub > "aab") << std::endl;

    std::cout << "'a' > sub == " << std::boolalpha
        << ('a' > sub) << std::endl;
    std::cout << "sub > 'a' == " << std::boolalpha
        << (sub > 'a') << std::endl;

    return (0);
}

```

```

sub == aaa

sub > sub == false
string("aab") > sub == true
sub > string("aab") == false
"aab" > sub == true
sub > "aab" == false
'a' > sub == false
sub > 'a' == true

```

operator>=

Greater than or equal comparison for various objects.

```

template <class BidIt>
bool operator>=(const sub_match<BidIt>& left,
               const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator>=(
    const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& left,
    const sub_match<BidIt>& right);

template <class BidIt, class IOtraits, class Alloc>
bool operator>=(const sub_match<BidIt>& left,
               const basic_string<typename iterator_traits<BidIt>::value_type, IOtraits, Alloc>& right);

template <class BidIt>
bool operator>=(const typename iterator_traits<BidIt>::value_type *left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator>=(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type *right);

template <class BidIt>
bool operator>=(const typename iterator_traits<BidIt>::value_type& left,
               const sub_match<BidIt>& right);

template <class BidIt>
bool operator>=(const sub_match<BidIt>& left,
               const typename iterator_traits<BidIt>::value_type& right);

```

Parameters

BidIt

The iterator type.

IOtraits

The string traits class.

Alloc

The allocator class.

left

The left object to compare.

right

The right object to compare.

Remarks

Each template operator returns `!(left < right)`.

Example

```

// std__regex__operator_ge.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

typedef std::cmatch::string_type Mystr;
int main()
{
    std::regex rx("c(a*)|(b)");
    std::cmatch mr;

    std::regex_search("xcaaay", mr, rx);

    std::csub_match sub = mr[1];
    std::cout << "sub == " << sub << std::endl;
    std::cout << std::endl;

    std::cout << "sub >= sub == " << std::boolalpha
        << (sub >= sub) << std::endl;

    std::cout << "string(\"aab\") >= sub == " << std::boolalpha
        << (Mystr("aab") >= sub) << std::endl;
    std::cout << "sub >= string(\"aab\") == " << std::boolalpha
        << (sub >= Mystr("aab")) << std::endl;

    std::cout << "\"aab\" >= sub == " << std::boolalpha
        << ("aab" >= sub) << std::endl;
    std::cout << "sub >= \"aab\" == " << std::boolalpha
        << (sub >= "aab") << std::endl;

    std::cout << "'a' >= sub == " << std::boolalpha
        << ('a' >= sub) << std::endl;
    std::cout << "sub >= 'a' == " << std::boolalpha
        << (sub >= 'a') << std::endl;

    return (0);
}

```

```

sub == aaa

sub >= sub == true
string("aab") >= sub == true
sub >= string("aab") == false
"aab" >= sub == true
sub >= "aab" == false
'a' >= sub == false
sub >= 'a' == true

```

<regex> typedefs

10/31/2018 • 2 minutes to read • [Edit Online](#)

cmatch	cregex_iterator	cregex_token_iterator
csub_match	regex	smatch
sregex_iterator	sregex_token_iterator	ssub_match
wcmatch	wcregex_iterator	wcregex_token_iterator
wsub_match	wregex	wsmatch
wsregex_iterator	wsregex_token_iterator	wssub_match

cmatch Typedef

Type definition for char match_results.

```
typedef match_results<const char*> cmatch;
```

Remarks

The type describes a specialization of template class [match_results Class](#) for iterators of type `const char*`.

cregex_iterator Typedef

Type definition for char regex_iterator.

```
typedef regex_iterator<const char*> cregex_iterator;
```

Remarks

The type describes a specialization of template class [regex_iterator Class](#) for iterators of type `const char*`.

cregex_token_iterator Typedef

Type definition for char regex_token_iterator

```
typedef regex_token_iterator<const char*> cregex_token_iterator;
```

Remarks

The type describes a specialization of template class [regex_token_iterator Class](#) for iterators of type `const char*`.

csub_match Typedef

Type definition for char sub_match.

```
typedef sub_match<const char*> csub_match;
```

Remarks

The type describes a specialization of template class [sub_match Class](#) for iterators of type `const char*`.

regex Typedef

Type definition for char basic_regex.

```
typedef basic_regex<char> regex;
```

Remarks

The type describes a specialization of template class [basic_regex Class](#) for elements of type **char**.

NOTE

High-bit characters will have unpredictable results with `regex`. Values outside the range of 0 to 127 may result in undefined behavior.

smatch Typedef

Type definition for string match_results.

```
typedef match_results<string::const_iterator> smatch;
```

Remarks

The type describes a specialization of template class [match_results Class](#) for iterators of type `string::const_iterator`.

sregex_iterator Typedef

Type definition for string regex_iterator.

```
typedef regex_iterator<string::const_iterator> sregex_iterator;
```

Remarks

The type describes a specialization of template class [regex_iterator Class](#) for iterators of type `string::const_iterator`.

sregex_token_iterator Typedef

Type definition for string regex_token_iterator.

```
typedef regex_token_iterator<string::const_iterator> sregex_token_iterator;
```

Remarks

The type describes a specialization of template class [regex_token_iterator Class](#) for iterators of type `string::const_iterator`.

ssub_match Typedef

Type definition for string sub_match.

```
typedef sub_match<string::const_iterator> ssub_match;
```

Remarks

The type describes a specialization of template class [sub_match Class](#) for iterators of type

```
string::const_iterator
```

.

wcmatch Typedef

Type definition for wchar_t match_results.

```
typedef match_results<const wchar_t*> wcmatch;
```

Remarks

The type describes a specialization of template class [match_results Class](#) for iterators of type `const wchar_t*`.

wcregex_iterator Typedef

Type definition for wchar_t regex_iterator.

```
typedef regex_iterator<const wchar_t*> wcregex_iterator;
```

Remarks

The type describes a specialization of template class [regex_iterator Class](#) for iterators of type `const wchar_t*`.

wcregex_token_iterator Typedef

Type definition for wchar_t regex_token_iterator.

```
typedef regex_token_iterator<const wchar_t*> wcregex_token_iterator;
```

Remarks

The type describes a specialization of template class [regex_token_iterator Class](#) for iterators of type

```
const wchar_t*
```

.

wcsub_match Typedef

Type definition for wchar_t sub_match.

```
typedef sub_match<const wchar_t*> wcsub_match;
```

Remarks

The type describes a specialization of template class [sub_match Class](#) for iterators of type `const wchar_t*`.

wregex Typedef

Type definition for `wchar_t` `basic_regex`.

```
typedef basic_regex<wchar_t> wregex;
```

Remarks

The type describes a specialization of template class [basic_regex Class](#) for elements of type **`wchar_t`**.

wsmatch Typedef

Type definition for `wstring` `match_results`.

```
typedef match_results<wstring::const_iterator> wsmatch;
```

Remarks

The type describes a specialization of template class [match_results Class](#) for iterators of type

`wstring::const_iterator`.

wsregex_iterator Typedef

Type definition for `wstring` `regex_iterator`.

```
typedef regex_iterator<wstring::const_iterator> wsregex_iterator;
```

Remarks

The type describes a specialization of template class [regex_iterator Class](#) for iterators of type

`wstring::const_iterator`.

wsregex_token_iterator Typedef

Type definition for `wstring` `regex_token_iterator`.

```
typedef regex_token_iterator<wstring::const_iterator> wsregex_token_iterator;
```

Remarks

The type describes a specialization of template class [regex_token_iterator Class](#) for iterators of type

`wstring::const_iterator`.

wssub_match Typedef

Type definition for `wstring` `sub_match`.

```
typedef sub_match<wstring::const_iterator> wssub_match;
```

Remarks

The type describes a specialization of template class [sub_match Class](#) for iterators of type

`wstring::const_iterator`.

basic_regex Class

3/28/2019 • 6 minutes to read • [Edit Online](#)

Wraps a regular expression.

Syntax

```
template <class Elem, class RXtraits>
class basic_regex
```

Parameters

Elem

The type of elements to match.

RXtraits

Traits class for elements.

Remarks

The template class describes an object that holds a regular expression. Objects of this template class can be passed to the template functions [regex_match](#), [regex_search](#), and [regex_replace](#), along with suitable text string arguments, to search for text that matches the regular expression. There are two specializations of this template class, with the type definitions [regex](#) for elements of type **char**, and [wregex](#) for elements of type **wchar_t**.

The template argument *RXtraits* describes various important properties of the syntax of the regular expressions that the template class supports. A class that specifies these regular expression traits must have the same external interface as an object of template class [regex_traits Class](#).

Some functions take an operand sequence that defines a regular expression. You can specify such an operand sequence several ways:

`ptr` -- a null-terminated sequence (such as a C string, for *Elem* of type **char**) beginning at `ptr` (which must not be a null pointer), where the terminating element is the value `value_type()` and is not part of the operand sequence

`ptr`, `count` -- a sequence of `count` elements beginning at `ptr` (which must not be a null pointer)

`str` -- the sequence specified by the `basic_string` object `str`

`first`, `last` -- a sequence of elements delimited by the iterators `first` and `last`, in the range `[first, last)`

`right` -- the `basic_regex` object `right`

These member functions also take an argument `flags` that specifies various options for the interpretation of the regular expression in addition to those described by the *RXtraits* type.

Members

MEMBER	DEFAULT VALUE
public static const flag_type icase	regex_constants::icase

MEMBER	DEFAULT VALUE
public static const flag_type nosubs	regex_constants::nosubs
public static const flag_type optimize	regex_constants::optimize
public static const flag_type collate	regex_constants::collate
public static const flag_type ECMAScript	regex_constants::ECMAScript
public static const flag_type basic	regex_constants::basic
public static const flag_type extended	regex_constants::extended
public static const flag_type awk	regex_constants::awk

public static const flag_type egrep	regex_constants::egrep
private RXtraits traits	

Constructors

CONSTRUCTOR	DESCRIPTION
basic_regex	Construct the regular expression object.

Typedefs

TYPE NAME	DESCRIPTION
flag_type	The type of syntax option flags.
locale_type	The type of the stored locale object.
value_type	The element type.

Member functions

MEMBER FUNCTION	DESCRIPTION
assign	Assigns a value to the regular expression object.
flags	Returns syntax option flags.
getloc	Returns the stored locale object.
imbue	Alters the stored locale object.
mark_count	Returns number of subexpressions matched.
swap	Swaps two regular expression objects.

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Assigns a value to the regular expression object.

Requirements

Header: <regex>

Namespace: std

Example

```
// std_regex_basic_regex.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

using namespace std;

int main()
{
    regex::value_type elem = 'x';
    regex::flag_type flag = regex::grep;

    elem = elem; // to quiet "unused" warnings
    flag = flag;

    // constructors
    regex rx0;
    cout << "match(\"abc\", \"\") == " << boolalpha
         << regex_match("abc", rx0) << endl;

    regex rx1("abcd", regex::ECMAScript);
    cout << "match(\"abc\", \"abcd\") == " << boolalpha
         << regex_match("abc", rx1) << endl;

    regex rx2("abcd", 3);
    cout << "match(\"abc\", \"abc\") == " << boolalpha
         << regex_match("abc", rx2) << endl;

    regex rx3(rx2);
    cout << "match(\"abc\", \"abc\") == " << boolalpha
         << regex_match("abc", rx3) << endl;

    string str("abcd");
    regex rx4(str);
    cout << "match(string(\"abcd\"), \"abc\") == " << boolalpha
         << regex_match("abc", rx4) << endl;

    regex rx5(str.begin(), str.end() - 1);
    cout << "match(string(\"abc\"), \"abc\") == " << boolalpha
         << regex_match("abc", rx5) << endl;
    cout << endl;

    // assignments
    rx0 = "abc";
    rx0 = rx1;
    rx0 = str;

    rx0.assign("abcd", regex::ECMAScript);
    rx0.assign("abcd", 3);
    rx0.assign(rx1);
    rx0.assign(str);
```

```

    rx0.assign(str);
    rx0.assign(str.begin(), str.end() - 1);

    rx0.swap(rx1);

    // mark_count
    cout << "\"abc\" mark_count == "
        << regex("abc").mark_count() << endl;
    cout << "\"(abc)\" mark_count == "
        << regex("(abc)").mark_count() << endl;

    // locales
    regex::locale_type loc = rx0.imbue(locale());
    cout << "getloc == imbued == " << boolalpha
        << (loc == rx0.getloc()) << endl;

    // initializer_list
    regex rx6({ 'a', 'b', 'c' }, regex::ECMAScript);
    cout << "match(\"abc\") == " << boolalpha
        << regex_match("abc", rx6);
    cout << endl;
}

```

```

match("abc", "") == false
match("abc", "abcd") == false
match("abc", "abc") == true
match("abc", "abc") == true
match(string("abcd"), "abc") == false
match(string("abc"), "abc") == true

"abc" mark_count == 0
"(abc)" mark_count == 1
getloc == imbued == true
match("abc") == true

```

basic_regex::assign

Assigns a value to the regular expression object.

```

basic_regex& assign(
    const basic_regex& right);

basic_regex& assign(
    const Elem* ptr,
    flag_type flags = ECMAScript);

basic_regex& assign(
    const Elem* ptr,
    size_type len,
    flag_type flags = ECMAScript);

basic_regex& assign(
    initializer_list<Elem> Ilist,
    flag_type flags = regex_constants::ECMAScript);

template <class STraits, class STalloc>
basic_regex& assign(
    const basic_string<Elem, STraits, STalloc>& str,
    flag_type flags = ECMAScript);

template <class InIt>
basic_regex& assign(
    InIt first, InIt last,
    flag_type flags = ECMAScript);

```

Parameters

STraits

Traits class for a string source.

STalloc

Allocator class for a string source.

InIt

Input iterator type for a range source.

right

Regex source to copy.

ptr

Pointer to beginning of sequence to copy.

flags

Syntax option flags to add while copying.

len/TD>

Length of sequence to copy.

str

String to copy.

first

Beginning of sequence to copy.

last

End of sequence to copy.

IList

The initializer_list to copy.

Remarks

The member functions each replace the regular expression held by `*this` with the regular expression described by the operand sequence, then return `*this`.

basic_regex::basic_regex

Construct the regular expression object.

```
basic_regex();

explicit basic_regex(
    const Elem* ptr,
    flag_type flags);

explicit basic_regex(
    const Elem* ptr,
    size_type len,
    flag_type flags);

basic_regex(
    const basic_regex& right);

basic_regex(
    initializer_list<Type> Ilist,
    flag_type flags);

template <class STraits, class STalloc>
explicit basic_regex(
    const basic_string<Elem, STraits, STalloc>& str,
    flag_type flags);

template <class InIt>
explicit basic_regex(
    InIt first,
    InIt last,
    flag_type flags);
```

Parameters

STraits

Traits class for a string source.

STalloc

Allocator class for a string source.

InIt

Input iterator type for a range source.

right

Regex source to copy.

ptr

Pointer to beginning of sequence to copy.

flags

Syntax option flags to add while copying.

len/TD>

Length of sequence to copy.

str

String to copy.

first

Beginning of sequence to copy.

last

End of sequence to copy.

/List

The initializer_list to copy.

Remarks

All constructors store a default-constructed object of type `RXtraits`.

The first constructor constructs an empty `basic_regex` object. The other constructors construct a `basic_regex` object that holds the regular expression described by the operand sequence.

An empty `basic_regex` object does not match any character sequence when passed to [regex_match](#), [regex_search](#), or [regex_replace](#).

basic_regex::flag_type

The type of syntax option flags.

```
typedef regex_constants::syntax_option_type flag_type;
```

Remarks

The type is a synonym for [regex_constants::syntax_option_type](#).

basic_regex::flags

Returns syntax option flags.

```
flag_type flags() const;
```

Remarks

The member function returns the value of the `flag_type` argument passed to the most recent call to one of the [basic_regex::assign](#) member functions or, if no such call has been made, the value passed to the constructor.

basic_regex::getloc

Returns the stored locale object.

```
locale_type getloc() const;
```

Remarks

The member function returns `traits::regex_traits::getloc()`.

basic_regex::imbue

Alters the stored locale object.

```
locale_type imbue(locale_type loc);
```

Parameters

loc

The locale object to store.

Remarks

The member function empties `*this` and returns `traits.regex_traits::imbue(loc)`.

basic_regex::locale_type

The type of the stored locale object.

```
typedef typename RXtraits::locale_type locale_type;
```

Remarks

The type is a synonym for `regex_traits::locale_type`.

basic_regex::mark_count

Returns number of subexpressions matched.

```
unsigned mark_count() const;
```

Remarks

The member function returns the number of capture groups in the regular expression.

basic_regex::operator=

Assigns a value to the regular expression object.

```
basic_regex& operator=(const basic_regex& right);

basic_regex& operator=(const Elem *str);

template <class STtraits, class STalloc>
basic_regex& operator=(const basic_string<Elem, STtraits, STalloc>& str);
```

Parameters

STtraits

Traits class for a string source.

STalloc

Allocator class for a string source.

right

Regex source to copy.

str

String to copy.

Remarks

The operators each replace the regular expression held by `*this` with the regular expression described by the operand sequence, then return `*this`.

basic_regex::swap

Swaps two regular expression objects.

```
void swap(basic_regex& right) throw();
```

Parameters

right

The regular expression object to swap with.

Remarks

The member function swaps the regular expressions between `*this` and *right*. It does so in constant time and throws no exceptions.

basic_regex::value_type

The element type.

```
typedef Elem value_type;
```

Remarks

The type is a synonym for the template parameter *Elem*.

[regex](#)

[wregex](#)

[regex_traits](#) Class

match_results Class

12/20/2018 • 7 minutes to read • [Edit Online](#)

Holds a sequence of submatches.

Syntax

```
template <class BidIt, class Alloc>
class match_results
```

Parameters

BidIt

The iterator type for submatches.

Alloc

The type of an allocator for managing storage.

Remarks

The template class describes an object that controls a non-modifiable sequence of elements of type `sub_match<BidIt>` generated by a regular expression search. Each element points to the subsequence that matched the capture group corresponding to that element.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>match_results</code>	Constructs the object.

Typedefs

TYPE NAME	DESCRIPTION
<code>allocator_type</code>	The type of an allocator for managing storage.
<code>char_type</code>	The type of an element.
<code>const_iterator</code>	The const iterator type for submatches.
<code>const_reference</code>	The type of an element const reference.
<code>difference_type</code>	The type of an iterator difference.
<code>iterator</code>	The iterator type for submatches.
<code>reference</code>	The type of an element reference.
<code>size_type</code>	The type of a submatch count.

TYPE NAME	DESCRIPTION
<code>string_type</code>	The type of a string.
<code>value_type</code>	The type of a submatch.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>begin</code>	Designates beginning of submatch sequence.
<code>empty</code>	Tests for no submatches.
<code>end</code>	Designates end of submatch sequence.
<code>format</code>	Formats submatches.
<code>get_allocator</code>	Returns the stored allocator.
<code>length</code>	Returns length of a submatch.
<code>max_size</code>	Gets largest number of submatches.
<code>position</code>	Get starting offset of a subgroup.
<code>prefix</code>	Gets sequence before first submatch.
<code>size</code>	Counts number of submatches.
<code>str</code>	Returns a submatch.
<code>suffix</code>	Gets sequence after last submatch.
<code>swap</code>	Swaps two <code>match_results</code> objects.

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Copy a <code>match_results</code> object.
<code>operator[]</code>	Access a subobject.

Requirements

Header: `<regex>`

Namespace: `std`

Example

```
// std__regex__match_results.cpp
```

```

// compile with: /EHsc
#include <regex>
#include <iostream>

int main()
{
    std::regex rx("c(a*)|(b)");
    std::cmatch mr;

    std::regex_search("xcaaay", mr, rx);

    std::cout << "prefix: matched == " << std::boolalpha
        << mr.prefix().matched
        << ", value == " << mr.prefix() << std::endl;
    std::cout << "whole match: " << mr.length() << " chars, value == "
        << mr.str() << std::endl;
    std::cout << "suffix: matched == " << std::boolalpha
        << mr.suffix().matched
        << ", value == " << mr.suffix() << std::endl;
    std::cout << std::endl;

    std::string fmt("\c(a*)|(b)\ matched \"%&\"\n"
        "\"(a*)\" matched \"%1\"\n"
        "\"(b)\ matched \"%2\"\n");
    std::cout << mr.format(fmt) << std::endl;
    std::cout << std::endl;

    // index through submatches
    for (size_t n = 0; n < mr.size(); ++n)
    {
        std::cout << "submatch[" << n << "]: matched == " << std::boolalpha
            << mr[n].matched <<
            " at position " << mr.position(n) << std::endl;
        std::cout << " " << mr.length(n)
            << " chars, value == " << mr[n] << std::endl;
    }
    std::cout << std::endl;

    // iterate through submatches
    for (std::cmatch::iterator it = mr.begin(); it != mr.end(); ++it)
    {
        std::cout << "next submatch: matched == " << std::boolalpha
            << it->matched << std::endl;
        std::cout << " " << it->length()
            << " chars, value == " << *it << std::endl;
    }
    std::cout << std::endl;

    // other members
    std::cout << "empty == " << std::boolalpha << mr.empty() << std::endl;

    std::cmatch::allocator_type al = mr.get_allocator();
    std::cmatch::string_type str = std::string("x");
    std::cmatch::size_type maxsiz = mr.max_size();
    std::cmatch::char_type ch = 'x';
    std::cmatch::difference_type dif = mr.begin() - mr.end();
    std::cmatch::const_iterator cit = mr.begin();
    std::cmatch::value_type val = *cit;
    std::cmatch::const_reference cref = val;
    std::cmatch::reference ref = val;

    maxsiz = maxsiz; // to quiet "unused" warnings
    if (ref == cref)
        ch = ch;
    dif = dif;

    return (0);
}

```

```

prefix: matched == true, value == x
whole match: 4 chars, value == caaa
suffix: matched == true, value == y

"c(a*)|(b)" matched "caaa"
"(a*)" matched "aaa"
"(b)" matched ""

submatch[0]: matched == true at position 1
  4 chars, value == caaa
submatch[1]: matched == true at position 2
  3 chars, value == aaa
submatch[2]: matched == false at position 6
  0 chars, value ==

next submatch: matched == true
  4 chars, value == caaa
next submatch: matched == true
  3 chars, value == aaa
next submatch: matched == false
  0 chars, value ==

empty == false

```

match_results::allocator_type

The type of an allocator for managing storage.

```
typedef Alloc allocator_type;
```

Remarks

The typedef is a synonym for the template argument *Alloc*.

match_results::begin

Designates beginning of submatch sequence.

```
const_iterator begin() const;
```

Remarks

The member function returns a random access iterator that points at the first element of the sequence (or just beyond the end of an empty sequence).

match_results::char_type

The type of an element.

```
typedef typename iterator_traits<BidIt>::value_type char_type;
```

Remarks

The typedef is a synonym for the type `iterator_traits<BidIt>::value_type`, which is the element type of the character sequence that was searched.

match_results::const_iterator

The const iterator type for submatches.

```
typedef T0 const_iterator;
```

Remarks

The typedef describes an object that can serve as a constant random-access iterator for the controlled sequence.

match_results::const_reference

The type of an element const reference.

```
typedef const typename Alloc::const_reference const_reference;
```

Remarks

The typedef describes an object that can serve as a constant reference to an element of the controlled sequence.

match_results::difference_type

The type of an iterator difference.

```
typedef typename iterator_traits<BidIt>::difference_type difference_type;
```

Remarks

The typedef is a synonym for the type `iterator_traits<BidIt>::difference_type`; it describes an object that can represent the difference between any two iterators that point at elements of the controlled sequence.

match_results::empty

Tests for no submatches.

```
bool empty() const;
```

Remarks

The member function returns true only if the regular expression search failed.

match_results::end

Designates end of submatch sequence.

```
const_iterator end() const;
```

Remarks

The member function returns an iterator that points just beyond the end of the sequence.

match_results::format

Formats submatches.

```
template <class OutIt>
OutIt format(OutIt out,
             const string_type& fmt, match_flag_type flags = format_default) const;

string_type format(const string_type& fmt, match_flag_type flags = format_default) const;
```

Parameters

OutIt

The output iterator type.

out

The output stream to write to.

fmt

The format string.

flags

The format flags.

Remarks

Each member function generates formatted text under the control of the format *fmt*. The first member function writes the formatted text to the sequence defined by its argument *out* and returns *out*. The second member function returns a string object holding a copy of the formatted text.

To generate formatted text, literal text in the format string is ordinarily copied to the target sequence. Each escape sequence in the format string is replaced by the text that it represents. The details of the copying and replacement are controlled by the format flags passed to the function.

match_results::get_allocator

Returns the stored allocator.

```
allocator_type get_allocator() const;
```

Remarks

The member function returns a copy of the allocator object used by `*this` to allocate its `sub_match` objects.

match_results::iterator

The iterator type for submatches.

```
typedef const_iterator iterator;
```

Remarks

The type describes an object that can serve as a random-access iterator for the controlled sequence.

match_results::length

Returns length of a submatch.

```
difference_type length(size_type sub = 0) const;
```

Parameters

sub

The index of the submatch.

Remarks

The member function returns `(*this)[sub].length()`.

match_results::match_results

Constructs the object.

```
explicit match_results(const Alloc& alloc = Alloc());  
  
match_results(const match_results& right);
```

Parameters

alloc

The allocator object to store.

right

The match_results object to copy.

Remarks

The first constructor constructs a `match_results` object that holds no submatches. The second constructor constructs a `match_results` object that is a copy of *right*.

match_results::max_size

Gets largest number of submatches.

```
size_type max_size() const;
```

Remarks

The member function returns the length of the longest sequence that the object can control.

match_results::operator=

Copy a match_results object.

```
match_results& operator=(const match_results& right);
```

Parameters

right

The match_results object to copy.

Remarks

The member operator replaces the sequence controlled by `*this` with a copy of the sequence controlled by *right*.

match_results::operator[]

Access a subobject.

```
const_reference operator[](size_type n) const;
```

Parameters

n

Index of the submatch.

Remarks

The member function returns a reference to element *n* of the controlled sequence, or a reference to an empty

`sub_match` object if `size() <= n` or if capture group *n* was not part of the match.

match_results::position

Get starting offset of a subgroup.

```
difference_type position(size_type sub = 0) const;
```

Parameters

sub

Index of the submatch.

Remarks

The member function returns `std::distance(prefix().first, (*this)[sub].first)`, that is, the distance from the first character in the target sequence to the first character in the submatch pointed to by element `n` of the controlled sequence.

match_results::prefix

Gets sequence before first submatch.

```
const_reference prefix() const;
```

Remarks

The member function returns a reference to an object of type `sub_match<BidIt>` that points to the character sequence that begins at the start of the target sequence and ends at `(*this)[0].first`, that is, it points to the text that precedes the matched subsequence.

match_results::reference

The type of an element reference.

```
typedef const_reference reference;
```

Remarks

The type is a synonym for the type `const_reference`.

match_results::size

Counts number of submatches.

```
size_type size() const;
```

Remarks

The member function returns one more than the number of capture groups in the regular expression that was used for the search, or zero if no search has been made.

match_results::size_type

The type of a submatch count.

```
typedef typename Alloc::size_type size_type;
```

Remarks

The type is a synonym for the type `Alloc::size_type`.

match_results::str

Returns a submatch.

```
string_type str(size_type sub = 0) const;
```

Parameters

sub

Index of the submatch.

Remarks

The member function returns `string_type((*this)[sub])`.

match_results::string_type

The type of a string.

```
typedef basic_string<char_type> string_type;
```

Remarks

The type is a synonym for the type `basic_string<char_type>`.

match_results::suffix

Gets sequence after last submatch.

```
const_reference suffix() const;
```

Remarks

The member function returns a reference to an object of type `sub_match<BidIt>` that points to the character sequence that begins at `(*this)[size() - 1].second` and ends at the end of the target sequence, that is, it points to the text that follows the matched subsequence.

match_results::swap

Swaps two match_results objects.

```
void swap(const match_results& right) throw();
```

Parameters

right

The match_results object to swap with.

Remarks

The member function swaps the contents of `*this` and *right* in constant time and does not throw exceptions.

match_results::value_type

The type of a submatch.

```
typedef sub_match<BidIt> value_type;
```

Remarks

The typedef is a synonym for the type `sub_match<BidIt>` .

See also

[<regex>](#)

regex_constants namespace

10/31/2018 • 3 minutes to read • [Edit Online](#)

Namespace for regular expression flags.

Syntax

```
namespace regex_constants {  
    enum syntax_option_type;  
    enum match_flag_type;  
    enum error_type;  
}
```

Remarks

The namespace `regex_constants` encapsulates several flag types and their associated flag values.

<code>error_type</code>	Flags for reporting regular expression syntax errors.
<code>match_flag_type</code>	Flags for regular expression matching options.
<code>syntax_option_type</code>	Flags for selecting syntax options.

Requirements

Header: <regex>

Namespace: std

regex_constants::error_type

Flags for reporting regular expression syntax errors.

```
enum error_type  
{    // identify error  
    error_collate,  
    error_ctype,  
    error_escape,  
    error_backref,  
    error_brack,  
    error_paren,  
    error_brace,  
    error_badbrace,  
    error_range,  
    error_space,  
    error_badrepeat,  
    error_complexity,  
    error_stack,  
    error_parse,  
    error_syntax  
};
```

Remarks

The type is an enumerated type that describes an object that can hold error flags. The distinct flag values are:

`error_backref` -- the expression contained an invalid back reference

`error_badbrace` -- the expression contained an invalid count in a `{ }` expression

`error_badrepeat` -- a repeat expression (one of `'*'`, `'+'`, `'{'` in most contexts) was not preceded by an expression

`error_brace` -- the expression contained an unmatched `'{'` or `'}'`

`error_brack` -- the expression contained an unmatched `'['` or `']'`

`error_collate` -- the expression contained an invalid collating element name

`error_complexity` -- an attempted match failed because it was too complex

`error_ctype` -- the expression contained an invalid character class name

`error_escape` -- the expression contained an invalid escape sequence

`error_paren` -- the expression contained an unmatched `'('` or `')'`

`error_parse` -- the expression failed to parse

`error_range` -- the expression contained an invalid character range specifier

`error_space` -- parsing a regular expression failed because there were not enough resources available

`error_stack` -- an attempted match failed because there was not enough memory available

`error_syntax` -- parsing failed on a syntax error

`error_backref` -- the expression contained an invalid back reference

regex_constants::match_flag_type

Flags for regular expression matching options.

```
enum match_flag_type
{
    // specify matching and formatting rules
    match_default = 0x0000,
    match_not_bol = 0x0001,
    match_not_eol = 0x0002,
    match_not_bow = 0x0004,
    match_not_eow = 0x0008,
    match_any = 0x0010,
    match_not_null = 0x0020,
    match_continuous = 0x0040,
    match_prev_avail = 0x0100,
    format_default = 0x0000,
    format_sed = 0x0400,
    format_no_copy = 0x0800,
    format_first_only = 0x1000,
    _Match_not_null = 0x2000
};
```

Remarks

The type is a bitmask type that describes options to be used when matching a text sequence against a regular expression and format flags to be used when replacing text. Options can be combined with `|`.

The match options are:

match_default

`match_not_bol` -- do not treat the first position in the target sequence as the beginning of a line

`match_not_eol` -- do not treat the past-the-end position in the target sequence as the end of a line

`match_not_bow` -- do not treat the first position in the target sequence as the beginning of a word

`match_not_eow` -- do not treat the past-the-end position in the target sequence as the end of a word

`match_any` -- if more than one match is possible any match is acceptable

`match_not_null` -- do not treat an empty subsequence as a match

`match_continuous` -- do not search for matches other than at the beginning of the target sequence

`match_prev_avail` -- `--first` is a valid iterator; ignore `match_not_bol` and `match_not_bow` if set

The format flags are:

`format_default` -- use ECMAScript format rules

`format_sed` -- use sed format rules

`format_no_copy` -- do not copy text that does not match the regular expression

`format_first_only` -- do not search for matches after the first one

regex_constants::syntax_option_type

Flags for selecting syntax options.

```
enum syntax_option_type
{
    // specify RE syntax rules
    ECMAScript = 0x01,
    basic = 0x02,
    extended = 0x04,
    awk = 0x08,
    grep = 0x10,
    egrep = 0x20,
    _Gmask = 0x3F,

    icase = 0x0100,
    nosubs = 0x0200,
    optimize = 0x0400,
    collate = 0x0800
};
```

Remarks

The type is a bitmask type that describes language specifiers and syntax modifiers to be used when compiling a regular expression. Options can be combined with `|`. No more than one language specifier should be used at a time.

The language specifiers are:

`ECMAScript` -- compile as ECMAScript

`basic` -- compile as BRE

`extended` -- compile as ERE

`awk` -- compile as awk

`grep` -- compile as grep

`egrep` -- compile as egrep

The syntax modifiers are:

`icase` -- make matches case-insensitive

`nosubs` -- the implementation need not keep track of the contents of capture groups

`optimize` -- the implementation should emphasize speed of matching rather than speed of regular expression compilation

`collate` -- make matches locale-sensitive

regex_error Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Reports a bad basic_regex object.

Syntax

```
class regex_error
: public std::runtime_error
```

Remarks

The class describes an exception object thrown to report an error in the construction or use of a `basic_regex` object.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>regex_error</code>	Constructs the object.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>code</code>	Returns the error code.

Requirements

Header: <regex>

Namespace: std

Example

```
// std_regex_regex_error.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

int main()
{
    std::regex_error paren(std::regex_constants::error_paren);

    try
    {
        std::regex rx("(a");
    }
    catch (const std::regex_error& rerr)
    {
        std::cout << "regex error: "
            << (rerr.code() == paren.code() ? "unbalanced parentheses" : "")
            << std::endl;
    }
    catch (...)
    {
        std::cout << "unknown exception" << std::endl;
    }

    return (0);
}
```

```
regex error: unbalanced parentheses
```

regex_error::code

Returns the error code.

```
regex_constants::error_code code() const;
```

Remarks

The member function returns the value that was passed to the object's constructor.

regex_error::regex_error

Constructs the object.

```
regex_error(regex_constants::error_code error);
```

Parameters

error

The error code.

Remarks

The constructor constructs an object that holds the value *error*.

regex_iterator Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Iterator class for matches.

Syntax

```
template<class BidIt,  
        class Elem = typename std::iterator_traits<BidIt>::value_type,  
        class RxTraits = regex_traits<Elem> >  
class regex_iterator
```

Parameters

BidIt

The iterator type for submatches.

Elem

The type of elements to match.

Rxtraits

Traits class for elements.

Remarks

The template class describes a constant forward iterator object. It extracts objects of type `match_results<BidIt>` by repeatedly applying its regular expression object `*pregex` to the character sequence defined by the iterator range `[begin, end)`.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>regex_iterator</code>	Constructs the iterator.

Typedefs

TYPE NAME	DESCRIPTION
<code>difference_type</code>	The type of an iterator difference.
<code>iterator_category</code>	The type of the iterator category.
<code>pointer</code>	The type of a pointer to a match.
<code>reference</code>	The type of a reference to a match.
<code>regex_type</code>	The type of the regular expression to match.
<code>value_type</code>	The type of a match.

Operators

OPERATOR	DESCRIPTION
operator!=	Compares iterators for inequality.
operator*	Accesses the designated match.
operator++	Increments the iterator.
operator=	Compares iterators for equality.
operator->	Accesses the designated match.

Requirements

Header: `<regex>`

Namespace: `std`

Examples

See the following topics for examples on regular expressions:

- [regex_match](#)
- [regex_replace](#)
- [regex_search](#)
- [swap](#)

```

// std_regex_regex_iterator.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

typedef std::regex_iterator<const char *> Myiter;
int main()
{
    const char *pat = "axayaz";
    Myiter::regex_type rx("a");
    Myiter next(pat, pat + strlen(pat), rx);
    Myiter end;

    for (; next != end; ++next)
        std::cout << "match == " << next->str() << std::endl;

// other members
    Myiter it1(pat, pat + strlen(pat), rx);
    Myiter it2(it1);
    next = it1;

    Myiter::iterator_category cat = std::forward_iterator_tag();
    Myiter::difference_type dif = -3;
    Myiter::value_type mr = *it1;
    Myiter::reference ref = mr;
    Myiter::pointer ptr = &ref;

    dif = dif; // to quiet "unused" warnings
    ptr = ptr;

    return (0);
}

```

```

match == a
match == a
match == a

```

regex_iterator::difference_type

The type of an iterator difference.

```
typedef std::ptrdiff_t difference_type;
```

Remarks

The type is a synonym for `std::ptrdiff_t`.

regex_iterator::iterator_category

The type of the iterator category.

```
typedef std::forward_iterator_tag iterator_category;
```

Remarks

The type is a synonym for `std::forward_iterator_tag`.

regex_iterator::operator!=

Compares iterators for inequality.

```
bool operator!=(const regex_iterator& right);
```

Parameters

right

The iterator to compare to.

Remarks

The member function returns `!(*this == right)`.

regex_iterator::operator*

Accesses the designated match.

```
const match_results<BidIt>& operator*();
```

Remarks

The member function returns the stored value `match`.

regex_iterator::operator++

Increments the iterator.

```
regex_iterator& operator++();  
regex_iterator& operator++(int);
```

Remarks

If the current match has no characters the first operator calls

```
regex_search(begin, end, match, *pregex, flags | regex_constants::match_prev_avail |  
regex_constants::match_not_null)
```

; otherwise it advances the stored value `begin` to point to the first character after the current match then calls

```
regex_search(begin, end, match, *pregex, flags | regex_constants::match_prev_avail)
```

. In either case, if the

search fails the operator sets the object to an end-of-sequence iterator. The operator returns the object.

The second operator makes a copy of the object, increments the object, then returns the copy.

regex_iterator::operator==

Compares iterators for equality.

```
bool operator==(const regex_iterator& right);
```

Parameters

right

The iterator to compare to.

Remarks

The member function returns true if `*this` and *right* are both end-of-sequence iterators or if neither is an end-of-sequence iterator and `begin == right.begin`, `end == right.end`, `pregex == right.pregex`, and `flags == right.flags`. Otherwise it returns false.

regex_iterator::operator->

Accesses the designated match.

```
const match_results<BidIt> * operator->();
```

Remarks

The member function returns the address of the stored value `match`.

regex_iterator::pointer

The type of a pointer to a match.

```
typedef match_results<BidIt> *pointer;
```

Remarks

The type is a synonym for `match_results<BidIt>*`, where `BidIt` is the template parameter.

regex_iterator::reference

The type of a reference to a match.

```
typedef match_results<BidIt>& reference;
```

Remarks

The type is a synonym for `match_results<BidIt>&`, where `BidIt` is the template parameter.

regex_iterator::regex_iterator

Constructs the iterator.

```
regex_iterator();

regex_iterator(BidIt first,
              BidIt last,
              const regex_type& re,
              regex_constants::match_flag_type f = regex_constants::match_default);
```

Parameters

first

Beginning of sequence to match.

last

End of sequence to match.

re

Regular expression for matches.

f

Flags for matches.

Remarks

The first constructor constructs an end-of-sequence iterator. The second constructor initializes the stored value

`begin` with *first*, the stored value `end` with *last*, the stored value `pregex` with `&re`, and the stored value `flags` with *f*. It then calls `regex_search(begin, end, match, *pregex, flags)`. If the search fails, the constructor sets the object to an end-of-sequence iterator.

regex_iterator::regex_type

The type of the regular expression to match.

```
typedef basic_regex<Elem, RXtraits> regex_type;
```

Remarks

The typedef is a synonym for `basic_regex<Elem, RXtraits>`.

regex_iterator::value_type

The type of a match.

```
typedef match_results<BidIt> value_type;
```

Remarks

The type is a synonym for `match_results<BidIt>`, where `BidIt` is the template parameter.

regex_token_iterator Class

10/31/2018 • 6 minutes to read • [Edit Online](#)

Iterator class for submatches.

Syntax

```
template<class BidIt,  
        class Elem = typename std::iterator_traits<BidIt>::value_type,  
        class RxTraits = regex_traits<Elem> >  
class regex_token_iterator
```

Parameters

BidIt

The iterator type for submatches.

Elem

The type of elements to match.

RXtraits

Traits class for elements.

Remarks

The template class describes a constant forward iterator object. Conceptually, it holds a `regex_iterator` object that it uses to search for regular expression matches in a character sequence. It extracts objects of type `sub_match<BidIt>` representing the submatches identified by the index values in the stored vector `subs` for each regular expression match.

An index value of -1 designates the character sequence beginning immediately after the end of the previous regular expression match, or beginning at the start of the character sequence if there was no previous regular expression match, and extending to but not including the first character of the current regular expression match, or to the end of the character sequence if there is no current match. Any other index value `idx` designates the contents of the capture group held in `it.match[idx]`.

Members

MEMBER	DEFAULT VALUE
<code>private regex_iterator<BidIt, Elem, RXtraits> it</code>	
<code>private vector<int> subs</code>	
<code>private int pos</code>	

Constructors

CONSTRUCTOR	DESCRIPTION
<code>regex_token_iterator</code>	Constructs the iterator.

Typedefs

TYPE NAME	DESCRIPTION
<code>difference_type</code>	The type of an iterator difference.
<code>iterator_category</code>	The type of the iterator category.
<code>pointer</code>	The type of a pointer to a match.
<code>reference</code>	The type of a reference to a submatch.
<code>regex_type</code>	The type of the regular expression to match.
<code>value_type</code>	The type of a submatch.

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Compares iterators for inequality.
<code>operator*</code>	Accesses the designated submatch.
<code>operator++</code>	Increments the iterator.
<code>operator==</code>	Compares iterators for equality.
<code>operator-></code>	Accesses the designated submatch.

Requirements

Header: `<regex>`

Namespace: `std`

Example

```

#include <regex>
#include <iostream>

typedef std::regex_token_iterator<const char *> Myiter;
int main()
{
    const char *pat = "aaxaayaaz";
    Myiter::regex_type rx("(a)a");
    Myiter next(pat, pat + strlen(pat), rx);
    Myiter end;

    // show whole match
    for (; next != end; ++next)
        std::cout << "match == " << next->str() << std::endl;
    std::cout << std::endl;

    // show prefix before match
    next = Myiter(pat, pat + strlen(pat), rx, -1);
    for (; next != end; ++next)
        std::cout << "match == " << next->str() << std::endl;
    std::cout << std::endl;

    // show (a) submatch only
    next = Myiter(pat, pat + strlen(pat), rx, 1);
    for (; next != end; ++next)
        std::cout << "match == " << next->str() << std::endl;
    std::cout << std::endl;

    // show prefixes and submatches
    std::vector<int> vec;
    vec.push_back(-1);
    vec.push_back(1);
    next = Myiter(pat, pat + strlen(pat), rx, vec);
    for (; next != end; ++next)
        std::cout << "match == " << next->str() << std::endl;
    std::cout << std::endl;

    // show prefixes and whole matches
    int arr[] = {-1, 0};
    next = Myiter(pat, pat + strlen(pat), rx, arr);
    for (; next != end; ++next)
        std::cout << "match == " << next->str() << std::endl;
    std::cout << std::endl;

    // other members
    Myiter it1(pat, pat + strlen(pat), rx);
    Myiter it2(it1);
    next = it1;

    Myiter::iterator_category cat = std::forward_iterator_tag();
    Myiter::difference_type dif = -3;
    Myiter::value_type mr = *it1;
    Myiter::reference ref = mr;
    Myiter::pointer ptr = &ref;

    dif = dif; // to quiet "unused" warnings
    ptr = ptr;

    return (0);
}

```

```
match == aa
match == aa
match == aa

match ==
match == x
match == y
match == z

match == a
match == a
match == a

match ==
match == a
match == x
match == a
match == y
match == a
match == z

match ==
match == aa
match == x
match == aa
match == y
match == aa
match == z
```

regex_token_iterator::difference_type

The type of an iterator difference.

```
typedef std::ptrdiff_t difference_type;
```

Remarks

The type is a synonym for `std::ptrdiff_t`.

regex_token_iterator::iterator_category

The type of the iterator category.

```
typedef std::forward_iterator_tag iterator_category;
```

Remarks

The type is a synonym for `std::forward_iterator_tag`.

regex_token_iterator::operator!=

Compares iterators for inequality.

```
bool operator!=(const regex_token_iterator& right);
```

Parameters

right

The iterator to compare to.

Remarks

The member function returns `!(*this == right)`.

regex_token_iterator::operator*

Accesses the designated submatch.

```
const sub_match<BidIt>& operator*();
```

Remarks

The member function returns a `sub_match<BidIt>` object representing the capture group identified by the index value `subs[pos]`.

regex_token_iterator::operator++

Increments the iterator.

```
regex_token_iterator& operator++();  
  
regex_token_iterator& operator++(int);
```

Remarks

If the stored iterator `it` is an end-of-sequence iterator the first operator sets the stored value `pos` to the value of `subs.size()` (thus making an end-of-sequence iterator). Otherwise the operator increments the stored value `pos`; if the result is equal to the value `subs.size()` it sets the stored value `pos` to zero and increments the stored iterator `it`. If incrementing the stored iterator leaves it unequal to an end-of-sequence iterator the operator does nothing further. Otherwise, if the end of the preceding match was at the end of the character sequence the operator sets the stored value of `pos` to `subs.size()`. Otherwise, the operator repeatedly increments the stored value `pos` until `pos == subs.size()` or `subs[pos] == -1` (thus ensuring that the next dereference of the iterator will return the tail of the character sequence if one of the index values is -1). In all cases the operator returns the object.

The second operator makes a copy of the object, increments the object, then returns the copy.

regex_token_iterator::operator==

Compares iterators for equality.

```
bool operator==(const regex_token_iterator& right);
```

Parameters

right

The iterator to compare to.

Remarks

The member function returns `it == right.it && subs == right.subs && pos == right.pos`.

regex_token_iterator::operator->

Accesses the designated submatch.

```
const sub_match<BidIt> * operator->();
```

Remarks

The member function returns a pointer to a `sub_match<BidIt>` object representing the capture group identified by the index value `subs[pos]`.

regex_token_iterator::pointer

The type of a pointer to a match.

```
typedef sub_match<BidIt> *pointer;
```

Remarks

The type is a synonym for `sub_match<BidIt>*`, where `BidIt` is the template parameter.

regex_token_iterator::reference

The type of a reference to a submatch.

```
typedef sub_match<BidIt>& reference;
```

Remarks

The type is a synonym for `sub_match<BidIt>&`, where `BidIt` is the template parameter.

regex_token_iterator::regex_token_iterator

Constructs the iterator.

```
regex_token_iterator();

regex_token_iterator(BidIt first, BidIt last,
    const regex_type& re, int submatch = 0,
    regex_constants::match_flag_type f = regex_constants::match_default);

regex_token_iterator(BidIt first, BidIt last,
    const regex_type& re, const vector<int> submatches,
    regex_constants::match_flag_type f = regex_constants::match_default);

template <std::size_t N>
regex_token_iterator(BidIt first, BidIt last,
    const regex_type& re, const int (&submatches)[N],
    regex_constants::match_flag_type f = regex_constants::match_default);
```

Parameters

first

Beginning of sequence to match.

last

End of sequence to match.

re

Regular expression for matches.

f

Flags for matches.

Remarks

The first constructor constructs an end-of-sequence iterator.

The second constructor constructs an object whose stored iterator `it` is initialized to `regex_iterator<BidIt, Elem, RXtraits>(first, last, re, f)`, whose stored vector `subs` holds exactly one integer, with value `submatch`, and whose stored value `pos` is zero. Note: the resulting object extracts the submatch identified by the index value `submatch` for each successful regular expression match.

The third constructor constructs an object whose stored iterator `it` is initialized to `regex_iterator<BidIt, Elem, RXtraits>(first, last, re, f)`, whose stored vector `subs` holds a copy of the constructor argument `submatches`, and whose stored value `pos` is zero.

The fourth constructor constructs an object whose stored iterator `it` is initialized to `regex_iterator<BidIt, Elem, RXtraits>(first, last, re, f)`, whose stored vector `subs` holds the `N` values pointed to by the constructor argument `submatches`, and whose stored value `pos` is zero.

regex_token_iterator::regex_type

The type of the regular expression to match.

```
typedef basic_regex<Elem, RXtraits> regex_type;
```

Remarks

The typedef is a synonym for `basic_regex<Elem, RXtraits>`.

regex_token_iterator::value_type

The type of a submatch.

```
typedef sub_match<BidIt> value_type;
```

Remarks

The type is a synonym for `sub_match<BidIt>`, where `BidIt` is the template parameter.

regex_traits Class

10/31/2018 • 7 minutes to read • [Edit Online](#)

Describes characteristics of elements for matching.

Syntax

```
template<class Elem>
class regex_traits
```

Parameters

Elem

The character element type to describe.

Remarks

The template class describes various regular expression traits for type *Elem*. The template class [basic_regex Class](#) uses this information to manipulate elements of type *Elem*.

Each `regex_traits` object holds an object of type `regex_traits::locale` which is used by some of its member functions. The default locale is a copy of `regex_traits::locale()`. The member function `imbue` replaces the locale object, and the member function `getloc` returns a copy of the locale object.

Constructors

CONSTRUCTOR	DESCRIPTION
regex_traits	Constructs the object.

Typedefs

TYPE NAME	DESCRIPTION
char_class_type	The type of character class designators.
char_type	The type of an element.
locale_type	The type of the stored locale object.
size_type	The type of a sequence length.
string_type	The type of a string of elements.

Member functions

MEMBER FUNCTION	DESCRIPTION
getloc	Returns the stored locale object.

MEMBER FUNCTION	DESCRIPTION
<code>imbue</code>	Alters the stored locale object.
<code>istype</code>	Tests for class membership.
<code>length</code>	Returns the length of a null-terminated sequence.
<code>lookup_classname</code>	Maps a sequence to a character class.
<code>lookup_collatename</code>	Maps a sequence to a collating element.
<code>transform</code>	Converts to equivalent ordered sequence.
<code>transform_primary</code>	Converts to equivalent caseless ordered sequence.
<code>translate</code>	Converts to equivalent matching element.
<code>translate_nocase</code>	Converts to equivalent caseless matching element.
<code>value</code>	Converts an element to a digit value.

Requirements

Header: <regex>

Namespace: std

Example

```

// std_regex_traits.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

typedef std::regex_traits<char> Mytr;
int main()
{
    Mytr tr;

    Mytr::char_type ch = tr.translate('a');
    std::cout << "translate('a') == 'a' == " << std::boolalpha
        << (ch == 'a') << std::endl;

    std::cout << "nocase 'a' == 'A' == " << std::boolalpha
        << (tr.translate_nocase('a') == tr.translate_nocase('A'))
        << std::endl;

    const char *lbegin = "abc";
    const char *lend = lbegin + strlen(lbegin);
    Mytr::size_type size = tr.length(lbegin);
    std::cout << "length(\"abc\") == " << size << std::endl;

    Mytr::string_type str = tr.transform(lbegin, lend);
    std::cout << "transform(\"abc\") < \"abc\" == " << std::boolalpha
        << (str < "abc") << std::endl;

    const char *ubegin = "ABC";
    const char *uend = ubegin + strlen(ubegin);
    std::cout << "primary \"ABC\" < \"abc\" == " << std::boolalpha
        << (tr.transform_primary(ubegin, uend) <
            tr.transform_primary(lbegin, lend))
        << std::endl;

    const char *dig = "digit";
    Mytr::char_class_type cl = tr.lookup_classname(dig, dig + 5);
    std::cout << "class digit == d == " << std::boolalpha
        << (cl == tr.lookup_classname(dig, dig + 1))
        << std::endl;

    std::cout << "'3' is digit == " << std::boolalpha
        << tr.istype('3', tr.lookup_classname(dig, dig + 5))
        << std::endl;

    std::cout << "hex C == " << tr.value('C', 16) << std::endl;

    // other members
    str = tr.lookup_collatename(dig, dig + 5);

    Mytr::locale_type loc = tr.getloc();
    tr.imbue(loc);

    return (0);
}

```

```

translate('a') == 'a' == true
nocase 'a' == 'A' == true
length("abc") == 3
transform("abc") < "abc" == false
primary "ABC" < "abc" == false
class digit == d == true
'3' is digit == true
hex C == 12

```

regex_traits::char_class_type

The type of character class designators.

```
typedef T8 char_class_type;
```

Remarks

The type is a synonym for an unspecified type that designates character classes. Values of this type can be combined using the `|` operator to designate character classes that are the union of the classes designated by the operands.

regex_traits::char_type

The type of an element.

```
typedef Elem char_type;
```

Remarks

The typedef is a synonym for the template argument `Elem`.

regex_traits::getloc

Returns the stored locale object.

```
locale_type getloc() const;
```

Remarks

The member function returns the stored `locale` object.

regex_traits::imbue

Alters the stored locale object.

```
locale_type imbue(locale_type loc);
```

Parameters

loc

The locale object to store.

Remarks

The member function copies *loc* to the stored `locale` object and returns a copy of the previous value of the stored `locale` object.

regex_traits::isctype

Tests for class membership.

```
bool isctype(char_type ch, char_class_type cls) const;
```

Parameters

ch

The element to test.

cls

The classes to test for.

Remarks

The member function returns true only if the character *ch* is in the character class designated by *cls*.

regex_traits::length

Returns the length of a null-terminated sequence.

```
static size_type length(const char_type *str);
```

Parameters

str

The null-terminated sequence.

Remarks

The static member function returns `std::char_traits<char_type>::length(str)`.

regex_traits::locale_type

The type of the stored locale object.

```
typedef T7 locale_type;
```

Remarks

The typedef is a synonym for a type that encapsulates locales. In the specializations `regex_traits<char>` and `regex_traits<wchar_t>` it is a synonym for `std::locale`.

regex_traits::lookup_classname

Maps a sequence to a character class.

```
template <class FwdIt>
char_class_type lookup_classname(FwdIt first, FwdIt last) const;
```

Parameters

first

Beginning of sequence to look up.

last

End of sequence to look up.

Remarks

The member function returns a value that designates the character class named by the character sequence pointed to by its arguments. The value does not depend on the case of the characters in the sequence.

The specialization `regex_traits<char>` recognizes the names `"d"`, `"s"`, `"w"`, `"alnum"`, `"alpha"`, `"blank"`, `"cntrl"`, `"digit"`, `"graph"`, `"lower"`, `"print"`, `"punct"`, `"space"`, `"upper"`, and `"xdigit"`, all without regard

to case.

The specialization `regex_traits<wchar_t>` recognizes the names `L"d"`, `L"s"`, `L"w"`, `L"alnum"`, `L"alpha"`, `L"blank"`, `L"cntrl"`, `L"digit"`, `L"graph"`, `L"lower"`, `L"print"`, `L"punct"`, `L"space"`, `L"upper"`, and `L"xdigit"`, all without regard to case.

regex_traits::lookup_collatename

Maps a sequence to a collating element.

```
template <class FwdIt>
string_type lookup_collatename(FwdIt first, FwdIt last) const;
```

Parameters

first

Beginning of sequence to look up.

last

End of sequence to look up.

Remarks

The member function returns a string object containing the collating element corresponding to the sequence `[first, last)`, or an empty string if the sequence is not a valid collating element.

regex_traits::regex_traits

Constructs the object.

```
regex_traits();
```

Remarks

The constructor constructs an object whose stored `locale` object is initialized to the default locale.

regex_traits::size_type

The type of a sequence length.

```
typedef T6 size_type;
```

Remarks

The typedef is a synonym for an unsigned integral type. In the specializations `regex_traits<char>` and `regex_traits<wchar_t>` it is a synonym for `std::size_t`.

The typedef is a synonym for `std::size_t`.

regex_traits::string_type

The type of a string of elements.

```
typedef basic_string<Elem> string_type;
```

Remarks

The typedef is a synonym for `basic_string<Elem>`.

regex_traits::transform

Converts to equivalent ordered sequence.

```
template <class FwdIt>
string_type transform(FwdIt first, FwdIt last) const;
```

Parameters

first

Beginning of sequence to transform.

last

End of sequence to transform.

Remarks

The member function returns a string that it generates by using a transformation rule that depends on the stored `locale` object. For two character sequences designated by the iterator ranges `[first1, last1)` and `[first2, last2)`, `transform(first1, last1) < transform(first2, last2)` if the character sequence designated by the iterator range `[first1, last1)` sorts before the character sequence designated by the iterator range `[first2, last2)`.

regex_traits::transform_primary

Converts to equivalent caseless ordered sequence.

```
template <class FwdIt>
string_type transform_primary(FwdIt first, FwdIt last) const;
```

Parameters

first

Beginning of sequence to transform.

last

End of sequence to transform.

Remarks

The member function returns a string that it generates by using a transformation rule that depends on the stored `locale` object. For two character sequences designated by the iterator ranges `[first1, last1)` and `[first2, last2)`, `transform_primary(first1, last1) < transform_primary(first2, last2)` if the character sequence designated by the iterator range `[first1, last1)` sorts before the character sequence designated by the iterator range `[first2, last2)` without regard for case or accents.

regex_traits::translate

Converts to equivalent matching element.

```
char_type translate(char_type ch) const;
```

Parameters

ch

The element to convert.

Remarks

The member function returns a character that it generates by using a transformation rule that depends on the stored `locale` object. For two `char_type` objects `ch1` and `ch2`, `translate(ch1) == translate(ch2)` only if `ch1` and `ch2` should match when one occurs in the regular expression definition and the other occurs at a corresponding position in the target sequence for a locale-sensitive match.

regex_traits::translate_nocase

Converts to equivalent caseless matching element.

```
char_type translate_nocase(char_type ch) const;
```

Parameters

ch

The element to convert.

Remarks

The member function returns a character that it generates by using a transformation rule that depends on the stored `locale` object. For two `char_type` objects `ch1` and `ch2`, `translate_nocase(ch1) == translate_nocase(ch2)` only if `ch1` and `ch2` should match when one occurs in the regular expression definition and the other occurs at a corresponding position in the target sequence for a case-insensitive match.

regex_traits::value

Converts an element to a digit value.

```
int value(Elem ch, int radix) const;
```

Parameters

ch

The element to convert.

radix

The arithmetic base to use.

Remarks

The member function returns the value represented by the character *ch* in the base *radix*, or -1 if *ch* is not a valid digit in the base *radix*. The function will only be called with a *radix* argument of 8, 10, or 16.

regex_traits<char> Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Specialization of `regex_traits` for **char**.

Syntax

```
template <>
class regex_traits<char>
```

Remarks

The class is an explicit specialization of template class [regex_traits](#) for elements of type **char** (so that it can take advantage of library functions that manipulate objects of this type).

Requirements

Header: <regex>

Namespace: std

regex_traits<wchar_t> Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Specialization of `regex_traits` for **wchar_t**.

Syntax

```
template <>
class regex_traits<wchar_t>
```

Remarks

The class is an explicit specialization of template class [regex_traits](#) for elements of type **wchar_t** (so that it can take advantage of library functions that manipulate objects of this type).

Requirements

Header: <regex>

Namespace: std

sub_match Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Describes a submatch.

Syntax

```
template <class BidIt>
class sub_match
: public std::pair<BidIt, BidIt>
```

Parameters

BidIt

The iterator type for submatches.

Remarks

The template class describes an object that designates a sequence of characters that matched a capture group in a call to [regex_match](#) or to [regex_search](#). Objects of type [match_results Class](#) hold an array of these objects, one for each capture group in the regular expression that was used in the search.

If the capture group was not matched the object's data member `matched` holds false, and the two iterators `first` and `second` (inherited from the base `std::pair`) are equal. If the capture group was matched, `matched` holds true, the iterator `first` points to the first character in the target sequence that matched the capture group, and the iterator `second` points one position past the last character in the target sequence that matched the capture group. Note that for a zero-length match the member `matched` holds true, the two iterators will be equal, and both will point to the position of the match.

A zero-length match can occur when a capture group consists solely of an assertion, or of a repetition that allows zero repeats. For example:

"^" matches the target sequence "a"; the `sub_match` object corresponding to capture group 0 holds iterators that both point to the first character in the sequence.

"b(a*)b" matches the target sequence "bb"; the `sub_match` object corresponding to capture group 1 holds iterators that both point to the second character in the sequence.

Typedefs

TYPE NAME	DESCRIPTION
difference_type	The type of an iterator difference.
iterator	The type of an iterator.
value_type	The type of an element.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>compare</code>	Compare submatch against a sequence.
<code>length</code>	Returns the length of a submatch.
<code>matched</code>	Indicates if match succeeded.
<code>str</code>	Converts submatch to a string.

Operators

OPERATOR	DESCRIPTION
<code>operator basic_string<value_type></code>	Casts submatch to a string.

Example

```
// std__regex__sub_match.cpp
// compile with: /EHsc
#include <regex>
#include <iostream>

int main()
{
    std::regex rx("c(a*)|(b)");
    std::cmatch mr;

    std::regex_search("xcaaay", mr, rx);

    std::csub_match sub = mr[1];
    std::cout << "matched == " << std::boolalpha
              << sub.matched << std::endl;
    std::cout << "length == " << sub.length() << std::endl;

    std::csub_match::difference_type dif = std::distance(sub.first, sub.second);
    std::cout << "difference == " << dif << std::endl;

    std::csub_match::iterator first = sub.first;
    std::csub_match::iterator last = sub.second;
    std::cout << "range == " << std::string(first, last)
              << std::endl;
    std::cout << "string == " << sub << std::endl;

    std::csub_match::value_type const *ptr = "aab";
    std::cout << "compare(\"aab\") == "
              << sub.compare(ptr) << std::endl;
    std::cout << "compare(string) == "
              << sub.compare(std::string("AAA")) << std::endl;
    std::cout << "compare(sub) == "
              << sub.compare(sub) << std::endl;

    return (0);
}
```

```
matched == true
length == 3
difference == 3
range == aaa
string == aaa
compare("aab") == -1
compare(string) == 1
compare(sub) == 0
```

Requirements

Header: <regex>

Namespace: std

sub_match::compare

Compare submatch against a sequence.

```
int compare(const sub_match& right) const;
int compare(const basic_string<value_type>& str) const;
int compare(const value_type *ptr) const;
```

Parameters

right

The submatch to compare to.

str

The string to compare to.

ptr

The null-terminated sequence to compare to.

Remarks

The first member function compares the matched sequence `[first, second)` to the matched sequence `[right.first, right.second)`. The second member function compares the matched sequence `[first, second)` to the character sequence `[right.begin(), right.end())`. The third member function compares the matched sequence `[first, second)` to the character sequence `[right, right + std::char_traits<value_type>::length(right))`.

Each function returns:

a negative value if the first differing value in the matched sequence compares less than the corresponding element in the operand sequence (as determined by `std::char_traits<value_type>::compare`), or if the two have a common prefix but the target sequence is longer

zero if the two compare equal element by element and have the same length

a positive value otherwise

sub_match::difference_type

The type of an iterator difference.

```
typedef typename iterator_traits<BidIt>::difference_type difference_type;
```

Remarks

The typedef is a synonym for `iterator_traits<BidIt>::difference_type` .

sub_match::iterator

The type of an iterator.

```
typedef BidIt iterator;
```

Remarks

The typedef is a synonym for the template type argument `Bidit` .

sub_match::length

Returns the length of a submatch.

```
difference_type length() const;
```

Remarks

The member function returns the length of the matched sequence, or zero if there was no matched sequence.

sub_match::matched

Indicates if match succeeded.

```
bool matched;
```

Remarks

The member holds **true** only if the capture group associated with `*this` was part of the regular expression match.

sub_match::operator basic_string<value_type>

Casts submatch to a string.

```
operator basic_string<value_type>() const;
```

Remarks

The member operator returns `str()` .

sub_match::str

Converts submatch to a string.

```
basic_string<value_type> str() const;
```

Remarks

The member function returns `basic_string<value_type>(first, second)` .

sub_match::value_type

The type of an element.

```
typedef typename iterator_traits<BidIt>::value_type value_type;
```

Remarks

The typedef is a synonym for `iterator_traits<BidIt>::value_type` .

<scoped_allocator>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template class `scoped_allocator`.

Syntax

```
#include <scoped_allocator>
```

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests if the <code>scoped_allocator</code> object on the left side of the operator is not equal to the list object on the right side.
<code>operator==</code>	Tests if the <code>scoped_allocator</code> object on the left side of the operator is equal to the list object on the right side.

Classes

CLASS	DESCRIPTION
<code>scoped_allocator_adaptor</code> Class	A template class that encapsulates a nest of one or more allocators.

See also

[C++ Standard Library Reference](#)

<scoped_allocator> operators

10/31/2018 • 2 minutes to read • [Edit Online](#)

`operator!=`

`operator==`

operator!=

Tests two `scoped_allocator_adaptor` objects for inequality.

```
template <class Outer, class... Inner>
bool operator!=(
    const scoped_allocator_adaptor<Outer, Inner...>& left,
    const scoped_allocator_adaptor<Outer, Inner...>& right) noexcept;
```

Parameters

left

The left `scoped_allocator_adaptor` object.

right

The right `scoped_allocator_adaptor` object.

Return Value

`!(left == right)`

operator==

Tests two `scoped_allocator_adaptor` objects for equality.

```
template <class Outer, class... Inner>
bool operator==(
    const scoped_allocator_adaptor<Outer, Inner...>& left,
    const scoped_allocator_adaptor<Outer, Inner...>& right) noexcept;
```

Parameters

left

The left `scoped_allocator_adaptor` object.

right

The right `scoped_allocator_adaptor` object.

Return Value

`left.outer_allocator() == right.outer_allocator() && left.inner_allocator() == right.inner_allocator()`

See also

[<scoped_allocator>](#)

scoped_allocator_adaptor Class

10/31/2018 • 6 minutes to read • [Edit Online](#)

Represents a nest of allocators.

Syntax

```
template <class Outer, class... Inner>
class scoped_allocator_adaptor;
```

Remarks

The template class encapsulates a nest of one or more allocators. Each such class has an outermost allocator of type `outer_allocator_type`, a synonym for `Outer`, which is a public base of the `scoped_allocator_adaptor` object. `Outer` is used to allocate memory to be used by a container. You can obtain a reference to this allocator base object by calling `outer_allocator`.

The remainder of the nest has type `inner_allocator_type`. An inner allocator is used to allocate memory for elements within a container. You can obtain a reference to the stored object of this type by calling `inner_allocator`. If `Inner...` is not empty, `inner_allocator_type` has type `scoped_allocator_adaptor<Inner...>`, and `inner_allocator` designates a member object. Otherwise, `inner_allocator_type` has type `scoped_allocator_adaptor<Outer>`, and `inner_allocator` designates the entire object.

The nest behaves as if it has arbitrary depth, replicating its innermost encapsulated allocator as needed.

Several concepts that are not a part of the visible interface aid in describing the behavior of this template class. An *outermost allocator* mediates all calls to the construct and destroy methods. It is effectively defined by the recursive function `OUTERMOST(X)`, where `OUTERMOST(X)` is one of the following.

- If `X.outer_allocator()` is well formed, then `OUTERMOST(X)` is `OUTERMOST(X.outer_allocator())`.
- Otherwise, `OUTERMOST(X)` is `X`.

Three types are defined for the sake of exposition:

TYPE	DESCRIPTION
<code>Outermost</code>	The type of <code>OUTERMOST(*this)</code> .
<code>Outermost_traits</code>	<code>allocator_traits<Outermost></code>
<code>Outer_traits</code>	<code>allocator_traits<Outer></code>

Constructors

NAME	DESCRIPTION
<code>scoped_allocator_adaptor</code>	Constructs a <code>scoped_allocator_adaptor</code> object.

Typedefs

NAME	DESCRIPTION
<code>const_pointer</code>	This type is a synonym for the <code>const_pointer</code> that is associated with the allocator <code>Outer</code> .
<code>const_void_pointer</code>	This type is a synonym for the <code>const_void_pointer</code> that is associated with the allocator <code>Outer</code> .
<code>difference_type</code>	This type is a synonym for the <code>difference_type</code> that is associated with the allocator <code>Outer</code> .
<code>inner_allocator_type</code>	This type is a synonym for the type of the nested adaptor <code>scoped_allocator_adaptor<Inner...></code> .
<code>outer_allocator_type</code>	This type is a synonym for the type of the base allocator <code>Outer</code> .
<code>pointer</code>	This type is a synonym for the <code>pointer</code> associated with the allocator <code>Outer</code> .
<code>propagate_on_container_copy_assignment</code>	The type holds true only if <code>Outer_traits::propagate_on_container_copy_assignment</code> holds true or <code>inner_allocator_type::propagate_on_container_copy_assignment</code> holds true.
<code>propagate_on_container_move_assignment</code>	The type holds true only if <code>Outer_traits::propagate_on_container_move_assignment</code> holds true or <code>inner_allocator_type::propagate_on_container_move_assignment</code> holds true.
<code>propagate_on_container_swap</code>	The type holds true only if <code>Outer_traits::propagate_on_container_swap</code> holds true or <code>inner_allocator_type::propagate_on_container_swap</code> holds true.
<code>size_type</code>	This type is a synonym for the <code>size_type</code> associated with the allocator <code>Outer</code> .
<code>value_type</code>	This type is a synonym for the <code>value_type</code> associated with the allocator <code>Outer</code> .
<code>void_pointer</code>	This type is a synonym for the <code>void_pointer</code> associated with the allocator <code>Outer</code> .

Structs

NAME	DESCRIPTION
scoped_allocator_adaptor::rebind Struct	Defines the type <code>Outer::rebind<Other>::other</code> as a synonym for <code>scoped_allocator_adaptor<Other, Inner...></code> .

Methods

NAME	DESCRIPTION
<code>allocate</code>	Allocates memory by using the <code>Outer</code> allocator.
<code>construct</code>	Constructs an object.
<code>deallocate</code>	Deallocates objects by using the outer allocator.
<code>destroy</code>	Destroys a specified object.
<code>inner_allocator</code>	Retrieves a reference to the stored object of type <code>inner_allocator_type</code> .
<code>max_size</code>	Determines the maximum number of objects that can be allocated by the outer allocator.
<code>outer_allocator</code>	Retrieves a reference to the stored object of type <code>outer_allocator_type</code> .
<code>select_on_container_copy_construction</code>	Creates a new <code>scoped_allocator_adaptor</code> object with each stored allocator object initialized by calling <code>select_on_container_copy_construction</code> for each corresponding allocator.

Requirements

Header: `<scoped_allocator>`

Namespace: `std`

`scoped_allocator_adaptor::allocate`

Allocates memory by using the `Outer` allocator.

```
pointer allocate(size_type count);
pointer allocate(size_type count, const_void_pointer hint);
```

Parameters

count

The number of elements for which sufficient storage is to be allocated.

hint

A pointer that might assist the allocator object by locating the address of an object allocated prior to the request.

Return Value

The first member function returns `Outer_traits::allocate(outer_allocator(), count)`. The second member function returns `Outer_traits::allocate(outer_allocator(), count, hint)`.

`scoped_allocator_adaptor::construct`

Constructs an object.

```

template <class Ty, class... Atypes>
void construct(Ty* ptr, Atypes&&... args);

template <class Ty1, class Ty2, class... Atypes1, class... Atypes2>
void construct(pair<Ty1, Ty2>* ptr, piecewise_construct_t,
    tuple<Atypes1&&...>
first, tuple<Atypes1&&...> second);

template <class Ty1, class Ty2>
void construct(pair<Ty1, Ty2>* ptr);

template <class Ty1, class Ty2, class Uy1, class Uy2>
void construct(pair<Ty1, Ty2>* ptr,
    class Uy1&& first, class Uy2&& second);

template <class Ty1, class Ty2, class Uy1, class Uy2>
void construct(pair<Ty1, Ty2>* ptr, const pair<Uy1, Uy2>& right);

template <class Ty1, class Ty2, class Uy1, class Uy2>
void construct(pair<Ty1, Ty2>* ptr, pair<Uy1, Uy2>&& right);

```

Parameters

ptr

A pointer to the memory location where the object is to be constructed.

args

A list of arguments.

first

An object of the first type in a pair.

second

An object of the second type in a pair.

right

An existing object to be moved or copied.

Remarks

The first method constructs the object at *ptr* by calling

`Outermost_traits::construct(OUTERMOST(*this), ptr, xargs...)`, where `xargs...` is one of the following.

- If `uses_allocator<Ty, inner_allocator_type>` holds false, then `xargs...` is `args...`.
- If `uses_allocator<Ty, inner_allocator_type>` holds true, and `is_constructible<Ty, allocator_arg_t, inner_allocator_type, args...>` holds true, then `xargs...` is `allocator_arg, inner_allocator(), args...`.
- If `uses_allocator<Ty, inner_allocator_type>` holds true, and `is_constructible<Ty, args..., inner_allocator()>` holds true, then `xargs...` is `args..., inner_allocator()`.

The second method constructs the pair object at *ptr* by calling

`Outermost_traits::construct(OUTERMOST(*this), &ptr->first, xargs...)`, where `xargs...` is `first...` modified as in the above list, and `Outermost_traits::construct(OUTERMOST(*this), &ptr->second, xargs...)`, where `xargs...` is `second...` modified as in the above list.

The third method behaves the same as `this->construct(ptr, piecewise_construct, tuple<>, tuple<>)`.

The fourth method behaves the same as

```
this->construct(ptr, piecewise_construct, forward_as_tuple(std::forward<Uy1>(first),
forward_as_tuple(std::forward<Uy2>(second)))
```

The fifth method behaves the same as

```
this->construct(ptr, piecewise_construct, forward_as_tuple(right.first), forward_as_tuple(right.second)).
```

The sixth method behaves the same as

```
this->construct(ptr, piecewise_construct, forward_as_tuple(std::forward<Uy1>(right.first),
forward_as_tuple(std::forward<Uy2>(right.second)))
```

scoped_allocator_adaptor::deallocate

Deallocates objects by using the outer allocator.

```
void deallocate(pointer ptr, size_type count);
```

Parameters

ptr

A pointer to the starting location of the objects to be deallocated.

count

The number of objects to deallocate.

scoped_allocator_adaptor::destroy

Destroys a specified object.

```
template <class Ty>
void destroy(Ty* ptr)
```

Parameters

ptr

A pointer to the object to be destroyed.

Return Value

```
Outermost_traits::destroy(OUTERMOST(*this), ptr)
```

scoped_allocator_adaptor::inner_allocator

Retrieves a reference to the stored object of type `inner_allocator_type`.

```
inner_allocator_type& inner_allocator() noexcept;
const inner_allocator_type& inner_allocator() const noexcept;
```

Return Value

A reference to the stored object of type `inner_allocator_type`.

scoped_allocator_adaptor::max_size

Determines the maximum number of objects that can be allocated by the outer allocator.

```
size_type max_size();
```

Return Value

```
Outer_traits::max_size(outer_allocator())
```

scoped_allocator_adaptor::outer_allocator

Retrieves a reference to the stored object of type `outer_allocator_type`.

```
outer_allocator_type& outer_allocator() noexcept;  
const outer_allocator_type& outer_allocator() const noexcept;
```

Return Value

A reference to the stored object of type `outer_allocator_type`.

scoped_allocator_adaptor::rebind Struct

Defines the type `Outer::rebind<Other>::other` as a synonym for `scoped_allocator_adaptor<Other, Inner...>`.

```
struct rebind{ typedef Other_traits::rebind<Other> Other_alloc; typedef scoped_allocator_adaptor<Other_alloc,  
Inner...> other; };
```

scoped_allocator_adaptor::scoped_allocator_adaptor Constructor

Constructs a `scoped_allocator_adaptor` object.

```
scoped_allocator_adaptor();  
  
scoped_allocator_adaptor(const scoped_allocator_adaptor& right) noexcept;  
template <class Outer2>  
scoped_allocator_adaptor(  
const scoped_allocator_adaptor<Outer2, Inner...>& right) noexcept;  
template <class Outer2>  
scoped_allocator_adaptor(  
scoped_allocator_adaptor<Outer2, Inner...>&& right) noexcept;  
template <class Outer2>  
scoped_allocator_adaptor(Outer2&& al,  
const Inner&... rest) noexcept;
```

Parameters

right

An existing `scoped_allocator_adaptor`.

al

An existing allocator to be used as the outer allocator.

rest

A list of allocators to be used as the inner allocators.

Remarks

The first constructor default constructs its stored allocator objects. Each of the next three constructors constructs its stored allocator objects from the corresponding objects in *right*. The last constructor constructs its stored allocator objects from the corresponding arguments in the argument list.

scoped_allocator_adaptor::select_on_container_copy_construction

Creates a new `scoped_allocator_adaptor` object with each stored allocator object initialized by calling `select_on_container_copy_construction` for each corresponding allocator.

```
scoped_allocator_adaptor select_on_container_copy_construction();
```

Return Value

This method effectively returns

```
scoped_allocator_adaptor(Outer_traits::select_on_container_copy_construction(*this),  
inner_allocator().select_on_container_copy_construction())
```

. The result is a new `scoped_allocator_adaptor` object with each stored allocator object initialized by calling `al.select_on_container_copy_construction()` for the corresponding allocator *al*.

<set> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

[swap \(map\)](#)

[swap \(multiset\)](#)

swap (map)

Exchanges the elements of two sets.

```
template <class Key, class Traits, class Allocator>
void swap(set<Key, Traits, Allocator>& left, set<Key, Traits, Allocator>& right);
```

Parameters

right

The set providing the elements to be swapped, or the set whose elements are to be exchanged with those of the set *left*.

left

The set whose elements are to be exchanged with those of the set *right*.

Remarks

The template function is an algorithm specialized on the container class `set` to execute the member function `left.swap(right)`. This is an instance of the partial ordering of function templates by the compiler. When template functions are overloaded in such a way that the match of the template with the function call is not unique, then the compiler will select the most specialized version of the template function. The general version of the template function

```
template < classT> void swap( T&, T&)
```

in the algorithm class works by assignment and is a slow operation. The specialized version in each container is much faster as it can work with the internal representation of the container class.

Example

See the code example for the member class `set::swap` for an example of the use of the template version of `swap`.

swap (multiset)

Exchanges the elements of two multisets.

```
template <class Key, class Traits, class Allocator>
void swap(multiset<Key, Traits, Allocator>& left, multiset<Key, Traits, Allocator>& right);
```

Parameters

right

The multiset providing the elements to be swapped, or the multiset whose elements are to be exchanged with those of the multiset *left*.

left

The multiset whose elements are to be exchanged with those of the multiset *right*.

Remarks

The template function is an algorithm specialized on the container class multiset to execute the member function `left.swap(right)`. This is an instance of the partial ordering of function templates by the compiler. When template functions are overloaded in such a way that the match of the template with the function call is not unique, then the compiler will select the most specialized version of the template function. The general version of the template function

```
template < classT> void swap( T&, T&)
```

in the algorithm class works by assignment and is a slow operation. The specialized version in each container is much faster as it can work with the internal representation of the container class.

Example

See the code example for the member class `multiset::swap` for an example of the use of the template version of

```
swap .
```

See also

[<set>](#)

<set> operators

3/28/2019 • 15 minutes to read • [Edit Online](#)

<code>operator!= (set)</code>	<code>operator> (set)</code>	<code>operator>= (set)</code>
<code>operator< (set)</code>	<code>operator<= (set)</code>	<code>operator== (set)</code>
<code>operator!= (multiset)</code>	<code>operator> (multiset)</code>	<code>operator>= (multiset)</code>
<code>operator< (multiset)</code>	<code>operator<= (multiset)</code>	<code>operator== (multiset)</code>

operator!= (set)

Tests if the set object on the left side of the operator is not equal to the set object on the right side.

```
bool operator!=(const set <Key, Traits, Allocator>& left, const set <Key, Traits, Allocator>& right);
```

Parameters

left

An object of type `set`.

right

An object of type `set`.

Return Value

true if the sets are not equal; **false** if sets are equal.

Remarks

The comparison between set objects is based on a pairwise comparison between their elements. Two sets are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```

// set_op_ne.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1, s2, s3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i );
    }

    if ( s1 != s2 )
        cout << "The sets s1 and s2 are not equal." << endl;
    else
        cout << "The sets s1 and s2 are equal." << endl;

    if ( s1 != s3 )
        cout << "The sets s1 and s3 are not equal." << endl;
    else
        cout << "The sets s1 and s3 are equal." << endl;
}
/* Output:
The sets s1 and s2 are not equal.
The sets s1 and s3 are equal.
*/

```

operator< (set)

Tests if the set object on the left side of the operator is less than the set object on the right side.

```
bool operator<(const set <Key, Traits, Allocator>& left, const set <Key, Traits, Allocator>& right);
```

Parameters

left

An object of type `set`.

right

An object of type `set`.

Return Value

true if the set on the left side of the operator is strictly less than the set on the right side of the operator; otherwise **false**.

Remarks

The comparison between set objects is based on a pairwise comparison of their elements. The less-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// set_op_lt.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1, s2, s3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i - 1 );
    }

    if ( s1 < s2 )
        cout << "The set s1 is less than the set s2." << endl;
    else
        cout << "The set s1 is not less than the set s2." << endl;

    if ( s1 < s3 )
        cout << "The set s1 is less than the set s3." << endl;
    else
        cout << "The set s1 is not less than the set s3." << endl;
}
/* Output:
The set s1 is less than the set s2.
The set s1 is not less than the set s3.
*/

```

operator<= (set)

Tests if the set object on the left side of the operator is less than or equal to the set object on the right side.

```
bool operator!<=(const set <Key, Traits, Allocator>& left, const set <Key, Traits, Allocator>& right);
```

Parameters

left

An object of type `set`.

right

An object of type `set`.

Return Value

true if the set on the left side of the operator is less than or equal to the set on the right side of the operator; otherwise **false**.

Remarks

The comparison between set objects is based on a pairwise comparison of their elements. The less than or equal to relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// set_op_le.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1, s2, s3, s4;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i - 1 );
        s4.insert ( i );
    }

    if ( s1 <= s2 )
        cout << "Set s1 is less than or equal to the set s2." << endl;
    else
        cout << "The set s1 is greater than the set s2." << endl;

    if ( s1 <= s3 )
        cout << "Set s1 is less than or equal to the set s3." << endl;
    else
        cout << "The set s1 is greater than the set s3." << endl;

    if ( s1 <= s4 )
        cout << "Set s1 is less than or equal to the set s4." << endl;
    else
        cout << "The set s1 is greater than the set s4." << endl;
}
/* Output:
Set s1 is less than or equal to the set s2.
The set s1 is greater than the set s3.
Set s1 is less than or equal to the set s4.
*/

```

operator== (set)

Tests if the set object on the left side of the operator is equal to the set object on the right side.

```
bool operator==(const set <Key, Traits, Allocator>& left, const set <Key, Traits, Allocator>& right);
```

Parameters

left

An object of type `set`.

right

An object of type `set`.

Return Value

true if the set on the left side of the operator is equal to the set on the right side of the operator; otherwise **false**.

Remarks

The comparison between set objects is based on a pairwise comparison of their elements. Two sets are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// set_op_eq.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1, s2, s3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i );
    }

    if ( s1 == s2 )
        cout << "The sets s1 and s2 are equal." << endl;
    else
        cout << "The sets s1 and s2 are not equal." << endl;

    if ( s1 == s3 )
        cout << "The sets s1 and s3 are equal." << endl;
    else
        cout << "The sets s1 and s3 are not equal." << endl;
}
/* Output:
The sets s1 and s2 are not equal.
The sets s1 and s3 are equal.
*/
```

operator> (set)

Tests if the set object on the left side of the operator is greater than the set object on the right side.

```
bool operator>(const set <Key, Traits, Allocator>& left, const set <Key, Traits, Allocator>& right);
```

Parameters

left

An object of type `set`.

right

An object of type `set`.

Return Value

true if the set on the left side of the operator is greater than the set on the right side of the operator; otherwise **false**.

Remarks

The comparison between set objects is based on a pairwise comparison of their elements. The greater-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// set_op_gt.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1, s2, s3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i - 1 );
    }

    if ( s1 > s2 )
        cout << "The set s1 is greater than the set s2." << endl;
    else
        cout << "The set s1 is not greater than the set s2." << endl;

    if ( s1 > s3 )
        cout << "The set s1 is greater than the set s3." << endl;
    else
        cout << "The set s1 is not greater than the set s3." << endl;
}
/* Output:
The set s1 is not greater than the set s2.
The set s1 is greater than the set s3.
*/

```

operator>= (set)

Tests if the set object on the left side of the operator is greater than or equal to the set object on the right side.

```
bool operator!>=(const set <Key, Traits, Allocator>& left, const set <Key, Traits, Allocator>& right);
```

Parameters

left

An object of type `set`.

right

An object of type `set`.

Return Value

true if the set on the left side of the operator is greater than or equal to the set on the right side of the list; otherwise **false**.

Remarks

The comparison between set objects is based on a pairwise comparison of their elements. The greater than or equal to relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// set_op_ge.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1, s2, s3, s4;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i - 1 );
        s4.insert ( i );
    }

    if ( s1 >= s2 )
        cout << "Set s1 is greater than or equal to set s2." << endl;
    else
        cout << "The set s1 is less than the set s2." << endl;

    if ( s1 >= s3 )
        cout << "Set s1 is greater than or equal to set s3." << endl;
    else
        cout << "The set s1 is less than the set s3." << endl;

    if ( s1 >= s4 )
        cout << "Set s1 is greater than or equal to set s4." << endl;
    else
        cout << "The set s1 is less than the set s4." << endl;
}
/* Output:
The set s1 is less than the set s2.
Set s1 is greater than or equal to set s3.
Set s1 is greater than or equal to set s4.
*/

```

operator!= (multiset)

Tests if the multiset object on the left side of the operator is not equal to the multiset object on the right side.

```
bool operator!=(const multiset <Key, Traits, Allocator>& left, const multiset <Key, Traits, Allocator>& right);
```

Parameters

left

An object of type `multiset`.

right

An object of type `multiset`.

Return Value

true if the sets or multisets are not equal; **false** if sets or multisets are equal.

Remarks

The comparison between multiset objects is based on a pairwise comparison between their elements. Two sets or multisets are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// multiset_op_ne.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> s1, s2, s3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i );
    }

    if ( s1 != s2 )
        cout << "The multisets s1 and s2 are not equal." << endl;
    else
        cout << "The multisets s1 and s2 are equal." << endl;

    if ( s1 != s3 )
        cout << "The multisets s1 and s3 are not equal." << endl;
    else
        cout << "The multisets s1 and s3 are equal." << endl;
}
/* Output:
The multisets s1 and s2 are not equal.
The multisets s1 and s3 are equal.
*/
```

operator< (multiset)

Tests if the multiset object on the left side of the operator is less than the multiset object on the right side.

```
bool operator<(const multiset <Key, Traits, Allocator>& left, const multiset <Key, Traits, Allocator>& right);
```

Parameters

left

An object of type `multiset`.

right

An object of type `multiset`.

Return Value

true if the multiset on the left side of the operator is strictly less than the multiset on the right side of the operator; otherwise **false**.

Remarks

The comparison between multiset objects is based on a pairwise comparison of their elements. The less-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```

// multiset_op_lt.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> s1, s2, s3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i - 1 );
    }

    if ( s1 < s2 )
        cout << "The multiset s1 is less than "
              << "the multiset s2." << endl;
    else
        cout << "The multiset s1 is not less than "
              << "the multiset s2." << endl;

    if ( s1 < s3 )
        cout << "The multiset s1 is less than "
              << "the multiset s3." << endl;
    else
        cout << "The multiset s1 is not less than "
              << "the multiset s3." << endl;
}
/* Output:
The multiset s1 is less than the multiset s2.
The multiset s1 is not less than the multiset s3.
*/

```

operator<= (multiset)

Tests if the multiset object on the left side of the operator is less than or equal to the multiset object on the right side.

```

bool operator!<=(const multiset <Key, Traits, Allocator>& left, const multiset <Key, Traits, Allocator>&
right);

```

Parameters

left

An object of type `multiset`.

right

An object of type `multiset`.

Return Value

true if the multiset on the left side of the operator is less than or equal to the multiset on the right side of the operator; otherwise **false**.

Remarks

The comparison between multiset objects is based on a pairwise comparison of their elements. The less than or equal to relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```
// multiset_op_le.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> s1, s2, s3, s4;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i - 1 );
        s4.insert ( i );
    }

    if ( s1 <= s2 )
        cout << "The multiset s1 is less than "
              << "or equal to the multiset s2." << endl;
    else
        cout << "The multiset s1 is greater than "
              << "the multiset s2." << endl;

    if ( s1 <= s3 )
        cout << "The multiset s1 is less than "
              << "or equal to the multiset s3." << endl;
    else
        cout << "The multiset s1 is greater than "
              << "the multiset s3." << endl;

    if ( s1 <= s4 )
        cout << "The multiset s1 is less than "
              << "or equal to the multiset s4." << endl;
    else
        cout << "The multiset s1 is greater than "
              << "the multiset s4." << endl;
}
/* Output:
The multiset s1 is less than or equal to the multiset s2.
The multiset s1 is greater than the multiset s3.
The multiset s1 is less than or equal to the multiset s4.
*/
```

operator== (multiset)

Tests if the multiset object on the left side of the operator is equal to the multiset object on the right side.

```
bool operator!=(const multiset <Key, Traits, Allocator>& left, const multiset <Key, Traits, Allocator>&
right);
```

Parameters

left

An object of type `multiset`.

right

An object of type `multiset`.

Return Value

true if the multiset on the left side of the operator is equal to the multiset on the right side of the operator; otherwise **false**.

Remarks

The comparison between multiset objects is based on a pairwise comparison of their elements. Two sets or multisets are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// multiset_op_eq.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> s1, s2, s3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i );
    }

    if ( s1 == s2 )
        cout << "The multisets s1 and s2 are equal." << endl;
    else
        cout << "The multisets s1 and s2 are not equal." << endl;

    if ( s1 == s3 )
        cout << "The multisets s1 and s3 are equal." << endl;
    else
        cout << "The multisets s1 and s3 are not equal." << endl;
}
/* Output:
The multisets s1 and s2 are not equal.
The multisets s1 and s3 are equal.
*/
```

operator> (multiset)

Tests if the multiset object on the left side of the operator is greater than the multiset object on the right side.

```
bool operator>(const multiset <Key, Traits, Allocator>& left, const multiset <Key, Traits, Allocator>& right);
```

Parameters

left

An object of type `multiset`.

right

An object of type `multiset`.

Return Value

true if the multiset on the left side of the operator is greater than the multiset on the right side of the operator;

otherwise **false**.

Remarks

The comparison between multiset objects is based on a pairwise comparison of their elements. The greater-than relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```
// multiset_op_gt.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> s1, s2, s3;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i - 1 );
    }

    if ( s1 > s2 )
        cout << "The multiset s1 is greater than "
              << "the multiset s2." << endl;
    else
        cout << "The multiset s1 is not greater "
              << "than the multiset s2." << endl;

    if ( s1 > s3 )
        cout << "The multiset s1 is greater than "
              << "the multiset s3." << endl;
    else
        cout << "The multiset s1 is not greater than "
              << "the multiset s3." << endl;
}
/* Output:
The multiset s1 is not greater than the multiset s2.
The multiset s1 is greater than the multiset s3.
*/
```

operator>= (multiset)

Tests if the multiset object on the left side of the operator is greater than or equal to the multiset object on the right side.

```
bool operator!=(const multiset <Key, Traits, Allocator>& left, const multiset <Key, Traits, Allocator>&
right);
```

Parameters

left

An object of type `multiset` .

right

An object of type `multiset` .

Return Value

true if the multiset on the left side of the operator is greater than or equal to the multiset on the right side of the list; otherwise **false**.

Remarks

The comparison between multiset objects is based on a pairwise comparison of their elements. The greater than or equal to relationship between two objects is based on a comparison of the first pair of unequal elements.

Example

```
// multiset_op_ge.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> s1, s2, s3, s4;
    int i;

    for ( i = 0 ; i < 3 ; i++ )
    {
        s1.insert ( i );
        s2.insert ( i * i );
        s3.insert ( i - 1 );
        s4.insert ( i );
    }

    if ( s1 >= s2 )
        cout << "The multiset s1 is greater than "
              << "or equal to the multiset s2." << endl;
    else
        cout << "The multiset s1 is less than "
              << "the multiset s2." << endl;

    if ( s1 >= s3 )
        cout << "The multiset s1 is greater than "
              << "or equal to the multiset s3." << endl;
    else
        cout << "The multiset s1 is less than "
              << "the multiset s3." << endl;

    if ( s1 >= s4 )
        cout << "The multiset s1 is greater than "
              << "or equal to the multiset s4." << endl;
    else
        cout << "The multiset s1 is less than "
              << "the multiset s4." << endl;
}
/* Output:
The multiset s1 is less than the multiset s2.
The multiset s1 is greater than or equal to the multiset s3.
The multiset s1 is greater than or equal to the multiset s4.
*/
```

[<set>](#)

set Class

11/15/2018 • 51 minutes to read • [Edit Online](#)

The C++ Standard Library container class `set` is used for the storage and retrieval of data from a collection in which the values of the elements contained are unique and serve as the key values according to which the data is automatically ordered. The value of an element in a set may not be changed directly. Instead, you must delete old values and insert elements with new values.

Syntax

```
template <class Key,  
         class Traits=less<Key>,  
         class Allocator=allocator<Key>>  
class set
```

Parameters

Key

The element data type to be stored in the set.

Traits

The type that provides a function object that can compare two element values as sort keys to determine their relative order in the set. This argument is optional, and the binary predicate **less** <Key> is the default value.

In C++ 14 you can enable heterogeneous lookup by specifying the `std::less<>` or `std::greater<>` predicate that has no type parameters. For more information, see [Heterogeneous Lookup in Associative Containers](#)

Allocator

The type that represents the stored allocator object that encapsulates details about the set's allocation and deallocation of memory. This argument is optional, and the default value is `allocator<Key>`.

Remarks

A C++ Standard Library `set` is:

- An associative container, which is a variable size container that supports the efficient retrieval of element values based on an associated key value. Further, it is a simple associative container because its element values are its key values.
- Reversible, because it provides a bidirectional iterator to access its elements.
- Sorted, because its elements are ordered by key values within the container in accordance with a specified comparison function.
- Unique in the sense that each of its elements must have a unique key. Since `set` is also a simple associative container, its elements are also unique.

A `set` is also described as a template class because the functionality it provides is generic and independent of the specific type of data contained as elements. The data type to be used is, instead, specified as a parameter in the class template along with the comparison function and allocator.

The choice of container type should be based in general on the type of searching and inserting required by the application. Associative containers are optimized for the operations of lookup, insertion and removal. The

member functions that explicitly support these operations are efficient, performing them in a time that is on average proportional to the logarithm of the number of elements in the container. Inserting elements invalidates no iterators, and removing elements invalidates only those iterators that had specifically pointed at the removed elements.

The set should be the associative container of choice when the conditions associating the values with their keys are satisfied by the application. The elements of a set are unique and serve as their own sort keys. A model for this type of structure is an ordered list of, say, words in which the words may occur only once. If multiple occurrences of the words were allowed, then a multiset would be the appropriate container structure. If values need to be attached to a list of unique key words, then a map would be an appropriate structure to contain this data. If instead the keys are not unique, then a multimap would be the container of choice.

The set orders the sequence it controls by calling a stored function object of type [key_compare](#). This stored object is a comparison function that may be accessed by calling the member function [key_comp](#). In general, the elements need to be merely less than comparable to establish this order so that, given any two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. On a more technical note, the comparison function is a binary predicate that induces a strict weak ordering in the standard mathematical sense. A binary predicate $f(x,y)$ is a function object that has two argument objects x and y and a return value of **true** or **false**. An ordering imposed on a set is a strict weak ordering if the binary predicate is irreflexive, antisymmetric, and transitive and if equivalence is transitive, where two objects x and y are defined to be equivalent when both $f(x,y)$ and $f(y,x)$ are false. If the stronger condition of equality between keys replaces that of equivalence, then the ordering becomes total (in the sense that all the elements are ordered with respect to each other) and the keys matched will be indiscernible from each other.

In C++ 14 you can enable heterogeneous lookup by specifying the `std::less<>` or `std::greater<>` predicate that has no type parameters. For more information, see [Heterogeneous Lookup in Associative Containers](#)

The iterator provided by the set class is a bidirectional iterator, but the class member functions [insert](#) and [set](#) have versions that take as template parameters a weaker input iterator, whose functionality requirements are more minimal than those guaranteed by the class of bidirectional iterators. The different iterator concepts form a family related by refinements in their functionality. Each iterator concept has its own set of requirements, and the algorithms that work with them must limit their assumptions to the requirements provided by that type of iterator. It may be assumed that an input iterator may be dereferenced to refer to some object and that it may be incremented to the next iterator in the sequence. This is a minimal set of functionality, but it is enough to be able to talk meaningfully about a range of iterators [`First` , `Last`) in the context of the class's member functions.

Constructors

CONSTRUCTOR	DESCRIPTION
set	Constructs a set that is empty or that is a copy of all or part of some other set.

Typedefs

TYPE NAME	DESCRIPTION
allocator_type	A type that represents the <code>allocator</code> class for the set object.
const_iterator	A type that provides a bidirectional iterator that can read a const element in the set.
const_pointer	A type that provides a pointer to a const element in a set.

TYPE NAME	DESCRIPTION
<code>const_reference</code>	A type that provides a reference to a const element stored in a set for reading and performing const operations.
<code>const_reverse_iterator</code>	A type that provides a bidirectional iterator that can read any const element in the set.
<code>difference_type</code>	A signed integer type that can be used to represent the number of elements of a set in a range between elements pointed to by iterators.
<code>iterator</code>	A type that provides a bidirectional iterator that can read or modify any element in a set.
<code>key_compare</code>	A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the set.
<code>key_type</code>	The type describes an object stored as an element of a set in its capacity as sort key.
<code>pointer</code>	A type that provides a pointer to an element in a set.
<code>reference</code>	A type that provides a reference to an element stored in a set.
<code>reverse_iterator</code>	A type that provides a bidirectional iterator that can read or modify an element in a reversed set.
<code>size_type</code>	An unsigned integer type that can represent the number of elements in a set.
<code>value_compare</code>	The type that provides a function object that can compare two elements to determine their relative order in the set.
<code>value_type</code>	The type describes an object stored as an element of a set in its capacity as a value.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>begin</code>	Returns an iterator that addresses the first element in the set.
<code>cbegin</code>	Returns a const iterator that addresses the first element in the set.
<code>cend</code>	Returns a const iterator that addresses the location succeeding the last element in a set.
<code>clear</code>	Erases all the elements of a set.
<code>count</code>	Returns the number of elements in a set whose key matches a parameter-specified key.

MEMBER FUNCTION	DESCRIPTION
<code>crbegin</code>	Returns a const iterator addressing the first element in a reversed set.
<code>crend</code>	Returns a const iterator that addresses the location succeeding the last element in a reversed set.
<code>emplace</code>	Inserts an element constructed in place into a set.
<code>emplace_hint</code>	Inserts an element constructed in place into a set, with a placement hint.
<code>empty</code>	Tests if a set is empty.
<code>end</code>	Returns an iterator that addresses the location succeeding the last element in a set.
<code>equal_range</code>	Returns a pair of iterators respectively to the first element in a set with a key that is greater than a specified key and to the first element in the set with a key that is equal to or greater than the key.
<code>erase</code>	Removes an element or a range of elements in a set from specified positions or removes elements that match a specified key.
<code>find</code>	Returns an iterator addressing the location of an element in a set that has a key equivalent to a specified key.
<code>get_allocator</code>	Returns a copy of the <code>allocator</code> object used to construct the set.
<code>insert</code>	Inserts an element or a range of elements into a set.
<code>key_comp</code>	Retrieves a copy of the comparison object used to order keys in a set.
<code>lower_bound</code>	Returns an iterator to the first element in a set with a key that is equal to or greater than a specified key.
<code>max_size</code>	Returns the maximum length of the set.
<code>rbegin</code>	Returns an iterator addressing the first element in a reversed set.
<code>rend</code>	Returns an iterator that addresses the location succeeding the last element in a reversed set.
<code>size</code>	Returns the number of elements in the set.
<code>swap</code>	Exchanges the elements of two sets.
<code>upper_bound</code>	Returns an iterator to the first element in a set with a key that is greater than a specified key.

MEMBER FUNCTION	DESCRIPTION
value_comp	Retrieves a copy of the comparison object used to order element values in a set.

Operators

OPERATOR	DESCRIPTION
operator=	Replaces the elements of a set with a copy of another set.

Requirements

Header: <set>

Namespace: std

set::allocator_type

A type that represents the allocator class for the set object.

```
typedef Allocator allocator_type;
```

Remarks

`allocator_type` is a synonym for the template parameter [Allocator](#).

Returns the function object that a multiset uses to order its elements, which is the template parameter `Allocator`.

For more information on `Allocator`, see the Remarks section of the [set Class](#) topic.

Example

See the example for [get_allocator](#) for an example that uses `allocator_type`.

set::begin

Returns an iterator that addresses the first element in the set.

```
const_iterator begin() const;

iterator begin();
```

Return Value

A bidirectional iterator addressing the first element in the set or the location succeeding an empty set.

Remarks

If the return value of `begin` is assigned to a `const_iterator`, the elements in the set object cannot be modified. If the return value of `begin` is assigned to an `iterator`, the elements in the set object can be modified.

Example

```

// set_begin.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;
    set <int>::iterator s1_Iter;
    set <int>::const_iterator s1_cIter;

    s1.insert( 1 );
    s1.insert( 2 );
    s1.insert( 3 );

    s1_Iter = s1.begin( );
    cout << "The first element of s1 is " << *s1_Iter << endl;

    s1_Iter = s1.begin( );
    s1.erase( s1_Iter );

    // The following 2 lines would err because the iterator is const
    // s1_cIter = s1.begin( );
    // s1.erase( s1_cIter );

    s1_cIter = s1.begin( );
    cout << "The first element of s1 is now " << *s1_cIter << endl;
}

```

```

The first element of s1 is 1
The first element of s1 is now 2

```

set::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** bidirectional-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin`, the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the [auto](#) type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```

auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator

```

set::cend

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A **const** bidirectional-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

set::clear

Erases all the elements of a set.

```
void clear();
```

Example

```
// set_clear.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;

    s1.insert( 1 );
    s1.insert( 2 );

    cout << "The size of the set is initially " << s1.size( )
         << "." << endl;

    s1.clear( );
    cout << "The size of the set after clearing is "
         << s1.size( ) << "." << endl;
}
```

The size of the set is initially 2.
The size of the set after clearing is 0.

set::const_iterator

A type that provides a bidirectional iterator that can read a **const** element in the set.

```
typedef implementation-defined const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

Example

See the example for [begin](#) for an example that uses `const_iterator`.

set::const_pointer

A type that provides a pointer to a **const** element in a set.

```
typedef typename allocator_type::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element.

In most cases, a [const_iterator](#) should be used to access the elements in a const set object.

set::const_reference

A type that provides a reference to a **const** element stored in a set for reading and performing **const** operations.

```
typedef typename allocator_type::const_reference const_reference;
```

Example

```
// set_const_ref.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;

    s1.insert( 10 );
    s1.insert( 20 );

    // Declare and initialize a const_reference &Ref1
    // to the 1st element
    const int &Ref1 = *s1.begin( );

    cout << "The first element in the set is "
         << Ref1 << "." << endl;

    // The following line would cause an error because the
    // const_reference cannot be used to modify the set
    // Ref1 = Ref1 + 5;
}
```

The first element in the set is 10.

set::const_reverse_iterator

A type that provides a bidirectional iterator that can read any **const** element in the set.

```
typedef std::reverse_iterator<const_iterator> const_reverse_iterator;
```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is use to iterate through the set in reverse.

Example

See the example for [rend](#) for an example of how to declare and use the `const_reverse_iterator`.

set::count

Returns the number of elements in a set whose key matches a parameter-specified key.

```
size_type count(const Key& key) const;
```

Parameters

key

The key of the elements to be matched from the set.

Return Value

1 if the set contains an element whose sort key matches the parameter key. 0 if the set does not contain an element with a matching key.

Remarks

The member function returns the number of elements in the following range:

[lower_bound(key), upper_bound(key)).

Example

The following example demonstrates the use of the set::count member function.

```
// set_count.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main()
{
    using namespace std;
    set<int> s1;
    set<int>::size_type i;

    s1.insert(1);
    s1.insert(1);

    // Keys must be unique in set, so duplicates are ignored
    i = s1.count(1);
    cout << "The number of elements in s1 with a sort key of 1 is: "
         << i << "." << endl;

    i = s1.count(2);
    cout << "The number of elements in s1 with a sort key of 2 is: "
         << i << "." << endl;
}
```

```
The number of elements in s1 with a sort key of 1 is: 1.
The number of elements in s1 with a sort key of 2 is: 0.
```

set::crbegin

Returns a const iterator addressing the first element in a reversed set.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse bidirectional iterator addressing the first element in a reversed set or addressing what had been the last element in the unreversed set.

Remarks

`crbegin` is used with a reversed set just as `begin` is used with a set.

With the return value of `crbegin`, the set object cannot be modified.

Example

```
// set_crbegin.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;
    set <int>::const_reverse_iterator s1_crIter;

    s1.insert( 10 );
    s1.insert( 20 );
    s1.insert( 30 );

    s1_crIter = s1.crbegin( );
    cout << "The first element in the reversed set is "
         << *s1_crIter << "." << endl;
}
```

```
The first element in the reversed set is 30.
```

set::crend

Returns a const iterator that addresses the location succeeding the last element in a reversed set.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse bidirectional iterator that addresses the location succeeding the last element in a reversed set (the location that had preceded the first element in the unreversed set).

Remarks

`crend` is used with a reversed set just as `end` is used with a set.

With the return value of `crend`, the set object cannot be modified. The value returned by `crend` should not be dereferenced.

`crend` can be used to test to whether a reverse iterator has reached the end of its set.

Example

```

// set_crend.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main() {
    using namespace std;
    set<int> s1;
    set<int>::const_reverse_iterator s1_crIter;

    s1.insert( 10 );
    s1.insert( 20 );
    s1.insert( 30 );

    s1_crIter = s1.crend( );
    s1_crIter--;
    cout << "The last element in the reversed set is "
         << *s1_crIter << "." << endl;
}

```

set::difference_type

A signed integer type that can be used to represent the number of elements of a set in a range between elements pointed to by iterators.

```
typedef typename allocator_type::difference_type difference_type;
```

Remarks

The `difference_type` is the type returned when subtracting or incrementing through iterators of the container. The `difference_type` is typically used to represent the number of elements in the range $[first, last)$ between the iterators `first` and `last`, includes the element pointed to by `first` and the range of elements up to, but not including, the element pointed to by `last`.

Note that although `difference_type` is available for all iterators that satisfy the requirements of an input iterator, which includes the class of bidirectional iterators supported by reversible containers such as `set`, subtraction between iterators is only supported by random-access iterators provided by a random-access container such as `vector`.

Example

```

// set_diff_type.cpp
// compile with: /EHsc
#include <iostream>
#include <set>
#include <algorithm>

int main( )
{
    using namespace std;

    set <int> s1;
    set <int>::iterator s1_iter, s1_bIter, s1_eIter;

    s1.insert( 20 );
    s1.insert( 10 );
    s1.insert( 20 );    // won't insert as set elements are unique

    s1_bIter = s1.begin( );
    s1_eIter = s1.end( );

    set <int>::difference_type  df_typ5, df_typ10, df_typ20;

    df_typ5 = count( s1_bIter, s1_eIter, 5 );
    df_typ10 = count( s1_bIter, s1_eIter, 10 );
    df_typ20 = count( s1_bIter, s1_eIter, 20 );

    // the keys, and hence the elements of a set are unique,
    // so there is at most one of a given value
    cout << "The number '5' occurs " << df_typ5
         << " times in set s1.\n";
    cout << "The number '10' occurs " << df_typ10
         << " times in set s1.\n";
    cout << "The number '20' occurs " << df_typ20
         << " times in set s1.\n";

    // count the number of elements in a set
    set <int>::difference_type  df_count = 0;
    s1_iter = s1.begin( );
    while ( s1_iter != s1_eIter)
    {
        df_count++;
        s1_iter++;
    }

    cout << "The number of elements in the set s1 is: "
         << df_count << "." << endl;
}

```

```

The number '5' occurs 0 times in set s1.
The number '10' occurs 1 times in set s1.
The number '20' occurs 1 times in set s1.
The number of elements in the set s1 is: 2.

```

set::emplace

Inserts an element constructed in place (no copy or move operations are performed).

```

template <class... Args>
pair<iterator, bool>
emplace(
    Args&&... args);

```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the set unless it already contains an element whose value is equivalently ordered.

Return Value

A [pair](#) whose bool component returns true if an insertion was made, and false if the map already contained an element whose value had an equivalent value in the ordering. The iterator component of the return value pair returns the address where a new element was inserted (if the bool component is true) or where the element was already located (if the bool component is false).

Remarks

No iterators or references are invalidated by this function.

During emplacement, if an exception is thrown, the container's state is not modified.

Example

```

// set_emplace.cpp
// compile with: /EHsc
#include <set>
#include <string>
#include <iostream>

using namespace std;

template <typename S> void print(const S& s) {
    cout << s.size() << " elements: ";

    for (const auto& p : s) {
        cout << "(" << p << ") ";
    }

    cout << endl;
}

int main()
{
    set<string> s1;

    auto ret = s1.emplace("ten");

    if (!ret.second){
        cout << "Emplace failed, element with value \"ten\" already exists."
              << endl << " The existing element is (" << *ret.first << ")"
              << endl;
        cout << "set not modified" << endl;
    }
    else{
        cout << "set modified, now contains ";
        print(s1);
    }
    cout << endl;

    ret = s1.emplace("ten");

    if (!ret.second){
        cout << "Emplace failed, element with value \"ten\" already exists."
              << endl << " The existing element is (" << *ret.first << ")"
              << endl;
    }
    else{
        cout << "set modified, now contains ";
        print(s1);
    }
    cout << endl;
}

```

set::emplace_hint

Inserts an element constructed in place (no copy or move operations are performed), with a placement hint.

```

template <class... Args>
iterator emplace_hint(
    const_iterator where,
    Args&&... args);

```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the set unless the set already contains that element or, more generally, unless it already contains an element whose value is equivalently ordered.
<i>where</i>	The place to start searching for the correct point of insertion. (If that point immediately precedes <i>where</i> , insertion can occur in amortized constant time instead of logarithmic time.)

Return Value

An iterator to the newly inserted element.

If the insertion failed because the element already exists, returns an iterator to the existing element.

Remarks

No iterators or references are invalidated by this function.

During emplacement, if an exception is thrown, the container's state is not modified.

Example

```
// set_emplace.cpp
// compile with: /EHsc
#include <set>
#include <string>
#include <iostream>

using namespace std;

template <typename S> void print(const S& s) {
    cout << s.size() << " elements: " << endl;

    for (const auto& p : s) {
        cout << "(" << p << " ) ";
    }

    cout << endl;
}

int main()
{
    set<string> s1;

    // Emplace some test data
    s1.emplace("Anna");
    s1.emplace("Bob");
    s1.emplace("Carmine");

    cout << "set starting data: ";
    print(s1);
    cout << endl;

    // Emplace with hint
    // s1.end() should be the "next" element after this emplacement
    s1.emplace_hint(s1.end(), "Doug");

    cout << "set modified, now contains ";
    print(s1);
    cout << endl;
}
```

set::empty

Tests if a set is empty.

```
bool empty() const;
```

Return Value

true if the set is empty; **false** if the set is nonempty.

Example

```
// set_empty.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1, s2;
    s1.insert ( 1 );

    if ( s1.empty( ) )
        cout << "The set s1 is empty." << endl;
    else
        cout << "The set s1 is not empty." << endl;

    if ( s2.empty( ) )
        cout << "The set s2 is empty." << endl;
    else
        cout << "The set s2 is not empty." << endl;
}
```

```
The set s1 is not empty.
The set s2 is empty.
```

set::end

Returns the past-the-end iterator.

```
const_iterator end() const;

iterator end();
```

Return Value

The past-the-end iterator. If the set is empty, then `set::end() == set::begin()`.

Remarks

end is used to test whether an iterator has passed the end of its set.

The value returned by **end** should not be dereferenced.

For a code example, see [set::find](#).

set::equal_range

Returns a pair of iterators respectively to the first element in a set with a key that is greater than or equal to a

specified key and to the first element in the set with a key that is greater than the key.

```
pair <const_iterator, const_iterator> equal_range (const Key& key) const;  
  
pair <iterator, iterator> equal_range (const Key& key);
```

Parameters

key

The argument key to be compared with the sort key of an element from the set being searched.

Return Value

A pair of iterators where the first is the [lower_bound](#) of the key and the second is the [upper_bound](#) of the key.

To access the first iterator of a pair `pr` returned by the member function, use `pr.first`, and to dereference the lower bound iterator, use `*(pr.first)`. To access the second iterator of a pair `pr` returned by the member function, use `pr.second`, and to dereference the upper bound iterator, use `*(pr.second)`.

Example

```

// set_equal_range.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    typedef set<int, less< int > > IntSet;
    IntSet s1;
    set<int, less< int > > :: const_iterator s1_RcIter;

    s1.insert( 10 );
    s1.insert( 20 );
    s1.insert( 30 );

    pair<IntSet::const_iterator, IntSet::const_iterator> p1, p2;
    p1 = s1.equal_range( 20 );

    cout << "The upper bound of the element with "
         << "a key of 20 in the set s1 is: "
         << *(p1.second) << "." << endl;

    cout << "The lower bound of the element with "
         << "a key of 20 in the set s1 is: "
         << *(p1.first) << "." << endl;

    // Compare the upper_bound called directly
    s1_RcIter = s1.upper_bound( 20 );
    cout << "A direct call of upper_bound( 20 ) gives "
         << *s1_RcIter << "," << endl
         << "matching the 2nd element of the pair"
         << " returned by equal_range( 20 )." << endl;

    p2 = s1.equal_range( 40 );

    // If no match is found for the key,
    // both elements of the pair return end( )
    if ( ( p2.first == s1.end( ) ) && ( p2.second == s1.end( ) ) )
        cout << "The set s1 doesn't have an element "
             << "with a key less than 40." << endl;
    else
        cout << "The element of set s1 with a key >= 40 is: "
             << *(p1.first) << "." << endl;
}

```

```

The upper bound of the element with a key of 20 in the set s1 is: 30.
The lower bound of the element with a key of 20 in the set s1 is: 20.
A direct call of upper_bound( 20 ) gives 30,
matching the 2nd element of the pair returned by equal_range( 20 ).
The set s1 doesn't have an element with a key less than 40.

```

set::erase

Removes an element or a range of elements in a set from specified positions or removes elements that match a specified key.

```

iterator erase(
    const_iterator Where);

iterator erase(
    const_iterator First,
    const_iterator Last);

size_type erase(
    const key_type& Key);

```

Parameters

Where

Position of the element to be removed.

First

Position of the first element to be removed.

Last

Position just beyond the last element to be removed.

Key

The key value of the elements to be removed.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or an element that is the end of the set if no such element exists.

For the third member function, returns the number of elements that have been removed from the set.

Remarks

Example

```

// set_erase.cpp
// compile with: /EHsc
#include <set>
#include <string>
#include <iostream>
#include <iterator> // next() and prev() helper functions

using namespace std;

using myset = set<string>;

void printset(const myset& s) {
    for (const auto& iter : s) {
        cout << " [" << iter << "]\n";
    }
    cout << endl << "size() == " << s.size() << endl << endl;
}

int main()
{
    myset s1;

    // Fill in some data to test with, one at a time
    s1.insert("Bob");
    s1.insert("Robert");
    s1.insert("Bert");
    s1.insert("Rob");
    s1.insert("Bobby");

    cout << "Starting data of set s1 is:" << endl;
}

```

```

printset(s1);
// The 1st member function removes an element at a given position
s1.erase(next(s1.begin()));
cout << "After the 2nd element is deleted, the set s1 is:" << endl;
printset(s1);

// Fill in some data to test with, one at a time, using an initializer list
myset s2{ "meow", "hiss", "purr", "growl", "yowl" };

cout << "Starting data of set s2 is:" << endl;
printset(s2);
// The 2nd member function removes elements
// in the range [First, Last)
s2.erase(next(s2.begin()), prev(s2.end()));
cout << "After the middle elements are deleted, the set s2 is:" << endl;
printset(s2);

myset s3;

// Fill in some data to test with, one at a time, using emplace
s3.emplace("C");
s3.emplace("C#");
s3.emplace("D");
s3.emplace("D#");
s3.emplace("E");
s3.emplace("E#");
s3.emplace("F");
s3.emplace("F#");
s3.emplace("G");
s3.emplace("G#");
s3.emplace("A");
s3.emplace("A#");
s3.emplace("B");

cout << "Starting data of set s3 is:" << endl;
printset(s3);
// The 3rd member function removes elements with a given Key
myset::size_type count = s3.erase("E#");
// The 3rd member function also returns the number of elements removed
cout << "The number of elements removed from s3 is: " << count << "." << endl;
cout << "After the element with a key of \"E#\" is deleted, the set s3 is:" << endl;
printset(s3);
}

```

set::find

Returns an iterator that refers to the location of an element in a set that has a key equivalent to a specified key.

```

iterator find(const Key& key);

const_iterator find(const Key& key) const;

```

Parameters

key

The key value to be matched by the sort key of an element from the set being searched.

Return Value

An iterator that refers to the location of an element with a specified key, or the location succeeding the last element in the set (`set::end()`) if no match is found for the key.

Remarks

The member function returns an iterator that refers to an element in the set whose key is equivalent to the

argument *key* under a binary predicate that induces an ordering based on a less than comparability relation.

If the return value of `find` is assigned to a `const_iterator`, the set object cannot be modified. If the return value of `find` is assigned to an `iterator`, the set object can be modified

Example

```
// compile with: /EHsc /W4 /MTd
#include <set>
#include <iostream>
#include <vector>
#include <string>

using namespace std;

template <typename T> void print_elem(const T& t) {
    cout << "(" << t << ") ";
}

template <typename T> void print_collection(const T& t) {
    cout << t.size() << " elements: ";

    for (const auto& p : t) {
        print_elem(p);
    }
    cout << endl;
}

template <typename C, class T> void findit(const C& c, T val) {
    cout << "Trying find() on value " << val << endl;
    auto result = c.find(val);
    if (result != c.end()) {
        cout << "Element found: "; print_elem(*result); cout << endl;
    } else {
        cout << "Element not found." << endl;
    }
}

int main()
{
    set<int> s1({ 40, 45 });
    cout << "The starting set s1 is: " << endl;
    print_collection(s1);

    vector<int> v;
    v.push_back(43);
    v.push_back(41);
    v.push_back(46);
    v.push_back(42);
    v.push_back(44);
    v.push_back(44); // attempt a duplicate

    cout << "Inserting the following vector data into s1: " << endl;
    print_collection(v);

    s1.insert(v.begin(), v.end());

    cout << "The modified set s1 is: " << endl;
    print_collection(s1);
    cout << endl;
    findit(s1, 45);
    findit(s1, 6);
}
```

`set::get_allocator`

Returns a copy of the allocator object used to construct the set.

```
allocator_type get_allocator() const;
```

Return Value

The allocator used by the set to manage memory, which is the template parameter `Allocator`.

For more information on `Allocator`, see the Remarks section of the [set Class](#) topic.

Remarks

Allocators for the set class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes is sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```

// set_get_allocator.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int>::allocator_type s1_Alloc;
    set <int>::allocator_type s2_Alloc;
    set <double>::allocator_type s3_Alloc;
    set <int>::allocator_type s4_Alloc;

    // The following lines declare objects
    // that use the default allocator.
    set <int> s1;
    set <int, allocator<int> > s2;
    set <double, allocator<double> > s3;

    s1_Alloc = s1.get_allocator( );
    s2_Alloc = s2.get_allocator( );
    s3_Alloc = s3.get_allocator( );

    cout << "The number of integers that can be allocated"
         << endl << "before free memory is exhausted: "
         << s2.max_size( ) << "." << endl;

    cout << "\nThe number of doubles that can be allocated"
         << endl << "before free memory is exhausted: "
         << s3.max_size( ) << "." << endl;

    // The following line creates a set s4
    // with the allocator of multiset s1.
    set <int> s4( less<int>( ), s1_Alloc );

    s4_Alloc = s4.get_allocator( );

    // Two allocators are interchangeable if
    // storage allocated from each can be
    // deallocated by the other
    if( s1_Alloc == s4_Alloc )
    {
        cout << "\nThe allocators are interchangeable."
             << endl;
    }
    else
    {
        cout << "\nThe allocators are not interchangeable."
             << endl;
    }
}

```

set::insert

Inserts an element or a range of elements into a set.

```

// (1) single element
pair<iterator, bool> insert(
    const value_type& Val);

// (2) single element, perfect forwarded
template <class ValTy>
pair<iterator, bool>
insert(
    ValTy&& Val);

// (3) single element with hint
iterator insert(
    const_iterator Where,
    const value_type& Val);

// (4) single element, perfect forwarded, with hint
template <class ValTy>
iterator insert(
    const_iterator Where,
    ValTy&& Val);

// (5) range
template <class InputIterator>
void insert(
    InputIterator First,
    InputIterator Last);

// (6) initializer list
void insert(
    initializer_list<value_type>
    IList);

```

Parameters

PARAMETER	DESCRIPTION
<i>Val</i>	The value of an element to be inserted into the set unless it already contains an element whose value is equivalently ordered.
<i>Where</i>	The place to start searching for the correct point of insertion. (If that point immediately precedes <i>Where</i> , insertion can occur in amortized constant time instead of logarithmic time.)
<i>ValTy</i>	Template parameter that specifies the argument type that the set can use to construct an element of value_type , and perfect-forwards <i>Val</i> as an argument.
<i>First</i>	The position of the first element to be copied.
<i>Last</i>	The position just beyond the last element to be copied.
<i>InputIterator</i>	Template function argument that meets the requirements of an input iterator that points to elements of a type that can be used to construct value_type objects.
<i>IList</i>	The initializer_list from which to copy the elements.

Return Value

The single-element member functions, (1) and (2), return a [pair](#) whose **bool** component is true if an insertion was

made, and false if the set already contained an element of equivalent value in the ordering. The iterator component of the return-value pair points to the newly inserted element if the **bool** component is true, or to the existing element if the **bool** component is false.

The single-element-with-hint member functions, (3) and (4), return an iterator that points to the position where the new element was inserted into the set or, if an element with an equivalent key already exists, to the existing element.

Remarks

No iterators, pointers, or references are invalidated by this function.

During the insertion of just one element, if an exception is thrown, the container's state is not modified. During the insertion of multiple elements, if an exception is thrown, the container is left in an unspecified but valid state.

To access the iterator component of a `pair` `pr` that's returned by the single-element member functions, use `pr.first`; to dereference the iterator within the returned pair, use `*pr.first`, giving you an element. To access the **bool** component, use `pr.second`. For an example, see the sample code later in this article.

The [value_type](#) of a container is a typedef that belongs to the container, and, for set, `set<V>::value_type` is type `const V`.

The range member function (5) inserts the sequence of element values into a set that corresponds to each element addressed by an iterator in the range `[First, Last)`; therefore, `Last` does not get inserted. The container member function `end()` refers to the position just after the last element in the container—for example, the statement `s.insert(v.begin(), v.end());` attempts to insert all elements of `v` into `s`. Only elements that have unique values in the range are inserted; duplicates are ignored. To observe which elements are rejected, use the single-element versions of `insert`.

The initializer list member function (6) uses an [initializer_list](#) to copy elements into the set.

For insertion of an element constructed in place—that is, no copy or move operations are performed—see [set::emplace](#) and [set::emplace_hint](#).

Example

```
// set_insert.cpp
// compile with: /EHsc
#include <set>
#include <iostream>
#include <string>
#include <vector>

using namespace std;

template <typename S> void print(const S& s) {
    cout << s.size() << " elements: ";

    for (const auto& p : s) {
        cout << "(" << p << ") ";
    }

    cout << endl;
}

int main()
{
    // insert single values
    set<int> s1;
    // call insert(const value_type&) version
    s1.insert({ 1, 10 });
    // call insert(ValTy&&) version
```

```

s1.insert(20);

cout << "The original set values of s1 are:" << endl;
print(s1);

// intentionally attempt a duplicate, single element
auto ret = s1.insert(1);
if (!ret.second){
    auto elem = *ret.first;
    cout << "Insert failed, element with value 1 already exists."
        << endl << " The existing element is (" << elem << ")"
        << endl;
}
else{
    cout << "The modified set values of s1 are:" << endl;
    print(s1);
}
cout << endl;

// single element, with hint
s1.insert(s1.end(), 30);
cout << "The modified set values of s1 are:" << endl;
print(s1);
cout << endl;

// The templated version inserting a jumbled range
set<int> s2;
vector<int> v;
v.push_back(43);
v.push_back(294);
v.push_back(41);
v.push_back(330);
v.push_back(42);
v.push_back(45);

cout << "Inserting the following vector data into s2:" << endl;
print(v);

s2.insert(v.begin(), v.end());

cout << "The modified set values of s2 are:" << endl;
print(s2);
cout << endl;

// The templated versions move-constructing elements
set<string> s3;
string str1("blue"), str2("green");

// single element
s3.insert(move(str1));
cout << "After the first move insertion, s3 contains:" << endl;
print(s3);

// single element with hint
s3.insert(s3.end(), move(str2));
cout << "After the second move insertion, s3 contains:" << endl;
print(s3);
cout << endl;

set<int> s4;
// Insert the elements from an initializer_list
s4.insert({ 4, 44, 2, 22, 3, 33, 1, 11, 5, 55 });
cout << "After initializer_list insertion, s4 contains:" << endl;
print(s4);
cout << endl;
}

```

set::iterator

A type that provides a constant [bidirectional iterator](#) that can read any element in a set.

```
typedef implementation-defined iterator;
```

Example

See the example for [begin](#) for an example of how to declare and use an `iterator`.

set::key_comp

Retrieves a copy of the comparison object used to order keys in a set.

```
key_compare key_comp() const;
```

Return Value

Returns the function object that a set uses to order its elements, which is the template parameter `Traits`.

For more information on `Traits` see the [set Class](#) topic.

Remarks

The stored object defines the member function:

```
bool operator()( const Key& _xVal, const Key& _yVal );
```

which returns **true** if `_xVal` precedes and is not equal to `_yVal` in the sort order.

Note that both [key_compare](#) and [value_compare](#) are synonyms for the template parameter `Traits`. Both types are provided for the set and multiset classes, where they are identical, for compatibility with the map and multimap classes, where they are distinct.

Example

```

// set_key_comp.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;

    set <int, less<int> > s1;
    set<int, less<int> >::key_compare kc1 = s1.key_comp( ) ;
    bool result1 = kc1( 2, 3 ) ;
    if( result1 == true )
    {
        cout << "kc1( 2,3 ) returns value of true, "
              << "where kc1 is the function object of s1."
              << endl;
    }
    else
    {
        cout << "kc1( 2,3 ) returns value of false "
              << "where kc1 is the function object of s1."
              << endl;
    }

    set <int, greater<int> > s2;
    set<int, greater<int> >::key_compare kc2 = s2.key_comp( ) ;
    bool result2 = kc2( 2, 3 ) ;
    if(result2 == true)
    {
        cout << "kc2( 2,3 ) returns value of true, "
              << "where kc2 is the function object of s2."
              << endl;
    }
    else
    {
        cout << "kc2( 2,3 ) returns value of false, "
              << "where kc2 is the function object of s2."
              << endl;
    }
}

```

```

kc1( 2,3 ) returns value of true, where kc1 is the function object of s1.
kc2( 2,3 ) returns value of false, where kc2 is the function object of s2.

```

set::key_compare

A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the set.

```
typedef Traits key_compare;
```

Remarks

`key_compare` is a synonym for the template parameter `Traits`.

For more information on `Traits` see the [set Class](#) topic.

Note that both `key_compare` and `value_compare` are synonyms for the template parameter `Traits`. Both types are provided for the set and multiset classes, where they are identical, for compatibility with the map and multimap classes, where they are distinct.

Example

See the example for [key_comp](#) for an example of how to declare and use `key_compare`.

set::key_type

A type that describes an object stored as an element of a set in its capacity as sort key.

```
typedef Key key_type;
```

Remarks

`key_type` is a synonym for the template parameter `Key`.

For more information on `key`, see the Remarks section of the [set Class](#) topic.

Note that both `key_type` and [value_type](#) are synonyms for the template parameter `Key`. Both types are provided for the set and multiset classes, where they are identical, for compatibility with the map and multimap classes, where they are distinct.

Example

See the example for [value_type](#) for an example of how to declare and use `key_type`.

set::lower_bound

Returns an iterator to the first element in a set with a key that is equal to or greater than a specified key.

```
const_iterator lower_bound(const Key& key) const;  
  
iterator lower_bound(const Key& key);
```

Parameters

key

The argument key to be compared with the sort key of an element from the set being searched.

Return Value

An iterator or `const_iterator` that addresses the location of an element in a set that with a key that is equal to or greater than the argument key or that addresses the location succeeding the last element in the set if no match is found for the key.

Example

```

// set_lower_bound.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;
    set <int> :: const_iterator s1_AcIter, s1_RcIter;

    s1.insert( 10 );
    s1.insert( 20 );
    s1.insert( 30 );

    s1_RcIter = s1.lower_bound( 20 );
    cout << "The element of set s1 with a key of 20 is: "
         << *s1_RcIter << "." << endl;

    s1_RcIter = s1.lower_bound( 40 );

    // If no match is found for the key, end( ) is returned
    if ( s1_RcIter == s1.end( ) )
        cout << "The set s1 doesn't have an element "
             << "with a key of 40." << endl;
    else
        cout << "The element of set s1 with a key of 40 is: "
             << *s1_RcIter << "." << endl;

    // The element at a specific location in the set can be found
    // by using a dereferenced iterator that addresses the location
    s1_AcIter = s1.end( );
    s1_AcIter--;
    s1_RcIter = s1.lower_bound( *s1_AcIter );
    cout << "The element of s1 with a key matching "
         << "that of the last element is: "
         << *s1_RcIter << "." << endl;
}

```

```

The element of set s1 with a key of 20 is: 20.
The set s1 doesn't have an element with a key of 40.
The element of s1 with a key matching that of the last element is: 30.

```

set::max_size

Returns the maximum length of the set.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the set.

Example

```
// set_max_size.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;
    set <int>::size_type i;

    i = s1.max_size( );
    cout << "The maximum possible length "
         << "of the set is " << i << "." << endl;
}
```

set::operator=

Replaces the elements of this `set` using elements from another `set`.

```
set& operator=(const set& right);

set& operator=(set&& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The <code>set</code> providing new elements to be assigned to this <code>set</code> .

Remarks

The first version of `operator=` uses an [lvalue reference](#) for *right*, to copy elements from *right* to this `set`.

The second version uses an [rvalue reference](#) for *right*. It moves elements from *right* to this `set`.

Any elements in this `set` before the operator function executes are discarded.

Example

```

// set_operator_as.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set<int> v1, v2, v3;
    set<int>::iterator iter;

    v1.insert(10);

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;
}

```

set::pointer

A type that provides a pointer to an element in a set.

```
typedef typename allocator_type::pointer pointer;
```

Remarks

A type **pointer** can be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a set object.

set::rbegin

Returns an iterator addressing the first element in a reversed set.

```

const_reverse_iterator rbegin() const;

reverse_iterator rbegin();

```

Return Value

A reverse bidirectional iterator addressing the first element in a reversed set or addressing what had been the last element in the unreversed set.

Remarks

`rbegin` is used with a reversed set just as [begin](#) is used with a set.

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, then the set object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, then the set object can be modified.

`rbegin` can be used to iterate through a set backwards.

Example

```
// set_rbegin.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;
    set <int>::iterator s1_Iter;
    set <int>::reverse_iterator s1_rIter;

    s1.insert( 10 );
    s1.insert( 20 );
    s1.insert( 30 );

    s1_rIter = s1.rbegin( );
    cout << "The first element in the reversed set is "
         << *s1_rIter << "." << endl;

    // begin can be used to start an iteration
    // through a set in a forward order
    cout << "The set is:";
    for ( s1_Iter = s1.begin( ) ; s1_Iter != s1.end( ) ; s1_Iter++ )
        cout << " " << *s1_Iter;
    cout << endl;

    // rbegin can be used to start an iteration
    // through a set in a reverse order
    cout << "The reversed set is:";
    for ( s1_rIter = s1.rbegin( ) ; s1_rIter != s1.rend( ) ; s1_rIter++ )
        cout << " " << *s1_rIter;
    cout << endl;

    // A set element can be erased by dereferencing to its key
    s1_rIter = s1.rbegin( );
    s1.erase ( *s1_rIter );

    s1_rIter = s1.rbegin( );
    cout << "After the erasure, the first element "
         << "in the reversed set is "<< *s1_rIter << "." << endl;
}
```

```
The first element in the reversed set is 30.
The set is: 10 20 30
The reversed set is: 30 20 10
After the erasure, the first element in the reversed set is 20.
```

set::reference

A type that provides a reference to an element stored in a set.

```
typedef typename allocator_type::reference reference;
```

Example

```
// set_reference.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;

    s1.insert( 10 );
    s1.insert( 20 );

    // Declare and initialize a reference &Ref1 to the 1st element
    const int &Ref1 = *s1.begin( );

    cout << "The first element in the set is "
         << Ref1 << "." << endl;
}
```

```
The first element in the set is 10.
```

set::rend

Returns an iterator that addresses the location succeeding the last element in a reversed set.

```
const_reverse_iterator rend() const;

reverse_iterator rend();
```

Return Value

A reverse bidirectional iterator that addresses the location succeeding the last element in a reversed set (the location that had preceded the first element in the unreversed set).

Remarks

`rend` is used with a reversed set just as `end` is used with a set.

If the return value of `rend` is assigned to a `const_reverse_iterator`, then the set object cannot be modified. If the return value of `rend` is assigned to a `reverse_iterator`, then the set object can be modified. The value returned by `rend` should not be dereferenced.

`rend` can be used to test to whether a reverse iterator has reached the end of its set.

Example

```

// set_rend.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main() {
    using namespace std;
    set <int> s1;
    set <int>::iterator s1_Iter;
    set <int>::reverse_iterator s1_rIter;
    set <int>::const_reverse_iterator s1_crIter;

    s1.insert( 10 );
    s1.insert( 20 );
    s1.insert( 30 );

    s1_rIter = s1.rend( );
    s1_rIter--;
    cout << "The last element in the reversed set is "
         << *s1_rIter << "." << endl;

    // end can be used to terminate an iteration
    // through a set in a forward order
    cout << "The set is: ";
    for ( s1_Iter = s1.begin( ) ; s1_Iter != s1.end( ) ; s1_Iter++ )
        cout << *s1_Iter << " ";
    cout << "." << endl;

    // rend can be used to terminate an iteration
    // through a set in a reverse order
    cout << "The reversed set is: ";
    for ( s1_rIter = s1.rbegin( ) ; s1_rIter != s1.rend( ) ; s1_rIter++ )
        cout << *s1_rIter << " ";
    cout << "." << endl;

    s1_rIter = s1.rend( );
    s1_rIter--;
    s1.erase ( *s1_rIter );

    s1_rIter = s1.rend( );
    --s1_rIter;
    cout << "After the erasure, the last element in the "
         << "reversed set is " << *s1_rIter << "." << endl;
}

```

set::reverse_iterator

A type that provides a bidirectional iterator that can read or modify an element in a reversed set.

```
typedef std::reverse_iterator<iterator> reverse_iterator;
```

Remarks

A type `reverse_iterator` is use to iterate through the set in reverse.

Example

See the example for [rbegin](#) for an example of how to declare and use `reverse_iterator`.

set::set

Constructs a set that is empty or that is a copy of all or part of some other set.

```

set();

explicit set(
    const Traits& Comp);

set(
    const Traits& Comp,
    const Allocator& Al);

set(
    const set& Right);

set(
    set&& Right);

set(
    initializer_list<Type> IList);

set(
    initializer_list<Type> IList,
    const Compare& Comp);

set(
    initializer_list<Type> IList,
    const Compare& Comp,
    const Allocator& Al);

template <class InputIterator>
set(
    InputIterator First,
    InputIterator Last);

template <class InputIterator>
set(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp);

template <class InputIterator>
set(
    InputIterator First,
    InputIterator Last,
    const Traits& Comp,
    const Allocator& Al);

```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The storage allocator class to be used for this set object, which defaults to <code>Allocator</code> .
<i>Comp</i>	The comparison function of type <code>const Traits</code> used to order the elements in the set, which defaults to <code>Compare</code> .
<i>Right</i>	The set of which the constructed set is to be a copy.
<i>First</i>	The position of the first element in the range of elements to be copied.
<i>Last</i>	The position of the first element beyond the range of elements to be copied.

PARAMETER	DESCRIPTION
<i>lList</i>	The initializer_list from which to copy the elements.

Remarks

All constructors store a type of allocator object that manages memory storage for the set and that can later be returned by calling [get_allocator](#). The allocator parameter is often omitted in the class declarations and preprocessing macros used to substitute alternative allocators.

All constructors initialize their sets.

All constructors store a function object of type `Traits` that is used to establish an order among the keys of the set and that can later be returned by calling [key_comp](#).

The first three constructors specify an empty initial set, the second specifying the type of comparison function (`comp`) to be used in establishing the order of the elements and the third explicitly specifying the allocator type (`al`) to be used. The keyword **explicit** suppresses certain kinds of automatic type conversion.

The fourth constructor specifies a copy of the set `right`.

The next three constructors use an initializer_list to specify the elements.

The next three constructors copy the range [`first`, `last`) of a set with increasing explicitness in specifying the type of comparison function of class `Traits` and **Allocator**.

The eighth constructor specifies a copy of the set by moving `right`.

Example

```
// set_set.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main()
{
    using namespace std;

    // Create an empty set s0 of key type integer
    set<int> s0;

    // Create an empty set s1 with the key comparison
    // function of less than, then insert 4 elements
    set<int, less<int> > s1;
    s1.insert(10);
    s1.insert(20);
    s1.insert(30);
    s1.insert(40);

    // Create an empty set s2 with the key comparison
    // function of less than, then insert 2 elements
    set<int, less<int> > s2;
    s2.insert(10);
    s2.insert(20);

    // Create a set s3 with the
    // allocator of set s1
    set<int::allocator_type s1_Alloc;
    s1_Alloc = s1.get_allocator();
    set<int> s3(less<int>(), s1_Alloc);
    s3.insert(30);

    // Create a copy, set s4, of set s1
```

```

set<int> s4(s1);

// Create a set s5 by copying the range s1[ first, last)
set<int>::const_iterator s1_bcIter, s1_ecIter;
s1_bcIter = s1.begin();
s1_ecIter = s1.begin();
s1_ecIter++;
s1_ecIter++;
set<int> s5(s1_bcIter, s1_ecIter);

// Create a set s6 by copying the range s4[ first, last)
// and with the allocator of set s2
set<int>::allocator_type s2_Alloc;
s2_Alloc = s2.get_allocator();
set<int> s6(s4.begin(), ++s4.begin(), less<int>(), s2_Alloc);

cout << "s1 =";
for (auto i : s1)
    cout << " " << i;
cout << endl;

cout << "s2 = " << *s2.begin() << " " << *++s2.begin() << endl;

cout << "s3 =";
for (auto i : s3)
    cout << " " << i;
cout << endl;

cout << "s4 =";
for (auto i : s4)
    cout << " " << i;
cout << endl;

cout << "s5 =";
for (auto i : s5)
    cout << " " << i;
cout << endl;

cout << "s6 =";
for (auto i : s6)
    cout << " " << i;
cout << endl;

// Create a set by moving s5
set<int> s7(move(s5));
cout << "s7 =";
for (auto i : s7)
    cout << " " << i;
cout << endl;

// Create a set with an initializer_list
cout << "s8 =";
set<int> s8{ { 1, 2, 3, 4 } };
for (auto i : s8)
    cout << " " << i;
cout << endl;

cout << "s9 =";
set<int> s9{ { 5, 6, 7, 8 }, less<int>() };
for (auto i : s9)
    cout << " " << i;
cout << endl;

cout << "s10 =";
set<int> s10{ { 10, 20, 30, 40 }, less<int>(), s9.get_allocator() };
for (auto i : s10)
    cout << " " << i;
cout << endl;
}

```

```
s1 = 10 20 30 40 s2 = 10 20 s3 = 30 s4 = 10 20 30 40 s5 = 10 20 s6 = 10 s7 = 10 20 s8 = 1 2 3 4 s9 = 5 6 7 8 s10 = 10 20 30 40
```

set::size

Returns the number of elements in the set.

```
size_type size() const;
```

Return Value

The current length of the set.

Example

```
// set_size.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;
    set <int> :: size_type i;

    s1.insert( 1 );
    i = s1.size( );
    cout << "The set length is " << i << "." << endl;

    s1.insert( 2 );
    i = s1.size( );
    cout << "The set length is now " << i << "." << endl;
}
```

```
The set length is 1.
The set length is now 2.
```

set::size_type

An unsigned integer type that can represent the number of elements in a set.

```
typedef typename allocator_type::size_type size_type;
```

Example

See the example for [size](#) for an example of how to declare and use `size_type`

set::swap

Exchanges the elements of two sets.

```
void swap(
    set<Key, Traits, Allocator>& right);
```

Parameters

right

The argument set providing the elements to be swapped with the target set.

Remarks

The member function invalidates no references, pointers, or iterators that designate elements in the two sets whose elements are being exchanged.

Example

```
// set_swap.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1, s2, s3;
    set <int>::iterator s1_Iter;

    s1.insert( 10 );
    s1.insert( 20 );
    s1.insert( 30 );
    s2.insert( 100 );
    s2.insert( 200 );
    s3.insert( 300 );

    cout << "The original set s1 is:";
    for ( s1_Iter = s1.begin( ); s1_Iter != s1.end( ); s1_Iter++ )
        cout << " " << *s1_Iter;
    cout << "." << endl;

    // This is the member function version of swap
    s1.swap( s2 );

    cout << "After swapping with s2, list s1 is:";
    for ( s1_Iter = s1.begin( ); s1_Iter != s1.end( ); s1_Iter++ )
        cout << " " << *s1_Iter;
    cout << "." << endl;

    // This is the specialized template version of swap
    swap( s1, s3 );

    cout << "After swapping with s3, list s1 is:";
    for ( s1_Iter = s1.begin( ); s1_Iter != s1.end( ); s1_Iter++ )
        cout << " " << *s1_Iter;
    cout << "." << endl;
}
```

```
The original set s1 is: 10 20 30.
After swapping with s2, list s1 is: 100 200.
After swapping with s3, list s1 is: 300.
```

set::upper_bound

Returns an iterator to the first element in a set that with a key that is greater than a specified key.

```
const_iterator upper_bound(const Key& key) const;
```

```
iterator upper_bound(const Key& key);
```

Parameters

key

The argument key to be compared with the sort key of an element from the set being searched.

Return Value

An `iterator` or `const_iterator` that addresses the location of an element in a set that with a key that is greater than the argument key, or that addresses the location succeeding the last element in the set if no match is found for the key.

Example

```
// set_upper_bound.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;
    set <int> :: const_iterator s1_AcIter, s1_RcIter;

    s1.insert( 10 );
    s1.insert( 20 );
    s1.insert( 30 );

    s1_RcIter = s1.upper_bound( 20 );
    cout << "The first element of set s1 with a key greater "
          << "than 20 is: " << *s1_RcIter << "." << endl;

    s1_RcIter = s1.upper_bound( 30 );

    // If no match is found for the key, end( ) is returned
    if ( s1_RcIter == s1.end( ) )
        cout << "The set s1 doesn't have an element "
              << "with a key greater than 30." << endl;
    else
        cout << "The element of set s1 with a key > 40 is: "
              << *s1_RcIter << "." << endl;

    // The element at a specific location in the set can be found
    // by using a dereferenced iterator addressing the location
    s1_AcIter = s1.begin( );
    s1_RcIter = s1.upper_bound( *s1_AcIter );
    cout << "The first element of s1 with a key greater than"
          << endl << "that of the initial element of s1 is: "
          << *s1_RcIter << "." << endl;
}
```

The first element of set s1 with a key greater than 20 is: 30.
The set s1 doesn't have an element with a key greater than 30.
The first element of s1 with a key greater than
that of the initial element of s1 is: 20.

set::value_comp

Retrieves a copy of the comparison object used to order element values in a set.

```
value_compare value_comp() const;
```

Return Value

Returns the function object that a set uses to order its elements, which is the template parameter `Traits`.

For more information on `Traits` see the [set Class](#) topic.

Remarks

The stored object defines the member function:

```
bool operator( const Key& _xVal , const Key& _yVal );
```

which returns **true** if `_xVal` precedes and is not equal to `_yVal` in the sort order.

Note that both `value_compare` and `key_compare` are synonyms for the template parameter `Traits`. Both types are provided for the set and multiset classes, where they are identical, for compatibility with the map and multimap classes, where they are distinct.

Example

```

// set_value_comp.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;

    set <int, less<int> > s1;
    set <int, less<int> >::value_compare vc1 = s1.value_comp( );
    bool result1 = vc1( 2, 3 );
    if( result1 == true )
    {
        cout << "vc1( 2,3 ) returns value of true, "
              << "where vc1 is the function object of s1."
              << endl;
    }
    else
    {
        cout << "vc1( 2,3 ) returns value of false, "
              << "where vc1 is the function object of s1."
              << endl;
    }

    set <int, greater<int> > s2;
    set<int, greater<int> >::value_compare vc2 = s2.value_comp( );
    bool result2 = vc2( 2, 3 );
    if( result2 == true )
    {
        cout << "vc2( 2,3 ) returns value of true, "
              << "where vc2 is the function object of s2."
              << endl;
    }
    else
    {
        cout << "vc2( 2,3 ) returns value of false, "
              << "where vc2 is the function object of s2."
              << endl;
    }
}

```

```

vc1( 2,3 ) returns value of true, where vc1 is the function object of s1.
vc2( 2,3 ) returns value of false, where vc2 is the function object of s2.

```

set::value_compare

A type that provides a function object that can compare two element values to determine their relative order in the set.

```
typedef key_compare value_compare;
```

Remarks

`value_compare` is a synonym for the template parameter `Traits`.

For more information on `Traits` see the [set Class](#) topic.

Note that both `key_compare` and `value_compare` are synonyms for the template parameter `Traits`. Both types are provided for the set and multiset classes, where they are identical, for compatibility with the map and multimap classes, where they are distinct.

Example

See the example for [value_comp](#) for an example of how to declare and use `value_compare`.

set::value_type

A type that describes an object stored as an element of a set in its capacity as a value.

```
typedef Key value_type;
```

Remarks

`value_type` is a synonym for the template parameter `Key`.

For more information on `key`, see the Remarks section of the [set Class](#) topic.

Note that both [key_type](#) and `value_type` are synonyms for the template parameter `Key`. Both types are provided for the set and multiset classes, where they are identical, for compatibility with the map and multimap classes, where they are distinct.

Example

```
// set_value_type.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    set <int> s1;
    set <int>::iterator s1_Iter;

    set <int>::value_type svt_Int;    // Declare value_type
    svt_Int = 10;                    // Initialize value_type

    set <int> :: key_type skt_Int;    // Declare key_type
    skt_Int = 20;                    // Initialize key_type

    s1.insert( svt_Int );             // Insert value into s1
    s1.insert( skt_Int );             // Insert key into s1

    // A set accepts key_types or value_types as elements
    cout << "The set has elements:";
    for ( s1_Iter = s1.begin( ) ; s1_Iter != s1.end( ) ; s1_Iter++)
        cout << " " << *s1_Iter;
    cout << "." << endl;
}
```

```
The set has elements: 10 20.
```

multiset Class

2/19/2019 • 47 minutes to read • [Edit Online](#)

The C++ Standard Library multiset class is used for the storage and retrieval of data from a collection in which the values of the elements contained need not be unique and in which they serve as the key values according to which the data is automatically ordered. The key value of an element in a multiset may not be changed directly. Instead, old values must be deleted and elements with new values inserted.

Syntax

```
template <class Key, class Compare =less <Key>, class Allocator =allocator <Key>>
class multiset
```

Parameters

Key

The element data type to be stored in the multiset.

Compare

The type that provides a function object that can compare two element values as sort keys to determine their relative order in the multiset. The binary predicate **less**<Key> is the default value.

In C++14 you can enable heterogeneous lookup by specifying the `std::less<>` or `std::greater<>` predicate that has no type parameters. For more information, see [Heterogeneous Lookup in Associative Containers](#)

Allocator

The type that represents the stored allocator object that encapsulates details about the multiset's allocation and deallocation of memory. The default value is `allocator<Key>`.

Remarks

The C++ Standard Library multiset class is:

- An associative container, which is a variable size container that supports the efficient retrieval of element values based on an associated key value.
- Reversible, because it provides bidirectional iterators to access its elements.
- Sorted, because its elements are ordered by key values within the container in accordance with a specified comparison function.
- Multiple in the sense that its elements do not need to have unique keys, so that one key value can have many element values associated with it.
- A simple associative container because its element values are its key values.
- A template class, because the functionality it provides is generic and so independent of the specific type of data contained as elements. The data type to be used is, instead, specified as a parameter in the class template along with the comparison function and allocator.

The iterator provided by the multiset class is a bidirectional iterator, but the class member functions [insert](#) and [multiset](#) have versions that take as template parameters a weaker input iterator, whose functionality requirements are more minimal than those guaranteed by the class of bidirectional iterators. The different iterator concepts

form a family related by refinements in their functionality. Each iterator concept has its own set of requirements and the algorithms that work with them must limit their assumptions to the requirements provided by that type of iterator. It may be assumed that an input iterator may be dereferenced to refer to some object and that it may be incremented to the next iterator in the sequence. This is a minimal set of functionality, but it is enough to be able to talk meaningfully about a range of iterators [`First` , `Last`) in the context of the class's member functions.

The choice of container type should be based in general on the type of searching and inserting required by the application. Associative containers are optimized for the operations of lookup, insertion and removal. The member functions that explicitly support these operations are efficient, performing them in a time that is on average proportional to the logarithm of the number of elements in the container. Inserting elements invalidates no iterators, and removing elements invalidates only those iterators that had specifically pointed at the removed elements.

The multiset should be the associative container of choice when the conditions associating the values with their keys are satisfied by the application. The elements of a multiset may be multiple and serve as their own sort keys, so keys are not unique. A model for this type of structure is an ordered list of, say, words in which the words may occur more than once. Had multiple occurrences of the words not been allowed, then a set would have been the appropriate container structure. If unique definitions were attached as values to the list of unique key words, then a map would be an appropriate structure to contain this data. If instead the definitions were not unique, then a multimap would be the container of choice.

The multiset orders the sequence it controls by calling a stored function object of type *Compare*. This stored object is a comparison function that may be accessed by calling the member function `key_comp`. In general, the elements need be merely less than comparable to establish this order: so that, given any two elements, it may be determined either that they are equivalent (in the sense that neither is less than the other) or that one is less than the other. This results in an ordering between the nonequivalent elements. On a more technical note, the comparison function is a binary predicate that induces a strict weak ordering in the standard mathematical sense. A binary predicate $f(x, y)$ is a function object that has two argument objects x and y and a return value of **true** or **false**. An ordering imposed on a set is a strict weak ordering if the binary predicate is irreflexive, antisymmetric, and transitive and if equivalence is transitive, where two objects x and y are defined to be equivalent when both $f(x, y)$ and $f(y, x)$ are false. If the stronger condition of equality between keys replaces that of equivalence, then the ordering becomes total (in the sense that all the elements are ordered with respect to each other) and the keys matched will be indiscernible from each other.

In C++14 you can enable heterogeneous lookup by specifying the `std::less<>` or `std::greater<>` predicate that has no type parameters. For more information, see [Heterogeneous Lookup in Associative Containers](#)

Constructors

CONSTRUCTOR	DESCRIPTION
<code>multiset</code>	Constructs a <code>multiset</code> that is empty or that is a copy of all or part of a specified <code>multiset</code> .

Typedefs

TYPE NAME	DESCRIPTION
<code>allocator_type</code>	A typedef for the <code>allocator</code> class for the <code>multiset</code> object.
<code>const_iterator</code>	A typedef for a bidirectional iterator that can read a const element in the <code>multiset</code> .
<code>const_pointer</code>	A typedef for a pointer to a const element in a <code>multiset</code> .

TYPE NAME	DESCRIPTION
<code>const_reference</code>	A typedef for a reference to a const element stored in a <code>multiset</code> for reading and performing const operations.
<code>const_reverse_iterator</code>	A typedef for a bidirectional iterator that can read any const element in the <code>multiset</code> .
<code>difference_type</code>	A signed integer typedef for the number of elements of a <code>multiset</code> in a range between elements pointed to by iterators.
<code>iterator</code>	A typedef for a bidirectional iterator that can read or modify any element in a <code>multiset</code> .
<code>key_compare</code>	A typedef for a function object that can compare two keys to determine the relative order of two elements in the <code>multiset</code> .
<code>key_type</code>	A typedef for a function object that can compare two sort keys to determine the relative order of two elements in the <code>multiset</code> .
<code>pointer</code>	A typedef for a pointer to an element in a <code>multiset</code> .
<code>reference</code>	A typedef for a reference to an element stored in a <code>multiset</code> .
<code>reverse_iterator</code>	A typedef for a bidirectional iterator that can read or modify an element in a reversed <code>multiset</code> .
<code>size_type</code>	An unsigned integer type that can represent the number of elements in a <code>multiset</code> .
<code>value_compare</code>	The typedef for a function object that can compare two elements as sort keys to determine their relative order in the <code>multiset</code> .
<code>value_type</code>	A typedef that describes an object stored as an element as a <code>multiset</code> in its capacity as a value.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>begin</code>	Returns an iterator that points to the first element in the <code>multiset</code> .
<code>cbegin</code>	Returns a const iterator that addresses the first element in the <code>multiset</code> .
<code>cend</code>	Returns a const iterator that addresses the location succeeding the last element in a <code>multiset</code> .

MEMBER FUNCTION	DESCRIPTION
<code>clear</code>	Erases all the elements of a <code>multiset</code> .
<code>count</code>	Returns the number of elements in a <code>multiset</code> whose key matches the key specified as a parameter.
<code>crbegin</code>	Returns a const iterator addressing the first element in a reversed set.
<code>crend</code>	Returns a const iterator that addresses the location succeeding the last element in a reversed set.
<code>emplace</code>	Inserts an element constructed in place into a <code>multiset</code> .
<code>emplace_hint</code>	Inserts an element constructed in place into a <code>multiset</code> , with a placement hint.
<code>empty</code>	Tests if a <code>multiset</code> is empty.
<code>end</code>	Returns an iterator that points to the location after the last element in a <code>multiset</code> .
<code>equal_range</code>	Returns a pair of iterators. The first iterator in the pair points to the first element in a <code>multiset</code> with a key that is greater than a specified key. The second iterator in the pair points to first element in the <code>multiset</code> with a key that is equal to or greater than the key.
<code>erase</code>	Removes an element or a range of elements in a <code>multiset</code> from specified positions or removes elements that match a specified key.
<code>find</code>	Returns an iterator that points to the first location of an element in a <code>multiset</code> that has a key equal to a specified key.
<code>get_allocator</code>	Returns a copy of the <code>allocator</code> object that is used to construct the <code>multiset</code> .
<code>insert</code>	Inserts an element or a range of elements into a <code>multiset</code> .
<code>key_comp</code>	Provides a function object that can compare two sort keys to determine the relative order of two elements in the <code>multiset</code> .
<code>lower_bound</code>	Returns an iterator to the first element in a <code>multiset</code> with a key that is equal to or greater than a specified key.
<code>max_size</code>	Returns the maximum length of the <code>multiset</code> .
<code>rbegin</code>	Returns an iterator that points to the first element in a reversed <code>multiset</code> .

MEMBER FUNCTION	DESCRIPTION
<code>rend</code>	Returns an iterator that points to the location succeeding the last element in a reversed <code>multiset</code> .
<code>size</code>	Returns the number of elements in a <code>multiset</code> .
<code>swap</code>	Exchanges the elements of two <code>multiset</code> s.
<code>upper_bound</code>	Returns an iterator to the first element in a <code>multiset</code> with a key that is greater than a specified key.
<code>value_comp</code>	Retrieves a copy of the comparison object that is used to order element values in a <code>multiset</code> .

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Replaces the elements of a <code>multiset</code> with a copy of another <code>multiset</code> .

Requirements

Header: `<set>`

Namespace: `std`

`multiset::allocator_type`

A type that represents the allocator class for the `multiset` object

```
typedef Allocator allocator_type;
```

Remarks

`allocator_type` is a synonym for the template parameter `Allocator`.

For more information on `Allocator`, see the Remarks section of the [multiset Class](#) topic.

Example

See the example for [get_allocator](#) for an example using `allocator_type`

`multiset::begin`

Returns an iterator addressing the first element in the `multiset`.

```
const_iterator begin() const;

iterator begin();
```

Return Value

A bidirectional iterator addressing the first element in the `multiset` or the location succeeding an empty `multiset`.

Example

```
// multiset_begin.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;
    multiset <int>::iterator ms1_Iter;
    multiset <int>::const_iterator ms1_cIter;

    ms1.insert( 1 );
    ms1.insert( 2 );
    ms1.insert( 3 );

    ms1_Iter = ms1.begin( );
    cout << "The first element of ms1 is " << *ms1_Iter << endl;

    ms1_Iter = ms1.begin( );
    ms1.erase( ms1_Iter );

    // The following 2 lines would err as the iterator is const
    // ms1_cIter = ms1.begin( );
    // ms1.erase( ms1_cIter );

    ms1_cIter = ms1.begin( );
    cout << "The first element of ms1 is now " << *ms1_cIter << endl;
}
```

```
The first element of ms1 is 1
The first element of ms1 is now 2
```

multiset::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** bidirectional-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin`, the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the [auto](#) type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

multiset::cend

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A **const** bidirectional-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non-**const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

multiset::clear

Erases all the elements of a multiset.

```
void clear();
```

Example

```
// multiset_clear.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;

    ms1.insert( 1 );
    ms1.insert( 2 );

    cout << "The size of the multiset is initially "
         << ms1.size( ) << "." << endl;

    ms1.clear( );
    cout << "The size of the multiset after clearing is "
         << ms1.size( ) << "." << endl;
}
```

```
The size of the multiset is initially 2.
The size of the multiset after clearing is 0.
```

multiset::const_iterator

A type that provides a bidirectional iterator that can read a **const** element in the multiset.

```
typedef implementation-defined const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

Example

See the example for [begin](#) for an example using `const_iterator`.

multiset::const_pointer

A type that provides a pointer to a **const** element in a multiset.

```
typedef typename allocator_type::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a multiset object.

multiset::const_reference

A type that provides a reference to a **const** element stored in a multiset for reading and performing **const** operations.

```
typedef typename allocator_type::const_reference const_reference;
```

Example

```
// multiset_const_ref.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;

    ms1.insert( 10 );
    ms1.insert( 20 );

    // Declare and initialize a const_reference &Ref1
    // to the 1st element
    const int &Ref1 = *ms1.begin( );

    cout << "The first element in the multiset is "
         << Ref1 << "." << endl;

    // The following line would cause an error because the
    // const_reference cannot be used to modify the multiset
    // Ref1 = Ref1 + 5;
}
```

The first element in the multiset is 10.

multiset::const_reverse_iterator

A type that provides a bidirectional iterator that can read any **const** element in the multiset.

```
typedef std::reverse_iterator<const_iterator> const_reverse_iterator;
```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is use to iterate through the multiset in reverse.

Example

See the example for [rend](#) for an example of how to declare and use the `const_reverse_iterator`.

multiset::count

Returns the number of elements in a multiset whose key matches a parameter-specified key.

```
size_type count(const Key& key) const;
```

Parameters

key

The key of the elements to be matched from the multiset.

Return Value

The number of elements in the multiset whose sort key matches the parameter key.

Remarks

The member function returns the number of elements x in the range

[lower_bound(*key*), upper_bound(*key*))

Example

The following example demonstrates the use of the `multiset::count` member function.

```
// multiset_count.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main()
{
    using namespace std;
    multiset<int> ms1;
    multiset<int>::size_type i;

    ms1.insert(1);
    ms1.insert(1);
    ms1.insert(2);

    // Elements do not need to be unique in multiset,
    // so duplicates are allowed and counted.
    i = ms1.count(1);
    cout << "The number of elements in ms1 with a sort key of 1 is: "
         << i << "." << endl;

    i = ms1.count(2);
    cout << "The number of elements in ms1 with a sort key of 2 is: "
         << i << "." << endl;

    i = ms1.count(3);
    cout << "The number of elements in ms1 with a sort key of 3 is: "
         << i << "." << endl;
}
```

```
The number of elements in ms1 with a sort key of 1 is: 2.
The number of elements in ms1 with a sort key of 2 is: 1.
The number of elements in ms1 with a sort key of 3 is: 0.
```

multiset::crbegin

Returns a const iterator addressing the first element in a reversed multiset.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse bidirectional iterator addressing the first element in a reversed multiset or addressing what had been the last element in the unreversed multiset.

Remarks

`crbegin` is used with a reversed multiset just as `begin` is used with a multiset.

With the return value of `crbegin`, the multiset object cannot be modified.

`crbegin` can be used to iterate through a multiset backwards.

Example

```
// multiset_crbegin.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;
    multiset <int>::const_reverse_iterator ms1_crIter;

    ms1.insert( 10 );
    ms1.insert( 20 );
    ms1.insert( 30 );

    ms1_crIter = ms1.crbegin( );
    cout << "The first element in the reversed multiset is "
         << *ms1_crIter << "." << endl;
}
```

The first element in the reversed multiset is 30.

multiset::crend

Returns a const iterator that addresses the location succeeding the last element in a reversed multiset.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse bidirectional iterator that addresses the location succeeding the last element in a reversed multiset (the location that had preceded the first element in the unreversed multiset).

Remarks

`crend` is used with a reversed multiset just as `end` is used with a multiset.

With the return value of `crend`, the multiset object cannot be modified.

`crend` can be used to test to whether a reverse iterator has reached the end of its multiset.

The value returned by `crend` should not be dereferenced.

Example

```

// multiset_crend.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main() {
    using namespace std;
    multiset <int> ms1;
    multiset <int>::const_reverse_iterator ms1_crIter;

    ms1.insert( 10 );
    ms1.insert( 20 );
    ms1.insert( 30 );

    ms1_crIter = ms1.crend( ) ;
    ms1_crIter--;
    cout << "The last element in the reversed multiset is "
         << *ms1_crIter << "." << endl;
}

```

multiset::difference_type

A signed integer type that can be used to represent the number of elements of a multiset in a range between elements pointed to by iterators.

```
typedef typename allocator_type::difference_type difference_type;
```

Remarks

The `difference_type` is the type returned when subtracting or incrementing through iterators of the container.

The `difference_type` is typically used to represent the number of elements in the range `[first, last)` between the iterators `first` and `last`, includes the element pointed to by `first` and the range of elements up to, but not including, the element pointed to by `last`.

Note that although `difference_type` is available for all iterators that satisfy the requirements of an input iterator, which includes the class of bidirectional iterators supported by reversible containers like `set`, subtraction between iterators is only supported by random-access iterators provided by a random-access container like `vector`.

Example

```

// multiset_diff_type.cpp
// compile with: /EHsc
#include <iostream>
#include <set>
#include <algorithm>

int main( )
{
    using namespace std;

    multiset <int> ms1;
    multiset <int>::iterator ms1_iter, ms1_bIter, ms1_eIter;

    ms1.insert( 20 );
    ms1.insert( 10 );
    ms1.insert( 20 );

    ms1_bIter = ms1.begin( );
    ms1_eIter = ms1.end( );

    multiset <int>::difference_type  df_typ5, df_typ10, df_typ20;

    df_typ5 = count( ms1_bIter, ms1_eIter, 5 );
    df_typ10 = count( ms1_bIter, ms1_eIter, 10 );
    df_typ20 = count( ms1_bIter, ms1_eIter, 20 );

    // The keys, and hence the elements, of a multiset are not unique
    cout << "The number '5' occurs " << df_typ5
         << " times in multiset ms1.\n";
    cout << "The number '10' occurs " << df_typ10
         << " times in multiset ms1.\n";
    cout << "The number '20' occurs " << df_typ20
         << " times in multiset ms1.\n";

    // Count the number of elements in a multiset
    multiset <int>::difference_type  df_count = 0;
    ms1_iter = ms1.begin( );
    while ( ms1_iter != ms1_eIter)
    {
        df_count++;
        ms1_iter++;
    }

    cout << "The number of elements in the multiset ms1 is: "
         << df_count << "." << endl;
}

```

```

The number '5' occurs 0 times in multiset ms1.
The number '10' occurs 1 times in multiset ms1.
The number '20' occurs 2 times in multiset ms1.
The number of elements in the multiset ms1 is: 3.

```

multiset::emplace

Inserts an element constructed in place (no copy or move operations are performed), with a placement hint.

```

template <class... Args>
iterator emplace(Args&&... args);

```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the multiset.

Return Value

An iterator to the newly inserted element.

Remarks

No references to container elements are invalidated by this function, but it may invalidate all iterators to the container.

During emplacement, if an exception is thrown, the container's state is not modified.

Example

```
// multiset_emplace.cpp
// compile with: /EHsc
#include <set>
#include <string>
#include <iostream>

using namespace std;

template <typename S> void print(const S& s) {
    cout << s.size() << " elements: ";

    for (const auto& p : s) {
        cout << "(" << p << ") ";
    }

    cout << endl;
}

int main()
{
    multiset<string> s1;

    s1.emplace("Anna");
    s1.emplace("Bob");
    s1.emplace("Carmin");

    cout << "multiset modified, now contains ";
    print(s1);
    cout << endl;

    s1.emplace("Bob");

    cout << "multiset modified, now contains ";
    print(s1);
    cout << endl;
}
```

multiset::emplace_hint

Inserts an element constructed in place (no copy or move operations are performed), with a placement hint.

```
template <class... Args>
iterator emplace_hint(
    const_iterator where,
    Args&&... args);
```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the multiset.
<i>where</i>	The place to start searching for the correct point of insertion. (If that point immediately precedes <i>where</i> , insertion can occur in amortized constant time instead of logarithmic time.)

Return Value

An iterator to the newly inserted element.

Remarks

No references to container elements are invalidated by this function, but it may invalidate all iterators to the container.

During emplacement, if an exception is thrown, the container's state is not modified.

For a code example, see [set::emplace_hint](#).

multiset::empty

Tests if a multiset is empty.

```
bool empty() const;
```

Return Value

true if the multiset is empty; **false** if the multiset is nonempty.

Example

```
// multiset_empty.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1, ms2;
    ms1.insert ( 1 );

    if ( ms1.empty( ) )
        cout << "The multiset ms1 is empty." << endl;
    else
        cout << "The multiset ms1 is not empty." << endl;

    if ( ms2.empty( ) )
        cout << "The multiset ms2 is empty." << endl;
    else
        cout << "The multiset ms2 is not empty." << endl;
}
```

```
The multiset ms1 is not empty.
The multiset ms2 is empty.
```

multiset::end

Returns the past-the-end iterator.

```
const_iterator end() const;

iterator end();
```

Return Value

The past-the-end iterator. If the multiset is empty, then `multiset::end() == multiset::begin()`.

Remarks

end is used to test whether an iterator has passed the end of its multiset.

The value returned by **end** should not be dereferenced.

For a code example, see [multiset::find](#).

multiset::equal_range

Returns a pair of iterators respectively to the first element in a multiset with a key that is greater than a specified key and to the first element in the multiset with a key that is equal to or greater than the key.

```
pair <const_iterator, const_iterator> equal_range (const Key& key) const;

pair <iterator, iterator> equal_range (const Key& key);
```

Parameters

key

The argument key to be compared with the sort key of an element from the multiset being searched.

Return Value

A pair of iterators such that the first is the [lower_bound](#) of the key and the second is the [upper_bound](#) of the key.

To access the first iterator of a pair `pr` returned by the member function, use `pr.first`, and to dereference the lower bound iterator, use `*(pr.first)`. To access the second iterator of a pair `pr` returned by the member function, use `pr.second`, and to dereference the upper bound iterator, use `*(pr.second)`.

Example

```
// multiset_equal_range.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    typedef multiset<int, less<int> > IntSet;
    IntSet ms1;
    multiset<int> :: const_iterator ms1_RcIter;

    ms1.insert( 10 );
    ms1.insert( 20 );
    ms1.insert( 30 );

    pair<IntSet::const_iterator, IntSet::const_iterator> p1, p2;
    p1 = ms1.equal_range( 20 );

    cout << "The upper bound of the element with "
         << "a key of 20 in the multiset ms1 is: "
         << *( p1.second ) << "." << endl;

    cout << "The lower bound of the element with "
         << "a key of 20 in the multiset ms1 is: "
         << *( p1.first ) << "." << endl;

    // Compare the upper_bound called directly
    ms1_RcIter = ms1.upper_bound( 20 );
    cout << "A direct call of upper_bound( 20 ) gives "
         << *ms1_RcIter << "," << endl
         << "matching the 2nd element of the pair"
         << " returned by equal_range( 20 )." << endl;

    p2 = ms1.equal_range( 40 );

    // If no match is found for the key,
    // both elements of the pair return end( )
    if ( ( p2.first == ms1.end( ) ) && ( p2.second == ms1.end( ) ) )
        cout << "The multiset ms1 doesn't have an element "
             << "with a key less than 40." << endl;
    else
        cout << "The element of multiset ms1 with a key >= 40 is: "
             << *( p1.first ) << "." << endl;
}
```

The upper bound of the element with a key of 20 in the multiset ms1 is: 30.
The lower bound of the element with a key of 20 in the multiset ms1 is: 20.
A direct call of `upper_bound(20)` gives 30,
matching the 2nd element of the pair returned by `equal_range(20)`.
The multiset ms1 doesn't have an element with a key less than 40.

multiset::erase

Removes an element or a range of elements in a multiset from specified positions or removes elements that match a specified key.

```
iterator erase(
    const_iterator Where);

iterator erase(
    const_iterator First,
    const_iterator Last);

size_type erase(
    const key_type& Key);
```

Parameters

Where

Position of the element to be removed.

First

Position of the first element to be removed.

Last

Position just beyond the last element to be removed.

Key

The key value of the elements to be removed.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or an element that is the end of the multiset if no such element exists.

For the third member function, returns the number of elements that have been removed from the multiset.

Remarks

For a code example, see [set::erase](#).

multiset::find

Returns an iterator that refers to the location of an element in a multiset that has a key equivalent to a specified key.

```
iterator find(const Key& key);

const_iterator find(const Key& key) const;
```

Parameters

key

The key value to be matched by the sort key of an element from the multiset being searched.

Return Value

An iterator that refers to the location of an element with a specified key, or the location succeeding the last element in the multiset (`multiset::end()`) if no match is found for the key.

Remarks

The member function returns an iterator that refers to an element in the multiset whose key is equivalent to the argument *key* under a binary predicate that induces an ordering based on a less than comparability relation.

If the return value of `find` is assigned to a `const_iterator`, the multiset object cannot be modified. If the return value of `find` is assigned to an `iterator`, the multiset object can be modified

Example

```
// compile with: /EHsc /W4 /MTd
#include <set>
#include <iostream>
#include <vector>
#include <string>

using namespace std;

template <typename T> void print_elem(const T& t) {
    cout << "(" << t << ") ";
}

template <typename T> void print_collection(const T& t) {
    cout << t.size() << " elements: ";

    for (const auto& p : t) {
        print_elem(p);
    }
    cout << endl;
}

template <typename C, class T> void findit(const C& c, T val) {
    cout << "Trying find() on value " << val << endl;
    auto result = c.find(val);
    if (result != c.end()) {
        cout << "Element found: "; print_elem(*result); cout << endl;
    } else {
        cout << "Element not found." << endl;
    }
}

int main()
{
    multiset<int> s1({ 40, 45 });
    cout << "The starting multiset s1 is: " << endl;
    print_collection(s1);

    vector<int> v;
    v.push_back(43);
    v.push_back(41);
    v.push_back(46);
    v.push_back(42);
    v.push_back(44);
    v.push_back(44); // attempt a duplicate

    cout << "Inserting the following vector data into s1: " << endl;
    print_collection(v);

    s1.insert(v.begin(), v.end());

    cout << "The modified multiset s1 is: " << endl;
    print_collection(s1);
    cout << endl;
    findit(s1, 45);
    findit(s1, 6);
}
```

multiset::get_allocator

Returns a copy of the allocator object used to construct the multiset.

```
allocator_type get_allocator() const;
```

Return Value

The allocator used by the multiset.

Remarks

Allocators for the multiset class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```
// multiset_get_allocator.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int>::allocator_type ms1_Alloc;
    multiset <int>::allocator_type ms2_Alloc;
    multiset <double>::allocator_type ms3_Alloc;
    multiset <int>::allocator_type ms4_Alloc;

    // The following lines declare objects
    // that use the default allocator.
    multiset <int> ms1;
    multiset <int, allocator<int> > ms2;
    multiset <double, allocator<double> > ms3;

    cout << "The number of integers that can be allocated"
         << endl << "before free memory is exhausted: "
         << ms2.max_size( ) << "." << endl;

    cout << "The number of doubles that can be allocated"
         << endl << "before free memory is exhausted: "
         << ms3.max_size( ) << "." << endl;

    // The following lines create a multiset ms4
    // with the allocator of multiset ms1
    ms1_Alloc = ms1.get_allocator( );
    multiset <int> ms4( less<int>( ), ms1_Alloc );
    ms4_Alloc = ms4.get_allocator( );

    // Two allocators are interchangeable if
    // storage allocated from each can be
    // deallocated with the other
    if( ms1_Alloc == ms4_Alloc )
    {
        cout << "Allocators are interchangeable."
             << endl;
    }
    else
    {
        cout << "Allocators are not interchangeable."
             << endl;
    }
}
```

multiset::insert

Inserts an element or a range of elements into a multiset.

```
// (1) single element
pair<iterator, bool> insert(
    const value_type& Val);

// (2) single element, perfect forwarded
template <class ValTy>
pair<iterator, bool>
insert(
    ValTy&& Val);

// (3) single element with hint
iterator insert(
    const_iterator Where,
    const value_type& Val);

// (4) single element, perfect forwarded, with hint
template <class ValTy>
iterator insert(
    const_iterator Where,
    ValTy&& Val);

// (5) range
template <class InputIterator>
void insert(
    InputIterator First,
    InputIterator Last);

// (6) initializer list
void insert(
    initializer_list<value_type>
    IList);
```

Parameters

PARAMETER	DESCRIPTION
<i>Val</i>	The value of an element to be inserted into the multiset.
<i>Where</i>	The place to start searching for the correct point of insertion. (If that point immediately precedes <i>Where</i> , insertion can occur in amortized constant time instead of logarithmic time.)
<i>ValTy</i>	Template parameter that specifies the argument type that the multiset can use to construct an element of value_type , and perfect-forwards <i>Val</i> as an argument.
<i>First</i>	The position of the first element to be copied.
<i>Last</i>	The position just beyond the last element to be copied.
<i>InputIterator</i>	Template function argument that meets the requirements of an input iterator that points to elements of a type that can be used to construct value_type objects.
<i>IList</i>	The initializer_list from which to copy the elements.

Return Value

The single-element-insert member functions, (1) and (2), return an iterator to the position where the new element

was inserted into the multiset.

The single-element-with-hint member functions, (3) and (4), return an iterator that points to the position where the new element was inserted into the multiset.

Remarks

No pointers or references are invalidated by this function, but it may invalidate all iterators to the container.

During the insertion of just one element, if an exception is thrown, the container's state is not modified. During the insertion of multiple elements, if an exception is thrown, the container is left in an unspecified but valid state.

The [value_type](#) of a container is a typedef that belongs to the container, and, for set, `multiset<V>::value_type` is type `const V`.

The range member function (5) inserts the sequence of element values into a multiset that corresponds to each element addressed by an iterator in the range `[First, Last)`; therefore, `Last` does not get inserted. The container member function `end()` refers to the position just after the last element in the container—for example, the statement `s.insert(v.begin(), v.end());` inserts all elements of `v` into `s`.

The initializer list member function (6) uses an [initializer_list](#) to copy elements into the multiset.

For insertion of an element constructed in place—that is, no copy or move operations are performed—see [multiset::emplace](#) and [multiset::emplace_hint](#).

Example

```
// multiset_insert.cpp
// compile with: /EHsc
#include <set>
#include <iostream>
#include <string>
#include <vector>

using namespace std;

template <typename S> void print(const S& s) {
    cout << s.size() << " elements: ";

    for (const auto& p : s) {
        cout << "(" << p << ") ";
    }

    cout << endl;
}

int main()
{
    // insert single values
    multiset<int> s1;
    // call insert(const value_type&) version
    s1.insert({ 1, 10 });
    // call insert(ValTy&&) version
    s1.insert(20);

    cout << "The original multiset values of s1 are:" << endl;
    print(s1);

    // intentionally attempt a duplicate, single element
    s1.insert(1);
    cout << "The modified multiset values of s1 are:" << endl;
    print(s1);
    cout << endl;

    // single element, with hint
```

```

// single element, with hint
s1.insert(s1.end(), 30);
cout << "The modified multiset values of s1 are:" << endl;
print(s1);
cout << endl;

// The templated version inserting a jumbled range
multiset<int> s2;
vector<int> v;
v.push_back(43);
v.push_back(294);
v.push_back(41);
v.push_back(330);
v.push_back(42);
v.push_back(45);

cout << "Inserting the following vector data into s2:" << endl;
print(v);

s2.insert(v.begin(), v.end());

cout << "The modified multiset values of s2 are:" << endl;
print(s2);
cout << endl;

// The templated versions move-constructing elements
multiset<string> s3;
string str1("blue"), str2("green");

// single element
s3.insert(move(str1));
cout << "After the first move insertion, s3 contains:" << endl;
print(s3);

// single element with hint
s3.insert(s3.end(), move(str2));
cout << "After the second move insertion, s3 contains:" << endl;
print(s3);
cout << endl;

multiset<int> s4;
// Insert the elements from an initializer_list
s4.insert({ 4, 44, 2, 22, 3, 33, 1, 11, 5, 55 });
cout << "After initializer_list insertion, s4 contains:" << endl;
print(s4);
cout << endl;
}

```

multiset::iterator

A type that provides a constant [bidirectional iterator](#) that can read any element in a multiset.

```
typedef implementation-defined iterator;
```

Example

See the example for [begin](#) for an example of how to declare and use an `iterator`.

multiset::key_comp

Retrieves a copy of the comparison object used to order keys in a multiset.

```
key_compare key_comp() const;
```

Return Value

Returns the function object that a multiset uses to order its elements, which is the template parameter `Compare`.

For more information on `Compare`, see the Remarks section of the [multiset Class](#) topic.

Remarks

The stored object defines the member function:

`bool operator(const Key& x, const Key& y);`

which returns true if *x* strictly precedes *y* in the sort order.

Note that both [key_compare](#) and [value_compare](#) are synonyms for the template parameter `Compare`. Both types are provided for the classes `set` and `multiset`, where they are identical, for compatibility with the classes `map` and `multimap`, where they are distinct.

Example

```
// multiset_key_comp.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;

    multiset <int, less<int> > ms1;
    multiset <int, less<int> >::key_compare kc1 = ms1.key_comp( ) ;
    bool result1 = kc1( 2, 3 ) ;
    if( result1 == true )
    {
        cout << "kc1( 2,3 ) returns value of true, "
              << "where kc1 is the function object of s1."
              << endl;
    }
    else
    {
        cout << "kc1( 2,3 ) returns value of false "
              << "where kc1 is the function object of ms1."
              << endl;
    }

    multiset <int, greater<int> > ms2;
    multiset <int, greater<int> >::key_compare kc2 = ms2.key_comp( ) ;
    bool result2 = kc2( 2, 3 ) ;
    if( result2 == true )
    {
        cout << "kc2( 2,3 ) returns value of true, "
              << "where kc2 is the function object of ms2."
              << endl;
    }
    else
    {
        cout << "kc2( 2,3 ) returns value of false, "
              << "where kc2 is the function object of ms2."
              << endl;
    }
}
```

kc1(2,3) returns value of true, where kc1 is the function object of s1.
kc2(2,3) returns value of false, where kc2 is the function object of ms2.

multiset::key_compare

A type that provides a function object that can compare two sort keys to determine the relative order of two elements in the multiset.

```
typedef Compare key_compare;
```

Remarks

`key_compare` is a synonym for the template parameter `Compare`.

For more information on `Compare`, see the Remarks section of the [multiset Class](#) topic.

Example

See the example for [key_comp](#) for an example of how to declare and use `key_compare`.

multiset::key_type

A type that provides a function object that can compare sort keys to determine the relative order of two elements in the multiset.

```
typedef Key key_type;
```

Remarks

`key_type` is a synonym for the template parameter `Key`.

For more information on `Key`, see the Remarks section of the [multiset Class](#) topic.

Example

See the example for [value_type](#) for an example of how to declare and use `key_type`.

multiset::lower_bound

Returns an iterator to the first element in a multiset with a key that is equal to or greater than a specified key.

```
const_iterator lower_bound(const Key& key) const;  
  
iterator lower_bound(const Key& key);
```

Parameters

key

The argument key to be compared with the sort key of an element from the multiset being searched.

Return Value

An `iterator` or `const_iterator` that addresses the location of an element in a multiset that with a key that is equal to or greater than the argument key, or that addresses the location succeeding the last element in the multiset if no match is found for the key.

Example

```

// multiset_lower_bound.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;
    multiset <int> :: const_iterator ms1_AcIter, ms1_RcIter;

    ms1.insert( 10 );
    ms1.insert( 20 );
    ms1.insert( 30 );

    ms1_RcIter = ms1.lower_bound( 20 );
    cout << "The element of multiset ms1 with a key of 20 is: "
         << *ms1_RcIter << "." << endl;

    ms1_RcIter = ms1.lower_bound( 40 );

    // If no match is found for the key, end( ) is returned
    if ( ms1_RcIter == ms1.end( ) )
        cout << "The multiset ms1 doesn't have an element "
             << "with a key of 40." << endl;
    else
        cout << "The element of multiset ms1 with a key of 40 is: "
             << *ms1_RcIter << "." << endl;

    // The element at a specific location in the multiset can be
    // found using a dereferenced iterator addressing the location
    ms1_AcIter = ms1.end( );
    ms1_AcIter--;
    ms1_RcIter = ms1.lower_bound( *ms1_AcIter );
    cout << "The element of ms1 with a key matching "
         << "that of the last element is: "
         << *ms1_RcIter << "." << endl;
}

```

The element of multiset ms1 with a key of 20 is: 20.
 The multiset ms1 doesn't have an element with a key of 40.
 The element of ms1 with a key matching that of the last element is: 30.

multiset::max_size

Returns the maximum length of the multiset.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the multiset.

Example

```
// multiset_max_size.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;
    multiset <int>::size_type i;

    i = ms1.max_size( );
    cout << "The maximum possible length "
         << "of the multiset is " << i << "." << endl;
}
```

multiset::multiset

Constructs a multiset that is empty or that is a copy of all or part of some other multiset.

```

multiset();

explicit multiset (
    const Compare& Comp);

multiset (
    const Compare& Comp,
    const Allocator& Al);

multiset(
    const multiset& Right);

multiset(
    multiset&& Right);

multiset(
    initializer_list<Type> IList);

multiset(
    initializer_list<Type> IList,
    const Compare& Comp);

multiset(
    initializer_list<Type> IList,
    const Compare& Comp,
    const Allocator& Al);

template <class InputIterator>
multiset (
    InputIterator First,
    InputIterator Last);

template <class InputIterator>
multiset (
    InputIterator First,
    InputIterator Last,
    const Compare& Comp);

template <class InputIterator>
multiset (
    InputIterator First,
    InputIterator Last,
    const Compare& Comp,
    const Allocator& Al);

```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The storage allocator class to be used for this multiset object, which defaults to <code>Allocator</code> .
<i>Comp</i>	The comparison function of type <code>const Compare</code> used to order the elements in the multiset, which defaults to <code>Compare</code> .
<i>Right</i>	The multiset of which the constructed multiset is to be a copy.
<i>First</i>	The position of the first element in the range of elements to be copied.

PARAMETER	DESCRIPTION
<i>Last</i>	The position of the first element beyond the range of elements to be copied.
<i>lList</i>	The initializer_list from which to copy the elements.

Remarks

All constructors store a type of allocator object that manages memory storage for the multiset and that can later be returned by calling [get_allocator](#). The allocator parameter is often omitted in the class declarations and preprocessing macros used to substitute alternative allocators.

All constructors initialize their multiset.

All constructors store a function object of type Compare that is used to establish an order among the keys of the multiset and that can later be returned by calling [key_comp](#).

The first three constructors specify an empty initial multiset, the second specifying the type of comparison function (*Comp*) to be used in establishing the order of the elements and the third explicitly specifying the allocator type (*Al*) to be used. The keyword **explicit** suppresses certain kinds of automatic type conversion.

The fourth constructor specifies a copy of the multiset *Right*.

The fifth constructor specifies a copy of the multiset by moving *Right*.

The sixth, seventh, and eighth constructors specify an initializer_list from which to copy the elements.

The next three constructors copy the range [First, Last) of a multiset with increasing explicitness in specifying the type of comparison function and allocator.

Example

```
// multiset_ctor.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main()
{
    using namespace std;
    //multiset <int>::iterator ms1_Iter, ms2_Iter, ms3_Iter;
    multiset <int>::iterator ms4_Iter, ms5_Iter, ms6_Iter, ms7_Iter;

    // Create an empty multiset ms0 of key type integer
    multiset <int> ms0;

    // Create an empty multiset ms1 with the key comparison
    // function of less than, then insert 4 elements
    multiset <int, less<int> > ms1;
    ms1.insert(10);
    ms1.insert(20);
    ms1.insert(20);
    ms1.insert(40);

    // Create an empty multiset ms2 with the key comparison
    // function of greater than, then insert 2 elements
    multiset <int, less<int> > ms2;
    ms2.insert(10);
    ms2.insert(20);

    // Create a multiset ms3 with the
    // allocator of multiset ms1
    multiset <int>::allocator_type ms1_Alloc;
```

```

ms1_Alloc = ms1.get_allocator();
multiset<int> ms3(less<int>(), ms1_Alloc);
ms3.insert(30);

// Create a copy, multiset ms4, of multiset ms1
multiset<int> ms4(ms1);

// Create a multiset ms5 by copying the range ms1[ first, last)
multiset<int>::const_iterator ms1_bcIter, ms1_ecIter;
ms1_bcIter = ms1.begin();
ms1_ecIter = ms1.begin();
ms1_ecIter++;
ms1_ecIter++;
multiset<int> ms5(ms1_bcIter, ms1_ecIter);

// Create a multiset ms6 by copying the range ms4[ first, last)
// and with the allocator of multiset ms2
multiset<int>::allocator_type ms2_Alloc;
ms2_Alloc = ms2.get_allocator();
multiset<int> ms6(ms4.begin(), ++ms4.begin(), less<int>(), ms2_Alloc);

cout << "ms1 =";
for (auto i : ms1)
    cout << " " << i;
cout << endl;

cout << "ms2 =";
for (auto i : ms2)
    cout << " " << i;
cout << endl;

cout << "ms3 =";
for (auto i : ms3)
    cout << " " << i;
cout << endl;

cout << "ms4 =";
for (auto i : ms4)
    cout << " " << i;
cout << endl;

cout << "ms5 =";
for (auto i : ms5)
    cout << " " << i;
cout << endl;

cout << "ms6 =";
for (auto i : ms6)
    cout << " " << i;
cout << endl;

// Create a multiset by moving ms5
multiset<int> ms7(move(ms5));
cout << "ms7 =";
for (auto i : ms7)
    cout << " " << i;
cout << endl;

// Create a multiset with an initializer_list
multiset<int> ms8({1, 2, 3, 4});
cout << "ms8=";
for (auto i : ms8)
    cout << " " << i;
cout << endl;
}

```

multiset::operator=

Replaces the elements of this `multiset` using elements from another `multiset`.

```
multiset& operator=(const multiset& right);

multiset& operator=(multiset&& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The <code>multiset</code> from which elements are copied or moved.

Remarks

`operator=` copies or moves the elements in *right* into this `multiset`, depending on the reference type (lvalue or rvalue) used. Elements that are in this `multiset` before `operator=` executes are discarded.

Example

```
// multiset_operator_as.cpp
// compile with: /EHsc
#include <multiset>
#include <iostream>

int main( )
{
    using namespace std;
    multiset<int> v1, v2, v3;
    multiset<int>::iterator iter;

    v1.insert(10);

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;
}
```

multiset::pointer

A type that provides a pointer to an element in a multiset.

```
typedef typename allocator_type::pointer pointer;
```

Remarks

A type **pointer** can be used to modify the value of an element.

In most cases, an [iterator](#) should be used to access the elements in a multiset object.

multiset::rbegin

Returns an iterator addressing the first element in a reversed multiset.

```
const_reverse_iterator rbegin() const;  
  
reverse_iterator rbegin();
```

Return Value

A reverse bidirectional iterator addressing the first element in a reversed multiset or addressing what had been the last element in the unreversed multiset.

Remarks

`rbegin` is used with a reversed multiset just as `rbegin` is used with a multiset.

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, then the multiset object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, then the multiset object can be modified.

`rbegin` can be used to iterate through a multiset backwards.

Example

```

// multiset_rbegin.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;
    multiset <int>::iterator ms1_iter;
    multiset <int>::reverse_iterator ms1_rIter;

    ms1.insert( 10 );
    ms1.insert( 20 );
    ms1.insert( 30 );

    ms1_rIter = ms1.rbegin( );
    cout << "The first element in the reversed multiset is "
         << *ms1_rIter << "." << endl;

    // begin can be used to start an iteration
    // through a multiset in a forward order
    cout << "The multiset is:";
    for ( ms1_iter = ms1.begin( ) ; ms1_iter != ms1.end( ); ms1_iter++ )
        cout << " " << *ms1_iter;
    cout << endl;

    // rbegin can be used to start an iteration
    // through a multiset in a reverse order
    cout << "The reversed multiset is:";
    for ( ms1_rIter = ms1.rbegin( ) ; ms1_rIter != ms1.rend( ); ms1_rIter++ )
        cout << " " << *ms1_rIter;
    cout << endl;

    // A multiset element can be erased by dereferencing to its key
    ms1_rIter = ms1.rbegin( );
    ms1.erase ( *ms1_rIter );

    ms1_rIter = ms1.rbegin( );
    cout << "After the erasure, the first element "
         << "in the reversed multiset is "<< *ms1_rIter << "."
         << endl;
}

```

```

The first element in the reversed multiset is 30.
The multiset is: 10 20 30
The reversed multiset is: 30 20 10
After the erasure, the first element in the reversed multiset is 20.

```

multiset::reference

A type that provides a reference to an element stored in a multiset.

```

typedef typename allocator_type::reference reference;

```

Example

```
// multiset_ref.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;

    ms1.insert( 10 );
    ms1.insert( 20 );

    // Declare and initialize a reference &Ref1 to the 1st element
    const int &Ref1 = *ms1.begin( );

    cout << "The first element in the multiset is "
         << Ref1 << "." << endl;
}
```

```
The first element in the multiset is 10.
```

multiset::rend

Returns an iterator that addresses the location succeeding the last element in a reversed multiset.

```
const_reverse_iterator rend() const;

reverse_iterator rend();
```

Return Value

A reverse bidirectional iterator that addresses the location succeeding the last element in a reversed multiset (the location that had preceded the first element in the unreversed multiset).

Remarks

`rend` is used with a reversed multiset just as `end` is used with a multiset.

If the return value of `rend` is assigned to a `const_reverse_iterator`, then the multiset object cannot be modified.

If the return value of `rend` is assigned to a `reverse_iterator`, then the multiset object can be modified.

`rend` can be used to test to whether a reverse iterator has reached the end of its multiset.

The value returned by `rend` should not be dereferenced.

Example

```

// multiset_rend.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main() {
    using namespace std;
    multiset <int> ms1;
    multiset <int>::iterator ms1_Iter;
    multiset <int>::reverse_iterator ms1_rIter;
    multiset <int>::const_reverse_iterator ms1_crIter;

    ms1.insert( 10 );
    ms1.insert( 20 );
    ms1.insert( 30 );

    ms1_rIter = ms1.rend( ) ;
    ms1_rIter--;
    cout << "The last element in the reversed multiset is "
         << *ms1_rIter << "." << endl;

    // end can be used to terminate an iteration
    // through a multiset in a forward order
    cout << "The multiset is: ";
    for ( ms1_Iter = ms1.begin( ) ; ms1_Iter != ms1.end( ); ms1_Iter++ )
        cout << *ms1_Iter << " ";
    cout << "." << endl;

    // rend can be used to terminate an iteration
    // through a multiset in a reverse order
    cout << "The reversed multiset is: ";
    for ( ms1_rIter = ms1.rbegin( ) ; ms1_rIter != ms1.rend( ); ms1_rIter++ )
        cout << *ms1_rIter << " ";
    cout << "." << endl;

    ms1_rIter = ms1.rend( );
    ms1_rIter--;
    ms1.erase ( *ms1_rIter );

    ms1_rIter = ms1.rend( );
    --ms1_rIter;
    cout << "After the erasure, the last element in the "
         << "reversed multiset is " << *ms1_rIter << "." << endl;
}

```

multiset::reverse_iterator

A type that provides a bidirectional iterator that can read or modify an element in a reversed multiset.

```
typedef std::reverse_iterator<iterator> reverse_iterator;
```

Remarks

A type `reverse_iterator` is use to iterate through the multiset in reverse.

Example

See example for [rbegin](#) for an example of how to declare and use `reverse_iterator`.

multiset::size

Returns the number of elements in the multiset.

```
size_type size() const;
```

Return Value

The current length of the multiset.

Example

```
// multiset_size.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;
    multiset <int> :: size_type i;

    ms1.insert( 1 );
    i = ms1.size( );
    cout << "The multiset length is " << i << "." << endl;

    ms1.insert( 2 );
    i = ms1.size( );
    cout << "The multiset length is now " << i << "." << endl;
}
```

```
The multiset length is 1.
The multiset length is now 2.
```

multiset::size_type

An unsigned integer type that can represent the number of elements in a multiset.

```
typedef typename allocator_type::size_type size_type;
```

Example

See example for [size](#) for an example of how to declare and use `size_type`

multiset::swap

Exchanges the elements of two multisets.

```
void swap(
    multiset<Key, Compare, Allocator>& right);
```

Parameters

right

The argument multiset providing the elements to be swapped with the target multiset.

Remarks

The member function invalidates no references, pointers, or iterators that designate elements in the two multisets whose elements are being exchanged.

Example

```
// multiset_swap.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1, ms2, ms3;
    multiset <int>::iterator ms1_Iter;

    ms1.insert( 10 );
    ms1.insert( 20 );
    ms1.insert( 30 );
    ms2.insert( 100 );
    ms2.insert( 200 );
    ms3.insert( 300 );

    cout << "The original multiset ms1 is:";
    for ( ms1_Iter = ms1.begin( ); ms1_Iter != ms1.end( ); ms1_Iter++ )
        cout << " " << *ms1_Iter;
    cout << "." << endl;

    // This is the member function version of swap
    ms1.swap( ms2 );

    cout << "After swapping with ms2, list ms1 is:";
    for ( ms1_Iter = ms1.begin( ); ms1_Iter != ms1.end( ); ms1_Iter++ )
        cout << " " << *ms1_Iter;
    cout << "." << endl;

    // This is the specialized template version of swap
    swap( ms1, ms3 );

    cout << "After swapping with ms3, list ms1 is:";
    for ( ms1_Iter = ms1.begin( ); ms1_Iter != ms1.end( ); ms1_Iter++ )
        cout << " " << *ms1_Iter;
    cout << "." << endl;
}
```

```
The original multiset ms1 is: 10 20 30.
After swapping with ms2, list ms1 is: 100 200.
After swapping with ms3, list ms1 is: 300.
```

multiset::upper_bound

Returns an iterator to the first element in a multiset with a key that is greater than a specified key.

```
const_iterator upper_bound(const Key& key) const;

iterator upper_bound(const Key& key);
```

Parameters

key

The argument *key* to be compared with the sort key of an element from the multiset being searched.

Return Value

An **iterator** or `const_iterator` that addresses the location of an element in a multiset with a key that is greater

than the argument key, or that addresses the location succeeding the last element in the multiset if no match is found for the key.

Example

```
// multiset_upper_bound.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;
    multiset <int> :: const_iterator ms1_AcIter, ms1_RcIter;

    ms1.insert( 10 );
    ms1.insert( 20 );
    ms1.insert( 30 );

    ms1_RcIter = ms1.upper_bound( 20 );
    cout << "The first element of multiset ms1 with a key greater "
         << "than 20 is: " << *ms1_RcIter << "." << endl;

    ms1_RcIter = ms1.upper_bound( 30 );

    // If no match is found for the key, end( ) is returned
    if ( ms1_RcIter == ms1.end( ) )
        cout << "The multiset ms1 doesn't have an element "
             << "with a key greater than 30." << endl;
    else
        cout << "The element of multiset ms1 with a key > 40 is: "
             << *ms1_RcIter << "." << endl;

    // The element at a specific location in the multiset can be
    // found using a dereferenced iterator addressing the location
    ms1_AcIter = ms1.begin( );
    ms1_RcIter = ms1.upper_bound( *ms1_AcIter );
    cout << "The first element of ms1 with a key greater than"
         << endl << "that of the initial element of ms1 is: "
         << *ms1_RcIter << "." << endl;
}
```

The first element of multiset ms1 with a key greater than 20 is: 30.
The multiset ms1 doesn't have an element with a key greater than 30.
The first element of ms1 with a key greater than
that of the initial element of ms1 is: 20.

multiset::value_comp

Retrieves a copy of the comparison object used to order element values in a multiset.

```
value_compare value_comp() const;
```

Return Value

Returns the function object that a multiset uses to order its elements, which is the template parameter `Compare`.

For more information on `Compare`, see the Remarks section of the [multiset Class](#) topic.

Remarks

The stored object defines the member function:

```
bool operator( const Key& _xVal, const Key& _yVal );
```

which returns true if `_xVal` precedes and is not equal to `_yVal` in the sort order.

Note that both `key_compare` and `value_compare` are synonyms for the template parameter `Compare`. Both types are provided for the classes `set` and `multiset`, where they are identical, for compatibility with the classes `map` and `multimap`, where they are distinct.

Example

```
// multiset_value_comp.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;

    multiset <int, less<int> > ms1;
    multiset <int, less<int> >::value_compare vc1 = ms1.value_comp( );
    bool result1 = vc1( 2, 3 );
    if( result1 == true )
    {
        cout << "vc1( 2,3 ) returns value of true, "
              << "where vc1 is the function object of ms1."
              << endl;
    }
    else
    {
        cout << "vc1( 2,3 ) returns value of false, "
              << "where vc1 is the function object of ms1."
              << endl;
    }

    set <int, greater<int> > ms2;
    set<int, greater<int> >::value_compare vc2 = ms2.value_comp( );
    bool result2 = vc2( 2, 3 );
    if( result2 == true )
    {
        cout << "vc2( 2,3 ) returns value of true, "
              << "where vc2 is the function object of ms2."
              << endl;
    }
    else
    {
        cout << "vc2( 2,3 ) returns value of false, "
              << "where vc2 is the function object of ms2."
              << endl;
    }
}
```

```
vc1( 2,3 ) returns value of true, where vc1 is the function object of ms1.
vc2( 2,3 ) returns value of false, where vc2 is the function object of ms2.
```

multiset::value_compare

The type that provides a function object that can compare two sort keys to determine their relative order in the `multiset`.

```
typedef key_compare value_compare;
```

Remarks

`value_compare` is a synonym for the template parameter `Compare`.

Note that both `key_compare` and `value_compare` are synonyms for the template parameter `Compare`. Both types are provided for the classes `set` and `multiset`, where they are identical, for compatibility with the classes `map` and `multimap`, where they are distinct.

For more information on `Compare`, see the Remarks section of the [multiset Class](#) topic.

Example

See the example for `value_comp` for an example of how to declare and use `value_compare`.

multiset::value_type

A type that describes an object stored as an element as a multiset in its capacity as a value.

```
typedef Key value_type;
```

Remarks

`value_type` is a synonym for the template parameter `Key`.

Note that both `key_type` and `value_type` are synonyms for the template parameter `Key`. Both types are provided for the classes `set` and `multiset`, where they are identical, for compatibility with the classes `map` and `multimap`, where they are distinct.

For more information on `Key`, see the Remarks section of the topic.

Example

```
// multiset_value_type.cpp
// compile with: /EHsc
#include <set>
#include <iostream>

int main( )
{
    using namespace std;
    multiset <int> ms1;
    multiset <int>::iterator ms1_Iter;

    multiset <int> :: value_type svt_Int; // Declare value_type
    svt_Int = 10;                        // Initialize value_type

    multiset <int> :: key_type skt_Int; // Declare key_type
    skt_Int = 20;                      // Initialize key_type

    ms1.insert( svt_Int );              // Insert value into s1
    ms1.insert( skt_Int );              // Insert key into s1

    // A multiset accepts key_types or value_types as elements
    cout << "The multiset has elements:";
    for ( ms1_Iter = ms1.begin( ) ; ms1_Iter != ms1.end( ) ; ms1_Iter++ )
        cout << " " << *ms1_Iter;
    cout << "." << endl;
}
```

```
The multiset has elements: 10 20.
```

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

<shared_mutex>

3/28/2019 • 4 minutes to read • [Edit Online](#)

The <shared_mutex> header provides synchronization primitives for protection of shared data that can be accessed by multiple threads. In addition to the exclusive access control provided by mutex classes, the shared mutex classes also allow shared ownership by multiple threads for non-exclusive access. Shared mutexes can be used to control resources that can be read by several threads without causing a race condition, but must be written exclusively by a single thread.

The header <shared_mutex> defines the classes `shared_mutex` and `shared_timed_mutex`, the template class `shared_lock`, and the template function `swap` for shared mutex support.

CLASSES	DESCRIPTION
shared_mutex Class	A shared mutex type that can be locked exclusively by one agent or shared non-exclusively by multiple agents.
shared_timed_mutex Class	A shared timed mutex type that can be locked exclusively by one agent or shared non-exclusively by multiple agents.
shared_lock Class	A template class that wraps a shared mutex to support timed lock operations and non-exclusive sharing by multiple agents.
FUNCTIONS	DESCRIPTION
swap	Swaps the content of the shared mutex objects referenced by the function parameters.

Syntax

```
namespace std {
    class shared_mutex;
    class shared_timed_mutex;
    template <class Mutex>
    class shared_lock;
    template <class Mutex>
    void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
}
```

Remarks

An instance of the class `shared_mutex` is a *shared mutex type*, a type that controls the shared ownership of a mutex within a scope. A shared mutex type meets all the requirements of a mutex type, as well as members to support shared non-exclusive ownership.

A shared mutex type supports the additional methods `lock_shared`, `unlock_shared`, and `try_lock_shared`:

- The `lock_shared` method blocks the calling thread until the thread obtains shared ownership of the mutex.
- The `unlock_shared` method releases shared ownership of the mutex held by the calling thread.

- The `try_lock_shared` method tries to obtain shared ownership of the mutex without blocking. Its return type is convertible to **bool** and is **true** if the method obtains ownership, but is otherwise **false**.

The class `shared_timed_mutex` is a *shared timed mutex type*, a type that meets the requirements of both a shared mutex type and a timed mutex type.

A shared timed mutex type supports the additional methods `try_lock_shared_for` and `try_lock_shared_until`:

- The `try_lock_shared_for` method attempts to obtain shared ownership of the mutex until the duration specified by the parameter has passed. If the duration is not positive, the method is equivalent to `try_lock_shared`. The method does not return within the duration specified unless shared ownership is obtained. Its return value is **true** if the method obtains ownership, but is otherwise **false**.
- The `try_lock_shared_until` method attempts to obtain shared ownership of the mutex until the specified absolute time has passed. If the specified time has already passed, the method is equivalent to `try_lock_shared`. The method does not return before the time specified unless shared ownership is obtained. Its return value is **true** if the method obtains ownership, but is otherwise **false**.

The `shared_lock` template class extends support for timed locking and transfer of ownership to a shared mutex. Ownership of the mutex may be obtained at or after construction, and may be transferred to another `shared_lock` object. Objects of type `shared_lock` can be moved, but not copied.

WARNING

Beginning in Visual Studio 2015, the C++ Standard Library synchronization types are based on Windows synchronization primitives and no longer use ConCRT (except when the target platform is Windows XP). The types defined in `<shared_mutex>` should not be used with any ConCRT types or functions.

Classes

shared_mutex Class

Class `shared_mutex` implements a non-recursive mutex with shared ownership semantics.

```
class shared_mutex {
public:
    shared_mutex();
    ~shared_mutex();
    shared_mutex(const shared_mutex&) = delete;
    shared_mutex& operator=(const shared_mutex&) = delete;
    // Exclusive ownership
    void lock();
    // blocking
    bool try_lock();
    void unlock();
    // Shared ownership
    void lock_shared();
    // blocking
    bool try_lock_shared();
    void unlock_shared();
    // Getters
    typedef void** native_handle_type; // implementation defined
    native_handle_type native_handle();
};
```

shared_timed_mutex Class

Class `shared_timed_mutex` implements a non-recursive mutex with shared ownership semantics that meets the requirements of a timed mutex type.

```

class shared_timed_mutex {
public:
    shared_timed_mutex();
    ~shared_timed_mutex();
    shared_timed_mutex(const shared_timed_mutex&) = delete;
    shared_timed_mutex& operator=(const shared_timed_mutex&) = delete;
    // Exclusive ownership
    void lock();
    // blocking
    bool try_lock();
    template <class Rep, class Period>
    bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
    template <class Clock, class Duration>
    bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
    void unlock();
    // Shared ownership
    void lock_shared();
    // blocking
    bool try_lock_shared();
    template <class Rep, class Period>
    bool try_lock_shared_for(const chrono::duration<Rep, Period>& rel_time);
    template <class Clock, class Duration>
    bool try_lock_shared_until(const chrono::time_point<Clock, Duration>& abs_time);
    void unlock_shared();
};

```

shared_lock Class

Template class `shared_lock` controls the shared ownership of a shared mutex object within a scope. The template parameter must be a shared mutex type.

```

class shared_lock {
public:
    typedef Mutex mutex_type;
    shared_lock() noexcept;
    explicit shared_lock(mutex_type& m);
    // blocking
    shared_lock(mutex_type& m, defer_lock_t) noexcept;
    shared_lock(mutex_type& m, try_to_lock_t);
    shared_lock(mutex_type& m, adopt_lock_t);
    template <class Clock, class Duration>
    shared_lock(mutex_type& m,
        const chrono::time_point<Clock, Duration>& abs_time);
    template <class Rep, class Period>
    shared_lock(mutex_type& m,
        const chrono::duration<Rep, Period>& rel_time);
    ~shared_lock();
    shared_lock(shared_lock const&) = delete;
    shared_lock& operator=(shared_lock const&) = delete;
    shared_lock(shared_lock&& u) noexcept;
    shared_lock& operator=(shared_lock&& u) noexcept;
    void lock();
    // blocking
    bool try_lock();
    template <class Rep, class Period>
    bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
    template <class Clock, class Duration>
    bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
    void unlock();
    // Setters
    void swap(shared_lock& u) noexcept;
    mutex_type* release() noexcept;
    // Getters
    bool owns_lock() const noexcept;
    explicit operator bool () const noexcept;
    mutex_type* mutex() const noexcept;
private:
    mutex_type* pm; // exposition only
    bool owns; // exposition only
};

```

Functions

swap

Swaps the `shared_lock` objects.

```

template <class Mutex>
void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;

```

Exchanges the content of two `shared_lock` objects. Effectively the same as `x.swap(y)`.

Requirements

Header: `<shared_mutex>`

Namespace: `std`

<sstream>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines several template classes that support iostreams operations on sequences stored in an allocated array object. Such sequences are easily converted to and from objects of template class [basic_string](#).

Syntax

```
namespace std {
    template <class CharType, class Traits = char_traits<CharType>, class Allocator = allocator<CharType>>
    class basic_stringbuf;
    typedef basic_stringbuf<char>
    stringbuf;
    typedef basic_stringbuf<wchar_t> wstringbuf;

    template <class CharType, class Traits = char_traits<CharType>, class Allocator = allocator<CharType>>
    class basic_istream;
    typedef basic_istream<char>
    istream;
    typedef basic_istream<wchar_t> wistream;

    template <class CharType, class Traits = char_traits<CharType>, class Allocator = allocator<CharType>>
    class basic_ostream;
    typedef basic_ostream<char>
    ostream;
    typedef basic_ostream<wchar_t> wostream;

    template <class CharType, class Traits = char_traits<CharType>, class Allocator = allocator<CharType>>
    class basic_stringstream;
    typedef basic_stringstream<char>
    stringstream;
    typedef basic_stringstream<wchar_t> wstringstream;
    // TEMPLATE FUNCTIONS
    template <class CharType, class Traits, class Allocator>
    void swap(
        basic_stringbuf<CharType, Traits, Allocator>& left,
        basic_stringbuf<CharType, Traits, Allocator>& right);

    template <class CharType, class Traits, class Allocator>
    void swap(
        basic_istream<CharType, Traits, Allocator>& left,
        basic_istream<CharType, Traits, Allocator>& right);

    template <class CharType, class Traits, class Allocator>
    void swap(
        basic_ostream<CharType, Traits, Allocator>& left,
        basic_ostream<CharType, Traits, Allocator>& right);

    template <class CharType, class Traits, class Allocator>
    void swap (
        basic_stringstream<CharType, Traits, Allocator>& left,
        basic_stringstream<CharType, Traits, Allocator>& right);

} // namespace std
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	Reference to an <code>sstream</code> object.
<i>right</i>	Reference to an <code>sstream</code> object.

Remarks

Objects of type `char *` can use the functionality in [<sstream>](#) for streaming. However, [<sstream>](#) is deprecated and the use of [<stream>](#) is encouraged.

Typedefs

TYPE NAME	DESCRIPTION
istringstream	Creates a type <code>basic_istringstream</code> specialized on a char template parameter.
ostringstream	Creates a type <code>basic_ostringstream</code> specialized on a char template parameter.
stringbuf	Creates a type <code>basic_stringbuf</code> specialized on a char template parameter.
stringstream	Creates a type <code>basic_stringstream</code> specialized on a char template parameter.
wistringstream	Creates a type <code>basic_istringstream</code> specialized on a wchar_t template parameter.
wostringstream	Creates a type <code>basic_ostringstream</code> specialized on a wchar_t template parameter.
wstringbuf	Creates a type <code>basic_stringbuf</code> specialized on a wchar_t template parameter.
wstringstream	Creates a type <code>basic_stringstream</code> specialized on a wchar_t template parameter.

Manipulators

swap	Exchanges the values between two <code>sstream</code> objects.
----------------------	--

Classes

CLASS	DESCRIPTION
basic_stringbuf	Describes a stream buffer that controls the transmission of elements of type <code>Elem</code> , whose character traits are determined by the class <code>Tr</code> , to and from a sequence of elements stored in an array object.

CLASS	DESCRIPTION
basic_istream	Describes an object that controls extraction of elements and encoded objects from a stream buffer of class basic_stringbuf < Elem , Tr , <code>Alloc</code> >, with elements of type <code>Elem</code> , whose character traits are determined by the class <code>Tr</code> , and whose elements are allocated by an allocator of class <code>Alloc</code> .
basic_ostringstream	Describes an object that controls insertion of elements and encoded objects into a stream buffer of class basic_stringbuf < Elem , Tr , <code>Alloc</code> >, with elements of type <code>Elem</code> , whose character traits are determined by the class <code>Tr</code> , and whose elements are allocated by an allocator of class <code>Alloc</code> .
basic_stringstream	Describes an object that controls insertion and extraction of elements and encoded objects using a stream buffer of class basic_stringbuf < Elem , Tr , <code>Alloc</code> >, with elements of type <code>Elem</code> , whose character traits are determined by the class <code>Tr</code> , and whose elements are allocated by an allocator of class <code>Alloc</code> .

Requirements

- **Header:** `<sstream>`
- **Namespace:** `std`

[iostreams Conventions](#)

<sstream> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

swap

swap

Exchanges the values between two `sstream` objects.

```
template <class Elem, class Tr, class Alloc>
void swap(
    basic_stringbuf<Elem, Tr, Alloc>& left,
    basic_stringbuf<Elem, Tr, Alloc>& right);

template <class Elem, class Tr, class Alloc>
void swap(
    basic_istringstream<Elem, Tr, Alloc>& left,
    basic_istringstream<Elem, Tr, Alloc>& right);

template <class Elem, class Tr, class Alloc>
void swap(
    basic_ostringstream<Elem, Tr, Alloc>& left,
    basic_ostringstream<Elem, Tr, Alloc>& right);

template <class Elem, class Tr, class Alloc>
void swap(
    basic_stringstream<Elem, Tr, Alloc>& left,
    basic_stringstream<Elem, Tr, Alloc>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	Reference to an <code>sstream</code> object.
<i>right</i>	Reference to an <code>sstream</code> object.

Remarks

The template function executes `left.swap(right)`.

[<sstream>](#)

<sstream> typedefs

10/31/2018 • 2 minutes to read • [Edit Online](#)

istringstream	ostreamstream	stringbuf
stringstream	wstringstream	wostringstream
wstringbuf	wstringstream	

istringstream

Creates a type `basic_istringstream` specialized on a **char** template parameter.

```
typedef basic_istringstream<char> istringstream;
```

Remarks

The type is a synonym for template class [basic_istringstream](#), specialized for elements of type **char**.

ostreamstream

Creates a type `basic_ostreamstream` specialized on a **char** template parameter.

```
typedef basic_ostreamstream<char> ostreamstream;
```

Remarks

The type is a synonym for template class [basic_ostreamstream](#), specialized for elements of type **char**.

stringbuf

Creates a type `basic_stringbuf` specialized on a **char** template parameter.

```
typedef basic_stringbuf<char> stringbuf;
```

Remarks

The type is a synonym for template class [basic_stringbuf](#), specialized for elements of type **char**.

stringstream

Creates a type `basic_stringstream` specialized on a **char** template parameter.

```
typedef basic_stringstream<char> stringstream;
```

Remarks

The type is a synonym for template class [basic_stringstream](#), specialized for elements of type **char**.

wstringstream

Creates a type `basic_istringstream` specialized on a **wchar_t** template parameter.

```
typedef basic_istringstream<wchar_t> wstringstream;
```

Remarks

The type is a synonym for template class [basic_istringstream](#), specialized for elements of type **wchar_t**.

wostringstream

Creates a type `basic_ostringstream` specialized on a **wchar_t** template parameter.

```
typedef basic_ostringstream<wchar_t> wostringstream;
```

Remarks

The type is a synonym for template class [basic_ostringstream](#), specialized for elements of type **wchar_t**.

wstringbuf

Creates a type `basic_stringbuf` specialized on a **wchar_t** template parameter.

```
typedef basic_stringbuf<wchar_t> wstringbuf;
```

Remarks

The type is a synonym for template class [basic_stringbuf](#), specialized for elements of type **wchar_t**.

wstringstream

Creates a type `basic_stringstream` specialized on a **wchar_t** template parameter.

```
typedef basic_stringstream<wchar_t> wstringstream;
```

Remarks

The type is a synonym for template class [basic_stringstream](#), specialized for elements of type **wchar_t**.

[<sstream>](#)

basic_stringbuf Class

11/8/2018 • 9 minutes to read • [Edit Online](#)

Describes a stream buffer that controls the transmission of elements of type `Elem`, whose character traits are determined by the class `Tr`, to and from a sequence of elements stored in an array object.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>,  
         class Alloc = allocator<Elem>>  
class basic_stringbuf : public basic_streambuf<Elem, Tr>
```

Parameters

Alloc

The allocator class.

Elem

The type of the basic element of the string.

Tr

The character traits specialized on the basic element of the string.

Remarks

The object is allocated, extended, and freed as necessary to accommodate changes in the sequence.

An object of class `basic_stringbuf<Elem, Tr, Alloc>` stores a copy of the `ios_base::openmode` argument from its constructor as its `stringbuf` mode **mode**:

- If `mode & ios_base::in` is nonzero, the input buffer is accessible. For more information, see [basic_streambuf Class](#).
- If `mode & ios_base::out` is nonzero, the output buffer is accessible.

Constructors

CONSTRUCTOR	DESCRIPTION
basic_stringbuf	Constructs an object of type <code>basic_stringbuf</code> .

Typedefs

TYPE NAME	DESCRIPTION
allocator_type	The type is a synonym for the template parameter <i>Alloc</i> .
char_type	Associates a type name with the <i>Elem</i> template parameter.
int_type	Makes this type within <code>basic_filebuf</code> 's scope equivalent to the type of the same name in the <i>Tr</i> scope.

TYPE NAME	DESCRIPTION
<code>off_type</code>	Makes this type within <code>basic_filebuf</code> 's scope equivalent to the type of the same name in the <i>Tr</i> scope.
<code>pos_type</code>	Makes this type within <code>basic_filebuf</code> 's scope equivalent to the type of the same name in the <i>Tr</i> scope.
<code>traits_type</code>	Associates a type name with the <i>Tr</i> template parameter.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>overflow</code>	A protected, virtual function that can be called when a new character is inserted into a full buffer.
<code>pbackfail</code>	The protected virtual member function tries to put back an element into the input buffer, then makes it the current element (pointed to by the next pointer).
<code>seekoff</code>	The protected virtual member function tries to alter the current positions for the controlled streams.
<code>seekpos</code>	The protected virtual member function tries to alter the current positions for the controlled streams.
<code>str</code>	Sets or gets the text in a string buffer without changing the write position.
<code>swap</code>	
<code>underflow</code>	The protected virtual member function to extract the current element from the input stream.

Requirements

Header: `<sstream>`

Namespace: `std`

`basic_stringbuf::allocator_type`

The type is a synonym for the template parameter *Alloc*.

```
typedef Alloc allocator_type;
```

`basic_stringbuf::basic_stringbuf`

Constructs an object of type `basic_stringbuf`.

```

basic_stringbuf(
    ios_base::openmode _Mode = ios_base::in | ios_base::out);

basic_stringbuf(
    const basic_string<Elem, Tr, Alloc>& str,
    ios_base::openmode _Mode = ios_base::in | ios_base::out);

```

Parameters

_Mode

One of the enumerations in [ios_base::openmode](#).

str

An object of type [basic_string](#).

Remarks

The first constructor stores a null pointer in all the pointers controlling the input buffer and the output buffer. For more information, see the Remarks section of the [basic_streambuf Class](#). It also stores *_Mode* as the stringbuf mode. For more information, see the Remarks section of the [basic_stringbuf Class](#).

The second constructor allocates a copy of the sequence controlled by the string object *str*. If

`_Mode & ios_base::in` is nonzero, it sets the input buffer to start reading at the start of the sequence. If

`_Mode & ios_base::out` is nonzero, it sets the output buffer to begin writing at the start of the sequence. It also stores *_Mode* as the stringbuf mode. For more information, see the Remarks section of the [basic_stringbuf Class](#).

basic_stringbuf::char_type

Associates a type name with the *Elem* template parameter.

```
typedef Elem char_type;
```

basic_stringbuf::int_type

Makes this type within `basic_filebuf`'s scope equivalent to the type of the same name in the `Tr` scope.

```
typedef typename traits_type::int_type int_type;
```

basic_stringbuf::off_type

Makes this type within `basic_filebuf`'s scope equivalent to the type of the same name in the `Tr` scope.

```
typedef typename traits_type::off_type off_type;
```

basic_stringbuf::overflow

A protected virtual function that can be called when a new character is inserted into a full buffer.

```
virtual int_type overflow(int_type _Meta = traits_type::eof());
```

Parameters

_Meta

The character to insert into the buffer, or `traits_type::eof`.

Return Value

If the function cannot succeed, it returns `traits_type::eof`. Otherwise, it returns **traits_type::not_eof**(*_Meta*).

Remarks

If *_Meta* does not compare equal to **traits_type::eof**, the protected virtual member function tries to insert the element **traits_type::to_char_type**(*_Meta*) into the output buffer. It can do so in various ways:

- If a write position is available, it can store the element into the write position and increment the next pointer for the output buffer.
- It can make a write position available by allocating new or additional storage for the output buffer. Extending the output buffer this way also extends any associated input buffer.

basic_stringbuf::pbackfail

The protected virtual member function tries to put back an element into the input buffer, and then make it the current element (pointed to by the next pointer).

```
virtual int_type pbackfail(int_type _Meta = traits_type::eof());
```

Parameters

_Meta

The character to insert into the buffer, or `traits_type::eof`.

Return Value

If the function cannot succeed, it returns `traits_type::eof`. Otherwise, it returns **traits_type::not_eof**(*_Meta*).

Remarks

If *_Meta* compares equal to **traits_type::eof**, the element to push back is effectively the one already in the stream before the current element. Otherwise, that element is replaced by **byte** = **traits_type::to_char_type**(*_Meta*). The function can put back an element in various ways:

- If a putback position is available, and the element stored there compares equal to byte, it can decrement the next pointer for the input buffer.
- If a putback position is available, and if the stringbuf mode permits the sequence to be altered (**mode & ios_base::out** is nonzero), it can store byte into the putback position and decrement the next pointer for the input buffer.

basic_stringbuf::pos_type

Makes this type within basic_filebuf's scope equivalent to the type of the same name in the `Tr` scope.

```
typedef typename traits_type::pos_type pos_type;
```

basic_stringbuf::seekoff

The protected virtual member function tries to alter the current positions for the controlled streams.

```
virtual pos_type seekoff(
    off_type _Off,
    ios_base::seekdir _Way,
    ios_base::openmode _Mode = ios_base::in | ios_base::out);
```

Parameters

_Off

The position to seek for relative to *_Way*. For more information, see [basic_stringbuf::off_type](#).

_Way

The starting point for offset operations. See [ios_base::seekdir](#) for possible values.

_Mode

Specifies the mode for the pointer position. The default is to allow you to modify the read and write positions. For more information, see [ios_base::openmode](#).

Return Value

Returns the new position or an invalid stream position.

Remarks

For an object of class `basic_stringbuf<Elem, Tr, Alloc>`, a stream position consists purely of a stream offset. Offset zero designates the first element of the controlled sequence.

The new position is determined as follows:

- If `_Way == ios_base::beg`, the new position is the beginning of the stream plus *_Off*.
- If `_Way == ios_base::cur`, the new position is the current stream position plus *_Off*.
- If `_Way == ios_base::end`, the new position is the end of the stream plus *_Off*.

If `_Mode & ios_base::in` is nonzero, the function alters the next position to read in the input buffer. If `_Mode & ios_base::out` is nonzero, the function alters the next position to write in the output buffer. For a stream to be affected, its buffer must exist. For a positioning operation to succeed, the resulting stream position must lie within the controlled sequence. If the function affects both stream positions, *_Way* must be `ios_base::beg` or `ios_base::end` and both streams are positioned at the same element. Otherwise (or if neither position is affected), the positioning operation fails.

If the function succeeds in altering either or both of the stream positions, it returns the resultant stream position. Otherwise, it fails and returns an invalid stream position.

basic_stringbuf::seekpos

The protected virtual member function tries to alter the current positions for the controlled streams.

```
virtual pos_type seekpos(pos_type _Sp, ios_base::openmode _Mode = ios_base::in | ios_base::out);
```

Parameters

_Sp

The position to seek for.

_Mode

Specifies the mode for the pointer position. The default is to allow you to modify the read and write positions.

Return Value

If the function succeeds in altering either or both of the stream positions, it returns the resultant stream position. Otherwise, it fails and returns an invalid stream position. To determine if the stream position is invalid, compare the return value with `pos_type(off_type(-1))`.

Remarks

For an object of class `basic_stringbuf< Elem, Tr, Alloc >`, a stream position consists purely of a stream offset. Offset zero designates the first element of the controlled sequence. The new position is determined by `_Sp`.

If **mode & ios_base::in** is nonzero, the function alters the next position to read in the input buffer. If **mode & ios_base::out** is nonzero, the function alters the next position to write in the output buffer. For a stream to be affected, its buffer must exist. For a positioning operation to succeed, the resulting stream position must lie within the controlled sequence. Otherwise (or if neither position is affected), the positioning operation fails.

basic_stringbuf::str

Sets or gets the text in a string buffer without changing the write position.

```
basic_string<Elem, Tr, Alloc> str() const;
void str(
    const basic_string<Elem, Tr, Alloc>& _Newstr);
```

Parameters

`_Newstr`

The new string.

Return Value

Returns an object of class `basic_string< Elem, Tr, Alloc >`, whose controlled sequence is a copy of the sequence controlled by ***this**.

Remarks

The first member function returns an object of class `basic_string< Elem, Tr, Alloc >`, whose controlled sequence is a copy of the sequence controlled by ***this**. The sequence copied depends on the stored stringbuf mode:

- If **mode & ios_base::out** is nonzero and an output buffer exists, the sequence is the entire output buffer (`egptr` - `pbase` elements beginning with `pbase`).
- If **mode & ios_base::in** is nonzero and an input buffer exists, the sequence is the entire input buffer (`egptr` - `eback` elements beginning with `eback`).
- Otherwise, the copied sequence is empty.

The second member function deallocates any sequence currently controlled by ***this**. It then allocates a copy of the sequence controlled by `_Newstr`. If **mode & ios_base::in** is nonzero, it sets the input buffer to start reading at the beginning of the sequence. If **mode & ios_base::out** is nonzero, it sets the output buffer to start writing at the beginning of the sequence.

Example

```
// basic_stringbuf_str.cpp
// compile with: /EHsc
#include <iostream>
#include <sstream>

using namespace std;

int main( )
{
    basic_string<char> i( "test" );
    stringstream ss;

    ss.rdbuf( )->str( i );
    cout << ss.str( ) << endl;

    ss << "z";
    cout << ss.str( ) << endl;

    ss.rdbuf( )->str( "be" );
    cout << ss.str( ) << endl;
}
```

```
test
zest
be
```

basic_stringbuf::traits_type

Associates a type name with the *Tr* template parameter.

```
typedef Tr traits_type;
```

Remarks

The type is a synonym for the template parameter *Tr*.

basic_stringbuf::underflow

Protected, virtual function to extract the current element from the input stream.

```
virtual int_type underflow();
```

Return Value

If the function cannot succeed, it returns **traits_type::eof**. Otherwise, it returns the current element in the input stream, which are converted.

Remarks

The protected virtual member function tries to extract the current element `byte` from the input buffer, advance the current stream position, and return the element as **traits_type::to_int_type(byte)**. It can do so in one way: If a read position is available, it takes `byte` as the element stored in the read position and advances the next pointer for the input buffer.

basic_streambuf::swap

Swaps the contents of this string buffer with another string buffer.

```
void basic_stringbuf<T>::swap(basic_stringbuf& other)
```

Parameters

other

The `basic_stringbuf` whose contents will be swapped with this `basic_stringbuf`.

Remarks

`basic_stringbuf::operator=`

Assigns the contents of the `basic_stringbuf` on the right side of the operator to the `basic_stringbuf` on the left side.

```
basic_stringbuf& basic_stringbuf:: operator=(const basic_stringbuf& other)
```

Parameters

other

A `basic_stringbuf` whose contents, including locale traits, will be assigned to the `stringbuf` on the left side of the operator.

basic_istream Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Describes an object that controls extraction of elements and encoded objects from a stream buffer of class [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>, class Alloc = allocator<Elem>>
class basic_istream : public basic_istream<Elem, Tr>
```

Parameters

Alloc

The allocator class.

Elem

The type of the basic element of the string.

Tr

The character traits specialized on the basic element of the string.

Remarks

The template class describes an object that controls extraction of elements and encoded objects from a stream buffer of class [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >, with elements of type *Elem*, whose character traits are determined by the class *Tr*, and whose elements are allocated by an allocator of class *Alloc*. The object stores an object of class [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >.

Constructors

CONSTRUCTOR	DESCRIPTION
basic_istream	Constructs an object of type <code>basic_istream</code> .

Typedefs

TYPE NAME	DESCRIPTION
allocator_type	The type is a synonym for the template parameter <code>Alloc</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
rdbuf	Returns the address of the stored stream buffer of type <code>pointer</code> to basic_stringbuf < <code>Elem</code> , <code>Tr</code> , <code>Alloc</code> >.
str	Sets or gets the text in a string buffer without changing the write position.

MEMBER FUNCTION	DESCRIPTION
swap	Exchanges the values in this <code>basic_istream</code> object for those of the provided object.

Operators

OPERATOR	DESCRIPTION
operator=	Assigns the values to this <code>basic_istream</code> object from the object parameter.

Requirements

Header: `<sstream>`

Namespace: `std`

`basic_istream::allocator_type`

The type is a synonym for the template parameter `Alloc`.

```
typedef Alloc allocator_type;
```

`basic_istream::basic_istream`

Constructs an object of type `basic_istream`.

```
explicit basic_istream(
    ios_base::openmode _Mode = ios_base::in);

explicit basic_istream(
    const basic_string<Elem, Tr, Alloc>& str,
    ios_base::openmode _Mode = ios_base::in);

basic_istream(
    basic_istream&& right);
```

Parameters

_Mode

One of the enumerations in [ios_base::openmode](#).

str

An object of type `basic_string`.

right

An rvalue reference of a `basic_istream` object.

Remarks

The first constructor initializes the base class by calling [basic_istream](#)(`sb`), where `sb` is the stored object of class [basic_stringbuf](#)< `Elem`, `Tr`, `Alloc` >. It also initializes `sb` by calling [basic_stringbuf](#) < `Elem`, `Tr`, `Alloc` >(`_Mode` | `ios_base::in`).

The second constructor initializes the base class by calling [basic_istream](#)(`sb`). It also initializes `sb` by calling

```
basic_stringbuf < Elem, Tr, Alloc > ( str, _Mode | ios_base::in ).
```

The third constructor initializes the object with the contents of *right*, treated as an rvalue reference.

basic_istream::operator=

Assigns the values to this `basic_istream` object from the object parameter.

```
basic_istream& operator=(basic_istream&& right);
```

Parameters

right

An rvalue reference to a `basic_istream` object.

Remarks

The member operator replaces the contents of the object with the contents of *right*, treated as an rvalue reference move assignment.

basic_istream::rdbuf

Returns the address of the stored stream buffer of type `pointer` to `basic_stringbuf< Elem, Tr, Alloc >`.

```
basic_stringbuf<Elem, Tr, Alloc> *rdbuf() const;
```

Return Value

The address of the stored stream buffer of type `pointer` to `basic_stringbuf< Elem, Tr, Alloc >`.

Example

See [basic_filebuf::close](#) for an example that uses `rdbuf`.

basic_istream::str

Sets or gets the text in a string buffer without changing the write position.

```
basic_string<Elem, Tr, Alloc> str() const;

void str(
    const basic_string<Elem, Tr, Alloc>& _Newstr);
```

Parameters

_Newstr

The new string.

Return Value

Returns an object of class `basic_string< Elem, Tr, Alloc >`, whose controlled sequence is a copy of the sequence controlled by ***this**.

Remarks

The first member function returns `rdbuf -> str`. The second member function calls `rdbuf -> str(_Newstr)`.

Example

See [basic_stringbuf::str](#) for an example that uses `str`.

basic_istream::swap

Exchanges the values of two `basic_istream` objects.

```
void swap(basic_istream& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	An <code>lvalue</code> reference to a <code>basic_istream</code> object.

Remarks

The member function exchanges the values of this object and the values of *right*.

basic_ostringstream Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an object that controls insertion of elements and encoded objects into a stream buffer of class [basic_stringbuf](#)< **Elem**, **Tr**, **Alloc** >.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>, class Alloc = allocator<Elem>>
class basic_ostringstream : public basic_ostream<Elem, Tr>
```

Parameters

Alloc

The allocator class.

Elem

The type of the basic element of the string.

Tr

The character traits specialized on the basic element of the string.

Remarks

The class describes an object that controls insertion of elements and encoded objects into a stream buffer, with elements of type **Elem**, whose character traits are determined by the class **Tr**, and whose elements are allocated by an allocator of class **Alloc**. The object stores an object of class [basic_stringbuf](#)< **Elem**, **Tr**, **Alloc** >.

Constructors

CONSTRUCTOR	DESCRIPTION
basic_ostringstream	Constructs an object of type basic_ostringstream .

Typedefs

TYPE NAME	DESCRIPTION
allocator_type	The type is a synonym for the template parameter <i>Alloc</i> .

Member functions

MEMBER FUNCTION	DESCRIPTION
rdbuf	Returns the address of the stored stream buffer of type pointer to basic_stringbuf < Elem , Tr , Alloc >.
str	Sets or gets the text in a string buffer without changing the write position.

Requirements

Header: <sstream>

Namespace: std

basic_ostringstream::allocator_type

The type is a synonym for the template parameter *Alloc*.

```
typedef Alloc allocator_type;
```

basic_ostringstream::basic_ostringstream

Constructs an object of type basic_ostringstream.

```
explicit basic_ostringstream(ios_base::openmode _Mode = ios_base::out);

explicit basic_ostringstream(const basic_string<Elem, Tr, Alloc>& str, ios_base::openmode _Mode =
ios_base::out);
```

Parameters

_Mode

One of the enumerations in [ios_base::openmode](#).

str

An object of type `basic_string`.

Remarks

The first constructor initializes the base class by calling [basic_ostream](#)(**sb**), where `sb` is the stored object of class [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >. It also initializes **sb** by calling [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` > (`_Mode` | `ios_base::out`).

The second constructor initializes the base class by calling [basic_ostream](#)(**sb**). It also initializes `sb` by calling [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` > (`_Str`, `_Mode` | `ios_base::out`).

basic_ostringstream::rdbuf

Returns the address of the stored stream buffer of type `pointer` to [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >.

```
basic_stringbuf<Elem, Tr, Alloc> *rdbuf() const;
```

Return Value

The address of the stored stream buffer, of type `pointer` to [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >.

Remarks

The member function returns the address of the stored stream buffer of type `pointer` to [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >.

Example

See [basic_filebuf::close](#) for an example that uses `rdbuf`.

basic_ostringstream::str

Sets or gets the text in a string buffer without changing the write position.

```
basic_string<Elem, Tr, Alloc> str() const;

void str(
    const basic_string<Elem, Tr, Alloc>& _Newstr);
```

Parameters

_Newstr

The new string.

Return Value

Returns an object of class `basic_string< Elem, Tr, Alloc >`, whose controlled sequence is a copy of the sequence controlled by ***this**.

Remarks

The first member function returns `rdbuf -> str`. The second member function calls `rdbuf -> str(_Newstr)`.

Example

See `basic_stringbuf::str` for an example that uses `str`.

basic_stringstream Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an object that controls insertion and extraction of elements and encoded objects using a stream buffer of class [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>, class Alloc = allocator<Elem>>
class basic_stringstream : public basic_istream<Elem, Tr>
```

Parameters

Alloc

The allocator class.

Elem

The type of the basic element of the string.

Tr

The character traits specialized on the basic element of the string.

Remarks

The template class describes an object that controls insertion and extraction of elements and encoded objects using a stream buffer of class [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >, with elements of type `Elem`, whose character traits are determined by the class `Tr`, and whose elements are allocated by an allocator of class `Alloc`. The object stores an object of class [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >.

Constructors

CONSTRUCTOR	DESCRIPTION
basic_stringstream	Constructs an object of type <code>basic_stringstream</code> .

Typedefs

TYPE NAME	DESCRIPTION
allocator_type	The type is a synonym for the template parameter <code>Alloc</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
rdbuf	Returns the address of the stored stream buffer of type <code>pointer</code> to basic_stringbuf < <code>Elem</code> , <code>Tr</code> , <code>Alloc</code> >.
str	Sets or gets the text in a string buffer without changing the write position.

Requirements

Header: <sstream>

Namespace: std

basic_stringstream::allocator_type

The type is a synonym for the template parameter `Alloc`.

```
typedef Alloc allocator_type;
```

basic_stringstream::basic_stringstream

Constructs an object of type `basic_stringstream`.

```
explicit basic_stringstream(ios_base::openmode _Mode = ios_base::in | ios_base::out);

explicit basic_stringstream(const basic_string<Elem, Tr, Alloc>& str, ios_base::openmode _Mode = ios_base::in
| ios_base::out);
```

Parameters

_Mode

One of the enumerations in [ios_base::openmode](#).

str

An object of type `basic_string`.

Remarks

The first constructor initializes the base class by calling [basic_istream](#)(**sb**), where `sb` is the stored object of class [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >. It also initializes `sb` by calling [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >(_Mode).

The second constructor initializes the base class by calling [basic_istream](#)(**sb**). It also initializes `sb` by calling [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >(_Str, _Mode).

basic_stringstream::rdbuf

Returns the address of the stored stream buffer of type **pointer** to [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >.

```
basic_stringbuf<Elem, Tr, Alloc> *rdbuf() const;
```

Return Value

The address of the stored stream buffer of type `pointer` to [basic_stringbuf](#)< **Elem**, **Tr**, `Alloc` >.

Example

See [basic_filebuf::close](#) for an example that uses `rdbuf`.

basic_stringstream::str

Sets or gets the text in a string buffer without changing the write position.

```
basic_string<Elem, Tr, Alloc> str() const;

void str(
    const basic_string<Elem, Tr, Alloc>& _Newstr);
```

Parameters

_Newstr

The new string.

Return Value

Returns an object of class `basic_string< Elem, Tr, Alloc >`, whose controlled sequence is a copy of the sequence controlled by ***this**.

Remarks

The first member function returns `rdbuf -> str`. The second member function calls `rdbuf -> str(_Newstr)`.

Example

See `basic_stringbuf::str` for an example that uses `str`.

<stack>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines the template class `stack` and two supporting templates.

Syntax

```
#include <stack>
```

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests if the stack object on the left side of the operator is not equal to the stack object on the right side.
<code>operator<</code>	Tests if the stack object on the left side of the operator is less than the stack object on the right side.
<code>operator<=</code>	Tests if the stack object on the left side of the operator is less than or equal to the stack object on the right side.
<code>operator==</code>	Tests if the stack object on the left side of the operator is equal to the stack object on the right side.
<code>operator></code>	Tests if the stack object on the left side of the operator is greater than the stack object on the right side.
<code>operator>=</code>	Tests if the stack object on the left side of the operator is greater than or equal to the stack object on the right side.

Classes

CLASS	DESCRIPTION
<code>stack Class</code>	A template container adaptor class that provides a restriction of functionality limiting access to the element most recently added to some underlying container type.

[C++ Standard Library Reference](#)

<stack> operators

10/31/2018 • 7 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<=</code>	<code>operator==</code>

operator!=

Tests if the stack object on the left side of the operator is not equal to stack object on the right side.

```
bool operator!=(const stack <Type, Container>& left, const stack <Type, Container>& right,);
```

Parameters

left

An object of type `stack`.

right

An object of type `stack`.

Return Value

true if the stacks or stacks are not equal; **false** if stacks or stacks are equal.

Remarks

The comparison between stacks objects is based on a pairwise comparison of their elements. Two stacks are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```

// stack_op_me.cpp
// compile with: /EHsc
#include <stack>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares stacks with vector base containers
    stack <int, vector<int> > s1, s2, s3;

    // The following would have cause an error because stacks with
    // different base containers are not equality comparable
    // stack <int, list<int> > s3;

    s1.push( 1 );
    s2.push( 2 );
    s3.push( 1 );

    if ( s1 != s2 )
        cout << "The stacks s1 and s2 are not equal." << endl;
    else
        cout << "The stacks s1 and s2 are equal." << endl;

    if ( s1 != s3 )
        cout << "The stacks s1 and s3 are not equal." << endl;
    else
        cout << "The stacks s1 and s3 are equal." << endl;
}

```

```

The stacks s1 and s2 are not equal.
The stacks s1 and s3 are equal.

```

operator<

Tests if the stack object on the left side of the operator is less than the stack object on the right side.

```
bool operator<(const stack <Type, Container>& left, const stack <Type, Container>& right);
```

Parameters

left

An object of type `stack`.

right

An object of type `stack`.

Return Value

true if the stack on the left side of the operator is less than and not equal to the stack on the right side of the operator; otherwise **false**.

Remarks

The comparison between stack objects is based on a pairwise comparison of their elements. The less-than relationship between two stack objects is based on a comparison of the first pair of unequal elements.

Example

```

// stack_op_lt.cpp
// compile with: /EHsc
#include <stack>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares stacks with list base container
    stack<int, list<int> > s1, s2, s3;

    s1.push( 2 );
    s1.push( 4 );
    s1.push( 6 );
    s1.push( 8 );
    s2.push( 5 );
    s2.push( 10 );
    s3.push( 2 );
    s3.push( 4 );
    s3.push( 6 );
    s3.push( 8 );

    if ( s1 >= s2 )
        cout << "The stack s1 is greater than or equal to "
              << "the stack s2." << endl;
    else
        cout << "The stack s1 is less than "
              << "the stack s2." << endl;

    if ( s1 >= s3 )
        cout << "The stack s1 is greater than or equal to "
              << "the stack s3." << endl;
    else
        cout << "The stack s1 is less than "
              << "the stack s3." << endl;

    // to print out the stack s1 ( by unstacking the elements):
    stack<int>::size_type i_size_s1 = s1.size( );
    cout << "The stack s1 from the top down is: ( ";
    unsigned int i;
    for ( i = 1 ; i <= i_size_s1 ; i++ )
    {
        cout << s1.top( ) << " ";
        s1.pop( );
    }
    cout << ")." << endl;
}

```

The stack s1 is less than the stack s2.
 The stack s1 is greater than or equal to the stack s3.
 The stack s1 from the top down is: (8 6 4 2).

operator<=

Tests if the stack object on the left side of the operator is less than or equal to the stack object on the right side.

```
bool operator<=(const stack<Type, Container>& left, const stack<Type, Container>& right);
```

Parameters

left

An object of type `stack`.

right

An object of type `stack`.

Return Value

true if the stack on the left side of the operator is less than or equal to the stack on the right side of the operator; otherwise **false**.

Remarks

The comparison between stack objects is based on a pairwise comparison of their elements. The less than or equal to relationship between two stack objects is based on a comparison of the first pair of unequal elements.

Example

```
// stack_op_le.cpp
// compile with: /EHsc
#include <stack>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares stacks with default deque base container
    stack <int> s1, s2, s3;

    s1.push( 5 );
    s1.push( 10 );
    s2.push( 1 );
    s2.push( 2 );
    s3.push( 5 );
    s3.push( 10 );

    if ( s1 <= s2 )
        cout << "The stack s1 is less than or equal to "
              << "the stack s2." << endl;
    else
        cout << "The stack s1 is greater than "
              << "the stack s2." << endl;

    if ( s1 <= s3 )
        cout << "The stack s1 is less than or equal to "
              << "the stack s3." << endl;
    else
        cout << "The stack s1 is greater than "
              << "the stack s3." << endl;
}
```

The stack s1 is greater than the stack s2.
The stack s1 is less than or equal to the stack s3.

operator==

Tests if the stack object on the left side of the operator is equal to stack object on the right side.

```
bool operator==(const stack <Type, Container>& left, const stack <Type, Container>& right);
```

Parameters

left

An object of type `stack`.

right

An object of type `stack`.

Return Value

true if the stacks or stacks are equal; **false** if stacks or stacks are not equal.

Remarks

The comparison between stack objects is based on a pairwise comparison of their elements. Two stacks are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// stack_op_eq.cpp
// compile with: /EHsc
#include <stack>
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares stacks with vector base containers
    stack <int, vector<int> > s1, s2, s3;

    // The following would have cause an error because stacks with
    // different base containers are not equality comparable
    // stack <int, list<int> > s3;

    s1.push( 1 );
    s2.push( 2 );
    s3.push( 1 );

    if ( s1 == s2 )
        cout << "The stacks s1 and s2 are equal." << endl;
    else
        cout << "The stacks s1 and s2 are not equal." << endl;

    if ( s1 == s3 )
        cout << "The stacks s1 and s3 are equal." << endl;
    else
        cout << "The stacks s1 and s3 are not equal." << endl;
}
```

The stacks s1 and s2 are not equal.
The stacks s1 and s3 are equal.

operator>

Tests if the stack object on the left side of the operator is greater than the stack object on the right side.

```
bool operator>(const stack <Type, Container>& left, const stack <Type, Container>& right);
```

Parameters

left

An object of type `stack`.

right

An object of type `stack`.

Return Value

true if the stack on the left side of the operator is greater than and not equal to the stack on the right side of the operator; otherwise **false**.

Remarks

The comparison between stack objects is based on a pairwise comparison of their elements. The greater-than relationship between two stack objects is based on a comparison of the first pair of unequal elements.

Example

```
// stack_op_gt.cpp
// compile with: /EHsc
#include <stack>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares stacks with list base container
    stack <int, list<int> > s1, s2, s3;

    s1.push( 1 );
    s1.push( 2 );
    s1.push( 3 );
    s2.push( 5 );
    s2.push( 10 );
    s3.push( 1 );
    s3.push( 2 );

    if ( s1 > s2 )
        cout << "The stack s1 is greater than "
              << "the stack s2." << endl;
    else
        cout << "The stack s1 is not greater than "
              << "the stack s2." << endl;

    if ( s1 > s3 )
        cout << "The stack s1 is greater than "
              << "the stack s3." << endl;
    else
        cout << "The stack s1 is not greater than "
              << "the stack s3." << endl;
}
```

```
The stack s1 is not greater than the stack s2.
The stack s1 is greater than the stack s3.
```

operator>=

Tests if the stack object on the left side of the operator is greater than or equal to the stack object on the right side.

```
bool operator>=(const stack <Type, Container>& left, const stack <Type, Container>& right);
```

Parameters

left

An object of type `stack`.

right

An object of type `stack`.

Return Value

true if the stack on the left side of the operator is strictly less than the stack on the right side of the operator; otherwise **false**.

Remarks

The comparison between stack objects is based on a pairwise comparison of their elements. The greater than or equal to relationship between two stack objects is based on a comparison of the first pair of unequal elements.

Example

```
// stack_op_ge.cpp
// compile with: /EHsc
#include <stack>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares stacks with list base container
    stack <int, list<int> > s1, s2, s3;

    s1.push( 1 );
    s1.push( 2 );
    s2.push( 5 );
    s2.push( 10 );
    s3.push( 1 );
    s3.push( 2 );

    if ( s1 >= s2 )
        cout << "The stack s1 is greater than or equal to "
              << "the stack s2." << endl;
    else
        cout << "The stack s1 is less than "
              << "the stack s2." << endl;

    if ( s1 >= s3 )
        cout << "The stack s1 is greater than or equal to "
              << "the stack s3." << endl;
    else
        cout << "The stack s1 is less than "
              << "the stack s3." << endl;
}
```

The stack s1 is less than the stack s2.
The stack s1 is greater than or equal to the stack s3.

<stack>

stack Class

10/31/2018 • 8 minutes to read • [Edit Online](#)

A template container adaptor class that provides a restriction of functionality limiting access to the element most recently added to some underlying container type. The stack class is used when it is important to be clear that only stack operations are being performed on the container.

Syntax

```
template <class Type, class Container= deque <Type>>
class stack
```

Parameters

Type

The element data type to be stored in the stack.

Container

The type of the underlying container used to implement the stack. The default value is the class `deque <Type>`.

Remarks

The elements of class `Type` stipulated in the first template parameter of a stack object are synonymous with [value_type](#) and must match the type of element in the underlying container class `Container` stipulated by the second template parameter. The `Type` must be assignable, so that it is possible to copy objects of that type and to assign values to variables of that type.

Suitable underlying container classes for stack include [deque](#), [list class](#), and [vector class](#), or any other sequence container that supports the operations of `back`, `push_back`, and `pop_back`. The underlying container class is encapsulated within the container adaptor, which exposes only the limited set of the sequence container member functions as a public interface.

The stack objects are equality comparable if and only if the elements of class `Type` are equality comparable and are less-than comparable if and only if the elements of class `Type` are less-than comparable.

- The stack class supports a last-in, first-out (LIFO) data structure. A good analogue to keep in mind would be a stack of plates. Elements (plates) may be inserted, inspected, or removed only from the top of the stack, which is the last element at the end of the base container. The restriction to accessing only the top element is the reason for using the stack class.
- The [queue class](#) supports a first-in, first-out (FIFO) data structure. A good analogue to keep in mind would be people lining up for a bank teller. Elements (people) may be added to the back of the line and are removed from the front of the line. Both the front and the back of a line may be inspected. The restriction to accessing only the front and back elements in this way is the reason for using the queue class.
- The [priority_queue class](#) orders its elements so that the largest element is always at the top position. It supports insertion of an element and the inspection and removal of the top element. A good analogue to keep in mind would be people lining up where they are arranged by age, height, or some other criterion.

Constructors

CONSTRUCTOR	DESCRIPTION
stack	Constructs a <code>stack</code> that is empty or that is a copy of a base container object.

Typedefs

TYPE NAME	DESCRIPTION
container_type	A type that provides the base container to be adapted by a <code>stack</code> .
size_type	An unsigned integer type that can represent the number of elements in a <code>stack</code> .
value_type	A type that represents the type of object stored as an element in a <code>stack</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
empty	Tests if the <code>stack</code> is empty.
pop	Removes the element from the top of the <code>stack</code> .
push	Adds an element to the top of the <code>stack</code> .
size	Returns the number of elements in the <code>stack</code> .
top	Returns a reference to an element at the top of the <code>stack</code> .

Requirements

Header: `<stack>`

Namespace: `std`

`stack::container_type`

A type that provides the base container to be adapted.

```
typedef Container container_type;
```

Remarks

The type is a synonym for the template parameter `Container`. All three C++ Standard Library sequence container classes — the vector class, list class, and the default class deque — meet the requirements to be used as the base container for a stack object. User-defined types satisfying these requirements may also be used.

For more information on `Container`, see the Remarks section of the [stack Class](#) topic.

Example

See the example for [stack::stack](#) for an example of how to declare and use `container_type`.

stack::empty

Tests if a stack is empty.

```
bool empty() const;
```

Return Value

true if the stack is empty; **false** if the stack is nonempty.

Example

```
// stack_empty.cpp
// compile with: /EHsc
#include <stack>
#include <iostream>

int main( )
{
    using namespace std;
    // Declares stacks with default deque base container
    stack <int> s1, s2;

    s1.push( 1 );

    if ( s1.empty( ) )
        cout << "The stack s1 is empty." << endl;
    else
        cout << "The stack s1 is not empty." << endl;

    if ( s2.empty( ) )
        cout << "The stack s2 is empty." << endl;
    else
        cout << "The stack s2 is not empty." << endl;
}
```

```
The stack s1 is not empty.
The stack s2 is empty.
```

stack::pop

Removes the element from the top of the stack.

```
void pop();
```

Remarks

The stack must be nonempty to apply the member function. The top of the stack is the position occupied by the most recently added element and is the last element at the end of the container.

Example

```

// stack_pop.cpp
// compile with: /EHsc
#include <stack>
#include <iostream>

int main( )
{
    using namespace std;
    stack <int> s1, s2;

    s1.push( 10 );
    s1.push( 20 );
    s1.push( 30 );

    stack <int>::size_type i;
    i = s1.size( );
    cout << "The stack length is " << i << "." << endl;

    i = s1.top( );
    cout << "The element at the top of the stack is "
        << i << "." << endl;

    s1.pop( );

    i = s1.size( );
    cout << "After a pop, the stack length is "
        << i << "." << endl;

    i = s1.top( );
    cout << "After a pop, the element at the top of the stack is "
        << i << "." << endl;
}

```

```

The stack length is 3.
The element at the top of the stack is 30.
After a pop, the stack length is 2.
After a pop, the element at the top of the stack is 20.

```

stack::push

Adds an element to the top of the stack.

```
void push(const Type& val);
```

Parameters

val

The element added to the top of the stack.

Remarks

The top of the stack is the position occupied by the most recently added element and is the last element at the end of the container.

Example

```
// stack_push.cpp
// compile with: /EHsc
#include <stack>
#include <iostream>

int main( )
{
    using namespace std;
    stack <int> s1;

    s1.push( 10 );
    s1.push( 20 );
    s1.push( 30 );

    stack <int>::size_type i;
    i = s1.size( );
    cout << "The stack length is " << i << "." << endl;

    i = s1.top( );
    cout << "The element at the top of the stack is "
        << i << "." << endl;
}
```

The stack length is 3.
The element at the top of the stack is 30.

stack::size

Returns the number of elements in the stack.

```
size_type size() const;
```

Return Value

The current length of the stack.

Example

```
// stack_size.cpp
// compile with: /EHsc
#include <stack>
#include <iostream>

int main( )
{
    using namespace std;
    stack <int> s1, s2;
    stack <int>::size_type i;

    s1.push( 1 );
    i = s1.size( );
    cout << "The stack length is " << i << "." << endl;

    s1.push( 2 );
    i = s1.size( );
    cout << "The stack length is now " << i << "." << endl;
}
```

```
The stack length is 1.  
The stack length is now 2.
```

stack::size_type

An unsigned integer type that can represent the number of elements in a stack.

```
typedef typename Container::size_type size_type;
```

Remarks

The type is a synonym for `size_type` of the base container adapted by the stack.

Example

See the example for [size](#) for an example of how to declare and use `size_type`.

stack::stack

Constructs a stack that is empty or that is a copy of a base container class.

```
stack();  
  
explicit stack(const container_type& right);
```

Parameters

right

The container of which the constructed stack is to be a copy.

Example

```

// stack_stack.cpp
// compile with: /EHsc
#include <stack>
#include <vector>
#include <list>
#include <iostream>

int main( )
{
    using namespace std;

    // Declares stack with default deque base container
    stack<char> dsc1;

    //Explicitly declares a stack with deque base container
    stack<char, deque<char> > dsc2;

    // Declares a stack with vector base containers
    stack<int, vector<int> > vsi1;

    // Declares a stack with list base container
    stack<int, list<int> > lsi;

    // The second member function copies elements from a container
    vector<int> v1;
    v1.push_back( 1 );
    stack<int, vector<int> > vsi2( v1 );
    cout << "The element at the top of stack vsi2 is "
         << vsi2.top( ) << "." << endl;
}

```

The element at the top of stack vsi2 is 1.

stack::top

Returns a reference to an element at the top of the stack.

```

reference top();

const_reference top() const;

```

Return Value

A reference to the last element in the container at the top of the stack.

Remarks

The stack must be nonempty to apply the member function. The top of the stack is the position occupied by the most recently added element and is the last element at the end of the container.

If the return value of `top` is assigned to a `const_reference`, the stack object cannot be modified. If the return value of `top` is assigned to a `reference`, the stack object can be modified.

Example

```
// stack_top.cpp
// compile with: /EHsc
#include <stack>
#include <iostream>

int main( )
{
    using namespace std;
    stack<int> s1;

    s1.push( 1 );
    s1.push( 2 );

    int& i = s1.top( );
    const int& ii = s1.top( );

    cout << "The top integer of the stack s1 is "
         << i << "." << endl;
    i--;
    cout << "The next integer down is "<< ii << "." << endl;
}
```

The top integer of the stack s1 is 2.
The next integer down is 1.

stack::value_type

A type that represents the type of object stored as an element in a stack.

```
typedef typename Container::value_type value_type;
```

Remarks

The type is a synonym for `value_type` of the base container adapted by the stack.

Example

```
// stack_value_type.cpp
// compile with: /EHsc
#include <stack>
#include <iostream>

int main( )
{
    using namespace std;
    // Declares stacks with default deque base container
    stack<int>::value_type AnInt;

    AnInt = 69;
    cout << "The value_type is AnInt = " << AnInt << endl;

    stack<int> s1;
    s1.push( AnInt );
    cout << "The element at the top of the stack is "
         << s1.top( ) << "." << endl;
}
```

The value_type is AnInt = 69
The element at the top of the stack is 69.

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

<stdexcept>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines several standard classes used for reporting exceptions. The classes form a derivation hierarchy all derived from class [exception](#) and include two general types of exceptions: logical errors and run-time errors. The logical errors are caused programmer mistakes. They derive from the base class `logic_error` and include:

- `domain_error`
- `invalid_argument`
- `length_error`
- `out_of_range`

The run-time errors occur because of mistakes in either the library functions or in the run-time system. They derive from the base class `runtime_error` and include:

- `overflow_error`
- `range_error`
- `underflow_error`

Classes

CLASS	DESCRIPTION
domain_error Class	The class serves as the base class for all exceptions thrown to report a domain error.
invalid_argument Class	The class serves as the base class for all exceptions thrown to report an invalid argument.
length_error Class	The class serves as the base class for all exceptions thrown to report an attempt to generate an object too long to be specified.
logic_error Class	The class serves as the base class for all exceptions thrown to report errors presumably detectable before the program executes, such as violations of logical preconditions.
out_of_range Class	The class serves as the base class for all exceptions thrown to report an argument that is out of its valid range.
overflow_error Class	The class serves as the base class for all exceptions thrown to report an arithmetic overflow.
range_error Class	The class serves as the base class for all exceptions thrown to report a range error.
runtime_error Class	The class serves as the base class for all exceptions thrown to report errors presumably detectable only when the program executes.

CLASS	DESCRIPTION
underflow_error Class	The class serves as the base class for all exceptions thrown to report an arithmetic underflow.

[Thread Safety in the C++ Standard Library](#)

domain_error Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The class serves as the base class for all exceptions thrown to report a domain error.

Syntax

```
class domain_error : public logic_error {
public:
    explicit domain_error(const string& message);

    explicit domain_error(const char *message);

};
```

Remarks

The value returned by [what](#) is a copy of **message** `.data`.

Example

```
// domain_error.cpp
// compile with: /EHsc /GR
#include <iostream>

using namespace std;

int main( )
{
    try
    {
        throw domain_error( "Your domain is in error!" );
    }
    catch (exception &e)
    {
        cerr << "Caught: " << e.what( ) << endl;
        cerr << "Type: " << typeid(e).name( ) << endl;
    }
};

/* Output:
Caught: Your domain is in error!
Type: class std::domain_error
*/
```

Requirements

[logic_error Class](#)

[Thread Safety in the C++ Standard Library](#)

invalid_argument Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The class serves as the base class for all exceptions thrown to report an invalid argument.

Syntax

```
class invalid_argument : public logic_error {
public:
    explicit invalid_argument(const string& message);

    explicit invalid_argument(const char *message);

};
```

Remarks

The value returned by [what](#) is a copy of **message** [data](#).

Example

```
// invalid_arg.cpp
// compile with: /EHsc /GR
#include <bitset>
#include <iostream>

using namespace std;

int main( )
{
    try
    {
        bitset< 32 > bitset( string( "11001010101100001b100101010110000" ) );
    }
    catch ( exception &e )
    {
        cerr << "Caught " << e.what( ) << endl;
        cerr << "Type " << typeid( e ).name( ) << endl;
    }
};

/* Output:
Caught invalid bitset<N> char
Type class std::invalid_argument
*/
```

Requirements

[logic_error Class](#)

length_error Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The class serves as the base class for all exceptions thrown to report an attempt to generate an object too long to be specified.

Syntax

```
class length_error : public logic_error {  
public:  
    explicit length_error(const string& message);  
  
    explicit length_error(const char *message);  
  
};
```

Remarks

The value returned by [what](#) is a copy of **message**.[data](#).

Example

```

// length_error.cpp
// compile with: /EHsc /GR /MDd
#include <vector>
#include <iostream>

using namespace std;

template<class T>
class stingyallocator : public allocator< T>
{
public:
    template <class U>
        struct rebind { typedef stingyallocator<U> other; };
    _SIZT max_size( ) const
    {
        return 10;
    };
};

int main( )
{
    try
    {
        vector<int, stingyallocator< int > > myv;
        for ( int i = 0; i < 11; i++ ) myv.push_back( i );
    }
    catch ( exception &e )
    {
        cerr << "Caught " << e.what( ) << endl;
        cerr << "Type " << typeid( e ).name( ) << endl;
    };
}
/* Output:
Caught vector<T> too long

exception Class

Thread Safety in the C++ Standard Library

underflow_error Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The class serves as the base class for all exceptions thrown to report an arithmetic underflow.

Syntax

```
class underflow_error : public runtime_error {
public:
    explicit underflow_error(const string& message);

    explicit underflow_error(const char *message);

};
```

Remarks

The value returned by [what](#) is a copy of **message** [.data](#).

Example

```
// underflow_error.cpp
// compile with: /EHsc /GR
#include <iostream>

using namespace std;

int main( )
{
    try
    {
        throw underflow_error( "The number's a bit small, captain!" );
    }
    catch ( exception &e ) {
        cerr << "Caught: " << e.what( ) << endl;
        cerr << "Type: " << typeid( e ).name( ) << endl;
    }
};

/* Output:
Caught: The number's a bit small, captain!
Type: class std::underflow_error
*/
```

<streambuf>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Include the iostreams standard header `<streambuf>` to define the template class `basic_streambuf`, which is basic to the operation of the iostreams classes. This header is typically included for you by another of the iostreams headers; you rarely need to include it directly.

Syntax

```
#include <streambuf>
```

Typedefs

TYPE NAME	DESCRIPTION
<code>streambuf</code>	A specialization of <code>basic_streambuf</code> that uses char as the template parameters.
<code>wstreambuf</code>	A specialization of <code>basic_streambuf</code> that uses wchar_t as the template parameters.

Classes

CLASS	DESCRIPTION
<code>basic_streambuf</code> Class	The template class describes an abstract base class for deriving a stream buffer, which controls the transmission of elements to and from a specific representation of a stream.

<streambuf> typedefs

10/31/2018 • 2 minutes to read • [Edit Online](#)

streambuf	wstreambuf

streambuf

A specialization of `basic_streambuf` that uses **char** as the template parameters.

```
typedef basic_streambuf<char, char_traits<char>> streambuf;
```

Remarks

The type is a synonym for the template class [basic_streambuf](#), specialized for elements of type **char** with default character traits.

wstreambuf

A specialization of `basic_streambuf` that uses **wchar_t** as the template parameters.

```
typedef basic_streambuf<wchar_t, char_traits<wchar_t>> wstreambuf;
```

Remarks

The type is a synonym for the template class [basic_streambuf](#), specialized for elements of type **wchar_t** with default character traits.

[<streambuf>](#)

basic_streambuf Class

11/9/2018 • 25 minutes to read • [Edit Online](#)

Describes an abstract base class for deriving a stream buffer, which controls the transmission of elements to and from a specific representation of a stream.

Syntax

```
template <class Elem, class Tr = char_traits<Elem>>
class basic_streambuf;
```

Parameters

Elem

A [char_type](#).

Tr

The character [traits_type](#).

Remarks

The template class describes an abstract base class for deriving a stream buffer, which controls the transmission of elements to and from a specific representation of a stream. An object of class `basic_streambuf` helps control a stream with elements of type *Tr*, also known as [char_type](#), whose character traits are determined by the class [char_traits](#), also known as [traits_type](#).

Every stream buffer conceptually controls two independent streams: one for extractions (input) and one for insertions (output). A specific representation may, however, make either or both of these streams inaccessible. It typically maintains some relationship between the two streams. What you insert into the output stream of a `basic_stringbuf< Elem, Tr >` object, for example, is what you later extract from its input stream. When you position one stream of a `basic_filebuf< Elem, Tr >` object, you position the other stream in tandem.

The public interface to template class `basic_streambuf` supplies the operations that are common to all stream buffers, however specialized. The protected interface supplies the operations needed for a specific representation of a stream to do its work. The protected virtual member functions let you tailor the behavior of a derived stream buffer for a specific representation of a stream. Each derived stream buffer in this library describes how it specializes the behavior of its protected virtual member functions. The default behavior for the base class, which is often to do nothing, is described in this topic.

The remaining protected member functions control copying to and from any storage supplied to buffer transmissions to and from streams. An input buffer, for example, is characterized by:

- [eback](#), a pointer to the beginning of the buffer.
- [gptr](#), a pointer to the next element to read.
- [egptr](#), a pointer just past the end of the buffer.

Similarly, an output buffer is characterized by:

- [pbase](#), a pointer to the beginning of the buffer.
- [pptr](#), a pointer to the next element to write.

- [epptr](#), a pointer just past the end of the buffer.

For any buffer, the following protocol is used:

- If the next pointer is null, no buffer exists. Otherwise, all three pointers point into the same sequence. They can be safely compared for order.
- For an output buffer, if the next pointer compares less than the end pointer, you can store an element at the write position designated by the next pointer.
- For an input buffer, if the next pointer compares less than the end pointer, you can read an element at the read position designated by the next pointer.
- For an input buffer, if the beginning pointer compares less than the next pointer, you can put back an element at the putback position designated by the decremented next pointer.

Any protected virtual member functions you write for a class derived from `basic_streambuf < Elem, Tr >` must cooperate in maintaining this protocol.

An object of class `basic_streambuf < Elem, Tr >` stores the six pointers previously described. It also stores a locale object in an object of type [locale](#) for potential use by a derived stream buffer.

Constructors

CONSTRUCTOR	DESCRIPTION
basic_streambuf	Constructs an object of type <code>basic_streambuf</code> .

Typedefs

TYPE NAME	DESCRIPTION
char_type	Associates a type name with the <code>Elem</code> template parameter.
int_type	Associates a type name within <code>basic_streambuf</code> scope with the <code>Elem</code> template parameter.
off_type	Associates a type name within <code>basic_streambuf</code> scope with the <code>Elem</code> template parameter.
pos_type	Associates a type name within <code>basic_streambuf</code> scope with the <code>Elem</code> template parameter.
traits_type	Associates a type name with the <code>Tr</code> template parameter.

Member functions

MEMBER FUNCTION	DESCRIPTION
eback	A protected function that returns a pointer to the beginning of the input buffer.
egptr	A protected function that returns a pointer just past the end of the input buffer.

MEMBER FUNCTION	DESCRIPTION
epptr	A protected function that returns a pointer just past the end of the output buffer.
gbump	A protected function that adds <code>count</code> to the next pointer for the input buffer.
getloc	Gets the <code>basic_streambuf</code> object's locale.
gptr	A protected function that returns a pointer to the next element of the input buffer.
imbue	A protected, virtual function called by pubimbue .
in_avail	Returns the number of elements that are ready to be read from the buffer.
overflow	A protected virtual function that can be called when a new character is inserted into a full buffer.
pbackfail	A protected virtual member function that tries to put back an element into the input stream, then make it the current element (pointed to by the next pointer).
pbase	A protected function that returns a pointer to the beginning of the output buffer.
pbump	A protected function that adds <code>count</code> to the next pointer for the output buffer.
pptr	A protected function that returns a pointer to the next element of the output buffer.
pubimbue	Sets the <code>basic_streambuf</code> object's locale.
pubseekoff	Calls seekoff , a protected virtual function that is overridden in a derived class.
pubseekpos	Calls seekpos , a protected virtual function that is overridden in a derived class and resets the current pointer position.
pubsetbuf	Calls setbuf , a protected virtual function that is overridden in a derived class.
pubsync	Calls sync , a protected virtual function that is overridden in a derived class and updates the external stream associated with this buffer.
sbumpc	Reads and returns the current element, moving the stream pointer.
seekoff	The protected virtual member function tries to alter the current positions for the controlled streams.

MEMBER FUNCTION	DESCRIPTION
seekpos	The protected virtual member function tries to alter the current positions for the controlled streams.
setbuf	The protected virtual member function performs an operation particular to each derived stream buffer.
setg	A protected function that stores <code>_Gbeg</code> in the beginning pointer, <code>_Gnext</code> in the next pointer, and <code>_Gend</code> in the end pointer for the input buffer.
setp	A protected function that stores <code>_Pbeg</code> in the beginning pointer and <code>_Pend</code> in the end pointer for the output buffer.
sgetc	Returns current element without changing position in the stream.
sgetn	Returns the number of elements read.
showmanyc	Protected virtual member function that returns a count of the number of characters that can be extracted from the input stream and ensure that the program will not be subject to an indefinite wait.
snextc	Reads the current element and returns the following element.
sputbackc	Puts a <code>char_type</code> in the stream.
sputc	Puts a character into the stream.
sputn	Puts a character string into the stream.
stossc	Move past the current element in the stream.
sungetc	Gets a character from the stream.
swap	Exchanges the values in this object for the values in the provided <code>basic_streambuf</code> object parameter.
sync	A protected virtual function that tries to synchronize the controlled streams with any associated external streams.
uflow	A protected virtual function that extracts the current element from the input stream.
underflow	A protected virtual function that extracts the current element from the input stream.
xsgetn	A protected virtual function that extracts elements from the input stream.
xsputn	A protected virtual function that inserts elements into the output stream.

Operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Assigns the values of this object from another <code>basic_streambuf</code> object.

Requirements

Header: <streambuf>

Namespace: std

basic_streambuf::basic_streambuf

Constructs an object of type `basic_streambuf`.

```
basic_streambuf();

basic_streambuf(const basic_streambuf& right);
```

Parameters

right

An lvalue reference to the `basic_streambuf` object that is used to set the values for this `basic_streambuf` object.

Remarks

The first protected constructor stores a null pointer in all pointers controlling the input buffer and the output buffer. It also stores `locale::classic` in the locale object. For more information, see [locale::classic](#).

The second protected constructor copies the pointers and locale from *right*.

basic_streambuf::char_type

Associates a type name with the **Elem** template parameter.

```
typedef Elem char_type;
```

basic_streambuf::eback

A protected function that returns a pointer to the beginning of the input buffer.

```
char_type *eback() const;
```

Return Value

A pointer to the beginning of the input buffer.

basic_streambuf::egptr

A protected function that returns a pointer just past the end of the input buffer.

```
char_type *egptr() const;
```

Return Value

A pointer just past the end of the input buffer.

basic_streambuf::epptr

A protected function that returns a pointer just past the end of the output buffer.

```
char_type *epptr() const;
```

Return Value

A pointer just past the end of the output buffer.

basic_streambuf::gbump

A protected function that adds *count* to the next pointer for the input buffer.

```
void gbump(int count);
```

Parameters

count

The amount by which to advance the pointer.

basic_streambuf::getloc

Gets the `basic_streambuf` object's locale.

```
locale getloc() const;
```

Return Value

The stored locale object.

Remarks

For related information, see [ios_base::getloc](#).

Example

```
// basic_streambuf_getloc.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    cout << cout.rdbuf( )->getloc( ).name( ).c_str( ) << endl;
}
```

```
c
```

basic_streambuf::gpptr

A protected function that returns a pointer to the next element of the input buffer.

```
char_type *gptr() const;
```

Return Value

A pointer to the next element of the input buffer.

basic_streambuf::imbue

A protected virtual function called by [pubimbue](#).

```
virtual void imbue(const locale& _Loc);
```

Parameters

_Loc

A reference to a locale.

Remarks

The default behavior is to do nothing.

basic_streambuf::in_avail

Returns the number of elements that are ready to be read from the buffer.

```
streamsize in_avail();
```

Return Value

The number of elements that are ready to be read from the buffer.

Remarks

If a [read position](#) is available, the member function returns [egptr](#) - [gptr](#). Otherwise, it returns [showmanyc](#).

Example

```
// basic_streambuf_in_avail.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    char c;
    // cin's buffer is empty, in_avail will return 0
    cout << cin.rdbuf( )->in_avail( ) << endl;
    cin >> c;
    cout << cin.rdbuf( )->in_avail( ) << endl;
}
```

basic_streambuf::int_type

Associates a type name within basic_streambuf scope with one of the types in a template parameter.

```
typedef typename traits_type::int_type int_type;
```

basic_streambuf::off_type

Associates a type name within basic_streambuf scope with one of the types in a template parameter.

```
typedef typename traits_type::off_type off_type;
```

basic_streambuf::operator=

Assigns the values of this object from another `basic_streambuf` object.

```
basic_streambuf& operator=(const basic_streambuf& right);
```

Parameters

right

An lvalue reference to the `basic_streambuf` object that is used to assign values to this object.

Remarks

The protected member operator copies from *right* the pointers that control the input buffer and the output buffer. It also stores `right.getloc()` in the `locale` object. It returns `*this`.

basic_streambuf::overflow

A protected virtual function that can be called when a new character is inserted into a full buffer.

```
virtual int_type overflow(int_type _Meta = traits_type::eof());
```

Parameters

_Meta

The character to insert into the buffer, or `traits_type::eof`.

Return Value

If the function cannot succeed, it returns `traits_type::eof` or throws an exception. Otherwise, it returns `traits_type::not_eof(_Meta)`. The default behavior is to return `traits_type::eof`.

Remarks

If *_Meta* does not compare equal to `traits_type::eof`, the protected virtual member function endeavors to insert the element `traits_type::to_char_type(_Meta)` into the output stream. It can do so in various ways:

- If a `write position` is available, it can store the element into the write position and increment the next pointer for the output buffer.
- It can make a write position available by allocating new or additional storage for the output buffer.
- It can make a write position available by writing out, to some external destination, some or all of the elements between the beginning and next pointers for the output buffer.

The virtual overflow function, together with the `sync` and `underflow` functions, defines the characteristics of the streambuf-derived class. Each derived class might implement overflow differently, but the interface with the calling stream class is the same.

The `overflow` function is most frequently called by public `streambuf` functions like `sputc` and `sputn` when the put area is full, but other classes, including the stream classes, can call `overflow` anytime.

The function consumes the characters in the put area between the `pbase` and `pptr` pointers and then reinitializes the put area. The `overflow` function must also consume `nCh` (if `nCh` is not `EOF`), or it might choose to put that character in the new put area so that it will be consumed on the next call.

The definition of consume varies among derived classes. For example, the `filebuf` class writes its characters to a file, while the `strstreambuf` class keeps them in its buffer and (if the buffer is designated as dynamic) expands the buffer in response to a call to `overflow`. This expansion is achieved by freeing the old buffer and replacing it with a new, larger one. The pointers are adjusted as necessary.

basic_streambuf::pbackfail

A protected virtual member function that tries to put back an element into the input stream, then make it the current element (pointed to by the next pointer).

```
virtual int_type pbackfail(int_type _Meta = traits_type::eof());
```

Parameters

_Meta

The character to insert into the buffer, or `traits_type::eof`.

Return Value

If the function cannot succeed, it returns `traits_type::eof` or throws an exception. Otherwise, it returns some other value. The default behavior is to return `traits_type::eof`.

Remarks

If *_Meta* compares equal to `traits_type::eof`, the element to push back is effectively the one already in the stream before the current element. Otherwise, that element is replaced by `traits_type::to_char_type(_Meta)`. The function can put back an element in various ways:

- If a putback position is available, it can store the element into the putback position and decrement the next pointer for the input buffer.
- It can make a putback position available by allocating new or additional storage for the input buffer.
- For a stream buffer with common input and output streams, it can make a putback position available by writing out, to some external destination, some or all of the elements between the beginning and next pointers for the output buffer.

basic_streambuf::pbase

A protected function that returns a pointer to the beginning of the output buffer.

```
char_type *pbase() const;
```

Return Value

A pointer to the beginning of the output buffer.

basic_streambuf::pbump

A protected function that adds *count* to the next pointer for the output buffer.

```
void pbump(int count);
```

Parameters

count

The number of characters by which to move the write position forward.

basic_streambuf::pos_type

Associates a type name within basic_streambuf scope with one of the types in a template parameter.

```
typedef typename traits_type::pos_type pos_type;
```

basic_streambuf::pptr

A protected function that returns a pointer to the next element of the output buffer.

```
char_type *pptr() const;
```

Return Value

A pointer to the next element of the output buffer.

basic_streambuf::pubimbue

Sets the basic_streambuf object's locale.

```
locale pubimbue(const locale& _Loc);
```

Parameters

_Loc

A reference to a locale.

Return Value

The previous value stored in the locale object.

Remarks

The member function stores *_Loc* in the locale object and calls [imbue](#).

Example

See [basic_ios::imbue](#) for an example that uses `pubimbue`.

basic_streambuf::pubseekoff

Calls [seekoff](#), a protected virtual function that is overridden in a derived class.

```
pos_type pubseekoff(off_type _Off,  
    ios_base::seekdir _Way,  
    ios_base::openmode _Which = ios_base::in | ios_base::out);
```

Parameters

_Off

The position to seek for relative to *_Way*.

_Way

The starting point for offset operations. See [seekdir](#) for possible values.

_Which

Specifies the mode for the pointer position. The default is to allow you to modify the read and write positions.

Return Value

Returns the new position or an invalid stream position ([seekoff](#)(*_Off*, *_Way*, *_Which*)).

Remarks

Moves the pointer relative to *_Way*.

basic_streambuf::pubseekpos

Calls [seekpos](#), a protected virtual function that is overridden in a derived class, and resets the current pointer position.

```
pos_type pubseekpos(pos_type _Sp, ios_base::openmode _Which = ios_base::in | ios_base::out);
```

Parameters

_Sp

The position to seek for.

_Which

Specifies the mode for the pointer position. The default is to allow you to modify the read and write positions.

Return Value

The new position or an invalid stream position. To determine if the stream position is invalid, compare the return value with `pos_type(off_type(-1))`.

Remarks

The member function returns [seekpos](#)(*_Sp*, *_Which*).

basic_streambuf::pubsetbuf

Calls [setbuf](#), a protected virtual function that is overridden in a derived class.

```
basic_streambuf<Elem, Tr> *pubsetbuf(  
    char_type* _Buffer,  
    streamsize count);
```

Parameters

_Buffer

A pointer to `char_type` for this instantiation.

count

The size of the buffer.

Return Value

Returns [setbuf](#)(*_Buffer*, *count*).

basic_streambuf::pubsync

Calls [sync](#), a protected virtual function that is overridden in a derived class, and updates the external stream associated with this buffer.

```
int pubsync();
```

Return Value

Returns [sync](#) or -1 if failure.

basic_streambuf::sbumpc

Reads and returns the current element, moving the stream pointer.

```
int_type sbumpc();
```

Return Value

The current element.

Remarks

If a read position is available, the member function returns **traits_type::to_int_type(*gptr)** and increments the next pointer for the input buffer. Otherwise, it returns [uflow](#).

Example

```
// basic_streambuf_sbumpc.cpp
// compile with: /EHsc
#include <iostream>

int main( )
{
    using namespace std;
    int i = 0;
    i = cin.rdbuf( )->sbumpc( );
    cout << i << endl;
}
```

```
3
```

```
33
51
```

basic_streambuf::seekoff

A protected virtual member function that tries to alter the current positions for the controlled streams.

```
virtual pos_type seekoff(
    off_type _Off,
    ios_base::seekdir _Way,
    ios_base::openmode _Which = ios_base::in | ios_base::out);
```

Parameters

_Off

The position to seek for relative to *_Way*.

_Way

The starting point for offset operations. See [seekdir](#) for possible values.

_Which

Specifies the mode for the pointer position. The default is to allow you to modify the read and write positions.

Return Value

Returns the new position or an invalid stream position (`seekoff` (`_Off`, `_Way`, `_Which`)).

Remarks

The new position is determined as follows:

- If `_Way` == `ios_base::beg`, the new position is the beginning of the stream plus `_Off`.
- If `_Way` == `ios_base::cur`, the new position is the current stream position plus `_Off`.
- If `_Way` == `ios_base::end`, the new position is the end of the stream plus `_Off`.

Typically, if **which & ios_base::in** is nonzero, the input stream is affected, and if **which & ios_base::out** is nonzero, the output stream is affected. Actual use of this parameter varies among derived stream buffers, however.

If the function succeeds in altering the stream position or positions, it returns the resulting stream position or one of the resulting stream positions. Otherwise, it returns an invalid stream position. The default behavior is to return an invalid stream position.

basic_streambuf::seekpos

A protected virtual member function that tries to alter the current positions for the controlled streams.

```
virtual pos_type seekpos(pos_type _Sp, ios_base::openmode _Which = ios_base::in | ios_base::out);
```

Parameters

_Sp

The position to seek for.

_Which

Specifies the mode for the pointer position. The default is to allow you to modify the read and write positions.

Return Value

The new position, or an invalid stream position. To determine if the stream position is invalid, compare the return value with `pos_type(off_type(-1))`.

Remarks

The new position is `_Sp`.

Typically, if **which & ios_base::in** is nonzero, the input stream is affected, and if **which & ios_base::out** is nonzero, the output stream is affected. Actual use of this parameter varies among derived stream buffers, however.

If the function succeeds in altering the stream position or positions, it returns the resulting stream position or one of the resulting stream positions. Otherwise, it returns an invalid stream position (-1). The default behavior is to return an invalid stream position.

basic_streambuf::setbuf

A protected virtual member function that performs an operation particular to each derived stream buffer.

```
virtual basic_streambuf<Elem, Tr> *setbuf(
    char_type* _Buffer,
    streamsize count);
```

Parameters

_Buffer

Pointer to a buffer.

count

Size of the buffer.

Return Value

The default behavior is to return **this**.

Remarks

See [basic_filebuf](#). `setbuf` provides an area of memory for the `streambuf` object to use. How the buffer is used in defined in the derived classes.

basic_streambuf::setg

A protected function that stores *_Gbeg* in the beginning pointer, `_Gnext` in the next pointer, and `_Gend` in the end pointer for the input buffer.

```
void setg(char_type* _Gbeg,
    char_type* _Gnext,
    char_type* _Gend);
```

Parameters

_Gbeg

A pointer to the beginning of the buffer.

_Gnext

A pointer to somewhere in the middle of the buffer.

_Gend

A pointer to the end of the buffer.

basic_streambuf::setp

A protected function that stores *_Pbeg* in the beginning pointer and *_Pend* in the end pointer for the output buffer.

```
void setp(char_type* _Pbeg, char_type* _Pend);
```

Parameters

_Pbeg

A pointer to the beginning of the buffer.

_Pend

A pointer to the end of the buffer.

basic_streambuf::sgetc

Returns current element without changing position in the stream.

```
int_type sgetc();
```

Return Value

The current element.

Remarks

If a read position is available, the member function returns **traits_type::to_int_type**(`*gptr`). Otherwise, it returns [underflow](#).

Example

```
// basic_streambuf_sgetc.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main( )
{
    using namespace std;
    ifstream myfile( "basic_streambuf_sgetc.txt", ios::in );

    char i = myfile.rdbuf( )->sgetc( );
    cout << i << endl;
    i = myfile.rdbuf( )->sgetc( );
    cout << i << endl;
}
```

basic_streambuf::sgetn

Extracts up to *count* characters from the input buffer and stores them in the provided buffer *ptr*.

This method is potentially unsafe, as it relies on the caller to check that the passed values are correct.

```
streamsize sgetn(
    char_type* ptr,
    streamsize count);
```

Parameters

ptr

The buffer to contain the extracted characters.

count

The number of elements to read.

Return Value

The number of elements read. See [streamsize](#) for more information.

Remarks

The member function returns [xsgetn](#)(`ptr`, `count`).

Example

```

// basic_streambuf_sgetn.cpp
// compile with: /EHsc /W3
#include <iostream>
#include <fstream>

int main()
{
    using namespace std;

    ifstream myfile("basic_streambuf_sgetn.txt", ios::in);
    char a[10];

    // Extract 3 characters from myfile and store them in a.
    streamsize i = myfile.rdbuf()->sgetn(&a[0], 3); // C4996
    a[i] = myfile.widen('\0');

    // Display the size and contents of the buffer passed to sgetn.
    cout << i << " " << a << endl;

    // Display the contents of the original input buffer.
    cout << myfile.rdbuf() << endl;
}

```

basic_streambuf::showmanyc

A protected virtual member function that returns a count of the number of characters that can be extracted from the input stream and ensure that the program will not be subject to an indefinite wait.

```
virtual streamsize showmanyc();
```

Return Value

The default behavior is to return zero.

basic_streambuf::snextc

Reads the current element and returns the following element.

```
int_type snextc();
```

Return Value

The next element in the stream.

Remarks

The member function calls [sbumpc](#) and, if that function returns **traits_type::eof**, returns **traits_type::eof**. Otherwise, it returns [sgetc](#).

Example

```
// basic_streambuf_snextc.cpp
// compile with: /EHsc
#include <iostream>
int main( )
{
    using namespace std;
    int i = 0;
    i = cin.rdbuf( )->snextc( );
    // cout << ( int )char_traits<char>::eof << endl;
    cout << i << endl;
}
```

aa

aa97

basic_streambuf::sputbackc

Puts a `char_type` in the stream.

```
int_type sputbackc(char_type _Ch);
```

Parameters

_Ch

The character.

Return Value

Returns the character or failure.

Remarks

If a putback position is available and *_Ch* compares equal to the character stored in that position, the member function decrements the next pointer for the input buffer and returns **traits_type::to_int_type**(`_Ch`). Otherwise, it returns **backfail**(`_Ch`).

Example

```
// basic_streambuf_sputbackc.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main( )
{
    using namespace std;

    ifstream myfile("basic_streambuf_sputbackc.txt",
        ios::in);

    int i = myfile.rdbuf()->sgetc();
    cout << (char)i << endl;
    int j = myfile.rdbuf()->sputbackc('z');
    if (j == 'z')
    {
        cout << "it worked" << endl;
    }
    i = myfile.rdbuf()->sgetc();
    cout << (char)i << endl;
}
```

basic_streambuf::sputc

Puts a character into the stream.

```
int_type sputc(char_type _Ch);
```

Parameters

_Ch

The character.

Return Value

Returns the character, if successful.

Remarks

If a `write position` is available, the member function stores *_Ch* in the write position, increments the next pointer for the output buffer, and returns **traits_type::to_int_type**(`_ch`). Otherwise, it returns `overflow`(`_ch`).

Example

```
// basic_streambuf_sputc.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main( )
{
    using namespace std;

    int i = cout.rdbuf( )->sputc( 'a' );
    cout << endl << ( char )i << endl;
}
```

```
a
a
```

basic_streambuf::sputn

Puts a character string into the stream.

```
streamsize sputn(const char_type* ptr, streamsize count);
```

Parameters

ptr

The character string.

count

The count of characters.

Return Value

The number of characters actually inserted into the stream.

Remarks

The member function returns [xsputn](#)(`ptr`, `count`). See the Remarks section of this member for more information.

Example

```
// basic_streambuf_sputn.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main()
{
    using namespace std;

    streamsize i = cout.rdbuf()->sputn("test", 4);
    cout << endl << i << endl;
}
```

```
test
4
```

basic_streambuf::stossc

Move past the current element in the stream.

```
void stossc();
```

Remarks

The member function calls [sbumpc](#). Note that an implementation is not required to supply this member function.

Example

```
// basic_streambuf_stossc.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main( )
{
    using namespace std;
    ifstream myfile( "basic_streambuf_stossc.txt", ios::in );

    myfile.rdbuf( )->stossc( );
    char i = myfile.rdbuf( )->sgetc( );
    cout << i << endl;
}
```

basic_streambuf::sungetc

Gets a character from the stream.

```
int_type sungetc();
```

Return Value

Returns either the character or failure.

Remarks

If a putback position is available, the member function decrements the next pointer for the input buffer and returns `traits_type::to_int_type(*gptr)`. However, it is not always possible to determine the last character read so that it can be captured in the state of the current buffer. If this is true, then the function returns `ebackfail`. To avoid this situation, keep track of the character to put back and call `sputbackc(ch)`, which will not fail provided you don't call it at the beginning of the stream and you don't try to put back more than one character.

Example

```

// basic_streambuf_sungetc.cpp
// compile with: /EHsc
#include <iostream>
#include <fstream>

int main( )
{
    using namespace std;

    ifstream myfile( "basic_streambuf_sungetc.txt", ios::in );

    // Read and increment
    int i = myfile.rdbuf( )->sgetc( );
    cout << ( char )i << endl;

    // Read and increment
    i = myfile.rdbuf( )->sgetc( );
    cout << ( char )i << endl;

    // Decrement, read, and do not increment
    i = myfile.rdbuf( )->sgetc( );
    cout << ( char )i << endl;

    i = myfile.rdbuf( )->sgetc( );
    cout << ( char )i << endl;

    i = myfile.rdbuf( )->sgetc( );
    cout << ( char )i << endl;
}

```

basic_streambuf::swap

Exchanges the values in this object for the values in the provided `basic_streambuf` object.

```
void swap(basic_streambuf& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	An lvalue reference to the <code>basic_streambuf</code> object that is used to exchange values.

Remarks

The protected member function exchanges with *right* all the pointers controlling the `input buffer` and the `output buffer`. It also exchanges `right.getloc()` with the `locale` object.

basic_streambuf::sync

A protected virtual function that tries to synchronize the controlled streams with any associated external streams.

```
virtual int sync();
```

Return Value

If the function cannot succeed, it returns -1. The default behavior is to return zero.

Remarks

`sync` involves writing out any elements between the beginning and next pointers for the output buffer. It does not involve putting back any elements between the next and end pointers for the input buffer.

basic_streambuf::traits_type

Associates a type name with the **Tr** template parameter.

```
typedef Tr traits_type;
```

basic_streambuf::uflow

A protected virtual function that extracts the current element from the input stream.

```
virtual int_type uflow();
```

Return Value

The current element.

Remarks

The protected virtual member function tries to extract the current element **ch** from the input stream, then advance the current stream position, and return the element as **traits_type::to_int_type(ch)**. It can do so in various ways:

- If a read position is available, it takes **ch** as the element stored in the read position and advances the next pointer for the input buffer.
- It can read an element directly, from some external source, and deliver it as the value **ch**.
- For a stream buffer with common input and output streams, it can make a read position available by writing out, to some external destination, some or all of the elements between the beginning and next pointers for the output buffer. Or it can allocate new or additional storage for the input buffer. The function then reads in, from some external source, one or more elements.

If the function cannot succeed, it returns **traits_type::eof**, or throws an exception. Otherwise, it returns the current element `ch` in the input stream, converted as described above, and advances the next pointer for the input buffer. The default behavior is to call `underflow` and, if that function returns **traits_type::eof**, to return **traits_type::eof**. Otherwise, the function returns the current element **ch** in the input stream, converted as previously described, and advances the next pointer for the input buffer.

basic_streambuf::underflow

Protected, virtual function to extract the current element from the input stream.

```
virtual int_type underflow();
```

Return Value

The current element.

Remarks

The protected virtual member function endeavors to extract the current element **ch** from the input stream, without advancing the current stream position, and return it as `traits_type::to_int_type(ch)`. It can do so in

various ways:

- If a read position is available, **ch** is the element stored in the read position. For more information on this, see the Remarks section of the [basic_streambuf Class](#).
- It can make a read position available by allocating new or additional storage for the input buffer, then reading in, from some external source, one or more elements. For more information on this, see the Remarks section of the [basic_streambuf Class](#).

If the function cannot succeed, it returns `traits_type::eof()` or throws an exception. Otherwise, it returns the current element in the input stream, converted as previously described. The default behavior is to return `traits_type::eof()`.

The virtual `underflow` function, with the [sync](#) and [overflow](#) functions, defines the characteristics of the `streambuf`-derived class. Each derived class might implement `underflow` differently, but the interface with the calling stream class is the same.

The `underflow` function is most frequently called by public `streambuf` functions like [sgetc](#) and [sgetn](#) when the get area is empty, but other classes, including the stream classes, can call `underflow` anytime.

The `underflow` function supplies the get area with characters from the input source. If the get area contains characters, `underflow` returns the first character. If the get area is empty, it fills the get area and returns the next character (which it leaves in the get area). If there are no more characters available, then `underflow` returns `EOF` and leaves the get area empty.

In the `strstreambuf` class, `underflow` adjusts the [egptr](#) pointer to access storage that was dynamically allocated by a call to `overflow`.

basic_streambuf::xsgetn

Protected, virtual function to extract elements from the input stream.

This method is potentially unsafe, as it relies on the caller to check that the passed values are correct.

```
virtual streamsize xsgetn(  
    char_type* ptr,  
    streamsize count);
```

Parameters

ptr

The buffer to contain the extracted characters.

count

The number of elements to extract.

Return Value

The number of elements extracted.

Remarks

The protected virtual member function extracts up to *count* elements from the input stream, as if by repeated calls to [sbumpc](#), and stores them in the array beginning at *ptr*. It returns the number of elements actually extracted.

basic_streambuf::xsputn

Protected, virtual function to insert elements into the output stream.

```
virtual streamsize xspn(const char_type* ptr, streamsize count);
```

Parameters

ptr

Pointer to elements to insert.

count

Number of elements to insert.

Return Value

The number of elements actually inserted into the stream.

Remarks

The protected virtual member function inserts up to *count* elements into the output stream, as if by repeated calls to [sputc](#), from the array beginning at *ptr*. The insertion of characters into the output stream stops once all *count* characters have been written, or if calling `sputc(count)` would return `traits::eof()`. It returns the number of elements actually inserted.

<string>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template class `basic_string` and various supporting templates.

For more information about `basic_string`, see [basic_string Class](#)

Syntax

```
#include <string>
```

Remarks

The C++ language and the C++ Standard Library support two types of strings:

- Null-terminated character arrays often referred to as C strings.
- Template class objects, of type `basic_string`, that handle all **char**-like template arguments.

Typedefs

TYPE NAME	DESCRIPTION
<code>string</code>	A type that describes a specialization of the template class <code>basic_string</code> with elements of type char as a <code>string</code> .
<code>wstring</code>	A type that describes a specialization of the template class <code>basic_string</code> with elements of type wchar_t as a <code>wstring</code> .
<code>u16string</code>	A type that describes a specialization of the template class <code>basic_string</code> based on elements of type <code>char16_t</code> .
<code>u32string</code>	A type that describes a specialization of the template class <code>basic_string</code> based on elements of type <code>char32_t</code> .

Operators

OPERATOR	DESCRIPTION
<code>operator+</code>	Concatenates two string objects.
<code>operator!=</code>	Tests if the string object on the left side of the operator is not equal to the string object on the right side.
<code>operator==</code>	Tests if the string object on the left side of the operator is equal to the string object on the right side.
<code>operator<</code>	Tests if the string object on the left side of the operator is less than to the string object on the right side.

OPERATOR	DESCRIPTION
<code>operator<=</code>	Tests if the string object on the left side of the operator is less than or equal to the string object on the right side.
<code>operator<<</code>	A template function that inserts a string into the output stream.
<code>operator></code>	Tests if the string object on the left side of the operator is greater than to the string object on the right side.
<code>operator>=</code>	Tests if the string object on the left side of the operator is greater than or equal to the string object on the right side.
<code>operator>></code>	A template function that extracts a string from the input stream.

Specialized Template Functions

<code>swap</code>	Exchanges the arrays of characters of two strings.
<code>stod</code>	Converts a character sequence to a double .
<code>stof</code>	Converts a character sequence to a float .
<code>stoi</code>	Converts a character sequence to an integer.
<code>stold</code>	Converts a character sequence to a long double .
<code>stoll</code>	Converts a character sequence to a long long .
<code>stoul</code>	Converts a character sequence to an unsigned long .
<code>stoull</code>	Converts a character sequence to an unsigned long long .
<code>to_string</code>	Converts a value to a <code>string</code> .
<code>to_wstring</code>	Converts a value to a wide <code>string</code> .

Functions

FUNCTION	DESCRIPTION
<code>getline Template</code>	Extract strings from the input stream line by line.

Classes

CLASS	DESCRIPTION
<code>basic_string Class</code>	A template class that describes objects that can store a sequence of arbitrary character-like objects.

CLASS	DESCRIPTION
char_traits Struct	A template class that describes attributes associated with a character of type CharType

Specializations

char_traits<char> Struct	A struct that is a specialization of the template struct <code>char_traits<CharType></code> to an element of type <code>char</code> .
char_traits<wchar_t> Struct	A struct that is a specialization of the template struct <code>char_traits<CharType></code> to an element of type <code>wchar_t</code> .
char_traits<char16_t> Struct	A struct that is a specialization of the template struct <code>char_traits<CharType></code> to an element of type <code>char16_t</code> .
char_traits<char32_t> Struct	A struct that is a specialization of the template struct <code>char_traits<CharType></code> to an element of type <code>char32_t</code> .

Requirements

- **Header:** `<string>`
- **Namespace:** `std`

<string> functions

11/9/2018 • 11 minutes to read • [Edit Online](#)

getline	stod	stof
stoi	stol	stold
stoll	stoul	stoull
swap	to_string	to_wstring

getline

Extract strings from the input stream line-by-line.

```
// (1) delimiter as parameter
template <class CharType, class Traits, class Allocator>
basic_istream<CharType, Traits>& getline(
    basic_istream<CharType, Traits>& is,
    basic_string<CharType, Traits, Allocator>& str,
    CharType delim);

template <class CharType, class Traits, class Allocator>
basic_istream<CharType, Traits>& getline(
    basic_istream<CharType, Traits>&& is,
    basic_string<CharType, Traits, Allocator>& str,
    const CharType delim);

// (2) default delimiter used
template <class CharType, class Traits, class Allocator>
basic_istream<CharType, Traits>& getline(
    basic_istream<CharType, Traits>& is,
    basic_string<CharType, Traits, Allocator>& str);

template <class Allocator, class Traits, class Allocator>
basic_istream<Allocator, Traits>& getline(
    basic_istream<Allocator, Traits>&& is,
    basic_string<Allocator, Traits, Allocator>& str);
```

Parameters

is

The input stream from which a string is to be extracted.

str

The string into which are read the characters from the input stream.

delim

The line delimiter.

Return Value

The input stream *is*.

Remarks

The pair of function signatures marked (1) extract characters from *is* until *delim* is found, storing them in *str*.

The pair of function signatures marked (2) use newline as the default line delimiter and behave as `getline(is, str, is.widen('\n'))`.

The second function of each pair is an analog to the first one to support [rvalue references](#).

Extraction stops when one of the following occurs:

- At end-of-file, in which case the internal state flag of *is* is set to `ios_base::eofbit`.
- After the function extracts an element that compares equal to `delim`, in which case the element is neither put back nor appended to the controlled sequence.
- After the function extracts `str.max_size` elements, in which case the internal state flag of *is* is set to `ios_base::failbit`.
- Some other error other than those previously listed, in which case the internal state flag of *is* is set to `ios_base::badbit`.

For information about internal state flags, see [ios_base::iostate](#).

If the function extracts no elements, the internal state flag of *is* is set to `ios_base::failbit`. In any case, `getline` returns *is*.

If an exception is thrown, *is* and *str* are left in a valid state.

Example

The following code demonstrates `getline()` in two modes: first with the default delimiter (newline) and second with a whitespace as delimiter. The end-of-file character (CTRL-Z on the keyboard) is used to control termination of the while loops. This sets the internal state flag of `cin` to `eofbit`, which must be cleared with [basic_ios::clear\(\)](#) before the second while loop will work properly.

```

// compile with: /EHsc /W4
#include <string>
#include <iostream>
#include <vector>

using namespace std;

int main()
{
    string str;
    vector<string> v1;
    cout << "Enter a sentence, press ENTER between sentences. (Ctrl-Z to stop): " << endl;
    // Loop until end-of-file (Ctrl-Z) is input, store each sentence in a vector.
    // Default delimiter is the newline character.
    while (getline(cin, str)) {
        v1.push_back(str);
    }

    cout << "The following input was stored with newline delimiter:" << endl;
    for (const auto& p : v1) {
        cout << p << endl;
    }

    cin.clear();

    vector<string> v2;
    // Now try it with a whitespace delimiter
    while (getline(cin, str, ' ')) {
        v2.push_back(str);
    }

    cout << "The following input was stored with whitespace as delimiter:" << endl;
    for (const auto& p : v2) {
        cout << p << endl;
    }
}

```

stod

Converts a character sequence to a **double**.

```

double stod(
    const string& str,
    size_t* idx = 0);

double stod(
    const wstring& str,
    size_t* idx = 0
);

```

Parameters

PARAMETER	DESCRIPTION
<i>str</i>	The character sequence to be converted.
<i>idx</i>	The index value of the first unconverted character.

Return Value

The **double** value.

Remarks

The function converts the sequence of elements in *str* to a value `val` of type **double** as if by calling `strtod(str.c_str(), _Eptr)`, where `_Eptr` is an object internal to the function. If `str.c_str() == *_Eptr` it throws an object of type `invalid_argument`. If such a call would set `errno`, it throws an object of type `out_of_range`. Otherwise, if *idx* is not a null pointer, the function stores `*_Eptr - str.c_str()` in `*idx` and returns `val`.

stof

Converts a character sequence to a float.

```
float stof(
    const string& str,
    size_t* idx = 0);

float stof(
    const wstring& str,
    size_t* idx = 0);
```

Parameters

PARAMETER	DESCRIPTION
<i>str</i>	The character sequence to be converted.
<i>idx</i>	The index value of the first unconverted character.

Return Value

The float value.

Remarks

The function converts the sequence of elements in *str* to a value `val` of type **float** as if by calling `strtof(str.c_str(), _Eptr)`, where `_Eptr` is an object internal to the function. If `str.c_str() == *_Eptr` it throws an object of type `invalid_argument`. If such a call would set `errno`, it throws an object of type `out_of_range`. Otherwise, if *idx* is not a null pointer, the function stores `*_Eptr - str.c_str()` in `*idx` and returns `val`.

stoi

Converts a character sequence to an integer.

```
int stoi(
    const string& str,
    size_t* idx = 0,
    int base = 10);

int stoi(
    const wstring& str,
    size_t* idx = 0,
    int base = 10);
```

Return Value

The integer value.

Parameters

PARAMETER	DESCRIPTION
<i>str</i>	The character sequence to be converted.
<i>idx</i>	Contains the index of the first unconverted character on return.
<i>base</i>	The number base to use.

Remarks

The function `stoi` converts the sequence of characters in *str* to a value of type **int** and returns the value. For example, when passed a character sequence "10", the value returned by `stoi` is the integer 10.

`stoi` behaves similarly to the function `strtol` for single-byte characters when it is called in the manner `strtol(str.c_str(), _Eptr, idx)`, where `_Eptr` is an object internal to the function; or `wcstol` for wide characters, when it is called in similar manner, `wcstol(Str.c_str(), _Eptr, idx)`. For more information, see [strtol](#), [wcstol](#), [_strtol_l](#), [_wcstol_l](#).

If `str.c_str() == *_Eptr`, `stoi` throws an object of type `invalid_argument`. If such a call would set `errno`, or if the returned value cannot be represented as an object of type **int**, it throws an object of type `out_of_range`. Otherwise, if *idx* is not a null pointer, the function stores `*_Eptr - str.c_str()` in `*idx`.

stol

Converts a character sequence to a **long**.

```
long stol(
    const string& str,
    size_t* idx = 0,
    int base = 10);

long stol(
    const wstring& str,
    size_t* idx = 0,
    int base = 10);
```

Parameters

PARAMETER	DESCRIPTION
<i>str</i>	The character sequence to be converted.
<i>idx</i>	The index value of the first unconverted character.
<i>base</i>	The number base to use.

Return Value

The long-integer value.

Remarks

The function converts the sequence of elements in *str* to a value `val` of type **long** as if by calling `strtol(str.c_str(), _Eptr, idx)`, where `_Eptr` is an object internal to the function. If `str.c_str() == *_Eptr` it throws an object of type `invalid_argument`. If such a call would set `errno`, it throws an object of type `out_of_range`. Otherwise, if *idx* is not a null pointer, the function stores `*_Eptr - str.c_str()` in `*idx` and returns `val`.

stold

Converts a character sequence to a **long double**.

```
double stold(
    const string& str,
    size_t* idx = 0);

double stold(
    const wstring& str,
    size_t* idx = 0);
```

Parameters

PARAMETER	DESCRIPTION
<i>str</i>	The character sequence to be converted.
<i>idx</i>	The index value of the first unconverted character.

Return Value

The **long double** value.

Remarks

The function converts the sequence of elements in *str* to a value `val` of type **long double** as if by calling `strtold(str.c_str(), _Eptr)`, where `_Eptr` is an object internal to the function. If `str.c_str() == *_Eptr` it throws an object of type `invalid_argument`. If such a call would set `errno`, it throws an object of type `out_of_range`. Otherwise, if *idx* is not a null pointer, the function stores `*_Eptr - str.c_str()` in `*idx` and returns `val`.

stoll

Converts a character sequence to a **long long**.

```
long long stoll(
    const string& str,
    size_t* idx = 0,
    int base = 10);

long long stoll(
    const wstring& str,
    size_t* idx = 0,
    int base = 10);
```

Parameters

PARAMETER	DESCRIPTION
<i>str</i>	The character sequence to be converted.
<i>idx</i>	The index value of the first unconverted character.
<i>base</i>	The number base to use.

Return Value

The **long long** value.

Remarks

The function converts the sequence of elements in *str* to a value `val` of type **long long** as if by calling `strtoll(str.c_str(), _Eptr, idx)`, where `_Eptr` is an object internal to the function. If `str.c_str() == *_Eptr` it throws an object of type `invalid_argument`. If such a call would set `errno`, it throws an object of type `out_of_range`. Otherwise, if *idx* is not a null pointer, the function stores `*_Eptr - str.c_str()` in `*idx` and returns `val`.

stoul

Converts a character sequence to an unsigned long.

```
unsigned long stoul(
    const string& str,
    size_t* idx = 0,
    int base = 10);

unsigned long stoul(
    const wstring& str,
    size_t* idx = 0,
    int base = 10);
```

Parameters

PARAMETER	DESCRIPTION
<i>str</i>	The character sequence to be converted.
<i>idx</i>	The index value of the first unconverted character.
<i>base</i>	The number base to use.

Return Value

The unsigned long-integer value.

Remarks

The function converts the sequence of elements in *str* to a value `val` of type **unsigned long** as if by calling `strtoul(str.c_str(), _Eptr, idx)`, where `_Eptr` is an object internal to the function. If `str.c_str() == *_Eptr` it throws an object of type `invalid_argument`. If such a call would set `errno`, it throws an object of type `out_of_range`. Otherwise, if *idx* is not a null pointer, the function stores `*_Eptr - str.c_str()` in `*idx` and returns `val`.

stoull

Converts a character sequence to an **unsigned long long**.

```
unsigned long long stoull(
    const string& str,
    size_t* idx = 0,
    int base = 10);

unsigned long long stoull(
    const wstring& str,
    size_t* idx = 0,
    int base = 10);
```

Parameters

PARAMETER	DESCRIPTION
<i>str</i>	The character sequence to be converted.
<i>idx</i>	The index value of the first unconverted character.
<i>base</i>	The number base to use.

Return Value

The **unsigned long long** value.

Remarks

The function converts the sequence of elements in *str* to a value `val` of type **unsigned long long** as if by calling `strtoull(str.c_str(), _Eptr, idx)`, where `_Eptr` is an object internal to the function. If `str.c_str() == *_Eptr` it throws an object of type `invalid_argument`. If such a call would set `errno`, it throws an object of type `out_of_range`. Otherwise, if *idx* is not a null pointer, the function stores `*_Eptr - str.c_str()` in `*idx` and returns `val`.

swap

Exchanges the arrays of characters of two strings.

```
template <class Traits, class Allocator>
void swap(basic_string<CharType, Traits, Allocator>& left, basic_string<CharType, Traits, Allocator>& right);
```

Parameters

left

One string whose elements are to be swapped with those of another string.

right

The other string whose elements are to be swapped with the first string.

Remarks

The template function executes the specialized member function *left.swap(right)* for strings, which guarantees constant complexity.

Example

```
// string_swap.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    // Declaring an object of type basic_string<char>
    string s1 ( "Tweedledee" );
    string s2 ( "Tweedledum" );
    cout << "Before swapping string s1 and s2:" << endl;
    cout << "The basic_string s1 = " << s1 << "." << endl;
    cout << "The basic_string s2 = " << s2 << "." << endl;

    swap ( s1 , s2 );
    cout << "\nAfter swapping string s1 and s2:" << endl;
    cout << "The basic_string s1 = " << s1 << "." << endl;
    cout << "The basic_string s2 = " << s2 << "." << endl;
}
```

Before swapping string s1 and s2:
The basic_string s1 = Tweedledee.
The basic_string s2 = Tweedledum.

After swapping string s1 and s2:
The basic_string s1 = Tweedledum.
The basic_string s2 = Tweedledee.

to_string

Converts a value to a `string`.

```
string to_string(int Val);
string to_string(unsigned int Val);
string to_string(long Val);
string to_string(unsigned long Val);
string to_string(long long Val);
string to_string(unsigned long long Val);
string to_string(float Val);
string to_string(double Val);
string to_string(long double Val);
```

Parameters

PARAMETER	DESCRIPTION
<i>Val</i>	The value to be converted.

Return Value

The `string` that represents the value.

Remarks

The function converts *Val* to a sequence of elements stored in an array object `Buf` internal to the function as if by calling `sprintf(Buf, Fmt, Val)`, where `Fmt` is

- `"%d"` if `Val` has type **int**

- "%u" if Val has type **unsigned int**
- "%ld" if Val has type **long**
- "%lu" if Val has type **unsigned long**
- "%lld" if Val has type **long long**
- "%llu" if Val has type **unsigned long long**
- "%f" if Val has type **float** or **double**
- "%Lf" if Val has type **long double**

The function returns `string(Buf)` .

to_wstring

Converts a value to a wide string.

```
wstring to_wstring(int Val);
wstring to_wstring(unsigned int Val);
wstring to_wstring(long Val);
wstring to_wstring(unsigned long Val);
wstring to_wstring(long long Val);
wstring to_wstring(unsigned long long Val);
wstring to_wstring(float Val);
wstring to_wstring(double Val);
wstring to_wstring(long double Val);
```

Parameters

PARAMETER	DESCRIPTION
Val	The value to be converted.

Return Value

The wide string that represents the value.

Remarks

The function converts Val to a sequence of elements stored in an array object Buf internal to the function as if by calling `swprintf(Buf, Len, Fmt, Val)` , where Fmt is

- L"%d" if Val has type **int**
- L"%u" if Val has type **unsigned int**
- L"%ld" if Val has type **long**
- L"%lu" if Val has type **unsigned long**
- L"%lld" if Val has type **long long**
- L"%llu" if Val has type **unsigned long long**
- L"%f" if Val has type **float** or **double**
- L"%Lf" if Val has type **long double**

The function returns `wstring(Buf)` .

<string> operators

11/8/2018 • 18 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>></code>
<code>operator>=</code>	<code>operator<</code>	<code>operator<<</code>
<code>operator<=</code>	<code>operator+</code>	<code>operator==</code>

operator+

Concatenates two string objects.

```

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator> operator+(
    const basic_string<CharType, Traits, Allocator>& left,
    const basic_string<CharType, Traits, Allocator>& right);

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator> operator+(
    const basic_string<CharType, Traits, Allocator>& left,
    const CharType* right);

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator> operator+(
    const basic_string<CharType, Traits, Allocator>& left,
    const CharType right);

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator> operator+(
    const CharType* left,
    const basic_string<CharType, Traits, Allocator>& right);

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator> operator+(
    const CharType left,
    const basic_string<CharType, Traits, Allocator>& right);

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator>&& operator+(
    const basic_string<CharType, Traits, Allocator>& left,
    const basic_string<CharType, Traits, Allocator>&& right);

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator>&& operator+(
    const basic_string<CharType, Traits, Allocator>&& left,
    const basic_string<CharType, Traits, Allocator>& right);

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator>&& operator+(
    const basic_string<CharType, Traits, Allocator>&& left,
    const CharType* right);

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator>&& operator+(
    const basic_string<CharType, Traits, Allocator>&& left,
    CharType right);

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator>&& operator+(
    const CharType* left,
    const basic_string<CharType, Traits, Allocator>&& right);

template <class CharType, class Traits, class Allocator>
basic_string<CharType, Traits, Allocator>&& operator+(
    CharType left,
    const basic_string<CharType, Traits, Allocator>&& right);

```

Parameters

left

A C-style string or an object of type `basic_string` to be concatenated.

right

A C-style string or an object of type `basic_string` to be concatenated.

Return Value

The string that is the concatenation of the input strings.

Remarks

The functions each overload `operator+` to concatenate two objects of template class `basic_string Class`. All effectively return `basic_string< CharType, Traits, Allocator>(Left).append(right)`. For more information, see [append](#).

Example

```
// string_op_con.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    // Declaring an object of type basic_string<char>
    string s1 ( "anti" );
    string s2 ( "gravity" );
    cout << "The basic_string s1 = " << s1 << "." << endl;
    cout << "The basic_string s2 = " << s2 << "." << endl;

    // Declaring a C-style string
    char *s3 = "heroine";
    cout << "The C-style string s3 = " << s3 << "." << endl;

    // Declaring a character constant
    char c1 = '!';
    cout << "The character constant c1 = " << c1 << "." << endl;

    // First member function: concatenates an object
    // of type basic_string with an object of type basic_string
    string s12 = s1 + s2;
    cout << "The string concatenating s1 & s2 is: " << s12 << endl;

    // Second & fourth member functions: concatenate an object
    // of type basic_string with an object of C-style string type
    string s1s3 = s1 + s3;
    cout << "The string concatenating s1 & s3 is: " << s1s3 << endl;

    // Third & fifth member functions: concatenate an object
    // of type basic_string with a character constant
    string s1s3c1 = s1s3 + c1;
    cout << "The string concatenating s1 & s3 is: " << s1s3c1 << endl;
}
```

```
The basic_string s1 = anti.
The basic_string s2 = gravity.
The C-style string s3 = heroine.
The character constant c1 = !.
The string concatenating s1 & s2 is: antigravity
The string concatenating s1 & s3 is: antiheroine
The string concatenating s1 & s3 is: antiheroine!
```

operator!=

Tests if the string object on the left side of the operator is not equal to the string object on the right side.

```
template <class CharType, class Traits, class Allocator>
bool operator!=(
    const basic_string<CharType, Traits, Allocator>& left,
    const basic_string<CharType, Traits, Allocator>& right);

template <class CharType, class Traits, class Allocator>
bool operator!=(
    const basic_string<CharType, Traits, Allocator>& left,
    const CharType* right);

template <class CharType, class Traits, class Allocator>
bool operator!=(
    const CharType* left,
    const basic_string<CharType, Traits, Allocator>& right);
```

Parameters

left

A C-style string or an object of type `basic_string` to be compared.

right

A C-style string or an object of type `basic_string` to be compared.

Return Value

true if the string object on the left side of the operator is not lexicographically equal to the string object on the right side; otherwise **false**.

Remarks

The comparison between string objects is based on a pairwise lexicographical comparison of their characters. Two strings are equal if they have the same number of characters and their respective character values are the same. Otherwise, they are unequal.

Example

```

// string_op_ne.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // Declaring an objects of type basic_string<char>
    string s1 ( "pluck" );
    string s2 ( "strum" );
    cout << "The basic_string s1 = " << s1 << "." << endl;
    cout << "The basic_string s2 = " << s2 << "." << endl;

    // Declaring a C-style string
    char *s3 = "pluck";
    cout << "The C-style string s3 = " << s3 << "." << endl;

    // First member function: comparison between left-side object
    // of type basic_string & right-side object of type basic_string
    if ( s1 != s2 )
        cout << "The strings s1 & s2 are not equal." << endl;
    else
        cout << "The strings s1 & s2 are equal." << endl;

    // Second member function: comparison between left-side object
    // of type basic_string & right-side object of C-syle string type
    if ( s1 != s3 )
        cout << "The strings s1 & s3 are not equal." << endl;
    else
        cout << "The strings s1 & s3 are equal." << endl;

    // Third member function: comparison between left-side object
    // of C-syle string type & right-side object of type basic_string
    if ( s3 != s2 )
        cout << "The strings s3 & s2 are not equal." << endl;
    else
        cout << "The strings s3 & s2 are equal." << endl;
}

```

```

The basic_string s1 = pluck.
The basic_string s2 = strum.
The C-style string s3 = pluck.
The strings s1 & s2 are not equal.
The strings s1 & s3 are equal.
The strings s3 & s2 are not equal.

```

operator==

Tests if the string object on the left side of the operator is equal to the string object on the right side.

```
template <class CharType, class Traits, class Allocator>
bool operator==(
    const basic_string<CharType, Traits, Allocator>& left,
    const basic_string<CharType, Traits, Allocator>& right);

template <class CharType, class Traits, class Allocator>
bool operator==(
    const basic_string<CharType, Traits, Allocator>& left,
    const CharType* right);

template <class CharType, class Traits, class Allocator>
bool operator==(
    const CharType* left,
    const basic_string<CharType, Traits, Allocator>& right);
```

Parameters

left

A C-style string or an object of type `basic_string` to be compared.

right

A C-style string or an object of type `basic_string` to be compared.

Return Value

true if the string object on the left side of the operator is lexicographically equal to the string object on the right side; otherwise **false**.

Remarks

The comparison between string objects is based on a pairwise lexicographical comparison of their characters. Two strings are equal if they have the same number of characters and their respective character values are the same. Otherwise, they are unequal.

Example

```

// string_op_eq.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // Declaring an objects of type basic_string<char>
    string s1 ( "pluck" );
    string s2 ( "strum" );
    cout << "The basic_string s1 = " << s1 << "." << endl;
    cout << "The basic_string s2 = " << s2 << "." << endl;

    // Declaring a C-style string
    char *s3 = "pluck";
    cout << "The C-style string s3 = " << s3 << "." << endl;

    // First member function: comparison between left-side object
    // of type basic_string & right-side object of type basic_string
    if ( s1 == s2 )
        cout << "The strings s1 & s2 are equal." << endl;
    else
        cout << "The strings s1 & s2 are not equal." << endl;

    // Second member function: comparison between left-side object
    // of type basic_string & right-side object of C-syle string type
    if ( s1 == s3 )
        cout << "The strings s1 & s3 are equal." << endl;
    else
        cout << "The strings s1 & s3 are not equal." << endl;

    // Third member function: comparison between left-side object
    // of C-syle string type & right-side object of type basic_string
    if ( s3 == s2 )
        cout << "The strings s3 & s2 are equal." << endl;
    else
        cout << "The strings s3 & s2 are not equal." << endl;
}

```

```

The basic_string s1 = pluck.
The basic_string s2 = strum.
The C-style string s3 = pluck.
The strings s1 & s2 are not equal.
The strings s1 & s3 are equal.
The strings s3 & s2 are not equal.

```

operator<

Tests if the string object on the left side of the operator is less than to the string object on the right side.

```

template <class CharType, class Traits, class Allocator>
bool operator<(
    const basic_string<CharType, Traits, Allocator>& left,
    const basic_string<CharType, Traits, Allocator>& right);

template <class CharType, class Traits, class Allocator>
bool operator<(
    const basic_string<CharType, Traits, Allocator>& left,
    const CharType* right);

template <class CharType, class Traits, class Allocator>
bool operator<(
    const CharType* left,
    const basic_string<CharType, Traits, Allocator>& right);

```

Parameters

left

A C-style string or an object of type `basic_string` to be compared.

right

A C-style string or an object of type `basic_string` to be compared.

Return Value

true if the string object on the left side of the operator is lexicographically less than the string object on the right side; otherwise **false**.

Remarks

A lexicographical comparison between strings compares them character by character until:

- It finds two corresponding characters unequal, and the result of their comparison is taken as the result of the comparison between the strings.
- It finds no inequalities, but one string has more characters than the other, and the shorter string is considered less than the longer string.
- It finds no inequalities and finds that the strings have the same number of characters, and so the strings are equal.

Example

```

// string_op_lt.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    // Declaring an objects of type basic_string<char>
    string s1 ( "strict" );
    string s2 ( "strum" );
    cout << "The basic_string s1 = " << s1 << "." << endl;
    cout << "The basic_string s2 = " << s2 << "." << endl;

    // Declaring a C-style string
    char *s3 = "strict";
    cout << "The C-style string s3 = " << s3 << "." << endl;

    // First member function: comparison between left-side object
    // of type basic_string & right-side object of type basic_string
    if ( s1 < s2 )
        cout << "The string s1 is less than the string s2." << endl;
    else
        cout << "The string s1 is not less than the string s2." << endl;

    // Second member function: comparison between left-hand object
    // of type basic_string & right-hand object of C-syle string type
    if ( s1 < s3 )
        cout << "The string s1 is less than the string s3." << endl;
    else
        cout << "The string s1 is not less than the string s3." << endl;

    // Third member function: comparison between left-hand object
    // of C-syle string type & right-hand object of type basic_string
    if ( s3 < s2 )
        cout << "The string s3 is less than the string s2." << endl;
    else
        cout << "The string s3 is not less than the string s2." << endl;
}

```

```

The basic_string s1 = strict.
The basic_string s2 = strum.
The C-style string s3 = strict.
The string s1 is less than the string s2.
The string s1 is not less than the string s3.
The string s3 is less than the string s2.

```

operator<=

Tests if the string object on the left side of the operator is less than or equal to the string object on the right side.

```
template <class CharType, class Traits, class Allocator>
bool operator<=(
    const basic_string<CharType, Traits, Allocator>& left,
    const basic_string<CharType, Traits, Allocator>& right);

template <class CharType, class Traits, class Allocator>
bool operator<=(
    const basic_string<CharType, Traits, Allocator>& left,
    const CharType* right);

template <class CharType, class Traits, class Allocator>
bool operator<=(
    const CharType* left,
    const basic_string<CharType, Traits, Allocator>& right);
```

Parameters

left

A C-style string or an object of type `basic_string` to be compared.

right

A C-style string or an object of type `basic_string` to be compared.

Return Value

true if the string object on the left side of the operator is lexicographically less than or equal to the string object on the right side; otherwise **false**.

Remarks

A lexicographical comparison between strings compares them character by character until:

- It finds two corresponding characters unequal, and the result of their comparison is taken as the result of the comparison between the strings.
- It finds no inequalities, but one string has more characters than the other, and the shorter string is considered less than the longer string.
- It finds no inequalities and finds that the strings have the same number of characters, so the strings are equal.

Example

```

// string_op_le.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // Declaring an objects of type basic_string<char>
    string s1 ( "strict" );
    string s2 ( "strum" );
    cout << "The basic_string s1 = " << s1 << "." << endl;
    cout << "The basic_string s2 = " << s2 << "." << endl;

    // Declaring a C-style string
    char *s3 = "strict";
    cout << "The C-style string s3 = " << s3 << "." << endl;

    // First member function: comparison between left-side object
    // of type basic_string & right-side object of type basic_string
    if ( s1 <= s2 )
        cout << "The string s1 is less than or equal to "
            << "the string s2." << endl;
    else
        cout << "The string s1 is greater than "
            << "the string s2." << endl;

    // Second member function: comparison between left-side object
    // of type basic_string & right-side object of C-syle string type
    if ( s1 <= s3 )
        cout << "The string s1 is less than or equal to "
            << "the string s3." << endl;
    else
        cout << "The string s1 is greater than "
            << "the string s3." << endl;

    // Third member function: comparison between left-side object
    // of C-syle string type & right-side object of type basic_string
    if ( s2 <= s3 )
        cout << "The string s2 is less than or equal to "
            << "the string s3." << endl;
    else
        cout << "The string s2 is greater than "
            << "the string s3." << endl;
}

```

```

The basic_string s1 = strict.
The basic_string s2 = strum.
The C-style string s3 = strict.
The string s1 is less than or equal to the string s2.
The string s1 is less than or equal to the string s3.
The string s2 is greater than the string s3.

```

operator<<

A template function that writes a string into the output stream.

```

template <class CharType, class Traits, class Allocator>
basic_ostream<CharType, Traits>& operator<<(
    basic_ostream<CharType, Traits>& _Ostr,
    const basic_string<CharType, Traits, Allocator>& str);

```

Parameters

_Ostr

The output stream being written to.

str

The string to be entered into the output stream.

Return Value

Writes the value of the specified string to the output stream *_Ostr*.

Remarks

The template function overloads **operator<<** to insert an object *str* of template class [basic_string](#) into the stream *_Ostr*. The function effectively returns `_Ostr.write(str.c_str, str.size)`.

operator>

Tests if the string object on the left side of the operator is greater than to the string object on the right side.

```
template <class CharType, class Traits, class Allocator>
bool operator>(  
    const basic_string<CharType, Traits, Allocator>& left,  
    const basic_string<CharType, Traits, Allocator>& right);  
  
template <class CharType, class Traits, class Allocator>  
bool operator>(  
    const basic_string<CharType, Traits, Allocator>& left,  
    const CharType* right);  
  
template <class CharType, class Traits, class Allocator>  
bool operator>(  
    const CharType* left,  
    const basic_string<CharType, Traits, Allocator>& right);
```

Parameters

left

A C-style string or an object of type `basic_string` to be compared.

right

A C-style string or an object of type `basic_string` to be compared.

Return Value

true if the string object on the left side of the operator is lexicographically greater than the string object on the right side; otherwise **false**.

Remarks

A lexicographical comparison between strings compares them character by character until:

- It finds two corresponding characters unequal, and the result of their comparison is taken as the result of the comparison between the strings.
- It finds no inequalities, but one string has more characters than the other, and the shorter string is considered less than the longer string.
- It finds no inequalities and finds that the strings have the same number of characters, and so the strings are equal.

Example

```

// string_op_gt.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // Declaring an objects of type basic_string<char>
    string s1 ( "strict" );
    string s2 ( "strum" );
    cout << "The basic_string s1 = " << s1 << "." << endl;
    cout << "The basic_string s2 = " << s2 << "." << endl;

    // Declaring a C-style string
    char *s3 = "stricture";
    cout << "The C-style string s3 = " << s3 << "." << endl;

    // First member function: comparison between left-side object
    // of type basic_string & right-side object of type basic_string
    if ( s1 > s2 )
        cout << "The string s1 is greater than "
            << "the string s2." << endl;
    else
        cout << "The string s1 is not greater than "
            << "the string s2." << endl;

    // Second member function: comparison between left-side object
    // of type basic_string & right-side object of C-syle string type
    if ( s3 > s1 )
        cout << "The string s3 is greater than "
            << "the string s1." << endl;
    else
        cout << "The string s3 is not greater than "
            << "the string s1." << endl;

    // Third member function: comparison between left-side object
    // of C-syle string type & right-side object of type basic_string
    if ( s2 > s3 )
        cout << "The string s2 is greater than "
            << "the string s3." << endl;
    else
        cout << "The string s2 is not greater than "
            << "the string s3." << endl;
}

```

```

The basic_string s1 = strict.
The basic_string s2 = strum.
The C-style string s3 = stricture.
The string s1 is not greater than the string s2.
The string s3 is greater than the string s1.
The string s2 is greater than the string s3.

```

operator>=

Tests if the string object on the left side of the operator is greater than or equal to the string object on the right side.

```

template <class CharType, class Traits, class Allocator>
bool operator>=(
    const basic_string<CharType, Traits, Allocator>& left,
    const basic_string<CharType, Traits, Allocator>& right);

template <class CharType, class Traits, class Allocator>
bool operator>=(
    const basic_string<CharType, Traits, Allocator>& left,
    const CharType* right);

template <class CharType, class Traits, class Allocator>
bool operator>=(
    const CharType* left,
    const basic_string<CharType, Traits, Allocator>& right);

```

Parameters

left

A C-style string or an object of type `basic_string` to be compared.

right

A C-style string or an object of type `basic_string` to be compared.

Return Value

true if the string object on the left side of the operator is lexicographically greater than or equal to the string object on the right side; otherwise **false**.

Remarks

A lexicographical comparison between strings compares them character by character until:

- It finds two corresponding characters unequal, and the result of their comparison is taken as the result of the comparison between the strings.
- It finds no inequalities, but one string has more characters than the other, and the shorter string is considered less than the longer string.
- It finds no inequalities and finds the strings have the same number of characters, and so the strings are equal.

Example

```

// string_op_ge.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // Declaring an objects of type basic_string<char>
    string s1 ( "strict" );
    string s2 ( "strum" );
    cout << "The basic_string s1 = " << s1 << "." << endl;
    cout << "The basic_string s2 = " << s2 << "." << endl;

    // Declaring a C-style string
    char *s3 = "stricture";
    cout << "The C-style string s3 = " << s3 << "." << endl;

    // First member function: comparison between left-side object
    // of type basic_string & right-side object of type basic_string
    if ( s1 >= s2 )
        cout << "The string s1 is greater than or equal to "
            << "the string s2." << endl;
    else
        cout << "The string s1 is less than "
            << "the string s2." << endl;

    // Second member function: comparison between left-side object
    // of type basic_string & right-side object of C-syle string type
    if ( s3 >= s1 )
        cout << "The string s3 is greater than or equal to "
            << "the string s1." << endl;
    else
        cout << "The string s3 is less than "
            << "the string s1." << endl;

    // Third member function: comparison between left-side object
    // of C-syle string type & right-side object of type basic_string
    if ( s2 >= s3 )
        cout << "The string s2 is greater than or equal to "
            << "the string s3." << endl;
    else
        cout << "The string s2 is less than "
            << "the string s3." << endl;
}

```

```

The basic_string s1 = strict.
The basic_string s2 = strum.
The C-style string s3 = stricture.
The string s1 is less than the string s2.
The string s3 is greater than or equal to the string s1.
The string s2 is greater than or equal to the string s3.

```

operator>>

A template function that reads a string from an input stream.

```

template <class CharType, class Traits, class Allocator>
basic_istream<CharType, Traits>& operator>>(
    basic_istream<CharType, Traits>& _Istr,
    basic_string<CharType, Traits, Allocator>& right);

```

Parameters

_Istr

The input stream used to extract the sequence

right

The string that is being extracted from the input stream.

Return Value

Reads the value of the specified string from *_Istr* and returns it into *right*.

Remarks

The operator skips the leading white spaces unless the `skipws` flag is set. It reads all the following characters until the next character is a white space or the end of the file is reached.

The template function overloads **operator>>** to replace the sequence controlled by *right* with a sequence of elements extracted from the stream *_Istr*. Extraction stops:

- At end of file.
- After the function extracts `_Istr.width` elements, if that value is nonzero.

After the function extracts `_Istr.max_size` elements.

- After the function extracts an element *ch* for which `use_facet<ctype< CharType>> (> (getloc)).is(ctype< CharType>::space, ch)` is true, in which case the character is put back.

If the function extracts no elements, it calls `setstate(ios_base::failbit)`. In any case, it calls `istr.width(0)` and returns `* this`.

Example

```
// string_op_read_.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    string c0;
    cout << "Input a string c0 ( try: Fibonacci numbers ): ";
    cin >> c0;
    cout << "The string entered is c0 = " << c0 << endl;
}
```

<string> typedefs

10/31/2018 • 2 minutes to read • [Edit Online](#)

string	u16string	u32string
wstring		

string

A type that describes a specialization of the template class [basic_string](#) with elements of type **char**.

Other typedefs that specialize `basic_string` include [wstring](#), [u16string](#), and [u32string](#).

```
typedef basic_string<char, char_traits<char>, allocator<char>> string;
```

Remarks

The following are equivalent declarations:

```
string str("");  
  
basic_string<char> str("");
```

For a list of string constructors, see [basic_string::basic_string](#).

u16string

A type that describes a specialization of the template class [basic_string](#) with elements of type `char16_t`.

Other typedefs that specialize `basic_string` include [wstring](#), [string](#), and [u32string](#).

```
typedef basic_string<char16_t, char_traits<char16_t>, allocator<char16_t>> u16string;
```

Remarks

For a list of string constructors, see [basic_string::basic_string](#).

u32string

A type that describes a specialization of the template class [basic_string](#) with elements of type `char32_t`.

Other typedefs that specialize `basic_string` include [string](#), [u16string](#), and [wstring](#).

```
typedef basic_string<char32_t, char_traits<char32_t>, allocator<char32_t>> u32string;
```

Remarks

For a list of string constructors, see [basic_string::basic_string](#).

wstring

A type that describes a specialization of the template class [basic_string](#) with elements of type **wchar_t**.

Other typedefs that specialize `basic_string` include [string](#), [u16string](#), and [u32string](#).

```
typedef basic_string<wchar_t, char_traits<wchar_t>, allocator<wchar_t>> wstring;
```

Remarks

The following are equivalent declarations:

```
wstring wstr(L "");  
  
basic_string<wchar_t> wstr(L "");
```

For a list of string constructors, see [basic_string::basic_string](#).

NOTE

The size of **wchar_t** is implementation-defined. If your code depends on **wchar_t** to be a certain size, check your platform's implementation (for example, with `sizeof(wchar_t)`). If you need a string character type with a width that is guaranteed to remain the same on all platforms, use [string](#), [u16string](#), or [u32string](#).

basic_string Class

10/31/2018 • 108 minutes to read • [Edit Online](#)

The sequences controlled by an object of template class `basic_string` are the Standard C++ string class and are usually referred to as strings, but they should not be confused with the null-terminated C-style strings used throughout the C++ Standard Library. The Standard C++ string is a container that enables the use of strings as normal types, such as comparison and concatenation operations, iterators, C++ Standard Library algorithms, and copying and assigning with class allocator managed memory. If you need to convert a Standard C++ string to a null-terminated C-style string, use the `basic_string::c_str` member.

Syntax

```
template <class CharType, class Traits = char_traits<CharType>, class Allocator = allocator<CharType>>
class basic_string;
```

Parameters

CharType

The data type of a single character to be stored in the string. The C++ Standard Library provides specializations of this template class, with the type definitions `string` for elements of type **char**, `wstring`, for **wchar_t**, `u16string` for `char16_t`, and `u32string` for `char32_t`.

Traits

Various important properties of the `CharType` elements in a `basic_string` specialization are described by the class `Traits`. The default value is `char_traits < CharType >`.

Allocator

The type that represents the stored allocator object that encapsulates details about the string's allocation and deallocation of memory. The default value is `allocator< CharType >`.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>basic_string</code>	Constructs a string that is empty or initialized by specific characters or that is a copy of all or part of some other string object or C-string.

Typedefs

TYPE NAME	DESCRIPTION
<code>allocator_type</code>	A type that represents the <code>allocator</code> class for a string object.
<code>const_iterator</code>	A type that provides a random-access iterator that can access and read a const element in the string.
<code>const_pointer</code>	A type that provides a pointer to a const element in a string.

TYPE NAME	DESCRIPTION
<code>const_reference</code>	A type that provides a reference to a const element stored in a string for reading and performing const operations.
<code>const_reverse_iterator</code>	A type that provides a random-access iterator that can read any const element in the string.
<code>difference_type</code>	A type that provides the difference between two iterators that refer to elements within the same string.
<code>iterator</code>	A type that provides a random-access iterator that can read or modify any element in a string.
<code>npos</code>	An unsigned integral value initialized to -1 that indicates either "not found" or "all remaining characters" when a search function fails.
<code>pointer</code>	A type that provides a pointer to a character element in a string or character array.
<code>reference</code>	A type that provides a reference to an element stored in a string.
<code>reverse_iterator</code>	A type that provides a random-access iterator that can read or modify an element in a reversed string.
<code>size_type</code>	An unsigned integral type for the number of elements in a string.
<code>traits_type</code>	A type for the character traits of the elements stored in a string.
<code>value_type</code>	A type that represents the type of characters stored in a string.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>append</code>	Adds characters to the end of a string.
<code>assign</code>	Assigns new character values to the contents of a string.
<code>at</code>	Returns a reference to the element at a specified location in the string.
<code>back</code>	
<code>begin</code>	Returns an iterator addressing the first element in the string.
<code>c_str</code>	Converts the contents of a string as a C-style, null-terminated, string.

MEMBER FUNCTION	DESCRIPTION
capacity	Returns the largest number of elements that could be stored in a string without increasing the memory allocation of the string.
cbegin	Returns a const iterator addressing the first element in the string.
cend	Returns a const iterator that addresses the location succeeding the last element in a string.
clear	Erases all elements of a string.
compare	Compares a string with a specified string to determine if the two strings are equal or if one is lexicographically less than the other.
copy	Copies at most a specified number of characters from an indexed position in a source string to a target character array. Deprecated. Use basic_string::_Copy_s instead.
crbegin	Returns a const iterator that addresses the first element in a reversed string.
crend	Returns a const iterator that addresses the location succeeding the last element in a reversed string.
_Copy_s	Copies at most a specified number of characters from an indexed position in a source string to a target character array.
data	Converts the contents of a string into an array of characters.
empty	Tests whether the string contains characters.
end	Returns an iterator that addresses the location succeeding the last element in a string.
erase	Removes an element or a range of elements in a string from a specified position.
find	Searches a string in a forward direction for the first occurrence of a substring that matches a specified sequence of characters.
find_first_not_of	Searches through a string for the first character that is not any element of a specified string.
find_first_of	Searches through a string for the first character that matches any element of a specified string.
find_last_not_of	Searches through a string for the last character that is not any element of a specified string.

MEMBER FUNCTION	DESCRIPTION
<code>find_last_of</code>	Searches through a string for the last character that is an element of a specified string.
<code>front</code>	Returns a reference to the first element in a string.
<code>get_allocator</code>	Returns a copy of the <code>allocator</code> object used to construct the string.
<code>insert</code>	Inserts an element or a number of elements or a range of elements into the string at a specified position.
<code>length</code>	Returns the current number of elements in a string.
<code>max_size</code>	Returns the maximum number of characters a string could contain.
<code>pop_back</code>	Erases the last element of the string.
<code>push_back</code>	Adds an element to the end of the string.
<code>rbegin</code>	Returns an iterator to the first element in a reversed string.
<code>rend</code>	Returns an iterator that points just beyond the last element in a reversed string.
<code>replace</code>	Replaces elements in a string at a specified position with specified characters or characters copied from other ranges or strings or C-strings.
<code>reserve</code>	Sets the capacity of the string to a number at least as great as a specified number.
<code>resize</code>	Specifies a new size for a string, appending or erasing elements as required.
<code>rfind</code>	Searches a string in a backward direction for the first occurrence of a substring that matches a specified sequence of characters.
<code>shrink_to_fit</code>	Discards the excess capacity of the string.
<code>size</code>	Returns the current number of elements in a string.
<code>substr</code>	Copies a substring of at most some number of characters from a string beginning from a specified position.
<code>swap</code>	Exchange the contents of two strings.

Operators

OPERATOR	DESCRIPTION
----------	-------------

OPERATOR	DESCRIPTION
<code>operator+=</code>	Appends characters to a string.
<code>operator=</code>	Assigns new character values to the contents of a string.
<code>operator[]</code>	Provides a reference to the character with a specified index in a string.

Remarks

If a function is asked to generate a sequence longer than `max_size` elements, the function reports a length error by throwing an object of type `length_error`.

References, pointers, and iterators that designate elements of the controlled sequence can become invalid after any call to a function that alters the controlled sequence, or after the first call to a non- **const** member function.

Requirements

Header: `<string>`

Namespace: `std`

`basic_string::allocator_type`

A type that represents the allocator class for a string object.

```
typedef Allocator allocator_type;
```

Remarks

The type is a synonym for the template parameter `Allocator`.

Example

```
// basic_string_allocator_type.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    // The following lines declare objects
    // that use the default allocator.
    string s1;
    basic_string<char>::allocator_type xchar = s1.get_allocator( );
    // You can now call functions on the allocator class xchar used by s1
}
```

`basic_string::append`

Adds characters to the end of a string.

```

basic_string<CharType, Traits, Allocator>& append(
    const value_type* ptr);

basic_string<CharType, Traits, Allocator>& append(
    const value_type* ptr,
    size_type count);

basic_string<CharType, Traits, Allocator>& append(
    const basic_string<CharType, Traits, Allocator>& str,
    size_type _Off,
    size_type count);

basic_string<CharType, Traits, Allocator>& append(
    const basic_string<CharType, Traits, Allocator>& str);

basic_string<CharType, Traits, Allocator>& append(
    size_type count,
    value_type _Ch);

template <class InputIterator>
basic_string<CharType, Traits, Allocator>& append(
    InputIterator first,
    InputIterator last);

basic_string<CharType, Traits, Allocator>& append(
    const_pointer first,
    const_pointer last);

basic_string<CharType, Traits, Allocator>& append(
    const_iterator first,
    const_iterator last);

```

Parameters

ptr

The C-string to be appended.

str

The string whose characters are to be appended.

_Off

The index of the part of the source string supplying the characters to be appended.

count

The number of characters to be appended, at most, from the source string.

_Ch

The character value to be appended.

first

An input iterator addressing the first element in the range to be appended.

last

An input iterator, `const_pointer`, or `const_iterator` addressing the position of the one beyond the last element in the range to be appended.

Return Value

A reference to the string object that is being appended with the characters passed by the member function.

Remarks

Characters may be appended to a string using the [operator+=](#) or the member functions `append` or `push_back`. `operator+=` appends single-argument values while the multiple-argument `append` member

function allows a specific part of a string to be specified for adding.

Example

```

// basic_string_append.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function
    // appending a C-string to a string
    string str1a ( "Hello " );
    cout << "The original string str1 is: " << str1a << endl;
    const char *cstr1a = "Out There ";
    cout << "The C-string cstr1a is: " << cstr1a << endl;
    str1a.append ( cstr1a );
    cout << "Appending the C-string cstr1a to string str1 gives: "
        << str1a << "." << endl << endl;

    // The second member function
    // appending part of a C-string to a string
    string str1b ( "Hello " );
    cout << "The string str1b is: " << str1b << endl;
    const char *cstr1b = "Out There ";
    cout << "The C-string cstr1b is: " << cstr1b << endl;
    str1b.append ( cstr1b , 3 );
    cout << "Appending the 1st part of the C-string cstr1b "
        << "to string str1 gives: " << str1b << "."
        << endl << endl;

    // The third member function
    // appending part of one string to another
    string str1c ( "Hello " ), str2c ( "Wide World " );
    cout << "The string str2c is: " << str2c << endl;
    str1c.append ( str2c , 5 , 5 );
    cout << "The appended string str1 is: "
        << str1c << "." << endl << endl;

    // The fourth member function
    // appending one string to another in two ways,
    // comparing append and operator [ ]
    string str1d ( "Hello " ), str2d ( "Wide " ), str3d ( "World " );
    cout << "The string str2d is: " << str2d << endl;
    str1d.append ( str2d );
    cout << "The appended string str1d is: "
        << str1d << "." << endl;
    str1d += str3d;
    cout << "The doubly appended string str1 is: "
        << str1d << "." << endl << endl;

    // The fifth member function
    // appending characters to a string
    string str1e ( "Hello " );
    str1e.append ( 4 , '!' );
    cout << "The string str1 appended with exclamations is: "
        << str1e << endl << endl;

    // The sixth member function
    // appending a range of one string to another
    string str1f ( "Hello " ), str2f ( "Wide World " );
    cout << "The string str2f is: " << str2f << endl;
    str1f.append ( str2f.begin ( ) + 5 , str2f.end ( ) - 1 );
    cout << "The appended string str1 is: "
        << str1f << "." << endl << endl;
}

```

```
The original string str1 is: Hello
The C-string cstr1a is: Out There
Appending the C-string cstr1a to string str1 gives: Hello Out There .

The string str1b is: Hello
The C-string cstr1b is: Out There
Appending the 1st part of the C-string cstr1b to string str1 gives: Hello Out.

The string str2c is: Wide World
The appended string str1 is: Hello World.

The string str2d is: Wide
The appended string str1d is: Hello Wide .
The doubly appended strig str1 is: Hello Wide World .

The string str1 appended with exclamations is: Hello !!!!

The string str2f is: Wide World
The appended string str1 is: Hello World.
```

basic_string::assign

Assigns new character values to the contents of a string.

```
basic_string<CharType, Traits, Allocator>& assign(
    const value_type* ptr);

basic_string<CharType, Traits, Allocator>& assign(
    const value_type* ptr,
    size_type count);

basic_string<CharType, Traits, Allocator>& assign(
    const basic_string<CharType, Traits, Allocator>& str,
    size_type off,
    size_type count);

basic_string<CharType, Traits, Allocator>& assign(
    const basic_string<CharType, Traits, Allocator>& str);

basic_string<CharType, Traits, Allocator>& assign(
    size_type count,
    value_type _Ch);

template <class InIt>
basic_string<CharType, Traits, Allocator>& assign(
    InputIterator first,
    InputIterator last);

basic_string<CharType, Traits, Allocator>& assign(
    const_pointer first,
    const_pointer last);

basic_string<CharType, Traits, Allocator>& assign(
    const_iterator first,
    const_iterator last);
```

Parameters

ptr

A pointer to the characters of the C-string to be assigned to the target string.

count

The number of characters to be assigned, from the source string.

str

The source string whose characters are to be assigned to the target string.

_Ch

The character value to be assigned.

first

An input iterator, `const_pointer`, or `const_iterator` addressing the first character in the range of the source string to be assigned to the target range.

last

An input iterator, `const_pointer`, or `const_iterator` addressing the one beyond the last character in the range of the source string to be assigned to the target range.

off

The position at which new characters will start to be assigned.

Return Value

A reference to the string object that is being assigned new characters by the member function.

Remarks

The strings can be assigned new character values. The new value can be either a string and C-string or a single character. The `operator=` may be used if the new value can be described by a single parameter; otherwise the member function `assign`, which has multiple parameters, can be used to specify which part of the string is to be assigned to a target string.

Example

```

// basic_string_assign.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function assigning the
    // characters of a C-string to a string
    string str1a;
    const char *cstr1a = "Out There";
    cout << "The C-string cstr1a is: " << cstr1a << "." << endl;
    str1a.assign ( cstr1a );
    cout << "Assigning the C-string cstr1a to string str1 gives: "
        << str1a << "." << endl << endl;

    // The second member function assigning a specific
    // number of the of characters a C-string to a string
    string str1b;
    const char *cstr1b = "Out There";
    cout << "The C-string cstr1b is: " << cstr1b << endl;
    str1b.assign ( cstr1b , 3 );
    cout << "Assigning the 1st part of the C-string cstr1b "
        << "to string str1 gives: " << str1b << "."
        << endl << endl;

    // The third member function assigning a specific number
    // of the characters from one string to another string
    string str1c ( "Hello " ), str2c ( "Wide World " );
    cout << "The string str2c is: " << str2c << endl;
    str1c.assign ( str2c , 5 , 5 );
    cout << "The newly assigned string str1 is: "
        << str1c << "." << endl << endl;

    // The fourth member function assigning the characters
    // from one string to another string in two equivalent
    // ways, comparing the assign and operator =
    string str1d ( "Hello" ), str2d ( "Wide" ), str3d ( "World" );
    cout << "The original string str1 is: " << str1d << "." << endl;
    cout << "The string str2d is: " << str2d << endl;
    str1d.assign ( str2d );
    cout << "The string str1 newly assigned with string str2d is: "
        << str1d << "." << endl;
    cout << "The string str3d is: " << str3d << "." << endl;
    str1d = str3d;
    cout << "The string str1 reassigned with string str3d is: "
        << str1d << "." << endl << endl;

    // The fifth member function assigning a specific
    // number of characters of a certain value to a string
    string str1e ( "Hello " );
    str1e.assign ( 4 , '!' );
    cout << "The string str1 assigned with exclamations is: "
        << str1e << endl << endl;

    // The sixth member function assigning the value from
    // the range of one string to another string
    string str1f ( "Hello " ), str2f ( "Wide World " );
    cout << "The string str2f is: " << str2f << endl;
    str1f.assign ( str2f.begin ( ) + 5 , str2f.end ( ) - 1 );
    cout << "The string str1 assigned a range of string str2f is: "
        << str1f << "." << endl << endl;
}

```

```
The C-string cstr1a is: Out There.
Assigning the C-string cstr1a to string str1 gives: Out There.

The C-string cstr1b is: Out There
Assigning the 1st part of the C-string cstr1b to string str1 gives: Out.

The string str2c is: Wide World
The newly assigned string str1 is: World.

The original string str1 is: Hello.
The string str2d is: Wide
The string str1 newly assigned with string str2d is: Wide.
The string str3d is: World.
The string str1 reassigned with string str3d is: World.

The string str1 assigned with exclamations is: !!!!

The string str2f is: Wide World
The string str1 assigned a range of string str2f is: World.
```

basic_string::at

Provides a reference to the character with a specified index in a string.

```
const_reference at(size_type _Off) const;

reference at(size_type _Off);
```

Parameters

_Off

The index of the position of the element to be referenced.

Return Value

A reference to the character of the string at the position specified by the parameter index.

Remarks

The first element of the string has an index of zero and the following elements are indexed consecutively by the positive integers, so that a string of length n has an n th element indexed by the number $n - 1$.

The member [operator\[\]](#) is faster than the member function `at` for providing read and write access to the elements of a string.

The member `operator[]` does not check whether the index passed as a parameter is valid but the member function `at` does and so should be used if the validity is not certain. An invalid index, which is an index less than zero or greater than or equal to the size of the string, passed to the member function `at` throws an [out_of_range Class](#) exception. An invalid index passed to the `operator[]` results in undefined behavior, but the index equal to the length of the string is a valid index for const strings and the operator returns the null-character when passed this index.

The reference returned may be invalidated by string reallocations or modifications for the non- **const** strings.

Example

```

// basic_string_at.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ( "Hello world" ), str2 ( "Goodbye world" );
    const string  cstr1 ( "Hello there" ), cstr2 ( "Goodbye now" );
    cout << "The original string str1 is: " << str1 << endl;
    cout << "The original string str2 is: " << str2 << endl;

    // Element access to the non const strings
    basic_string<char>::reference refStr1 = str1 [6];
    basic_string<char>::reference refStr2 = str2.at ( 3 );

    cout << "The character with an index of 6 in string str1 is: "
        << refStr1 << "." << endl;
    cout << "The character with an index of 3 in string str2 is: "
        << refStr2 << "." << endl;

    // Element access to the const strings
    basic_string<char>::const_reference crefStr1 = cstr1 [ cstr1.length ( ) ];
    basic_string<char>::const_reference crefStr2 = cstr2.at ( 8 );

    if ( crefStr1 == '\0' )
        cout << "The null character is returned as a valid reference."
            << endl;
    else
        cout << "The null character is not returned." << endl;
    cout << "The character with index 8 in the const string cstr2 is: "
        << crefStr2 << "." << endl;
}

```

basic_string::back

Returns a reference to the last element in the string.

```

const_reference back() const;

reference back();

```

Return Value

A reference to the last element of the string, which must be non-empty.

Remarks

basic_string::basic_string

Constructs a string that is empty, initialized by specific characters, or is a copy of all or part of another string object or C style (null-terminated) string.

```

basic_string();

explicit basic_string(
    const allocator_type& _Al);

basic_string(
    const basic_string& right);

basic_string(
    basic_string&& right);

basic_string(
    const basic_string& right,
    size_type _Roff,
    size_type count = npos);

basic_string(
    const basic_string& right,
    size_type _Roff,
    size_type count,
    const allocator_type& _Al);

basic_string(
    const value_type* ptr,
    size_type count);

basic_string(
    const value_type* ptr,
    size_type count,
    const allocator_type& _Al);

basic_string(
    const value_type* ptr);

basic_string(
    const value_type* ptr,
    const allocator_type& _Al);

basic_string(
    size_type count,
    value_type _Ch);

basic_string(
    size_type count,
    value_type _Ch,
    const allocator_type& _Al);

template <class InputIterator>
basic_string(
    InputIterator first,
    InputIterator last);

template <class InputIterator>
basic_string(
    InputIterator first,
    InputIterator last,
    const allocator_type& _Al);

basic_string(
    const_pointer first,
    const_pointer last);

basic_string(
    const_iterator first,
    const_iterator last);

```

Parameters

ptr

The C-string whose characters are to be used to initialize the `string` being constructed. This value cannot be a null pointer.

_Al

The storage allocator class for the string object being constructed.

count

The number of characters to be initialized.

right

The string to initialize the string being constructed.

_Roff

The index of a character in a string that is the first to be used to initialize character values for the string being constructed.

_Ch

The character value to be copied into the string being constructed.

first

An input iterator, `const_pointer`, or `const_iterator` addressing the first element in the source range to be inserted.

last

An input iterator, `const_pointer`, or `const_iterator` addressing the position of the one beyond the last element in the source range to be inserted.

Return Value

A reference to the string object that is being constructed by the constructors.

Remarks

All constructors store an `basic_string::allocator_type` and initialize the controlled sequence. The allocator object is the argument `a1`, if present. For the copy constructor, it is `right.basic_string::get_allocator()`. Otherwise, it is `Alloc()`.

The controlled sequence is initialized to a copy of the operand sequence specified by the remaining operands. A constructor without an operand sequence specifies an empty initial controlled sequence. If `InputIterator` is an integer type in a template constructor, the operand sequence `_F first, last` behaves the same as `(size_type) first, (value_type) last`.

Example

```

// basic_string_ctor.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function initializing with a C-string
    const char *cstr1a = "Hello Out There.";
    basic_string<char> str1a ( cstr1a , 5);
    cout << "The string initialized by C-string cstr1a is: "
         << str1a << "." << endl;

    // The second member function initializing with a string
    string str2a ( "How Do You Do" );
    basic_string<char> str2b ( str2a , 7 , 7 );
    cout << "The string initialized by part of the string cstr2a is: "
         << str2b << "." << endl;

    // The third member function initializing a string
    // with a number of characters of a specific value
    basic_string<char> str3a ( 5, '9' );
    cout << "The string initialized by five number 9s is: "
         << str3a << endl;

    // The fourth member function creates an empty string
    // and string with a specified allocator
    basic_string<char> str4a;
    string str4b;
    basic_string<char> str4c ( str4b.get_allocator( ) );
    if (str4c.empty( ) )
        cout << "The string str4c is empty." << endl;
    else
        cout << "The string str4c is not empty." << endl;

    // The fifth member function initializes a string from
    // another range of characters
    string str5a ( "Hello World" );
    basic_string<char> str5b ( str5a.begin( ) + 5 , str5a.end( ) );
    cout << "The string initialized by another range is: "
         << str5b << "." << endl;
}

```

basic_string::begin

Returns an iterator addressing the first element in the string.

```

const_iterator begin() const;

iterator begin();

```

Return Value

A random-access iterator that addresses the first element of the sequence or just beyond the end of an empty sequence.

Example

```

// basic_string_begin.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( ) {
    using namespace std;
    string str1 ( "No way out." ), str2;
    basic_string<char>::iterator strp_Iter, str1_Iter, str2_Iter;
    basic_string<char>::const_iterator str1_cIter;

    str1_Iter = str1.begin ( );
    cout << "The first character of the string str1 is: "
         << *str1_Iter << endl;
    cout << "The full original string str1 is: " << str1 << endl;

    // The dereferenced iterator can be used to modify a character
    *str1_Iter = 'G';
    cout << "The first character of the modified str1 is now: "
         << *str1_Iter << endl;
    cout << "The full modified string str1 is now: " << str1 << endl;

    // The following line would be an error because iterator is const
    // *str1_cIter = 'g';

    // For an empty string, begin is equivalent to end
    if ( str2.begin ( ) == str2.end ( ) )
        cout << "The string str2 is empty." << endl;
    else
        cout << "The string str2 is not empty." << endl;
}

```

basic_string::c_str

Converts the contents of a string as a C-style, null-terminated string.

```
const value_type *c_str() const;
```

Return Value

A pointer to the C-style version of the invoking string. The pointer value is not valid after calling a non-const function, including the destructor, in the `basic_string` class on the object.

Remarks

Objects of type `string` belonging to the C++ template class `basic_string<char>` are not necessarily null terminated. The null character `'\0'` is used as a special character in a C-string to mark the end of the string but has no special meaning in an object of type `string` and may be a part of the string just like any other character. There is an automatic conversion from **const char*** into strings, but the string class does not provide for automatic conversions from C-style strings to objects of type **basic_string<char>**.

The returned C-style string should not be modified, as this could invalidate the pointer to the string, or deleted, as the string has a limited lifetime and is owned by the class `string`.

Example

```

// basic_string_c_str.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    string str1 ( "Hello world" );
    cout << "The original string object str1 is: "
          << str1 << endl;
    cout << "The length of the string object str1 = "
          << str1.length ( ) << endl << endl;

    // Converting a string to an array of characters
    const char *ptr1 = 0;
    ptr1= str1.data ( );
    cout << "The modified string object ptr1 is: " << ptr1
          << endl;
    cout << "The length of character array str1 = "
          << strlen ( ptr1) << endl << endl;

    // Converting a string to a C-style string
    const char *c_str1 = str1.c_str ( );
    cout << "The C-style string c_str1 is: " << c_str1
          << endl;
    cout << "The length of C-style string str1 = "
          << strlen ( c_str1) << endl << endl;
}

```

```

The original string object str1 is: Hello world
The length of the string object str1 = 11

The modified string object ptr1 is: Hello world
The length of character array str1 = 11

The C-style string c_str1 is: Hello world
The length of C-style string str1 = 11

```

basic_string::capacity

Returns the largest number of elements that could be stored in a string without increasing the memory allocation of the string.

```
size_type capacity() const;
```

Return Value

The size of storage currently allocated in memory to hold the string.

Remarks

The member function returns the storage currently allocated to hold the controlled sequence, a value at least as large as [size](#).

Example

```

// basic_string_capacity.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ("Hello world");
    cout << "The original string str1 is: " << str1 << endl;

    // The size and length member functions differ in name only
    basic_string<char>::size_type sizeStr1, lenStr1;
    sizeStr1 = str1.size ( );
    lenStr1 = str1.length ( );

    basic_string<char>::size_type capStr1, max_sizeStr1;
    capStr1 = str1.capacity ( );
    max_sizeStr1 = str1.max_size ( );

    // Compare size, length, capacity & max_size of a string
    cout << "The current size of original string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The current length of original string str1 is: "
        << lenStr1 << "." << endl;
    cout << "The capacity of original string str1 is: "
        << capStr1 << "." << endl;
    cout << "The max_size of original string str1 is: "
        << max_sizeStr1 << "." << endl << endl;

    str1.erase ( 6, 5 );
    cout << "The modified string str1 is: " << str1 << endl;

    sizeStr1 = str1.size ( );
    lenStr1 = str1.length ( );
    capStr1 = str1.capacity ( );
    max_sizeStr1 = str1.max_size ( );

    // Compare size, length, capacity & max_size of a string
    // after erasing part of the original string
    cout << "The current size of modified string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The current length of modified string str1 is: "
        << lenStr1 << "." << endl;
    cout << "The capacity of modified string str1 is: "
        << capStr1 << "." << endl;
    cout << "The max_size of modified string str1 is: "
        << max_sizeStr1 << "." << endl;
}

```

basic_string::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** random-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin` , the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

`basic_string::cend`

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A **const** random-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

`basic_string::clear`

Erases all elements of a string.

```
void clear();
```

Remarks

The string on which the member function is called will be empty.

Example

```

// basic_string_clear.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ("Hello world"), str2;
    basic_string<char>::iterator str_Iter;
    cout << "The original string str1 is: ";
    for ( str_Iter = str1.begin( ); str_Iter != str1.end( ); str_Iter++ )
        cout << *str_Iter;
    cout << endl;

    str1.clear ( );
    cout << "The modified string str1 is: ";
    for ( str_Iter = str1.begin( ); str_Iter != str1.end( ); str_Iter++ )
        cout << *str_Iter;
    cout << endl;

    //For an empty string, begin is equivalent to end
    if ( str1.begin ( ) == str1.end ( ) )
        cout << "Nothing printed above because "
            << "the string str1 is empty." << endl;
    else
        cout << "The string str1 is not empty." << endl;
}

```

```

The original string str1 is: Hello world
The modified string str1 is:
Nothing printed above because the string str1 is empty.

```

basic_string::compare

Performs a case sensitive comparison with a specified string to determine if the two strings are equal or if one is lexicographically less than the other.

```

int compare(
    const basic_string<CharType, Traits, Allocator>& str) const;

int compare(
    size_type _Pos1,
    size_type _Num1,
    const basic_string<CharType, Traits, Allocator>& str) const;

int compare(
    size_type _Pos1,
    size_type _Num1,
    const basic_string<CharType, Traits, Allocator>& str,
    size_type _Off,
    size_type count) const;

int compare(
    const value_type* ptr) const;

int compare(
    size_type _Pos1,
    size_type _Num1,
    const value_type* ptr) const;

int compare(
    size_type _Pos1,
    size_type _Num1,
    const value_type* ptr
    size_type _Num2) const;

```

Parameters

str

The string that is to be compared to the operand string.

_Pos1

The index of the operand string at which the comparison begins.

_Num1

The maximum number of characters from the operand string to be compared.

_Num2

The maximum number of characters from the parameter string to be compared.

_Off

The index of the parameter string at which the comparison begins.

count

The maximum number of characters from the parameter string to be compared.

ptr

The C-string to be compared to the operand string.

Return Value

A negative value if the operand string is less than the parameter string; zero if the two strings are equal; or a positive value if the operand string is greater than the parameter string.

Remarks

The `compare` member functions compare either all or part of the parameter and operand strings depending on which is used.

The comparison performed is case sensitive.

Example

```
// basic_string_compare.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function compares
    // an operand string to a parameter string
    int comp1;
    string s1o ( "CAB" );
    string s1p ( "CAB" );
    cout << "The operand string is: " << s1o << endl;
    cout << "The parameter string is: " << s1p << endl;
    comp1 = s1o.compare ( s1p );
    if ( comp1 < 0 )
        cout << "The operand string is less than "
            << "the parameter string." << endl;
    else if ( comp1 == 0 )
        cout << "The operand string is equal to "
            << "the parameter string." << endl;
    else
        cout << "The operand string is greater than "
            << "the parameter string." << endl;
    cout << endl;

    // The second member function compares part of
    // an operand string to a parameter string
    int comp2a, comp2b;
    string s2o ( "AACAB" );
    string s2p ( "CAB" );
    cout << "The operand string is: " << s2o << endl;
    cout << "The parameter string is: " << s2p << endl;
    comp2a = s2o.compare ( 2 , 3 , s2p );
    if ( comp2a < 0 )
        cout << "The last three characters of "
            << "the operand string\n are less than "
            << "the parameter string." << endl;
    else if ( comp2a == 0 )
        cout << "The last three characters of "
            << "the operand string\n are equal to "
            << "the parameter string." << endl;
    else
        cout << "The last three characters of "
            << "the operand string\n is greater than "
            << "the parameter string." << endl;

    comp2b = s2o.compare ( 0 , 3 , s2p );
    if ( comp2b < 0 )
        cout << "The first three characters of "
            << "the operand string\n are less than "
            << "the parameter string." << endl;
    else if ( comp2b == 0 )
        cout << "The first three characters of "
            << "the operand string\n are equal to "
            << "the parameter string." << endl;
    else
        cout << "The first three characters of "
            << "the operand string\n is greater than "
            << "the parameter string." << endl;
    cout << endl;

    // The third member function compares part of
    // an operand string to part of a parameter string
```

```

int comp3a;
string s3o ( "AACAB" );
string s3p ( "DCABD" );
cout << "The operand string is: " << s3o << endl;
cout << "The parameter string is: " << s3p << endl;
comp3a = s3o.compare ( 2 , 3 , s3p , 1 , 3 );
if ( comp3a < 0 )
    cout << "The three characters from position 2 of "
        << "the operand string are less than\n "
        << "the 3 characters parameter string "
        << "from position 1." << endl;
else if ( comp3a == 0 )
    cout << "The three characters from position 2 of "
        << "the operand string are equal to\n "
        << "the 3 characters parameter string "
        << "from position 1." << endl;
else
    cout << "The three characters from position 2 of "
        << "the operand string is greater than\n "
        << "the 3 characters parameter string "
        << "from position 1." << endl;
cout << endl;

// The fourth member function compares
// an operand string to a parameter C-string
int comp4a;
string s4o ( "ABC" );
const char* cs4p = "DEF";
cout << "The operand string is: " << s4o << endl;
cout << "The parameter C-string is: " << cs4p << endl;
comp4a = s4o.compare ( cs4p );
if ( comp4a < 0 )
    cout << "The operand string is less than "
        << "the parameter C-string." << endl;
else if ( comp4a == 0 )
    cout << "The operand string is equal to "
        << "the parameter C-string." << endl;
else
    cout << "The operand string is greater than "
        << "the parameter C-string." << endl;
cout << endl;

// The fifth member function compares part of
// an operand string to a parameter C-string
int comp5a;
string s5o ( "AACAB" );
const char* cs5p = "CAB";
cout << "The operand string is: " << s5o << endl;
cout << "The parameter string is: " << cs5p << endl;
comp5a = s5o.compare ( 2 , 3 , s2p );
if ( comp5a < 0 )
    cout << "The last three characters of "
        << "the operand string\n are less than "
        << "the parameter C-string." << endl;
else if ( comp5a == 0 )
    cout << "The last three characters of "
        << "the operand string\n are equal to "
        << "the parameter C-string." << endl;
else
    cout << "The last three characters of "
        << "the operand string\n is greater than "
        << "the parameter C-string." << endl;
cout << endl;

// The sixth member function compares part of
// an operand string to part of an equal length of
// a parameter C-string
int comp6a;
string s6o ( "AACAB" );

```

```

const char* cs6p = "ACAB";
cout << "The operand string is: " << s6o << endl;
cout << "The parameter C-string is: " << cs6p << endl;
comp6a = s6o.compare ( 1 , 3 , cs6p , 3 );
if ( comp6a < 0 )
    cout << "The 3 characters from position 1 of "
        << "the operand string are less than\n "
        << "the first 3 characters of the parameter C-string."
        << endl;
else if ( comp6a == 0 )
    cout << "The 3 characters from position 2 of "
        << "the operand string are equal to\n "
        << "the first 3 characters of the parameter C-string."
        << endl;
else
    cout << "The 3 characters from position 2 of "
        << "the operand string is greater than\n "
        << "the first 3 characters of the parameter C-string."
        << endl;
cout << endl;
}

```

The operand string is: CAB
 The parameter string is: CAB
 The operand string is equal to the parameter string.

The operand string is: AACAB
 The parameter string is: CAB
 The last three characters of the operand string
 are equal to the parameter string.
 The first three characters of the operand string
 are less than the parameter string.

The operand string is: AACAB
 The parameter string is: DCABD
 The three characters from position 2 of the operand string are equal to
 the 3 characters parameter string from position 1.

The operand string is: ABC
 The parameter C-string is: DEF
 The operand string is less than the parameter C-string.

The operand string is: AACAB
 The parameter string is: CAB
 The last three characters of the operand string
 are equal to the parameter C-string.

The operand string is: AACAB
 The parameter C-string is: ACAB
 The 3 characters from position 2 of the operand string are equal to
 the first 3 characters of the parameter C-string.

basic_string::const_iterator

A type that provides a random-access iterator that can access and read a **const** element in the string.

```
typedef implementation-defined const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of a character and is used to iterate through a string in a forward direction.

Example

See the example for [begin](#) for an example of how to declare and use `const_iterator`.

basic_string::const_pointer

A type that provides a pointer to a **const** element in a string.

```
typedef typename allocator_type::const_pointer const_pointer;
```

Remarks

The type is a synonym for `allocator_type::const_pointer`.

For type `string`, it is equivalent to `char*`.

Pointers that are declared const must be initialized when they are declared. Const pointers always point to the same memory location and may point to constant or nonconstant data.

Example

```
// basic_string_const_ptr.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    basic_string<char>::const_pointer pstr1a = "In Here";
    const char *cstr1c = "Out There";

    cout << "The string pstr1a is: " << pstr1a << "." << endl;
    cout << "The C-string cstr1c is: " << cstr1c << "." << endl;
}
```

```
The string pstr1a is: In Here.
The C-string cstr1c is: Out There.
```

basic_string::const_reference

A type that provides a reference to a **const** element stored in a string for reading and performing **const** operations.

```
typedef typename allocator_type::const_reference const_reference;
```

Remarks

A type `const_reference` cannot be used to modify the value of an element.

The type is a synonym for `allocator_type::const_reference`. For string `type`, it is equivalent to `const char&`.

Example

See the example for [at](#) for an example of how to declare and use `const_reference`.

basic_string::const_reverse_iterator

A type that provides a random-access iterator that can read any **const** element in the string.

```
typedef std::reverse_iterator<const_iterator> const_reverse_iterator;
```

Remarks

A type `const_reverse_iterator` cannot modify the value of a character and is used to iterate through a string in reverse.

Example

See the example for [rbegin](#) for an example of how to declare and use `const_reverse_iterator`.

basic_string::copy

Copies at most a specified number of characters from an indexed position in a source string to a target character array.

This method is potentially unsafe, as it relies on the caller to check that the passed values are correct. Consider using [basic_string::_Copy_s](#) instead.

```
size_type copy(  
    value_type* ptr,  
    size_type count,  
    size_type _Off = 0) const;
```

Parameters

ptr

The target character array to which the elements are to be copied.

_Count The number of characters to be copied, at most, from the source string.

_Off

The beginning position in the source string from which copies are to be made.

Return Value

The number of characters actually copied.

Remarks

A null character is not appended to the end of the copy.

Example

```

// basic_string_copy.cpp
// compile with: /EHsc /W3
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ( "Hello World" );
    basic_string<char>::iterator str_Iter;
    char array1 [ 20 ] = { 0 };
    char array2 [ 10 ] = { 0 };
    basic_string<char>:: pointer array1Ptr = array1;
    basic_string<char>:: value_type *array2Ptr = array2;

    cout << "The original string str1 is: ";
    for ( str_Iter = str1.begin( ); str_Iter != str1.end( ); str_Iter++ )
        cout << *str_Iter;
    cout << endl;

    basic_string<char>:: size_type nArray1;
    // Note: string::copy is potentially unsafe, consider
    // using string::_Copy_s instead.
    nArray1 = str1.copy ( array1Ptr , 12 ); // C4996
    cout << "The number of copied characters in array1 is: "
        << nArray1 << endl;
    cout << "The copied characters array1 is: " << array1 << endl;

    basic_string<char>:: size_type nArray2;
    // Note: string::copy is potentially unsafe, consider
    // using string::_Copy_s instead.
    nArray2 = str1.copy ( array2Ptr , 5 , 6 ); // C4996
    cout << "The number of copied characters in array2 is: "
        << nArray2 << endl;
    cout << "The copied characters array2 is: " << array2Ptr << endl;
}

```

```

The original string str1 is: Hello World
The number of copied characters in array1 is: 11
The copied characters array1 is: Hello World
The number of copied characters in array2 is: 5
The copied characters array2 is: World

```

basic_string::crbegin

Returns a const iterator that addresses the first element in a reversed string.

```
const_reverse_iterator crbegin() const;
```

Return Value

A reverse iterator that points just beyond the end of the string. The position designates the beginning of the reverse string.

basic_string::crend

Returns a const iterator that addresses the location succeeding the last element in a reversed string.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse iterator that addresses the location succeeding the last element in a reversed string (the location that had preceded the first element in the unreversed string).

Remarks

basic_string::_Copy_s

Copies at most a specified number of characters from an indexed position in a source string to a target character array.

```
size_type _Copy_s(  
    value_type* dest,  
    size_type dest_size,  
    size_type count,  
    size_type _Off = 0) const;
```

Parameters

dest

The target character array to which the elements are to be copied.

dest_size

The size of *dest*.

_Count The number of characters to be copied, at most, from the source string.

_Off

The beginning position in the source string from which copies are to be made.

Return Value

The number of characters actually copied.

Remarks

A null character is not appended to the end of the copy.

Example

```

// basic_string_Copy_s.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1("Hello World");
    basic_string<char>::iterator str_Iter;
    const int array1_size = 20;
    char array1[array1_size] = { 0 };
    const int array2_size = 10;
    char array2[array2_size] = { 0 };
    basic_string<char>:: pointer array1Ptr = array1;
    basic_string<char>:: value_type *array2Ptr = array2;

    cout << "The original string str1 is: ";
    for (str_Iter = str1.begin(); str_Iter != str1.end(); str_Iter++)
        cout << *str_Iter;
    cout << endl;

    basic_string<char>::size_type nArray1;
    nArray1 = str1._Copy_s(array1Ptr, array1_size, 12);
    cout << "The number of copied characters in array1 is: "
        << nArray1 << endl;
    cout << "The copied characters array1 is: " << array1 << endl;

    basic_string<char>:: size_type nArray2;
    nArray2 = str1._Copy_s(array2Ptr, array2_size, 5, 6);
    cout << "The number of copied characters in array2 is: "
        << nArray2 << endl;
    cout << "The copied characters array2 is: " << array2Ptr << endl;
}

```

```

The original string str1 is: Hello World
The number of copied characters in array1 is: 11
The copied characters array1 is: Hello World
The number of copied characters in array2 is: 5
The copied characters array2 is: World

```

basic_string::data

Converts the contents of a string into an array of characters.

```
const value_type *data() const;
```

Return Value

A pointer to the first element of the array containing the contents of the string, or, for an empty array, a non-null pointer that cannot be dereferenced.

Remarks

Objects of type string belonging to the C++ template class `basic_string <char>` are not necessarily null terminated. The return type for `data` is not a valid C-string, because no null character gets appended. The null character `'\0'` is used as a special character in a C-string to mark the end of the string, but has no special meaning in an object of type string and may be a part of the string object just like any other character.

There is an automatic conversion from **const char*** into strings, but the string class does not provide for automatic conversions from C-style strings to objects of type **basic_string <char>**.

The returned string should not be modified, because this could invalidate the pointer to the string, or deleted, because the string has a limited lifetime and is owned by the class string.

Example

```
// basic_string_data.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    string str1 ( "Hello world" );
    cout << "The original string object str1 is: "
          << str1 << endl;
    cout << "The length of the string object str1 = "
          << str1.length ( ) << endl << endl;

    // Converting a string to an array of characters
    const char *ptr1 = 0;
    ptr1= str1.data ( );
    cout << "The modified string object ptr1 is: " << ptr1
          << endl;
    cout << "The length of character array str1 = "
          << strlen ( ptr1) << endl << endl;

    // Converting a string to a C-style string
    const char *c_str1 = str1.c_str ( );
    cout << "The C-style string c_str1 is: " << c_str1
          << endl;
    cout << "The length of C-style string str1 = "
          << strlen ( c_str1) << endl << endl;
}
```

```
The original string object str1 is: Hello world
The length of the string object str1 = 11

The modified string object ptr1 is: Hello world
The length of character array str1 = 11

The C-style string c_str1 is: Hello world
The length of C-style string str1 = 11
```

basic_string::difference_type

A type that provides the difference between two iterators that refer to elements within the same string.

```
typedef typename allocator_type::difference_type difference_type;
```

Remarks

The signed integer type describes an object that can represent the difference between the addresses of any two elements in the controlled sequence.

For type `string`, it is equivalent to `ptrdiff_t`.

Example

```

// basic_string_diff_type.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ( "quintillion" );
    cout << "The original string str1 is: " << str1 << endl;
    basic_string<char>::size_type indexChFi, indexChLi;

    indexChFi = str1.find_first_of ( "i" );
    indexChLi = str1.find_last_of ( "i" );
    basic_string<char>::difference_type diffi = indexChLi - indexChFi;

    cout << "The first character i is at position: "
        << indexChFi << "." << endl;
    cout << "The last character i is at position: "
        << indexChLi << "." << endl;
    cout << "The difference is: " << diffi << "." << endl;
}

```

```

The original string str1 is: quintillion
The first character i is at position: 2.
The last character i is at position: 8.
The difference is: 6.

```

basic_string::empty

Tests whether the string contains characters or not.

```
bool empty() const;
```

Return Value

true if the string object contains no characters; **false** if it has at least one character.

Remarks

The member function is equivalent to `size == 0`.

Example

```

// basic_string_empty.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main() {
    using namespace std;

    bool b1, b2;

    string str1 ("Hello world");
    cout << "The original string object str1 is: " << str1 << endl;
    b1 = str1.empty();
    if (b1)
        cout << "The string object str1 is empty." << endl;
    else
        cout << "The string object str1 is not empty." << endl;
    cout << endl;

    // An example of an empty string object
    string str2;
    b2 = str2.empty();
    if (b2)
        cout << "The string object str2 is empty." << endl;
    else
        cout << "The string object str2 is not empty." << endl;
}

```

basic_string::end

Returns an iterator that addresses the location succeeding the last element in a string.

```

const_iterator end() const;

iterator end();

```

Return Value

Returns a random-access iterator that addresses the location succeeding the last element in a string.

Remarks

`end` is often used to test whether an iterator has reached the end of its string. The value returned by `end` should not be dereferenced.

If the return value of `end` is assigned to a `const_iterator`, the string object cannot be modified. If the return value of `end` is assigned to an `iterator`, the string object can be modified.

Example

```

// basic_string_end.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ( "No way out." ), str2;
    basic_string<char>::iterator str_Iter, str1_Iter, str2_Iter;
    basic_string<char>::const_iterator str1_cIter;

    str1_Iter = str1.end ( );
    str1_Iter--;
    str1_Iter--;
    cout << "The last character-letter of the string str1 is: " << *str1_Iter << endl;
    cout << "The full original string str1 is: " << str1 << endl;

    // end used to test when an iterator has reached the end of its string
    cout << "The string is now: ";
    for ( str_Iter = str1.begin( ); str_Iter != str1.end( ); str_Iter++ )
        cout << *str_Iter;
    cout << endl;

    // The dereferenced iterator can be used to modify a character
    *str1_Iter = 'T';
    cout << "The last character-letter of the modified str1 is now: "
        << *str1_Iter << endl;
    cout << "The modified string str1 is now: " << str1 << endl;

    // The following line would be an error because iterator is const
    // *str1_cIter = 'T';

    // For an empty string, end is equivalent to begin
    if ( str2.begin( ) == str2.end ( ) )
        cout << "The string str2 is empty." << endl;
    else
        cout << "The stringstr2 is not empty." << endl;
}

```

```

The last character-letter of the string str1 is: t
The full original string str1 is: No way out.
The string is now: No way out.
The last character-letter of the modified str1 is now: T
The modified string str1 is now: No way ouT.
The string str2 is empty.

```

basic_string::erase

Removes an element or a range of elements in a string from a specified position.

```

iterator erase(
    iterator first,
    iterator last);

iterator erase(
    iterator _It);

basic_string<CharType, Traits, Allocator>& erase(
    size_type _Pos = 0,
    size_type count = npos);

```

Parameters

first

An iterator addressing the position of the first element in the range to be erased.

last

An iterator addressing the position one past the last element in the range to be erased.

_It

An iterator addressing the position of the element in the string to be erased.

_Pos

The index of the first character in the string to be removed.

count

The number of elements that will be removed if there are as many in the range of the string beginning with *_Pos*.

Return Value

For the first two member functions, an iterator addressing the first character after the last character removed by the member function. For the third member function, a reference to the string object from which the elements have been erased.

Remarks

The third member function returns ***this**.

Example

```

// basic_string_erase.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The 1st member function using a range demarcated
    // by iterators
    string str1 ( "Hello world" );
    basic_string<char>::iterator str1_Iter;
    cout << "The original string object str1 is: "
        << str1 << "." << endl;
    str1_Iter = str1.erase ( str1.begin ( ) + 3 , str1.end ( ) - 1 );
    cout << "The first element after those removed is: "
        << *str1_Iter << "." << endl;
    cout << "The modified string object str1 is: " << str1
        << "." << endl << endl;

    // The 2nd member function erasing a char pointed to
    // by an iterator
    string str2 ( "Hello World" );
    basic_string<char>::iterator str2_Iter;
    cout << "The original string object str2 is: " << str2
        << "." << endl;
    str2_Iter = str2.erase ( str2.begin ( ) + 5 );
    cout << "The first element after those removed is: "
        << *str2_Iter << "." << endl;
    cout << "The modified string object str2 is: " << str2
        << "." << endl << endl;

    // The 3rd member function erasing a number of chars
    // after a char
    string str3 ( "Hello computer" ), str3m;
    basic_string<char>::iterator str3_Iter;
    cout << "The original string object str3 is: "
        << str3 << "." << endl;
    str3m = str3.erase ( 6 , 8 );
    cout << "The modified string object str3m is: "
        << str3m << "." << endl;
}

```

```

The original string object str1 is: Hello world.
The first element after those removed is: d.
The modified string object str1 is: Held.

The original string object str2 is: Hello World.
The first element after those removed is: W.
The modified string object str2 is: HelloWorld.

The original string object str3 is: Hello computer.
The modified string object str3m is: Hello .

```

basic_string::find

Searches a string in a forward direction for the first occurrence of a substring that matches a specified sequence of characters.

```

size_type find(
    value_type _Ch,
    size_type _Off = 0) const;

size_type find(
    const value_type* ptr,
    size_type _Off = 0) const;

size_type find(
    const value_type* ptr,
    size_type _Off,
    size_type count) const;

size_type find(
    const basic_string<CharType, Traits, Allocator>& str,
    size_type _Off = 0) const;

```

Parameters

_Ch

The character value for which the member function is to search.

_Off

Index of the position at which the search is to begin.

ptr

The C-string for which the member function is to search.

count

The number of characters, counting forward from the first character, in the C-string for which the member function is to search.

str

The string for which the member function is to search.

Return Value

The index of the first character of the substring searched for when successful; otherwise `npos`.

Example

```

// basic_string_find.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function
    // searches for a single character in a string
    string str1 ( "Hello Everyone" );
    cout << "The original string str1 is: " << str1 << endl;
    basic_string<char>::size_type indexCh1a, indexCh1b;

    indexCh1a = str1.find ( "e" , 3 );
    if (indexCh1a != string::npos )
        cout << "The index of the 1st 'e' found after the 3rd"
            << " position in str1 is: " << indexCh1a << endl;
    else
        cout << "The character 'e' was not found in str1 ." << endl;

    indexCh1b = str1.find ( "x" );
    if (indexCh1b != string::npos )

```

```

        cout << "The index of the 'x' found in str1 is: "
              << indexCh1b << endl << endl;
    else
        cout << "The Character 'x' was not found in str1."
              << endl << endl;

    // The second member function searches a string
    // for a substring as specified by a C-string
    string str2 ( "Let me make this perfectly clear." );
    cout << "The original string str2 is: " << str2 << endl;
    basic_string<char>::size_type indexCh2a, indexCh2b;

    const char *cstr2 = "perfect";
    indexCh2a = str2.find ( cstr2 , 5 );
    if ( indexCh2a != string::npos )
        cout << "The index of the 1st element of 'perfect' "
              << "after\n the 5th position in str2 is: "
              << indexCh2a << endl;
    else
        cout << "The substring 'perfect' was not found in str2 ."
              << endl;

    const char *cstr2b = "imperfectly";
    indexCh2b = str2.find ( cstr2b , 0 );
    if (indexCh2b != string::npos )
        cout << "The index of the 1st element of 'imperfect' "
              << "after\n the 5th position in str3 is: "
              << indexCh2b << endl;
    else
        cout << "The substring 'imperfect' was not found in str2 ."
              << endl << endl;

    // The third member function searches a string
    // for a substring as specified by a C-string
    string str3 ( "This is a sample string for this program" );
    cout << "The original string str3 is: " << str3 << endl;
    basic_string<char>::size_type indexCh3a, indexCh3b;

    const char *cstr3a = "sample";
    indexCh3a = str3.find ( cstr3a );
    if ( indexCh3a != string::npos )
        cout << "The index of the 1st element of sample "
              << "in str3 is: " << indexCh3a << endl;
    else
        cout << "The substring 'perfect' was not found in str3 ."
              << endl;

    const char *cstr3b = "for";
    indexCh3b = str3.find ( cstr3b , indexCh3a + 1 , 2 );
    if (indexCh3b != string::npos )
        cout << "The index of the next occurrence of 'for' is in "
              << "str3 begins at: " << indexCh3b << endl << endl;
    else
        cout << "There is no next occurrence of 'for' in str3 ."
              << endl << endl;

    // The fourth member function searches a string
    // for a substring as specified by a string
    string str4 ( "clearly this perfectly unclear." );
    cout << "The original string str4 is: " << str4 << endl;
    basic_string<char>::size_type indexCh4a, indexCh4b;

    string str4a ( "clear" );
    indexCh4a = str4.find ( str4a , 5 );
    if ( indexCh4a != string::npos )
        cout << "The index of the 1st element of 'clear' "
              << "after\n the 5th position in str4 is: "
              << indexCh4a << endl;
    else

```

```

else
    cout << "The substring 'clear' was not found in str4 ."
        << endl;

    string str4b ( "clear" );
    indexCh4b = str4.find ( str4b );
    if (indexCh4b != string::npos )
        cout << "The index of the 1st element of 'clear' "
            << "in str4 is: "
            << indexCh4b << endl;
    else
        cout << "The substring 'clear' was not found in str4 ."
            << endl << endl;
}

```

The original string str1 is: Hello Everyone
 The index of the 1st 'e' found after the 3rd position in str1 is: 8
 The Character 'x' was not found in str1.

The original string str2 is: Let me make this perfectly clear.
 The index of the 1st element of 'perfect' after
 the 5th position in str2 is: 17
 The substring 'imperfect' was not found in str2 .

The original string str3 is: This is a sample string for this program
 The index of the 1st element of sample in str3 is: 10
 The index of the next occurrence of 'for' is in str3 begins at: 24

The original string str4 is: clearly this perfectly unclear.
 The index of the 1st element of 'clear' after
 the 5th position in str4 is: 25
 The index of the 1st element of 'clear' in str4 is: 0

basic_string::find_first_not_of

Searches through a string for the first character that is not an element of a specified string.

```

size_type find_first_not_of(
    value_type _Ch,
    size_type _Off = 0) const;

size_type find_first_not_of(
    const value_type* ptr,
    size_type _Off = 0) const;

size_type find_first_not_of(
    const value_type* ptr,
    size_type _Off,
    size_type count) const;

size_type find_first_not_of(
    const basic_string<CharType, Traits, Allocator>& str,
    size_type _Off = 0) const;

```

Parameters

_Ch

The character value for which the member function is to search.

_Off

Index of the position at which the search is to begin.

ptr

The C-string for which the member function is to search.

count

The number of characters, counting forward from the first character, in the C-string for which the member function is to search.

str

The string for which the member function is to search.

Return Value

The index of the first character of the substring searched for when successful; otherwise `npos`.

Example

```
// basic_string_find_first_not_of.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function
    // searches for a single character in a string
    string str1 ( "xddd-1234-abcd" );
    cout << "The original string str1 is: " << str1 << endl;

basic_string::find_first_of

Searches through a string for the first character that matches any element of a specified string.

```
size_type find_first_of(
    value_type _Ch,
    size_type _Off = 0) const;

size_type find_first_of(
    const value_type* ptr,
    size_type _Off = 0) const;

size_type find_first_of(
    const value_type* ptr,
    size_type _Off,
    size_type count) const;

size_type find_first_of(
    const basic_string<CharType, Traits, Allocator>& str,
    size_type _Off = 0) const;
```

Parameters

_Ch

The character value for which the member function is to search.

_Off

Index of the position at which the search is to begin.

ptr

The C-string for which the member function is to search.

count

The number of characters, counting forward from the first character, in the C-string for which the member function is to search.

str

The string for which the member function is to search.

Return Value

The index of the first character of the substring searched for when successful; otherwise `npos`.

Example

```
// basic_string_find_first_of.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function
    // searches for a single character in a string
    string str1 ( "abcd-1234-abcd-1234" );
    cout << "The original string str1 is: " << str1 << endl;
    basic_string<char>::size_type indexCh1a, indexCh1b;
    static const basic_string<char>::size_type npos = -1;

    indexCh1a = str1.find_first_of ( "d" , 5 );
    if ( indexCh1a != npos )
        cout << "The index of the 1st 'd' found after the 5th"
              << " position in str1 is: " << indexCh1a << endl;
    else
        cout << "The character 'd' was not found in str1 ." << endl;

    indexCh1b = str1.find_first_of ( "x" );
    if ( indexCh1b != npos )
        cout << "The index of the 'x' found in str1 is: "
              << indexCh1b << endl << endl;
    else
        cout << "The character 'x' was not found in str1."

    cout << "Elements of the substring 'a2' were not "
        << "found in str4\n after the 0th position."
        << endl;
}

```

The original string str1 is: abcd-1234-abcd-1234
The index of the 1st 'd' found after the 5th position in str1 is: 13
The character 'x' was not found in str1.

The original string str2 is: ABCD-1234-ABCD-1234
The index of the 1st occurrence of an element of 'B1' in str2 after the 6th position is: 11
The index of the 1st element of 'D2' after the 0th position in str2 is: 3

The original string str3 is: 123-abc-123-abc-456-EFG-456-EFG
The index of the 1st occurrence of an element of '5G' in str3 after the 0th position is: 17
The index of the second occurrence of an element of '5G' in str3 after the 0th position is: 22

The original string str4 is: 12-ab-12-ab
The index of the 1st occurrence of an element of 'ba3' in str4 after the 5th position is: 9
The index of the 1st occurrence of an element of 'a2' in str4 after the 0th position is: 1

basic_string::find_last_not_of

Searches through a string for the last character that is not any element of a specified string.

```
size_type find_last_not_of(
    value_type _Ch,
    size_type _Off = npos) const;

size_type find_last_not_of(
    const value_type* ptr,
    size_type _Off = npos) const;

size_type find_last_not_of(
    const value_type* ptr,
    size_type _Off,
    size_type count) const;

size_type find_last_not_of(
    const basic_string<CharType, Traits, Allocator>& str,
    size_type _Off = npos) const;
```

Parameters

_Ch

The character value for which the member function is to search.

_Off

Index of the position at which the search is to finish.

ptr

The C-string for which the member function is to search.

count

The number of characters, counting forward from the first character, in the C-string for which the member function is to search.

str

The string for which the member function is to search.

Return Value

The index of the first character of the substring searched for when successful; otherwise `npos`.

Example

```

The original string str1 is: dddd-1dd4-abdd
The index of the last non 'd'
found before the 7th position in str1 is: 5
The index of the non 'd' found in str1 is: 11

The original string str2 is: BBB-1111
The index of the last occurrence of a element
not of 'B1' in str2 before the 6th position is: 3
The elements of the substring 'B-1' were not found in str2 .

The original string str3 is: 444-555-GGG
The index of the last occurrence of an element in str3
other than one of the characters in '45G' is: 7
The index of the penultimate occurrence of an element
not in '45G' in str3 is: 3

The original string str4 is: 12-ab-12-ab
The index of the last occurrence of an element not
in 'b-a' in str4 before the 5th position is: 1
The index of the last occurrence of an element not in '12'
in str4 before the end position is: 10

basic_string::find_last_of

Searches through a string for the last character that matches any element of a specified string.

```
size_type find_last_of(
    value_type _Ch,
    size_type _Off = npos) const;

size_type find_last_of(
    const value_type* ptr,
    size_type _Off = npos) const;

size_type find_last_of(
    const value_type* ptr,
    size_type _Off,
    size_type count) const;

size_type find_last_of(
    const basic_string<CharType, Traits, Allocator>& str,
    size_type _Off = npos) const;
```

Parameters

_Ch

The character value for which the member function is to search.

_Off

Index of the position at which the search is to finish.

ptr

The C-string for which the member function is to search.

count

The number of characters, counting forward from the first character, in the C-string for which the member function is to search.

str

The string for which the member function is to search.

Return Value

The index of the last character of the substring searched for when successful; otherwise `npos`.

Example

```
// basic_string_find_last_of.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

    indexCh2b = str2.find_last_of ( cstr2b );
    if ( indexCh2b != npos )
        cout << "The index of the last element of 'D2' "
              << "after\n the 0th position in str2 is: "
              << indexCh2b << endl << endl;
    else
        cout << "The substring 'D2' was not found in str2 ."
              << endl << endl << endl;

    // The third member function searches a string
    // for a substring as specified by a C-string
    string str3 ( "456-EFG-456-EFG" );
    cout << "The original string str3 is: " << str3 << endl;
    basic_string<char>::size_type indexCh3a;
```

```

const char *cstr3a = "5E";
indexCh3a = str3.find_last_of ( cstr3a , 8 , 8 );
if ( indexCh3a != npos )
    cout << "The index of the last occurrence of an "
        << "element of '5E' in str3 before\n the 8th "
        << "position is: " << indexCh3a << endl << endl;
else
    cout << "Elements of the substring '5G' were not "
        << "found in str3\n before the 8th position."
        << endl << endl;

// The fourth member function searches a string
// for a substring as specified by a string
string str4 ( "12-ab-12-ab" );
cout << "The original string str4 is: " << str4 << endl;
basic_string<char>::size_type indexCh4a, indexCh4b;

string str4a ( "ba3" );
indexCh4a = str4.find_last_of ( str4a , 8 );
if ( indexCh4a != npos )
    cout << "The index of the last occurrence of an "
        << "element of 'ba3' in str4 before\n the 8th "
        << "position is: " << indexCh4a << endl;
else
    cout << "Elements of the substring 'ba3' were not "
        << "found in str4\n after the 0th position."
        << endl;

string str4b ( "a2" );
indexCh4b = str4.find_last_of ( str4b );
if ( indexCh4b != npos )
    cout << "The index of the last occurrence of an "
        << "element of 'a2' in str4 before\n the 0th "
        << "position is: " << indexCh4b << endl;
else
    cout << "Elements of the substring 'a2' were not "
        << "found in str4\n after the 0th position."
        << endl;
}

```

The original string str1 is: abcd-1234-abcd-1234
 The index of the last 'd' found before the 14th position in str1 is: 13
 The character 'x' was not found in str1.

The original string str2 is: ABCD-1234-ABCD-1234
 The index of the last occurrence of an element of 'B1' in str2 before
 the 12th position is: 11
 The index of the last element of 'D2' after
 the 0th position in str2 is: 16

The original string str3 is: 456-EFG-456-EFG
 The index of the last occurrence of an element of '5E' in str3 before
 the 8th position is: 4

The original string str4 is: 12-ab-12-ab
 The index of the last occurrence of an element of 'ba3' in str4 before
 the 8th position is: 4
 The index of the last occurrence of an element of 'a2' in str4 before
 the 0th position is: 9

basic_string::front

Returns a reference to the first element in a string.

```
const_reference front() const;

reference front();
```

Return Value

A reference to the first element of the string, which must be non-empty.

Remarks

basic_string::get_allocator

Returns a copy of the allocator object used to construct the string.

```
allocator_type get_allocator() const;
```

Return Value

The allocator used by the string.

Remarks

The member function returns the stored allocator object.

Allocators for the string class specify how the class manages storage. The default allocators supplied with container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```
// basic_string_get_allocator.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    // The following lines declare objects
    // that use the default allocator.
    string s1;
    basic_string <char> s2;
    basic_string <char, char_traits< char >, allocator< char > > s3;

    // s4 will use the same allocator class as s1
    basic_string <char> s4( s1.get_allocator ( ) );

    basic_string <char>::allocator_type xchar = s1.get_allocator( );
    // You can now call functions on the allocator class xchar used by s1
}
```

basic_string::insert

Inserts an element or a number of elements or a range of elements into the string at a specified position.

```

basic_string<CharType, Traits, Allocator>& insert(
    size_type _P0,
    const value_type* ptr);

basic_string<CharType, Traits, Allocator>& insert(
    size_type _P0,
    const value_type* ptr,
    size_type count);

basic_string<CharType, Traits, Allocator>& insert(
    size_type _P0,
    const basic_string<CharType, Traits, Allocator>& str);

basic_string<CharType, Traits, Allocator>& insert(
    size_type _P0,
    const basic_string<CharType, Traits, Allocator>& str,
    size_type _Off,
    size_type count);

basic_string<CharType, Traits, Allocator>& insert(
    size_type _P0,
    size_type count,
    value_type _Ch);

iterator insert(
    iterator _It);

iterator insert(
    iterator _It,
    value_type _Ch)l
template <class InputIterator>
void insert(
    iterator _It,
    InputIterator first,
    InputIterator last);

void insert(
    iterator _It,
    size_type count,
    value_type _Ch);

void insert(
    iterator _It,
    const_pointer first,
    const_pointer last);

void insert(
    iterator _It,
    const_iterator first,
    const_iterator last);

```

Parameters

_P0

The index of the position behind the point of insertion the new characters.

ptr

The C-string to be wholly or partly inserted into the string.

count

The number of characters to be inserted.

str

The string to be wholly or partly inserted into the target string.

_Off

The index of the part of the source string supplying the characters to be appended.

_Ch

The character value of the elements to be inserted.

_It

An iterator addressing the position behind which a character is to be inserted.

first

An input iterator, `const_pointer`, or `const_iterator` addressing the first element in the source range to be inserted.

last

An input iterator, `const_pointer`, or `const_iterator` addressing the position of the one beyond the last element in the source range to be inserted.

Return Value

Either a reference to the string object that is being assigned new characters by the member function or, in the case of individual character insertions, an iterator addressing the position of the character inserted, or none, depending on the particular member function.

Example

```
// basic_string_insert.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function inserting a C-string
    // at a given position
    basic_string<char> str1a ( "way" );
    const char *cstr1a = "a";
    str1a.insert ( 0, cstr1a );
    cout << "The string with a C-string inserted at position 0 is: "
         << str1a << "." << endl;

    // The second member function inserting a C-string
    // at a given position for a specified number of elements
    basic_string<char> str2a ( "Good" );
    const char *cstr2a = "Bye Bye Baby";
    str2a.insert ( 4, cstr2a ,3 );
    cout << "The string with a C-string inserted at the end is: "
         << str2a << "." << endl;

    // The third member function inserting a string
    // at a given position
    basic_string<char> str3a ( "Bye" );
    string str3b ( "Good" );
    str3a.insert ( 0, str3b );
    cout << "The string with a string inserted at position 0 is: "
         << str3a << "." << endl;

    // The fourth member function inserting part of
    // a string at a given position
    basic_string<char> str4a ( "Good " );
    string str4b ( "Bye Bye Baby" );
    str4a.insert ( 5, str4b , 8 , 4 );
    cout << "The string with part of a string inserted at position 4 is: "
         << str4a << "." << endl;
```

```

// The fifth member function inserts a number of characters
// at a specified position in the string
string str5 ( "The number is: ." );
str5.insert ( 15 , 3 , '3' );
cout << "The string with characters inserted is: "
      << str5 << endl;

// The sixth member function inserts a character
// at a specified position in the string
string str6 ( "ABCDFG" );
basic_string<char>::iterator str6_Iter = ( str6.begin ( ) + 4 );
str6.insert ( str6_Iter , 'e' );
cout << "The string with a character inserted is: "
      << str6 << endl;

// The seventh member function inserts a range
// at a specified position in the string
string str7a ( "ABCDHIJ" );
string str7b ( "abcdefgh" );
basic_string<char>::iterator str7a_Iter = (str7a.begin ( ) + 4 );
str7a.insert ( str7a_Iter , str7b.begin ( ) + 4 , str7b.end ( ) -1 );
cout << "The string with a character inserted from a range is: "
      << str7a << endl;

// The eighth member function inserts a number of
// characters at a specified position in the string
string str8 ( "ABCDHIJ" );
basic_string<char>::iterator str8_Iter = ( str8.begin ( ) + 4 );
str8.insert ( str8_Iter , 3 , 'e' );
cout << "The string with a character inserted from a range is: "
      << str8 << endl;
}

```

```

The string with a C-string inserted at position 0 is: away.
The string with a C-string inserted at the end is: GoodBye.
The string with a string inserted at position 0 is: GoodBye.
The string with part of a string inserted at position 4 is: Good Baby.
The string with characters inserted is: The number is: 333.
The string with a character inserted is: ABCDeFG
The string with a character inserted from a range is: ABCDefgHIJ
The string with a character inserted from a range is: ABCDeeeHIJ

```

basic_string::iterator

A type that provides a random-access iterator that can access and read a **const** element in the string.

```
typedef implementation-defined iterator;
```

Remarks

A type `iterator` can be used to modify the value of a character and is used to iterate through a string in a forward direction.

Example

See the example for [begin](#) for an example of how to declare and use `iterator`.

basic_string::length

Returns the current number of elements in a string.

```
size_type length() const;
```

Remarks

The member function is the same as [size](#).

Example

```
// basic_string_length.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ("Hello world");
    cout << "The original string str1 is: " << str1 << endl;

    // The size and length member functions differ in name only
    basic_string<char>::size_type sizeStr1, lenStr1;
    sizeStr1 = str1.size ( );
    lenStr1 = str1.length ( );

    basic_string<char>::size_type capStr1, max_sizeStr1;
    capStr1 = str1.capacity ( );
    max_sizeStr1 = str1.max_size ( );

    // Compare size, length, capacity & max_size of a string
    cout << "The current size of original string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The current length of original string str1 is: "
        << lenStr1 << "." << endl;
    cout << "The capacity of original string str1 is: "
        << capStr1 << "." << endl;
    cout << "The max_size of original string str1 is: "
        << max_sizeStr1 << "." << endl << endl;

    str1.erase ( 6, 5 );
    cout << "The modified string str1 is: " << str1 << endl;

    sizeStr1 = str1.size ( );
    lenStr1 = str1.length ( );
    capStr1 = str1.capacity ( );
    max_sizeStr1 = str1.max_size ( );

    // Compare size, length, capacity & max_size of a string
    // after erasing part of the original string
    cout << "The current size of modified string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The current length of modified string str1 is: "
        << lenStr1 << "." << endl;
    cout << "The capacity of modified string str1 is: "
        << capStr1 << "." << endl;
    cout << "The max_size of modified string str1 is: "
        << max_sizeStr1 << "." << endl;
}
```

basic_string::max_size

Returns the maximum number of characters a string could contain.

```
size_type max_size() const;
```

Return Value

The maximum number of characters a string could contain.

Remarks

An exception of type [length_error Class](#) is thrown when an operation produces a string with a length greater than the maximum size.

Example

```
// basic_string_max_size.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ("Hello world");
    cout << "The original string str1 is: " << str1 << endl;

    // The size and length member functions differ in name only
    basic_string<char>::size_type sizeStr1, lenStr1;
    sizeStr1 = str1.size ( );
    lenStr1 = str1.length ( );

    basic_string<char>::size_type capStr1, max_sizeStr1;
    capStr1 = str1.capacity ( );
    max_sizeStr1 = str1.max_size ( );

    // Compare size, length, capacity & max_size of a string
    cout << "The current size of original string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The current length of original string str1 is: "
        << lenStr1 << "." << endl;
    cout << "The capacity of original string str1 is: "
        << capStr1 << "." << endl;
    cout << "The max_size of original string str1 is: "
        << max_sizeStr1 << "." << endl << endl;

    str1.erase ( 6, 5 );
    cout << "The modified string str1 is: " << str1 << endl;

    sizeStr1 = str1.size ( );
    lenStr1 = str1.length ( );
    capStr1 = str1.capacity ( );
    max_sizeStr1 = str1.max_size ( );

    // Compare size, length, capacity & max_size of a string
    // after erasing part of the original string
    cout << "The current size of modified string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The current length of modified string str1 is: "
        << lenStr1 << "." << endl;
    cout << "The capacity of modified string str1 is: "
        << capStr1 << "." << endl;
    cout << "The max_size of modified string str1 is: "
        << max_sizeStr1 << "." << endl;
}
```

basic_string::npos

An unsigned integral value initialized to -1 that indicates either "not found" or "all remaining characters" when a search function fails.

```
static const size_type npos = -1;
```

Remarks

When the return value is to be checked for the `npos` value, it might not work unless the return value is of type `size_type` and not either `int` or `unsigned`.

Example

See the example for [find](#) for an example of how to declare and use `npos`.

basic_string::operator+=

Appends characters to a string.

```
basic_string<CharType, Traits, Allocator>& operator+=(  
    value_type _Ch);  
  
basic_string<CharType, Traits, Allocator>& operator+=(  
    const value_type* ptr);  
  
basic_string<CharType, Traits, Allocator>& operator+=(  
    const basic_string<CharType, Traits, Allocator>& right);
```

Parameters

_Ch

The character to be appended.

ptr

The characters of the C-string to be appended.

right

The characters of the string to be appended.

Return Value

A reference to the string object that is being appended with the characters passed by the member function.

Remarks

Characters may be appended to a string using the `operator+=` or the member functions [append](#) or [push_back](#). The `operator+=` appends single-argument values while the multiple argument append member function allows a specific part of a string to be specified for adding.

Example

```

// basic_string_op_app.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function
    // appending a single character to a string
    string str1a ( "Hello" );
    cout << "The original string str1 is: " << str1a << endl;
    str1a += '!' ;
    cout << "The string str1 appended with an exclamation is: "
        << str1a << endl << endl;

    // The second member function
    // appending a C-string to a string
    string str1b ( "Hello " );
    const char *cstr1b = "Out There";
    cout << "The C-string cstr1b is: " << cstr1b << endl;
    str1b += cstr1b;
    cout << "Appending the C-string cstr1b to string str1 gives: "
        << str1b << "." << endl << endl;

    // The third member function
    // appending one string to another in two ways,
    // comparing append and operator [ ]
    string str1d ( "Hello " ), str2d ( "Wide " ), str3d ( "World" );
    cout << "The string str2d is: " << str2d << endl;
    str1d.append ( str2d );
    cout << "The appended string str1d is: "
        << str1d << "." << endl;
    str1d += str3d;
    cout << "The doubly appended string str1 is: "
        << str1d << "." << endl << endl;
}

```

```

The original string str1 is: Hello
The string str1 appended with an exclamation is: Hello!

The C-string cstr1b is: Out There
Appending the C-string cstr1b to string str1 gives: Hello Out There.

The string str2d is: Wide
The appended string str1d is: Hello Wide .
The doubly appended string str1 is: Hello Wide World.

```

basic_string::operator=

Assigns new character values to the contents of a string.

```
basic_string<CharType, Traits, Allocator>& operator=(  
    value_type _Ch);  
  
basic_string<CharType, Traits, Allocator>& operator=(  
    const value_type* ptr);  
  
basic_string<CharType, Traits, Allocator>& operator=(  
    const basic_string<CharType, Traits, Allocator>& right);  
  
basic_string<CharType, Traits, Allocator>& operator=(  
    const basic_string<CharType, Traits, Allocator>&& right);
```

Parameters

_Ch

The character value to be assigned.

ptr

A pointer to the characters of the C-string to be assigned to the target string.

right

The source string whose characters are to be assigned to the target string.

Return Value

A reference to the string object that is being assigned new characters by the member function.

Remarks

The strings may be assigned new character values. The new value may be either a string and C-string or a single character. The `operator=` may be used if the new value can be described by a single parameter, otherwise the member function [assign](#), which has multiple parameters, may be used to specify which part of the string is to be assigned to a target string.

Example

```

// basic_string_op_assign.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function assigning a
    // character of a certain value to a string
    string str1a ( "Hello " );
    str1a = '0';
    cout << "The string str1 assigned with the zero character is: "
         << str1a << endl << endl;

    // The second member function assigning the
    // characters of a C-string to a string
    string str1b;
    const char *cstr1b = "Out There";
    cout << "The C-string cstr1b is: " << cstr1b << "." << endl;
    str1b = cstr1b;
    cout << "Assigning the C-string cstr1a to string str1 gives: "
         << str1b << "." << endl << endl;

    // The third member function assigning the characters
    // from one string to another string in two equivalent
    // ways, comparing the assign and operator =
    string str1c ( "Hello" ), str2c ( "Wide" ), str3c ( "World" );
    cout << "The original string str1 is: " << str1c << "." << endl;
    cout << "The string str2c is: " << str2c << "." << endl;
    str1c.assign ( str2c );
    cout << "The string str1 newly assigned with string str2c is: "
         << str1c << "." << endl;
    cout << "The string str3c is: " << str3c << "." << endl;
    str1c = str3c;
    cout << "The string str1 reassigned with string str3c is: "
         << str1c << "." << endl << endl;
}

```

The string str1 assigned with the zero character is: 0

The C-string cstr1b is: Out There.

Assigning the C-string cstr1a to string str1 gives: Out There.

The original string str1 is: Hello.

The string str2c is: Wide.

The string str1 newly assigned with string str2c is: Wide.

The string str3c is: World.

The string str1 reassigned with string str3c is: World.

basic_string::operator[]

Provides a reference to the character with a specified index in a string.

```

const_reference operator[](size_type _Off) const;
reference operator[](size_type _Off);

```

Parameters

_Off

The index of the position of the element to be referenced.

Return Value

A reference to the character of the string at the position specified by the parameter index.

Remarks

The first element of the string has an index of zero, and the following elements are indexed consecutively by the positive integers, so that a string of length n has an n th element indexed by the number $n - 1$.

`operator[]` is faster than the member function `at` for providing read and write access to the elements of a string.

`operator[]` does not check whether the index passed as a parameter is valid, but the member function `at` does and so should be used in the validity is not certain. An invalid index (an index less than zero or greater than or equal to the size of the string) passed to the member function `at` throws an [out_of_range Class](#) exception. An invalid index passed to `operator[]` results in undefined behavior, but the index equal to the length of the string is a valid index for const strings and the operator returns the null character when passed this index.

The reference returned may be invalidated by string reallocations or modifications for the non- **const** strings.

When compiling with `_ITERATOR_DEBUG_LEVEL` set to 1 or 2, a runtime error will occur if you attempt to access an element outside the bounds of the string. For more information, see [Checked Iterators](#).

Example

```
// basic_string_op_ref.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ( "Hello world" ), str2 ( "Goodbye world" );
    const string cstr1 ( "Hello there" ), cstr2 ( "Goodbye now" );
    cout << "The original string str1 is: " << str1 << endl;
    cout << "The original string str2 is: " << str2 << endl;

    // Element access to the non-const strings
    basic_string<char>::reference refStr1 = str1 [6];
    basic_string<char>::reference refStr2 = str2.at ( 3 );

    cout << "The character with an index of 6 in string str1 is: "
        << refStr1 << "." << endl;
    cout << "The character with an index of 3 in string str2 is: "
        << refStr2 << "." << endl;

    // Element access to the const strings
    basic_string<char>::const_reference crefStr1 = cstr1 [ cstr1.length ( ) ];
    basic_string<char>::const_reference crefStr2 = cstr2.at ( 8 );

    if ( crefStr1 == '\0' )
        cout << "The null character is returned as a valid reference."
            << endl;
    else
        cout << "The null character is not returned." << endl;
    cout << "The character with index of 8 in the const string cstr2 is: "
        << crefStr2 << "." << endl;
}
```

`basic_string::pointer`

A type that provides a pointer to a character element in a string or character array.

```
typedef typename allocator_type::pointer pointer;
```

Remarks

The type is a synonym for `allocator_type::pointer`.

For type `string`, it is equivalent to **char***.

Example

```
// basic_string_pointer.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    basic_string<char>::pointer pstr1a = "In Here";
    char *cstr1b = "Out There";
    cout << "The string pstr1a is: " << pstr1a << "." << endl;
    cout << "The C-string cstr1b is: " << cstr1b << "." << endl;
}
```

```
The string pstr1a is: In Here.
The C-string cstr1b is: Out There.
```

basic_string::pop_back

Erases the last element of the string.

```
void pop_back();
```

Remarks

This member function effectively calls `erase(size() - 1)` to erase the last element of the sequence, which must be non-empty.

basic_string::push_back

Adds an element to the end of the string.

```
void push_back(value_type _Ch);
```

Parameters

_Ch

The character to be added to the end of the string.

Remarks

The member function effectively calls `insert(end, _Ch)`.

Example

```

// basic_string_push_back.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ( "abc" );
    basic_string<char>::iterator str_Iter, str1_Iter;

    cout << "The original string str1 is: ";
    for ( str_Iter = str1.begin( ); str_Iter != str1.end( ); str_Iter++ )
        cout << *str_Iter;
    cout << endl;

    // str1.push_back ( 'd' );
    str1_Iter = str1.end ( );
    str1_Iter--;
    cout << "The last character-letter of the modified str1 is now: "
        << *str1_Iter << endl;

    cout << "The modified string str1 is: ";
    for ( str_Iter = str1.begin( ); str_Iter != str1.end( ); str_Iter++ )
        cout << *str_Iter;
    cout << endl;
}

```

```

The original string str1 is: abc
The last character-letter of the modified str1 is now: c
The modified string str1 is: abc

```

basic_string::rbegin

Returns an iterator to the first element in a reversed string.

```

const_reverse_iterator rbegin() const;

reverse_iterator rbegin();

```

Return Value

Returns a random-access iterator to the first element in a reversed string, addressing what would be the last element in the corresponding unreversed string.

Remarks

`rbegin` is used with a reversed string just as `begin` is used with a string.

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, the string object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, the string object can be modified.

`rbegin` can be used to initialize an iteration through a string backwards.

Example

```

// basic_string_rbegin.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ( "Able was I ere I saw Elba" ), str2;
    basic_string<char>::reverse_iterator str_rIter, str1_rIter, str2_rIter;
    basic_string<char>::const_reverse_iterator str1_rcIter;

    str1_rIter = str1.rbegin ( );
    // str1_rIter--;
    cout << "The first character-letter of the reversed string str1 is: "
         << *str1_rIter << endl;
    cout << "The full reversed string str1 is:\n ";
    for ( str_rIter = str1.rbegin( ); str_rIter != str1.rend( ); str_rIter++ )
        cout << *str_rIter;
    cout << endl;

    // The dereferenced iterator can be used to modify a character
    *str1_rIter = 'A';
    cout << "The first character-letter of the modified str1 is now: "
         << *str1_rIter << endl;
    cout << "The full modified reversed string str1 is now:\n ";
    for ( str_rIter = str1.rbegin( ); str_rIter != str1.rend( ); str_rIter++ )
        cout << *str_rIter;
    cout << endl;

    // The following line would be an error because iterator is const
    // *str1_rcIter = 'A';

    // For an empty string, begin is equivalent to end
    if ( str2.rbegin( ) == str2.rend( ) )
        cout << "The string str2 is empty." << endl;
    else
        cout << "The stringstr2  is not empty." << endl;
}

```

```

The first character-letter of the reversed string str1 is: a
The full reversed string str1 is:
ablE was I ere I saw elbA
The first character-letter of the modified str1 is now: A
The full modified reversed string str1 is now:
Ab1E was I ere I saw elbA
The string str2 is empty.

```

basic_string::reference

A type that provides a reference to an element stored in a string.

```
typedef typename allocator_type::reference reference;
```

Remarks

A type `reference` can be used to modify the value of an element.

The type is a synonym for `allocator_type::reference`.

For type `string`, it is equivalent to `chr&`.

Example

See the example for [at](#) for an example of how to declare and use `reference`.

basic_string::rend

Returns an iterator that addresses the location succeeding the last element in a reversed string.

```
const_reverse_iterator rend() const;  
  
reverse_iterator rend();
```

Return Value

A reverse random-access iterator that addresses the location succeeding the last element in a reversed string.

Remarks

`rend` is used with a reversed string just as [end](#) is used with a string.

If the return value of `rend` is assigned to a `const_reverse_iterator`, the string object cannot be modified. If the return value of `rend` is assigned to a `reverse_iterator`, the string object can be modified.

`rend` can be used to test whether a reverse iterator has reached the end of its string.

The value returned by `rend` should not be dereferenced.

Example

```

// basic_string_rend.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ("Able was I ere I saw Elba"), str2;
    basic_string<char>::reverse_iterator str_rIter, str1_rIter, str2_rIter;
    basic_string<char>::const_reverse_iterator str1_rcIter;

    str1_rIter = str1.rend( );
    str1_rIter--;
    cout << "The last character-letter of the reversed string str1 is: "
         << *str1_rIter << endl;
    cout << "The full reversed string str1 is:\n ";
    for ( str_rIter = str1.rbegin( ); str_rIter != str1.rend( ); str_rIter++ )
        cout << *str_rIter;
    cout << endl;

    // The dereferenced iterator can be used to modify a character
    *str1_rIter = 'o';
    cout << "The last character-letter of the modified str1 is now: "
         << *str1_rIter << endl;
    cout << "The full modified reversed string str1 is now:\n ";
    for ( str_rIter = str1.rbegin( ); str_rIter != str1.rend( ); str_rIter++ )
        cout << *str_rIter;
    cout << endl;

    // The following line would be an error because iterator is const
    // *str1_rcIter = 'T';

    // For an empty string, end is equivalent to begin
    if ( str2.rbegin( ) == str2.rend( ) )
        cout << "The string str2 is empty." << endl;
    else
        cout << "The stringstr2  is not empty." << endl;
}

```

```

The last character-letter of the reversed string str1 is: A
The full reversed string str1 is:
ablE was I ere I saw elbA
The last character-letter of the modified str1 is now: o
The full modified reversed string str1 is now:
ablE was I ere I saw elbo
The string str2 is empty.

```

basic_string::replace

Replaces elements in a string at a specified position with specified characters or characters copied from other ranges or strings or C-strings.

```

basic_string<CharType, Traits, Allocator>& replace(
    size_type _Pos1,
    size_type _Num1,
    const value_type* ptr);

basic_string<CharType, Traits, Allocator>& replace(
    size_type _Pos1,
    size_type _Num1,
    const basic_string<CharType, Traits, Allocator>& str);

```

```

basic_string<CharType, Traits, Allocator>& replace(
    size_type _Pos1,
    size_type _Num1,
    const value_type* ptr,
    size_type _Num2);

basic_string<CharType, Traits, Allocator>& replace(
    size_type _Pos1,
    size_type _Num1,
    const basic_string<CharType, Traits, Allocator>& str,
    size_type _Pos2,
    size_type _Num2);

basic_string<CharType, Traits, Allocator>& replace(
    size_type _Pos1,
    size_type _Num1,
    size_type count,
    value_type _Ch);

basic_string<CharType, Traits, Allocator>& replace(
    iterator first0,
    iterator last0,
    const value_type* ptr);

basic_string<CharType, Traits, Allocator>& replace(
    iterator first0,
    iterator last0,
    const basic_string<CharType, Traits, Allocator>& str);

basic_string<CharType, Traits, Allocator>& replace(
    iterator first0,
    iterator last0,
    const value_type* ptr,
    size_type _Num2);

basic_string<CharType, Traits, Allocator>& replace(
    iterator first0,
    iterator last0,
    size_type _Num2,
    value_type _Ch);

template <class InputIterator>
basic_string<CharType, Traits, Allocator>& replace(
    iterator first0,
    iterator last0,
    InputIterator first,
    InputIterator last);

basic_string<CharType, Traits, Allocator>& replace(
    iterator first0,
    iterator last0,
    const_pointer first,
    const_pointer last);

basic_string<CharType, Traits, Allocator>& replace(
    iterator first0,
    iterator last0,
    const_iterator first,
    const_iterator last);

```

Parameters

str

The string that is to be a source of characters for the operand string.

_Pos1

The index of the operand string at which the replacement begins.

_Num1

The maximum number of characters to be replaced in the operand string.

_Pos2

The index of the parameter string at which the copying begins.

_Num2

The maximum number of characters to be used from the parameter C-string.

ptr

The C-string that is to be a source of characters for the operand string.

_Ch

The character to be copied into the operand string.

first0

An iterator addressing the first character to be removed in the operand string.

last0

An iterator addressing the last character to be removed in the operand string.

first

An iterator, `const_pointer`, or `const_iterator` addressing the first character to be copied in the parameter string.

last

An iterator, `const_pointer`, or `const_iterator` addressing the last character to be copied in the parameter string.

count

The number of times *_Ch* is copied into the operand string.

Return Value

The operand string with the replacement made.

Example

```
// basic_string_replace.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first two member functions replace
    // part of the operand string with
    // characters from a parameter string or C-string
    string result1a, result1b;
    string s1o ( "AAAAAAA" );
    string s1p ( "BBB" );
    const char* cs1p = "CCC";
    cout << "The operand string s1o is: " << s1o << endl;
    cout << "The parameter string s1p is: " << s1p << endl;
    cout << "The parameter C-string cs1p is: " << cs1p << endl;
    result1a = s1o.replace ( 1 , 3 , s1p );
    cout << "The result of s1o.replace ( 1 , 3 , s1p )\n is "
        << "the string: " << result1a << "." << endl;
    result1b = s1o.replace ( 5 , 3 , cs1p );
    cout << "The result of s1o.replace ( 5 , 3 , cs1p )\n is "
        << "the string: " << result1b << "." << endl;
    cout << endl;

    // The third & fourth member function replace
    // part of the operand string with characters
```

```

// part of the operand string with characters
// form part of a parameter string or C-string
string result2a, result2b;
string s2o ( "AAAAAAA" );
string s2p ( "BBB" );
const char* cs2p = "CCC";
cout << "The operand string s2o is: " << s2o << endl;
cout << "The parameter string s1p is: " << s2p << endl;
cout << "The parameter C-string cs2p is: " << cs2p << endl;
result2a = s2o.replace ( 1 , 3 , s2p , 1 , 2 );
cout << "The result of s2o.replace (1, 3, s2p, 1, 2)\n is "
    << "the string: " << result2a << "." << endl;
result2b = s2o.replace ( 4 , 3 , cs2p , 1 );
cout << "The result of s2o.replace (4 ,3 ,cs2p)\n is "
    << "the string: " << result2b << "." << endl;
cout << endl;

// The fifth member function replaces
// part of the operand string with characters
string result3a;
string s3o ( "AAAAAAA" );
char ch3p = 'C';
cout << "The operand string s3o is: " << s3o << endl;
cout << "The parameter character c1p is: " << ch3p << endl;
result3a = s3o.replace ( 1 , 3 , 4 , ch3p );
cout << "The result of s3o.replace(1, 3, 4, ch3p)\n is "
    << "the string: " << result3a << "." << endl;
cout << endl;

// The sixth & seventh member functions replace
// part of the operand string, delineated with iterators,
// with a parameter string or C-string
string s4o ( "AAAAAAA" );
string s4p ( "BBB" );
const char* cs4p = "CCC";
cout << "The operand string s4o is: " << s4o << endl;
cout << "The parameter string s4p is: " << s4p << endl;
cout << "The parameter C-string cs4p is: " << cs4p << endl;
basic_string<char>::iterator IterF0, IterL0;
IterF0 = s4o.begin ( );
IterL0 = s4o.begin ( ) + 3;
string result4a, result4b;
result4a = s4o.replace ( IterF0 , IterL0 , s4p );
cout << "The result of s1o.replace (IterF0, IterL0, s4p)\n is "
    << "the string: " << result4a << "." << endl;
result4b = s4o.replace ( IterF0 , IterL0 , cs4p );
cout << "The result of s4o.replace (IterF0, IterL0, cs4p)\n is "
    << "the string: " << result4b << "." << endl;
cout << endl;

// The 8th member function replaces
// part of the operand string delineated with iterators
// with a number of characters from a parameter C-string
string s5o ( "AAAAAAAF" );
const char* cs5p = "CCCB";
cout << "The operand string s5o is: " << s5o << endl;
cout << "The parameter C-string cs5p is: " << cs5p << endl;
basic_string<char>::iterator IterF1, IterL1;
IterF1 = s5o.begin ( );
IterL1 = s5o.begin ( ) + 4;
string result5a;
result5a = s5o.replace ( IterF1 , IterL1 , cs5p , 4 );
cout << "The result of s5o.replace (IterF1, IterL1, cs4p ,4)\n is "
    << "the string: " << result5a << "." << endl;
cout << endl;

// The 9th member function replaces
// part of the operand string delineated with iterators
// with specified characters
string s6o ( "AAAAAAG" );

```

```

string s6o ( "AAAAAA" );
char ch6p = 'q';
cout << "The operand string s6o is: " << s6o << endl;
cout << "The parameter character ch6p is: " << ch6p << endl;
basic_string<char>::iterator IterF2, IterL2;
IterF2 = s6o.begin ( );
IterL2 = s6o.begin ( ) + 3;
string result6a;
result6a = s6o.replace ( IterF2 , IterL2 , 4 , ch6p );
cout << "The result of s6o.replace (IterF1, IterL1, 4, ch6p)\n is "
    << "the string: " << result6a << "." << endl;
cout << endl;

// The 10th member function replaces
// part of the operand string delineated with iterators
// with part of a parameter string delineated with iterators
string s7o ( "0000000" );
string s7p ( "PPPP" );
cout << "The operand string s7o is: " << s7o << endl;
cout << "The parameter string s7p is: " << s7p << endl;
basic_string<char>::iterator IterF3, IterL3, IterF4, IterL4;
IterF3 = s7o.begin ( ) + 1;
IterL3 = s7o.begin ( ) + 3;
IterF4 = s7p.begin ( );
IterL4 = s7p.begin ( ) + 2;
string result7a;
result7a = s7o.replace ( IterF3 , IterL3 , IterF4 , IterL4 );
cout << "The result of s7o.replace (IterF3 ,IterL3 ,IterF4 ,IterL4)\n is "
    << "the string: " << result7a << "." << endl;
cout << endl;
}

```

The operand string s1o is: AAAAAAAA
The parameter string s1p is: BBB
The parameter C-string cs1p is: CCC
The result of s1o.replace (1 , 3 , s1p)
is the string: ABBBAAAA.
The result of s1o.replace (5 , 3 , cs1p)
is the string: ABBBACCC.

The operand string s2o is: AAAAAAAA
The parameter string s1p is: BBB
The parameter C-string cs2p is: CCC
The result of s2o.replace (1, 3, s2p, 1, 2)
is the string: ABBAAAA.
The result of s2o.replace (4 ,3 ,cs2p)
is the string: ABBAC.

The operand string s3o is: AAAAAAAA
The parameter character c1p is: C
The result of s3o.replace(1, 3, 4, ch3p)
is the string: ACCCCAAAA.

The operand string s4o is: AAAAAAAA
The parameter string s4p is: BBB
The parameter C-string cs4p is: CCC
The result of s1o.replace (IterF0, IterL0, s4p)
is the string: ABBBAAAA.
The result of s4o.replace (IterF0, IterL0, cs4p)
is the string: CCCAAAAA.

The operand string s5o is: AAAAAAAF
The parameter C-string cs5p is: CCCBB
The result of s5o.replace (IterF1, IterL1, cs4p ,4)
is the string: CCCBAAAF.

The operand string s6o is: AAAAAAAG
The parameter character ch6p is: q
The result of s6o.replace (IterF1, IterL1, 4, ch6p)
is the string: qqqaAAAAG.

The operand string s7o is: 0000000
The parameter string s7p is: PPPP
The result of s7o.replace (IterF3 ,IterL3 ,IterF4 ,IterL4)
is the string: OPP0000.

basic_string::reserve

Sets the capacity of the string to a number at least as great as a specified number.

```
void reserve(size_type count = 0);
```

Parameters

count

The number of characters for which memory is being reserved.

Remarks

Having sufficient capacity is important because reallocations is a time-consuming process and invalidates all references, pointers, and iterators that refer to characters in a string.

The concept of capacity for objects of type strings is the same as for objects of type vector. Unlike vector, the member function `reserve` may be called to shrink the capacity of an object. The request is nonbinding and may or may not happen. As the default value for the parameter is zero, a call of `reserve` is a non-binding

request to shrink the capacity of the string to fit the number of characters currently in the string. The capacity is never reduced below the current number of characters.

Calling `reserve` is the only possible way to shrink the capacity of a string. However, as noted above, this request is nonbinding and may not happen.

Example

```
// basic_string_reserve.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ("Hello world");
    cout << "The original string str1 is: " << str1 << endl;

    basic_string<char>::size_type sizeStr1, sizerStr1;
    sizeStr1 = str1.size ( );
    basic_string<char>::size_type capStr1, caprStr1;
    capStr1 = str1.capacity ( );

    // Compare size & capacity of the original string
    cout << "The current size of original string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The capacity of original string str1 is: "
        << capStr1 << "." << endl << endl;

    // Compare size & capacity of the string
    // with added capacity
    str1.reserve ( 40 );
    sizerStr1 = str1.size ( );
    caprStr1 = str1.capacity ( );

    cout << "The string str1with augmented capacity is: "
        << str1 << endl;
    cout << "The current size of string str1 is: "
        << sizerStr1 << "." << endl;
    cout << "The new capacity of string str1 is: "
        << caprStr1 << "." << endl << endl;

    // Compare size & capacity of the string
    // with downsized capacity
    str1.reserve ( );
    basic_string<char>::size_type sizedStr1;
    basic_string<char>::size_type capdStr1;
    sizedStr1 = str1.size ( );
    capdStr1 = str1.capacity ( );

    cout << "The string str1 with downsized capacity is: "
        << str1 << endl;
    cout << "The current size of string str1 is: "
        << sizedStr1 << "." << endl;
    cout << "The reduced capacity of string str1 is: "
        << capdStr1 << "." << endl << endl;
}
```

```
The original string str1 is: Hello world
The current size of original string str1 is: 11.
The capacity of original string str1 is: 15.

The string str1with augmented capacity is: Hello world
The current size of string str1 is: 11.
The new capacity of string str1 is: 47.

The string str1 with downsized capacity is: Hello world
The current size of string str1 is: 11.
The reduced capacity of string str1 is: 47.
```

basic_string::resize

Specifies a new size for a string, appending or erasing elements as required.

```
void resize(
    size_type count,);

void resize(
    size_type count,
    _Elem _Ch);
```

Parameters

count

The new size of the string.

_Ch

The value that appended characters are initialized with if additional elements are required.

Remarks

If the resulting size exceeds the maximum number of characters, the form throws `length_error`.

Example

```

// basic_string_resize.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ( "Hello world" );
    cout << "The original string str1 is: " << str1 << endl;

    basic_string<char>::size_type sizeStr1;
    sizeStr1 = str1.size ( );
    basic_string<char>::size_type capStr1;
    capStr1 = str1.capacity ( );

    // Compare size & capacity of the original string
    cout << "The current size of original string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The capacity of original string str1 is: "
        << capStr1 << "." << endl << endl;

    // Use resize to increase size by 2 elements: exclamations
    str1.resize ( str1.size ( ) + 2 , '!' );
    cout << "The resized string str1 is: " << str1 << endl;

    sizeStr1 = str1.size ( );
    capStr1 = str1.capacity ( );

    // Compare size & capacity of a string after resizing
    cout << "The current size of resized string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The capacity of resized string str1 is: "
        << capStr1 << "." << endl << endl;

    // Use resize to increase size by 20 elements:
    str1.resize ( str1.size ( ) + 20 );
    cout << "The resized string str1 is: " << str1 << endl;

    sizeStr1 = str1.size ( );
    capStr1 = str1.capacity ( );

    // Compare size & capacity of a string after resizing
    // note capacity increases automatically as required
    cout << "The current size of modified string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The capacity of modified string str1 is: "
        << capStr1 << "." << endl << endl;

    // Use resize to downsize by 28 elements:
    str1.resize ( str1.size ( ) - 28 );
    cout << "The downsized string str1 is: " << str1 << endl;

    sizeStr1 = str1.size ( );
    capStr1 = str1.capacity ( );

    // Compare size & capacity of a string after downsizing
    cout << "The current size of downsized string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The capacity of downsized string str1 is: "
        << capStr1 << "." << endl;
}

```

```
The original string str1 is: Hello world
The current size of original string str1 is: 11.
The capacity of original string str1 is: 15.
```

```
The resized string str1 is: Hello world!!
The current size of resized string str1 is: 13.
The capacity of resized string str1 is: 15.
```

```
The resized string str1 is: Hello world!!
The current size of modified string str1 is: 33.
The capacity of modified string str1 is: 47.
```

```
The downsized string str1 is: Hello
The current size of downsized string str1 is: 5.
The capacity of downsized string str1 is: 47.
```

basic_string::reverse_iterator

A type that provides a reference to an element stored in a string.

```
typedef std::reverse_iterator<iterator> reverse_iterator;
```

Remarks

A type `reverse_iterator` can be used to modify the value of a character and is used to iterate through a string in reverse.

Example

See the example for [rbegin](#) for an example of how to declare and use `reverse_iterator`.

basic_string::rfind

Searches a string in a backward direction for the first occurrence of a substring that matches a specified sequence of characters.

```
size_type rfind(
    value_type _Ch,
    size_type _Off = npos) const;

size_type rfind(
    const value_type* ptr,
    size_type _Off = npos) const;

size_type rfind(
    const value_type* ptr,
    size_type _Off,
    size_type count) const;

size_type rfind(
    const basic_string<CharType, Traits, Allocator>& str,
    size_type _Off = npos) const;
```

Parameters

_Ch

The character value for which the member function is to search.

_Off

Index of the position at which the search is to begin.

ptr

The C-string for which the member function is to search.

count

The number of characters, counting forward from the first character, in the C-string for which the member function is to search.

str

The string for which the member function is to search.

Return Value

The index of the last occurrence, when searched backwards, of the first character of the substring when successful; otherwise `npos`.

Example

```
// basic_string_rfind.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function
    // searches for a single character in a string
    string str1 ( "Hello Everyone" );
    cout << "The original string str1 is: " << str1 << endl;
    basic_string<char>::size_type indexCh1a, indexCh1b;
    static const basic_string<char>::size_type npos = -1;

    indexCh1a = str1.rfind ( "e" , 9 );
    if ( indexCh1a != npos )
        cout << "The index of the 1st 'e' found before the 9th"
              << " position in str1 is: " << indexCh1a << endl;
    else
        cout << "The character 'e' was not found in str1 ." << endl;

    indexCh1b = str1.rfind ( "x" );
    if ( indexCh1b != npos )
        cout << "The index of the 'x' found in str1 is: "
              << indexCh1b << endl << endl;
    else
        cout << "The character 'x' was not found in str1."
              << endl << endl;

    // The second member function searches a string
    // for a substring as specified by a C-string
    string str2 ( "Let me make this perfectly clear." );
    cout << "The original string str2 is: " << str2 << endl;
    basic_string<char>::size_type indexCh2a, indexCh2b;

    const char *cstr2 = "perfect";
    indexCh2a = str2.rfind ( cstr2 , 30 );
    if ( indexCh2a != npos )
        cout << "The index of the 1st element of 'perfect' "
              << "before\n the 30th position in str2 is: "
              << indexCh2a << endl;
    else
        cout << "The substring 'perfect' was not found in str2 ."
              << endl;

    const char *cstr2b = "imperfectly";
    indexCh2b = str2.rfind ( cstr2b , 30 );
    if ( indexCh2b != npos )
```

```

11 ( indexCh2b != npos )
    cout << "The index of the 1st element of 'imperfect' "
        << "before\n the 5th position in str3 is: "
        << indexCh2b << endl;
else
    cout << "The substring 'imperfect' was not found in str2 ."
        << endl << endl;

// The third member function searches a string
// for a substring as specified by a C-string
string str3 ( "It is a nice day. I am happy." );
cout << "The original string str3 is: " << str3 << endl;
basic_string<char>::size_type indexCh3a, indexCh3b;

const char *cstr3a = "nice";
indexCh3a = str3.rfind ( cstr3a );
if ( indexCh3a != npos )
    cout << "The index of the 1st element of 'nice' "
        << "in str3 is: " << indexCh3a << endl;
else
    cout << "The substring 'nice' was not found in str3 ."
        << endl;

const char *cstr3b = "am";
indexCh3b = str3.rfind ( cstr3b , indexCh3a + 25 , 2 );
if ( indexCh3b != npos )
    cout << "The index of the next occurrence of 'am' in "
        << "str3 begins at: " << indexCh3b << endl << endl;
else
    cout << "There is no next occurrence of 'am' in str3 ."
        << endl << endl;

// The fourth member function searches a string
// for a substring as specified by a string
string str4 ( "This perfectly unclear." );
cout << "The original string str4 is: " << str4 << endl;
basic_string<char>::size_type indexCh4a, indexCh4b;

string str4a ( "clear" );
indexCh4a = str4.rfind ( str4a , 15 );
if ( indexCh4a != npos )
    cout << "The index of the 1st element of 'clear' "
        << "before\n the 15th position in str4 is: "
        << indexCh4a << endl;
else
    cout << "The substring 'clear' was not found in str4 "
        << "before the 15th position." << endl;

string str4b ( "clear" );
indexCh4b = str4.rfind ( str4b );
if ( indexCh4b != npos )
    cout << "The index of the 1st element of 'clear' "
        << "in str4 is: "
        << indexCh4b << endl;
else
    cout << "The substring 'clear' was not found in str4 ."
        << endl << endl;
}

```

The original string str1 is: Hello Everyone
The index of the 1st 'e' found before the 9th position in str1 is: 8
The character 'x' was not found in str1.

The original string str2 is: Let me make this perfectly clear.
The index of the 1st element of 'perfect' before
the 30th position in str2 is: 17
The substring 'imperfect' was not found in str2 .

The original string str3 is: It is a nice day. I am happy.
The index of the 1st element of 'nice' in str3 is: 8
The index of the next occurrence of 'am' in str3 begins at: 20

The original string str4 is: This perfectly unclear.
The substring 'clear' was not found in str4 before the 15th position.
The index of the 1st element of 'clear' in str4 is: 17

basic_string::shrink_to_fit

Discards the excess capacity of the string.

```
void shrink_to_fit();
```

Remarks

This member function eliminates any unneeded storage in the container.

basic_string::size

Returns the current number of elements in a string.

```
size_type size() const;
```

Return Value

The length of the string.

Example

```

// basic_string_size.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ("Hello world");
    cout << "The original string str1 is: " << str1 << endl;

    // The size and length member functions differ in name only
    basic_string<char>::size_type sizeStr1, lenStr1;
    sizeStr1 = str1.size ( );
    lenStr1 = str1.length ( );

    basic_string<char>::size_type capStr1, max_sizeStr1;
    capStr1 = str1.capacity ( );
    max_sizeStr1 = str1.max_size ( );

    // Compare size, length, capacity & max_size of a string
    cout << "The current size of original string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The current length of original string str1 is: "
        << lenStr1 << "." << endl;
    cout << "The capacity of original string str1 is: "
        << capStr1 << "." << endl;
    cout << "The max_size of original string str1 is: "
        << max_sizeStr1 << "." << endl << endl;

    str1.erase ( 6, 5 );
    cout << "The modified string str1 is: " << str1 << endl;

    sizeStr1 = str1.size ( );
    lenStr1 = str1.length ( );
    capStr1 = str1.capacity ( );
    max_sizeStr1 = str1.max_size ( );

    // Compare size, length, capacity & max_size of a string
    // after erasing part of the original string
    cout << "The current size of modified string str1 is: "
        << sizeStr1 << "." << endl;
    cout << "The current length of modified string str1 is: "
        << lenStr1 << "." << endl;
    cout << "The capacity of modified string str1 is: "
        << capStr1 << "." << endl;
    cout << "The max_size of modified string str1 is: "
        << max_sizeStr1 << "." << endl;
}

```

basic_string::size_type

An unsigned integer type that can represent the number of elements and indices in a string.

```
typedef typename allocator_type::size_type size_type;
```

Remarks

It is equivalent to `allocator_type::size_type`.

For type `string`, it is equivalent to `size_t`.

Example

```

// basic_string_size_type.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    string str1 ( "Hello world" );

    basic_string<char>::size_type sizeStr1, capStr1;
    sizeStr1 = str1.size ( );
    capStr1 = str1.capacity ( );

    cout << "The current size of string str1 is: "
         << sizeStr1 << "." << endl;
    cout << "The capacity of string str1 is: " << capStr1
         << "." << endl;
}

```

```

The current size of string str1 is: 11.
The capacity of string str1 is: 15.

```

basic_string::substr

Copies a substring of at most some number of characters from a string beginning from a specified position.

```

basic_string<CharType, Traits, Allocator> substr(
    size_type _Off = 0,
    size_type count = npos) const;

```

Parameters

_Off

An index locating the element at the position from which the copy of the string is made, with a default value of 0.

count

The number of characters that are to be copied if they are present.

Return Value

A substring object that is a copy of elements of the string operand beginning at the position specified by the first argument.

Example

```
// basic_string_substr.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    string str1 ("Heterological paradoxes are persistent.");
    cout << "The original string str1 is: \n " << str1
        << endl << endl;

    basic_string<char> str2 = str1.substr ( 6 , 7 );
    cout << "The substring str1 copied is: " << str2
        << endl << endl;

    basic_string<char> str3 = str1.substr ( );
    cout << "The default substring str3 is: \n " << str3
        << "\n which is the entire original string." << endl;
}
```

```
The original string str1 is:
Heterological paradoxes are persistent.

The substring str1 copied is: logical

The default substring str3 is:
Heterological paradoxes are persistent.
which is the entire original string.
```

basic_string::swap

Exchange the contents of two strings.

```
void swap(
    basic_string<CharType, Traits, Allocator>& str);
```

Parameters

str

The source string whose elements are to be exchanged with those in the destination string.

Remarks

If the strings being swapped have the same allocator object, the `swap` member function:

- Occurs in constant time.
- Throws no exceptions.
- Invalidates no references, pointers, or iterators that designate elements in the two strings.

Otherwise, it performs a number of element assignments and constructor calls proportional to the number of elements in the two controlled sequences.

Example

```
// basic_string_swap.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // Declaring an objects of type basic_string<char>
    string s1 ( "Tweedledee" );
    string s2 ( "Tweedledum" );
    cout << "Before swapping string s1 and s2:" << endl;
    cout << " The basic_string s1 = " << s1 << "." << endl;
    cout << " The basic_string s2 = " << s2 << "." << endl;

    s1.swap ( s2 );
    cout << "After swapping string s1 and s2:" << endl;
    cout << " The basic_string s1 = " << s1 << "." << endl;
    cout << " The basic_string s2 = " << s2 << "." << endl;
}
```

```
Before swapping string s1 and s2:
The basic_string s1 = Tweedledee.
The basic_string s2 = Tweedledum.
After swapping string s1 and s2:
The basic_string s1 = Tweedledum.
The basic_string s2 = Tweedledee.
```

basic_string::traits_type

A type for the character traits of the elements stored in a string.

```
typedef Traits traits_type;
```

Remarks

The type is a synonym for the second template parameter `Traits`.

For type `string`, it is equivalent to **char_traits<char>**.

Example

See the example for [copy](#) for an example of how to declare and use `traits_type`.

basic_string::value_type

A type that represents the type of characters stored in a string.

```
typedef typename allocator_type::value_type value_type;
```

Remarks

It is equivalent to `traits_type::char_type` and is equivalent to **char** for objects of type `string`.

Example

```
// basic_string_value_type.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    basic_string<char>::value_type ch1 = 'G';

    char ch2 = 'H';

    cout << "The character ch1 is: " << ch1 << "." << endl;
    cout << "The character ch2 is: " << ch2 << "." << endl;
}
```

```
The character ch1 is: G.
The character ch2 is: H.
```

[Thread Safety in the C++ Standard Library](#)

char_traits Struct

5/7/2019 • 23 minutes to read • [Edit Online](#)

The char_traits struct describes attributes associated with a character.

Syntax

```
template <class CharType>
struct char_traits;
```

Parameters

CharType

The element data type.

Remarks

The template struct describes various character traits for type `CharType`. The template class `basic_string` as well as several iostream template classes, including `basic_ios`, use this information to manipulate elements of type `CharType`. Such an element type must not require explicit construction or destruction. It must supply a default constructor, a copy constructor, and an assignment operator, with the expected semantics. A bitwise copy must have the same effect as an assignment. None of the member functions of struct char_traits can throw exceptions.

Typedefs

TYPE NAME	DESCRIPTION
<code>char_type</code>	A type of character.
<code>int_type</code>	An integer type that can represent a character of type <code>char_type</code> or an end-of-file (EOF) character.
<code>off_type</code>	An integer type that can represent offsets between positions in a stream.
<code>pos_type</code>	An integer type that can represent positions in a stream.
<code>state_type</code>	A type that represents the conversion state in for multibyte characters in a stream.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>assign</code>	Assigns one character value to another.
<code>compare</code>	Compares up to a specified number of characters in two strings.
<code>copy</code>	Copies a specified number of characters from one string to another. Deprecated. Use <code>char_traits::_Copy_s</code> instead.

MEMBER FUNCTION	DESCRIPTION
_Copy_s	Copies a specified number of characters from one string to another.
eof	Returns the end-of-file (EOF) character.
eq	Tests whether two <code>char_type</code> characters are equal.
eq_int_type	Tests whether two characters represented as <code>int_type</code> s are equal.
find	Searches for the first occurrence of a specified character in a range of characters.
length	Returns the length of a string.
lt	Tests whether one character is less than another.
move	Copies a specified number of characters in a sequence to another, possible overlapping, sequence. Deprecated. Use char_traits::Move_s instead.
_Move_s	Copies a specified number of characters in a sequence to another, possible overlapping, sequence.
not_eof	Tests whether a character is the end-of-file (EOF) character.
to_char_type	Converts an <code>int_type</code> character to the corresponding <code>char_type</code> character and returns the result.
to_int_type	Converts a <code>char_type</code> character to the corresponding <code>int_type</code> character and returns the result.

Requirements

Header: <string>

Namespace: std

char_traits::assign

Assigns one character value to another or to a range of elements in a string.

```
static void assign(char_type& _CharTo,
                  const char_type& _CharFrom);

static char_type *assign(char_type* strTo,
                        size_t _Num,
                        char_type _CharFrom);
```

Parameters

`_CharFrom` The character whose value is to be assigned.

`_CharTo`

The element that is to be assigned the character value.

strTo

The string or character array whose initial elements are to be assigned character values.

_Num

The number of elements that are going to be assigned values.

Return Value

The second member function returns a pointer to the string whose first *_Num* elements have been assigned values of *_CharFrom*.

Example

```
// char_traits_assign.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    // The first member function assigning
    // one character value to another character
    char ChTo = 't';
    const char ChFrom = 'f';
    cout << "The initial characters ( ChTo , ChFrom ) are: ( "
         << ChTo << " , " << ChFrom << " )." << endl;
    char_traits<char>::assign ( ChTo , ChFrom );
    cout << "After assigning, the characters ( ChTo , ChFrom ) are: ( "
         << ChTo << " , " << ChFrom << " )." << endl << endl;

    // The second member function assigning
    // character values to initial part of a string
    char_traits<char>::char_type s1[] = "abcd-1234-abcd";
    char_traits<char>::char_type* result1;
    cout << "The target string s1 is: " << s1 << endl;
    result1 = char_traits<char>::assign ( s1 , 4 , 'f' );
    cout << "The result1 = assign ( s1 , 4 , 'f' ) is: "
         << result1 << endl;
}
```

The initial characters (ChTo , ChFrom) are: (t , f).
After assigning, the characters (ChTo , ChFrom) are: (f , f).

The target string s1 is: abcd-1234-abcd
The result1 = assign (s1 , 4 , 'f') is: ffff-1234-abcd

char_traits::char_type

A type of character.

```
typedef CharType char_type;
```

Remarks

The type is a synonym for the template parameter `CharType`.

Example

See the example for [copy](#) for an example of how to declare and use `char_type`.

char_traits::compare

Compares up to a specified number of characters in two strings.

```
static int compare(const char_type* str1,
                  const char_type* str2,
                  size_t _Num);
```

Parameters

str1

The first of two strings to be compared to each other.

str2

The second of two strings to be compared to each other.

_Num

The number of elements in the strings to be compared.

Return Value

A negative value if the first string is less than the second string, 0 if the two strings are equal, or a positive value if the first string is greater than the second string.

Remarks

The comparison between the strings is made element by element, first testing for equality and then, if a pair of elements in the sequence tests not equal, they are tested for less than.

If two strings compare equal over a range but one is longer than the other, then the shorter of the two is less than the longer one.

Example

```

// char_traits_compare.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main() {
    using namespace std;

    char_traits<char>::char_type* s1 = "CAB";
    char_traits<char>::char_type* s2 = "ABC";
    char_traits<char>::char_type* s3 = "ABC";
    char_traits<char>::char_type* s4 = "ABCD";

    cout << "The string s1 is: " << s1 << endl;
    cout << "The string s2 is: " << s2 << endl;
    cout << "The string s3 is: " << s3 << endl;
    cout << "The string s4 is: " << s4 << endl;

    int comp1, comp2, comp3, comp4;
    comp1 = char_traits<char>::compare ( s1 , s2 , 2 );
    comp2 = char_traits<char>::compare ( s2 , s3 , 3 );
    comp3 = char_traits<char>::compare ( s3 , s4 , 4 );
    comp4 = char_traits<char>::compare ( s4 , s3 , 4 );
    cout << "compare ( s1 , s2 , 2 ) = " << comp1 << endl;
    cout << "compare ( s2 , s3 , 3 ) = " << comp2 << endl;
    cout << "compare ( s3 , s4 , 4 ) = " << comp3 << endl;
    cout << "compare ( s4 , s3 , 4 ) = " << comp4 << endl;
}

```

char_traits::copy

Copies a specified number of characters from one string to another.

This method is potentially unsafe, as it relies on the caller to check that the passed values are correct. Consider using [char_traits::_Copy_s](#) instead.

```

static char_type *copy(char_type* _To,
    const char_type* _From,
    size_t _Num);

```

Parameters

_To

The element at the beginning of the string or character array targeted to receive the copied sequence of characters.

_From

The element at the beginning of the source string or character array to be copied.

_Num

The number of elements to be copied.

Return Value

The first element copied into the string or character array targeted to receive the copied sequence of characters.

Remarks

The source and destination character sequences must not overlap.

Example

```

// char_traits_copy.cpp
// compile with: /EHsc /W3
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    char_traits<char>::char_type s1[] = "abcd-1234-abcd";
    char_traits<char>::char_type s2[] = "ABCD-1234";
    char_traits<char>::char_type* result1;
    cout << "The source string is: " << s1 << endl;
    cout << "The destination string is: " << s2 << endl;
    // Note: char_traits::copy is potentially unsafe, consider
    // using char_traits::_Copy_s instead.
    result1 = char_traits<char>::copy ( s1 , s2 , 4 ); // C4996
    cout << "The result1 = copy ( s1 , s2 , 4 ) is: "
        << result1 << endl;
}

```

```

The source string is: abcd-1234-abcd
The destination string is: ABCD-1234
The result1 = copy ( s1 , s2 , 4 ) is: ABCD-1234-abcd

```

char_traits::_Copy_s

Copies a specified number of characters from one string to another.

```

static char_type *_Copy_s(
    char_type* dest,
    size_t dest_size,
    const char_type* _From,
    size_t count);

```

Parameters

dest

The string or character array targeted to receive the copied sequence of characters.

dest_size

The size of *dest*. If `char_type` is **char**, then this size is in bytes. If `char_type` is **wchar_t**, then this size is in words.

_From

The source string or character array to be copied.

count

The number of elements to be copied.

Return Value

The string or character array targeted to receive the copied sequence of characters.

Remarks

The source and destination character sequences must not overlap.

Example

```
// char_traits_Copy_s.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    char_traits<char>::char_type s1[] = "abcd-1234-abcd";
    char_traits<char>::char_type s2[] = "ABCD-1234";
    char_traits<char>::char_type* result1;
    cout << "The source string is: " << s1 << endl;
    cout << "The destination string is: " << s2 << endl;
    result1 = char_traits<char>::_Copy_s(s1,
        char_traits<char>::length(s1), s2, 4);
    cout << "The result1 = _Copy_s(s1, "
        << "char_traits<char>::length(s1), s2, 4) is: "
        << result1 << endl;
}
```

```
The source string is: abcd-1234-abcd
The destination string is: ABCD-1234
The result1 = _Copy_s(s1, char_traits<char>::length(s1), s2, 4) is: ABCD-1234-abcd
```

char_traits::eof

Returns the end-of-file (EOF) character.

```
static int_type eof();
```

Return Value

The EOF character.

Remarks

A value that represents end of file (such as EOF or WEOF).

The C++ standard states that this value must not correspond to a valid `char_type` value. The Microsoft C++ compiler enforces this constraint for type **char**, but not for type **wchar_t**. The example below demonstrates this.

Example

```
// char_traits_eof.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main()
{
    using namespace std;

    char_traits<char>::char_type ch1 = 'x';
    char_traits<char>::int_type int1;
    int1 = char_traits<char>::to_int_type(ch1);
    cout << "char_type ch1 is '" << ch1 << "' and corresponds to int_type "
         << int1 << "." << endl << endl;

    char_traits<char>::int_type int2 = char_traits<char>::eof();
    cout << "The eof marker for char_traits<char> is: " << int2 << endl;

    char_traits<wchar_t>::int_type int3 = char_traits<wchar_t>::eof();
    cout << "The eof marker for char_traits<wchar_t> is: " << int3 << endl;
}
```

char_type ch1 is 'x' and corresponds to int_type 120.

The eof marker for char_traits<char> is: -1

The eof marker for char_traits<wchar_t> is: 65535

char_traits::eq

Tests whether two `char_type` characters are equal.

```
static bool eq(const char_type& _Ch1, const char_type& _Ch2);
```

Parameters

_Ch1

The first of two characters to be tested for equality.

_Ch2

The second of two characters to be tested for equality.

Return Value

true if the first character is equal to the second character; otherwise **false**.

Example

```

// char_traits_eq.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    char_traits<char>::char_type ch1 = 'x';
    char_traits<char>::char_type ch2 = 'y';
    char_traits<char>::char_type ch3 = 'x';

    // Testing for equality
    bool b1 = char_traits<char>::eq ( ch1 , ch2 );
    if ( b1 )
        cout << "The character ch1 is equal "
              << "to the character ch2." << endl;
    else
        cout << "The character ch1 is not equal "
              << "to the character ch2." << endl;

    // An equivalent and alternatively test procedure
    if ( ch1 == ch3 )
        cout << "The character ch1 is equal "
              << "to the character ch3." << endl;
    else
        cout << "The character ch1 is not equal "
              << "to the character ch3." << endl;
}

```

```

The character ch1 is not equal to the character ch2.
The character ch1 is equal to the character ch3.

```

char_traits::eq_int_type

Tests whether two characters represented as `int_type`s are equal or not.

```
static bool eq_int_type(const int_type& _Ch1, const int_type& _Ch2);
```

Parameters

`_Ch1`

The first of the two characters to be tested for equality as `int_type`s.

`_Ch2`

The second of the two characters to be tested for equality as `int_type`s.

Return Value

true if the first character is equal to the second character; otherwise **false**.

Example

```

// char_traits_eq_int_type.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    char_traits<char>::char_type ch1 = 'x';
    char_traits<char>::char_type ch2 = 'y';
    char_traits<char>::char_type ch3 = 'x';

    // Converting from char_type to int_type
    char_traits<char>::int_type int1, int2 , int3;
    int1 =char_traits<char>:: to_int_type ( ch1 );
    int2 =char_traits<char>:: to_int_type ( ch2 );
    int3 =char_traits<char>:: to_int_type ( ch3 );

    cout << "The char_types and corresponding int_types are:"
        << "\n    ch1 = " << ch1 << " corresponding to int1 = "
        << int1 << "."
        << "\n    ch2 = " << ch2 << " corresponding to int1 = "
        << int2 << "."
        << "\n    ch3 = " << ch3 << " corresponding to int1 = "
        << int3 << "." << endl << endl;

    // Testing for equality of int_type representations
    bool b1 = char_traits<char>::eq_int_type ( int1 , int2 );
    if ( b1 )
        cout << "The int_type representation of character ch1\n "
            << "is equal to the int_type representation of ch2."
            << endl;
    else
        cout << "The int_type representation of character ch1\n is "
            << "not equal to the int_type representation of ch2."
            << endl;

    // An equivalent and alternatively test procedure
    if ( int1 == int3 )
        cout << "The int_type representation of character ch1\n "
            << "is equal to the int_type representation of ch3."
            << endl;
    else
        cout << "The int_type representation of character ch1\n is "
            << "not equal to the int_type representation of ch3."
            << endl;
}

```

The char_types and corresponding int_types are:
 ch1 = x corresponding to int1 = 120.
 ch2 = y corresponding to int1 = 121.
 ch3 = x corresponding to int1 = 120.

The int_type representation of character ch1
 is not equal to the int_type representation of ch2.
 The int_type representation of character ch1
 is equal to the int_type representation of ch3.

char_traits::find

Searches for the first occurrence of a specified character in a range of characters.

```
static const char_type* find(const char_type* str,
    size_t _Num,
    const char_type& _Ch);
```

Parameters

str

The first character in the string to be searched.

_Num

The number of positions, counting from the first, in the range to be searched.

_Ch

The character to be searched for in the range.

Return Value

A pointer to the first occurrence of the specified character in the range if a match is found; otherwise, a null pointer.

Example

```
// char_traits_find.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    const char* s1 = "f2d-1234-abcd";
    const char* result1;
    cout << "The string to be searched is: " << s1 << endl;

    // Searching for a 'd' in the first 6 positions of string s1
    result1 = char_traits<char>::find ( s1 , 6 , 'd');
    cout << "The character searched for in s1 is: "
        << *result1 << endl;
    cout << "The string beginning with the first occurrence\n "
        << "of the character 'd' is: " << result1 << endl;

    // When no match is found the NULL value is returned
    const char* result2;
    result2 = char_traits<char>::find ( s1 , 3 , 'a');
    if ( result2 == NULL )
        cout << "The result2 of the search is NULL." << endl;
    else
        cout << "The result2 of the search is: " << result1
            << endl;
}
```

```
The string to be searched is: f2d-1234-abcd
The character searched for in s1 is: d
The string beginning with the first occurrence
of the character 'd' is: d-1234-abcd
The result2 of the search is NULL.
```

char_traits::int_type

An integer type that can represent a character of type `char_type` or an end-of-file (EOF) character.

```
typedef long int_type;
```

Remarks

It must be possible to type cast a value of type `CharType` to `int_type` then back to `CharType` without altering the original value.

Example

See the example for [eq_int_type](#) for an example of how to declare and use `int_type`.

char_traits::length

Returns the length of a string.

```
static size_t length(const char_type* str);
```

Parameters

str

The C-string whose length is to be measured.

Return Value

The number of elements in the sequence being measured, not including the null terminator.

Example

```
// char_traits_length.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    const char* str1= "Hello";
    cout << "The C-string str1 is: " << str1 << endl;

    size_t lenStr1;
    lenStr1 = char_traits<char>::length ( str1 );
    cout << "The length of C-string str1 is: "
         << lenStr1 << "." << endl;
}
```

```
The C-string str1 is: Hello
The length of C-string str1 is: 5.
```

char_traits::lt

Tests whether one character is less than another.

```
static bool lt(const char_type& _Ch1, const char_type& _Ch2);
```

Parameters

_Ch1

The first of two characters to be tested for less than.

_Ch2

The second of two characters to be tested for less than.

Return Value

true if the first character is less than the second character; otherwise **false**.

Example

```
// char_traits_lt.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    char_traits<char>::char_type ch1 = 'x';
    char_traits<char>::char_type ch2 = 'y';
    char_traits<char>::char_type ch3 = 'z';

    // Testing for less than
    bool b1 = char_traits<char>::lt ( ch1 , ch2 );
    if ( b1 )
        cout << "The character ch1 is less than "
              << "the character ch2." << endl;
    else
        cout << "The character ch1 is not less "
              << "than the character ch2." << endl;

    // An equivalent and alternatively test procedure
    if ( ch3 < ch2 )
        cout << "The character ch3 is less than "
              << "the character ch2." << endl;
    else
        cout << "The character ch3 is not less "
              << "than the character ch2." << endl;
}
```

```
The character ch1 is less than the character ch2.
The character ch3 is not less than the character ch2.
```

char_traits::move

Copies a specified number of characters in a sequence to another, possibly overlapping sequence.

This method is potentially unsafe, as it relies on the caller to check that the passed values are correct. Consider using [char_traits::_Move_s](#) instead.

```
static char_type *move(char_type* _To,
    const char_type* _From,
    size_t _Num);
```

Parameters

_To

The element at the beginning of the string or character array targeted to receive the copied sequence of characters.

_From

The element at the beginning of the source string or character array to be copied.

_Num

The number of elements to be copied from the source string.

Return Value

The first element *_To* copied into the string or character array targeted to receive the copied sequence of characters.

Remarks

The source and destination may overlap.

Example

```
// char_traits_move.cpp
// compile with: /EHsc /W3
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    char_traits<char>::char_type sFrom1[] = "abcd-1234-abcd";
    char_traits<char>::char_type sTo1[] = "ABCD-1234";
    char_traits<char>::char_type* result1;
    cout << "The source string sFrom1 is: " << sFrom1 << endl;
    cout << "The destination stringsTo1 is: " << sTo1 << endl;
    // Note: char_traits::move is potentially unsafe, consider
    // using char_traits::_Move_s instead.
    result1 = char_traits<char>::move ( sTo1 , sFrom1 , 4 ); // C4996
    cout << "The result1 = move ( sTo1 , sFrom1 , 4 ) is: "
        << result1 << endl << endl;

    // When source and destination overlap
    char_traits<char>::char_type sToFrom2[] = "abcd-1234-ABCD";
    char_traits<char>::char_type* result2;
    cout << "The source/destination string sToFrom2 is: "
        << sToFrom2 << endl;
    const char* findc = char_traits<char>::find ( sToFrom2 , 4 , 'c' );
    // Note: char_traits::move is potentially unsafe, consider
    // using char_traits::_Move_s instead.
    result2 = char_traits<char>::move ( sToFrom2 , findc , 8 ); // C4996
    cout << "The result2 = move ( sToFrom2 , findc , 8 ) is: "
        << result2 << endl;
}
```

```
The source string sFrom1 is: abcd-1234-abcd
The destination stringsTo1 is: ABCD-1234
The result1 = move ( sTo1 , sFrom1 , 4 ) is: abcd-1234

The source/destination string sToFrom2 is: abcd-1234-ABCD
The result2 = move ( sToFrom2 , findc , 8 ) is: cd-1234-4-ABCD
```

char_traits::_Move_s

Copies a specified number of characters in a sequence to another, possibly overlapping sequence.

```
static char_type *_Move_s(
    char_type* dest,
    size_t dest_size,
    const char_type* _From,
    size_t count);
```

Parameters

dest

The element at the beginning of the string or character array targeted to receive the copied sequence of characters.

dest_size

The size of *dest*. If `char_type` is **char**, then this is in bytes. If `char_type` is **wchar_t**, then this is in words.

_From

The element at the beginning of the source string or character array to be copied.

count

The number of elements to be copied from the source string.

Return Value

The first element *dest* copied into the string or character array targeted to receive the copied sequence of characters.

Remarks

The source and destination may overlap.

Example

```
// char_traits_Move_s.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    char_traits<char>::char_type sFrom1[] = "abcd-1234-abcd";
    char_traits<char>::char_type sTo1[] = "ABCD-1234";
    char_traits<char>::char_type* result1;
    cout << "The source string sFrom1 is: " << sFrom1 << endl;
    cout << "The destination stringsTo1 is: " << sTo1 << endl;
    result1 = char_traits<char>::_Move_s(sTo1,
        char_traits<char>::length(sTo1), sFrom1, 4);
    cout << "The result1 = _Move_s(sTo1, "
        << "char_traits<char>::length(sTo1), sFrom1, 4) is: "
        << result1 << endl << endl;

    // When source and destination overlap
    char_traits<char>::char_type sToFrom2[] = "abcd-1234-ABCD";
    char_traits<char>::char_type* result2;
    cout << "The source/destination string sToFrom2 is: "
        << sToFrom2 << endl;
    const char* findc = char_traits<char>::find(sToFrom2, 4, 'c');
    result2 = char_traits<char>::_Move_s(sToFrom2,
        char_traits<char>::length(sToFrom2), findc, 8);
    cout << "The result2 = _Move_s(sToFrom2, "
        << "char_traits<char>::length(sToFrom2), findc, 8) is: "
        << result2 << endl;
}
```

```
The source string sFrom1 is: abcd-1234-abcd
The destination stringsTo1 is: ABCD-1234
The result1 = _Move_s(sTo1, char_traits<char>::length(sTo1), sFrom1, 4) is: abcd-1234

The source/destination string sToFrom2 is: abcd-1234-ABCD
The result2 = _Move_s(sToFrom2, char_traits<char>::length(sToFrom2), findc, 8) is: cd-1234-4-ABCD
```

char_traits::not_eof

Tests whether a character is not the end-of-file (EOF) character or is the EOF.

```
static int_type not_eof(const int_type& _Ch);
```

Parameters

_Ch

The character represented as an `int_type` to be tested for whether it is the EOF character or not.

Return Value

The `int_type` representation of the character tested, if the `int_type` of the character is not equal to that of the EOF character.

If the character `int_type` value is equal to the EOF `int_type` value, then **false**.

Example

```

// char_traits_not_eof.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( ) {
    using namespace std;

    char_traits<char>::char_type ch1 = 'x';
    char_traits<char>::int_type int1;
    int1 = char_traits<char>:: to_int_type ( ch1 );
    cout << "The char_type ch1 is " << ch1
         << " corresponding to int_type: "
         << int1 << "." << endl;

    // EOF member function
    char_traits <char>::int_type int2 = char_traits<char>::eof ( );
    cout << "The eofReturn is: " << int2 << endl;

    // Testing for EOF or another character
    char_traits <char>::int_type eofTest1, eofTest2;
    eofTest1 = char_traits<char>::not_eof ( int1 );
    if ( !eofTest1 )
        cout << "The eofTest1 indicates ch1 is an EOF character."
             << endl;
    else
        cout << "The eofTest1 returns: " << eofTest1
             << ", which is the character: "
             << char_traits<char>::to_char_type ( eofTest1 )
             << "." << endl;

    eofTest2 = char_traits<char>::not_eof ( int2 );
    if ( !eofTest2 )
        cout << "The eofTest2 indicates int2 is an EOF character."
             << endl;
    else
        cout << "The eofTest1 returns: " << eofTest2
             << ", which is the character: "
             << char_traits<char>::to_char_type ( eofTest2 )
             << "." << endl;
}

```

```

The char_type ch1 is x corresponding to int_type: 120.
The eofReturn is: -1
The eofTest1 returns: 120, which is the character: x.
The eofTest2 indicates int2 is an EOF character.

```

char_traits::off_type

An integer type that can represent offsets between positions in a stream.

```
typedef streamoff off_type;
```

Remarks

The type is a signed integer that describes an object that can store a byte offset involved in various stream positioning operations. It is typically a synonym for [streamoff](#), but it has essentially the same properties as that type.

char_traits::pos_type

An integer type that can represent positions in a stream.

```
typedef streampos pos_type;
```

Remarks

The type describes an object that can store all the information needed to restore an arbitrary file-position indicator within a stream. It is typically a synonym for [streampos](#), but in any case it has essentially the same properties as that type.

char_traits::state_type

A type that represents the conversion state for multibyte characters in a stream.

```
typedef implementation-defined state_type;
```

Remarks

The type describes an object that can represent a conversion state. It is typically a synonym for `mbstate_t`, but in any case it has essentially the same properties as that type.

char_traits::to_char_type

Converts an `int_type` character to the corresponding `char_type` character and returns the result.

```
static char_type to_char_type(const int_type& _Ch);
```

Parameters

`_Ch`

The `int_type` character to be represented as a `char_type`.

Return Value

The `char_type` character corresponding to the `int_type` character.

A value of `_Ch` that cannot be represented as such yields an unspecified result.

Remarks

The conversion operations [to_int_type](#) and `to_char_type` are inverse to each other, so that:

$$\text{to_int_type} (\text{to_char_type} (x)) == x$$

for any `int_type` x and

$$\text{to_char_type} (\text{to_int_type} (x)) == x$$

for any `char_type` x .

Example

```

// char_traits_to_char_type.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;

    char_traits<char>::char_type ch1 = 'a';
    char_traits<char>::char_type ch2 = 'b';
    char_traits<char>::char_type ch3 = 'a';

    // Converting from char_type to int_type
    char_traits<char>::int_type int1, int2 , int3;
    int1 =char_traits<char>:: to_int_type ( ch1 );
    int2 =char_traits<char>:: to_int_type ( ch2 );
    int3 =char_traits<char>:: to_int_type ( ch3 );

    cout << "The char_types and corresponding int_types are:"
        << "\n    ch1 = " << ch1 << " corresponding to int1 = "
        << int1 << "."
        << "\n    ch2 = " << ch2 << " corresponding to int1 = "
        << int2 << "."
        << "\n    ch3 = " << ch3 << " corresponding to int1 = "
        << int3 << "." << endl << endl;

    // Converting from int_type back to char_type
    char_traits<char>::char_type rec_ch1;
    rec_ch1 = char_traits<char>:: to_char_type ( int1);
    char_traits<char>::char_type rec_ch2;
    rec_ch2 = char_traits<char>:: to_char_type ( int2);

    cout << "The recovered char_types and corresponding int_types are:"
        << "\n    recovered ch1 = " << rec_ch1 << " from int1 = "
        << int1 << "."
        << "\n    recovered ch2 = " << rec_ch2 << " from int2 = "
        << int2 << "." << endl << endl;

    // Testing that the conversions are inverse operations
    bool b1 = char_traits<char>::eq ( rec_ch1 , ch1 );
    if ( b1 )
        cout << "The recovered char_type of ch1"
            << " is equal to the original ch1." << endl;
    else
        cout << "The recovered char_type of ch1"
            << " is not equal to the original ch1." << endl;

    // An equivalent and alternatively test procedure
    if ( rec_ch2 == ch2 )
        cout << "The recovered char_type of ch2"
            << " is equal to the original ch2." << endl;
    else
        cout << "The recovered char_type of ch2"
            << " is not equal to the original ch2." << endl;
}

```

The `char_types` and corresponding `int_types` are:

`ch1 = a` corresponding to `int1 = 97`.

`ch2 = b` corresponding to `int1 = 98`.

`ch3 = a` corresponding to `int1 = 97`.

The recovered `char_types` and corresponding `int_types` are:

recovered `ch1 = a` from `int1 = 97`.

recovered `ch2 = b` from `int2 = 98`.

The recovered `char_type` of `ch1` is equal to the original `ch1`.

The recovered `char_type` of `ch2` is equal to the original `ch2`.

`char_traits::to_int_type`

Converts a `char_type` character to the corresponding `int_type` character and returns the result.

```
static int_type to_int_type(const char_type& _Ch);
```

Parameters

_Ch

The `char_type` character to be represented as an `int_type`.

Return Value

The `int_type` character corresponding to the `char_type` character.

Remarks

The conversion operations `to_int_type` and `to_char_type` are inverse to each other, so that:

$$\text{to_int_type} \left(\text{to_char_type} (x) \right) == x$$

for any `int_type` x , and

$$\text{to_char_type} \left(\text{to_int_type} (x) \right) == x$$

for any `char_type` x .

Example

```

// char_traits_to_int_type.cpp
// compile with: /EHsc
#include <string>
#include <iostream>

int main( )
{
    using namespace std;
    char_traits<char>::char_type ch1 = 'a';
    char_traits<char>::char_type ch2 = 'b';
    char_traits<char>::char_type ch3 = 'a';

    // Converting from char_type to int_type
    char_traits<char>::int_type int1, int2 , int3;
    int1 =char_traits<char>:: to_int_type ( ch1 );
    int2 =char_traits<char>:: to_int_type ( ch2 );
    int3 =char_traits<char>:: to_int_type ( ch3 );

    cout << "The char_types and corresponding int_types are:"
        << "\n    ch1 = " << ch1 << " corresponding to int1 = "
        << int1 << "."
        << "\n    ch2 = " << ch2 << " corresponding to int1 = "
        << int2 << "."
        << "\n    ch3 = " << ch3 << " corresponding to int1 = "
        << int3 << "." << endl << endl;

    // Converting from int_type back to char_type
    char_traits<char>::char_type rec_ch1;
    rec_ch1 = char_traits<char>:: to_char_type ( int1);
    char_traits<char>::char_type rec_ch2;
    rec_ch2 = char_traits<char>:: to_char_type ( int2);

    cout << "The recovered char_types and corresponding int_types are:"
        << "\n    recovered ch1 = " << rec_ch1 << " from int1 = "
        << int1 << "."
        << "\n    recovered ch2 = " << rec_ch2 << " from int2 = "
        << int2 << "." << endl << endl;

    // Testing that the conversions are inverse operations
    bool b1 = char_traits<char>::eq ( rec_ch1 , ch1 );
    if ( b1 )
        cout << "The recovered char_type of ch1"
            << " is equal to the original ch1." << endl;
    else
        cout << "The recovered char_type of ch1"
            << " is not equal to the original ch1." << endl;

    // An equivalent and alternatively test procedure
    if ( rec_ch2 == ch2 )
        cout << "The recovered char_type of ch2"
            << " is equal to the original ch2." << endl;
    else
        cout << "The recovered char_type of ch2"
            << " is not equal to the original ch2." << endl;
}

```

The `char_types` and corresponding `int_types` are:

`ch1 = a` corresponding to `int1 = 97`.

`ch2 = b` corresponding to `int1 = 98`.

`ch3 = a` corresponding to `int1 = 97`.

The recovered `char_types` and corresponding `int_types` are:

recovered `ch1 = a` from `int1 = 97`.

recovered `ch2 = b` from `int2 = 98`.

The recovered `char_type` of `ch1` is equal to the original `ch1`.

The recovered `char_type` of `ch2` is equal to the original `ch2`.

char_traits<char> Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

A struct that is a specialization of the template struct **char_traits<CharType>** to an element of type **char**.

Syntax

```
template <>
struct char_traits<char>;
```

Remarks

Specialization allows the struct to take advantage of library functions that manipulate objects of this type **char**.

Example

See the typedefs and member functions of the template class [char_traits Class](#)

char_traits<char16_t> Struct

10/31/2018 • 2 minutes to read • [Edit Online](#)

A struct that is a specialization of the template struct **char_traits<CharType>** to an element of type `char16_t`.

Syntax

```
template <>
struct char_traits<char16_t>;
```

Remarks

Specialization allows the struct to take advantage of library functions that manipulate objects of the type `char16_t`.

Requirements

Header: `<string>`

Namespace: `std`

<string_view>

4/24/2019 • 2 minutes to read • [Edit Online](#)

Defines the class template `basic_string_view` and related types and operators. (Requires compiler option `std:c++17` or later.)

Syntax

```
#include <string_view>
```

Remarks

The `string_view` family of template specializations provides an efficient way to pass a read-only, exception-safe, non-owning handle to the character data of any string-like objects with the first element of the sequence at position zero. A function parameter of type `string_view` (which is a typedef for `basic_string_view<char>`) can accept arguments such as `std::string`, `char*`, or any other string-like class of narrow characters for which an implicit conversion to `string_view` is defined. Similarly, a parameter of `wstring_view`, `u16string_view` or `u32string_view` can accept any string type for which an implicit conversion is defined. For more information, see [basic_string_view Class](#).

Typedefs

TYPE NAME	DESCRIPTION
<code>string_view</code>	A specialization of the class template <code>basic_string_view</code> with elements of type <code>char</code> .
<code>wstring_view</code>	A specialization of the class template <code>basic_string_view</code> with elements of type <code>wchar_t</code> .
<code>u16string_view</code>	A specialization of the class template <code>basic_string_view</code> with elements of type <code>char16_t</code> .
<code>u32string_view</code>	A specialization of the class template <code>basic_string_view</code> with elements of type <code>char32_t</code> .

Operators

The `<string_view>` operators can compare `string_view` objects to objects of any convertible string types.

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests if the object on the left side of the operator is not equal to the object on the right side.
<code>operator==</code>	Tests if the object on the left side of the operator is equal to the object on the right side.
<code>operator<</code>	Tests if the object on the left side of the operator is less than to the object on the right side.

OPERATOR	DESCRIPTION
operator<=	Tests if the object on the left side of the operator is less than or equal to the object on the right side.
operator<<	A template function that inserts a <code>string_view</code> into an output stream.
operator>	Tests if the object on the left side of the operator is greater than to the object on the right side.
operator>=	Tests if the object on the left side of the operator is greater than or equal to the object on the right side.

Literals

OPERATOR	DESCRIPTION
sv	Constructs a <code>string_view</code> , <code>wstring_view</code> , <code>u16string_view</code> , or <code>u32string_view</code> depending on the type of the string literal to which it is appended.

Classes

CLASS	DESCRIPTION
basic_string_view Class	A class template that provides a read-only view into a sequence of arbitrary character-like objects.
hash	Function object that produces a hash value for a <code>string_view</code> .

Requirements

- **Header:** `<string_view>`
- **Namespace:** `std`
- **Compiler Option:** `std:c++17` (or later)

[Header Files Reference](#)

<string_view> operators

4/24/2019 • 5 minutes to read • [Edit Online](#)

Use these operators to compare two `string_view` objects, or a `string_view` and some other string object (for example `std::string`, or `char*`) for which an implicit conversion is provided.

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<<</code>	<code>operator<=</code>
<code>operator==</code>	<code>operator""sv</code>	

`operator!=`

Tests if the object on the left side of the operator is not equal to the object on the right side.

```
template <class CharType, class Traits>
bool operator!=(
    const basic_string_view<CharType, Traits>& left,
    const basic_string_view<CharType, Traits>& right);

template <class CharType, class Traits>
bool operator!=(
    const basic_string_view<CharType, Traits>& left,
    convertible_string_type right);

template <class CharType, class Traits>
bool operator!=(
    convertible_string_type left,
    const basic_string_view<CharType, Traits>& right);
```

Parameters

left

Any convertible string type or an object of type `basic_string_view` to be compared.

right

Any convertible string type or an object of type `basic_string_view` to be compared.

Return Value

true if the object on the left side of the operator is not lexicographically equal to the object on the right side; otherwise **false**.

Remarks

An implicit conversion must exist from *convertible_string_type* to the `string_view` on the other side.

The comparison is based on a pairwise lexicographical comparison of the character sequences. If they have the same number of elements and the elements are all equal, the two objects are equal. Otherwise, they are unequal.

`operator==`

Tests if the object on the left side of the operator is equal to the object on the right side.

```

template <class CharType, class Traits>
bool operator==(
    const basic_string_view<CharType, Traits>& left,
    const basic_string_view<CharType, Traits>& right);

template <class CharType, class Traits>
bool operator==(
    const basic_string_view<CharType, Traits>& left,
    convertible_string_type right);

template <class CharType, class Traits>
bool operator==(
    convertible_string_type left,
    const basic_string_view<CharType, Traits>& right);

```

Parameters

left

Any convertible string type or an object of type `basic_string_view` to be compared.

right

Any convertible string type or an object of type `basic_string_view` to be compared.

Return Value

true if the object on the left side of the operator is lexicographically equal to the object on the right side; otherwise **false**.

Remarks

An implicit conversion must exist from *convertible_string_type* to the *string_view* on the other side.

The comparison is based on a pairwise lexicographical comparison of the character sequences. If they have the same number of elements and the elements are all equal, the two objects are equal.

operator<

Tests if the object on the left side of the operator is less than the object on the right side *string_view*

```

template <class CharType, class Traits>
bool operator<(
    const basic_string_view<CharType, Traits>& left,
    const basic_string_view<CharType, Traits>& right);

template <class CharType, class Traits>
bool operator<(
    const basic_string_view<CharType, Traits>& left,
    convertible_string_type right);

template <class CharType, class Traits>
bool operator<(
    convertible_string_type left,
    const basic_string_view<CharType, Traits>& right);

```

Parameters

left

Any convertible string type or an object of type `basic_string_view` to be compared.

right

Any convertible string type or an object of type `basic_string_view` to be compared.

Return Value

true if the object on the left side of the operator is lexicographically less than the object on the right side; otherwise **false**.

Remarks

An implicit conversion must exist from *convertible_string_type* to the *string_view* on the other side.

The comparison is based on a pairwise lexicographical comparison of the character sequences. When the first unequal pair of characters is encountered, the result of that comparison is returned. If no unequal characters are found, but one sequence is shorter, the shorter sequence is less than the longer one. In other words, "cat" is less than "cats".

Example

```
#include <string>
#include <string_view>

using namespace std;

int main()
{
    string_view sv1 { "ABA" };
    string_view sv2{ "ABAC" };
    string_view sv3{ "ABAD" };
    string_view sv4{ "ABACE" };

    bool result = sv2 > sv1; // true
    result = sv3 > sv2; // true
    result = sv3 != sv1; // true
    result = sv4 < sv3; // true because `C` < `D`
}
```

operator<=

Tests if the object on the left side of the operator is less than or equal to the object on the right side.

```
template <class CharType, class Traits>
bool operator<=(
    const basic_string_view<CharType, Traits>& left,
    const basic_string_view<CharType, Traits>& right);

template <class CharType, class Traits>
bool operator<=(
    const basic_string_view<CharType, Traits>& left,
    convertible_string_type right);

template <class CharType, class Traits>
bool operator<=(
    convertible_string_type left,
    const basic_string_view<CharType, Traits>& right);
```

Parameters

left

Any convertible string type or an object of type `basic_string_view` to be compared.

right

Any convertible string type or an object of type `basic_string_view` to be compared.

Return Value

true if the object on the left side of the operator is lexicographically less than or equal to the object on the right

side; otherwise **false**.

Remarks

See [operator<](#).

operator<<

Writes a string_view into an output stream.

```
template <class CharType, class Traits>
inline basic_ostream<CharType, Traits>& operator<<(
    basic_ostream<CharType, Traits>& Ostr, const basic_string_view<CharType, Traits> Str);
```

Parameters

Ostr

an output stream being written to.

Str

The string_view to be entered into an output stream.

Return Value

an output stream being written to.

Remarks

Use this operator to insert the contents of a string_view into an output stream, for example using [std::cout](#).

operator>

Tests if the object on the left side of the operator is greater than the object on the right side.

```
template <class CharType, class Traits>
bool operator>(
    const basic_string_view<CharType, Traits>& left,
    const basic_string_view<CharType, Traits>& right);

template <class CharType, class Traits>
bool operator>(
    const basic_string_view<CharType, Traits>& left,
    convertible_string_type right);

template <class CharType, class Traits>
bool operator>(
    convertible_string_type left,
    const basic_string_view<CharType, Traits>& right);
```

Parameters

left

Any convertible string type or an object of type `basic_string_view` to be compared.

right

Any convertible string type or an object of type `basic_string_view` to be compared.

Return Value

true if the object on the left side of the operator is lexicographically greater than the string_view object on the right side; otherwise **false**.

Remarks

See [operator<](#).

operator>=

Tests if the object on the left side of the operator is greater than or equal to the object on the right side.

```
template <class CharType, class Traits>
bool operator>=(
    const basic_string_view<CharType, Traits>& left,
    const basic_string_view<CharType, Traits>& right);

template <class CharType, class Traits>
bool operator>=(
    const basic_string_view<CharType, Traits>& left,
    convertible_string_type right);

template <class CharType, class Traits>
bool operator>=(
    convertible_string_type left,
    const basic_string_view<CharType, Traits>& right);
```

Parameters

left

Any convertible string type or an object of type `basic_string_view` to be compared.

right

Any convertible string type or an object of type `basic_string_view` to be compared.

Return Value

true if the object on the left side of the operator is lexicographically greater than or equal to the object on the right side; otherwise **false**.

Remarks

See [operator<](#).

operator"" sv (string_view literal)

Constructs a string_view from a string literal. Requires namespace `std::literals::string_view_literals`.

Example

```
using namespace std;
using namespace literals::string_view_literals;

string_view sv{ "Hello"sv };
wstring_view wsv{ L"Hello"sv };
u16string_view sv16{ u"Hello"sv };
u32string_view sv32{ U"Hello"sv };
```

<string_view> typedefs

4/24/2019 • 2 minutes to read • [Edit Online](#)

string_view	u16string_view	u32string_view
wstring_view		

string_view

A type that describes a specialization of the class template [basic_string_view](#) with elements of type **char**.

```
typedef basic_string_view<char, char_traits<char>> string_view;
```

Remarks

The following are equivalent declarations:

```
string_view str("Hello");  
  
basic_string_view<char> str("Hello");
```

For a list of string constructors, see [basic_string::basic_string](#).

u16string_view

A type that describes a specialization of the class template [basic_string_view](#) with elements of type `char16_t`.

```
typedef basic_string_view<char16_t, char_traits<char16_t>> u16string_view;
```

Remarks

For a list of string constructors, see [basic_string::basic_string](#).

u32string_view

A type that describes a specialization of the class template [basic_string_view](#) with elements of type `char32_t`.

```
typedef basic_string_view<char32_t, char_traits<char32_t>> u32string_view;
```

Remarks

For a list of string constructors, see [basic_string::basic_string](#).

wstring_view

A type that describes a specialization of the class template [basic_string_view](#) with elements of type **wchar_t**.

```
typedef basic_string_view<wchar_t, char_traits<wchar_t>> wstring_view;
```

Remarks

The following are equivalent declarations:

```
wstring_view wstr(L"Hello");  
  
basic_string_view<wchar_t> wstr(L"Hello");
```

For a list of string constructors, see [basic_string::basic_string](#).

NOTE

The size of **wchar_t** is two bytes on Windows but this is not necessarily the case for all platforms. If you need a `string_view` wide character type with a width that is guaranteed to remain the same on all platforms, use [u16string_view](#) or [u32string_view](#).

[<string_view>](#)

basic_string_view Class

4/24/2019 • 21 minutes to read • [Edit Online](#)

The class template `basic_string_view<charT>` was added in C++17 to serve as a safe and efficient way for a function to accept various unrelated string types without the function having to be templated on those types. The class holds a non-owning pointer to a contiguous sequence of character data, and a length that specifies the number of characters in the sequence. No assumption is made with respect to whether the sequence is null-terminated.

The standard library defines several specializations based on the type of the elements:

- `string_view`
- `wstring_view`
- `u16string_view`
- `u32string_view`

In this document, the term "string_view" refers generally to any of these typedefs.

A `string_view` describes the minimum common interface necessary to read string data. It provides const access to the underlying data; it makes no copies (except for the `copy` function). The data may or may not contain null values (`'\0'`) at any position. A `string_view` has no control over the object's lifetime. It is the caller's responsibility to ensure that the underlying string data is valid.

A function that accepts a parameter of type `string_view` can be made to work with any string-like type, without making the function into a template, or constraining the function to a particular subset of string types. The only requirement is that an implicit conversion exists from the string type to `string_view`. All the standard string types are implicitly convertible to a `string_view` that contains the same element type. In other words, a `std::string` is convertible to a `string_view` but not to a `wstring_view`.

The following example shows a non-template function `f` that takes a parameter of type `wstring_view`. It can be called with arguments of type `std::wstring`, `wchar_t*`, and `winrt::hstring`.

```
// compile with: /std:c++17
// string_view that uses elements of wchar_t
void f(wstring_view);

// pass a std::wstring:
const std::wstring& s { L"Hello" };
f(s);

// pass a C-style null-terminated string (string_view is not null-terminated):
const wchar_t* ns = L"Hello";
f(ns);

// pass a C-style character array of len characters (excluding null terminator):
const wchar_t* cs { L"Hello" };
size_t len { 5 };
f({cs,len});

// pass a WinRT string
winrt::hstring hs { L"Hello" };
f(hs);
```

Syntax

```
template <class CharType, class Traits = char_traits<CharType>>
class basic_string_view;
```

Parameters

CharType

The type of the characters that are stored in the `string_view`. The C++ Standard Library provides the following typedefs for specializations of this template.

- [string_view](#) for elements of type **char**
- [wstring_view](#), for **wchar_t**
- [u16string_view](#) for **char16_t**
- [u32string_view](#) for **char32_t**.

Traits

Defaults to [char_traits](#)<*CharType*>.

Constructors

CONSTRUCTOR	DESCRIPTION
basic_string_view	Constructs a <code>string_view</code> that is empty or else points to all or part of some other string object's data, or to a C-style character array.

Typedefs

TYPE NAME	DESCRIPTION
const_iterator	Random-access iterator that can read const elements.
const_pointer	<pre>using const_pointer = const value_type*;</pre>
const_reference	<pre>using const_reference = const value_type&;</pre>
const_reverse_iterator	<pre>using const_reverse_iterator = std::reverse_iterator<const_iterator>;</pre>
difference_type	<pre>using difference_type = ptrdiff_t;</pre>
iterator	<pre>using iterator = const_iterator;</pre>
npos	<pre>static constexpr size_type npos = size_type(-1);</pre>
pointer	<pre>using pointer = value_type*;</pre>
reference	<pre>using reference = value_type&;</pre>
reverse_iterator	<pre>using reverse_iterator = const_reverse_iterator;</pre>
size_type	<pre>using size_type = size_t;</pre>

TYPE NAME	DESCRIPTION
traits_type	<pre>using traits_type = Traits;</pre>
value_type	<pre>using value_type = CharType;</pre>

Member operators

OPERATOR	DESCRIPTION
<code>operator=</code>	Assigns a <code>string_view</code> or convertible string object to another <code>string_view</code> .
<code>operator[]</code>	Returns the element at the specified index.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>at</code>	Returns a <code>const_reference</code> to the element at a specified location.
<code>back</code>	Returns a <code>const_reference</code> to the last element.
<code>begin</code>	Returns a <code>const</code> iterator addressing the first element. (<code>string_views</code> are immutable.)
<code>cbegin</code>	Same as <code>begin</code> .
<code>cend</code>	Returns a <code>const</code> iterator that points to one past the last element.
<code>copy</code>	Copies at most a specified number of characters from an indexed position in a source <code>string_view</code> to a target character array. (Not recommended. Use <code>_Copy_s</code> instead.)
<code>_Copy_s</code>	Secure CRT copy function.
<code>compare</code>	Compares a <code>string_view</code> with a specified <code>string_view</code> to determine if they are equal or if one is lexicographically less than the other.
<code>crbegin</code>	Same as <code>rbegin</code> .
<code>crend</code>	Same as <code>rend</code> .
<code>data</code>	Returns a raw non-owning pointer to the character sequence.
<code>empty</code>	Tests whether the <code>string_view</code> contains characters.
<code>end</code>	Same as <code>cend</code> .
<code>find</code>	Searches in a forward direction for the first occurrence of a substring that matches a specified sequence of characters.

MEMBER FUNCTION	DESCRIPTION
find_first_not_of	Searches for the first character that is not any element of a specified <code>string_view</code> or convertible string object.
find_first_of	Searches for the first character that matches any element of a specified <code>string_view</code> or convertible string object.
find_last_not_of	Searches for the last character that is not any element of a specified <code>string_view</code> or convertible string object.
find_last_of	Searches for the last character that is an element of a specified <code>string_view</code> or convertible string object.
front	Returns a <code>const_reference</code> to the first element.
length	Returns the current number of elements.
max_size	Returns the maximum number of characters a <code>string_view</code> could contain.
rbegin	Returns a <code>const</code> iterator that addresses the first element in a reversed <code>string_view</code> .
remove_prefix	Moves the pointer forward by the specified number of elements.
remove_suffix	Reduces the size of the view by the specified number of elements starting from the back.
rend	Returns a <code>const</code> iterator that points to one past the last element in a reversed <code>string_view</code> .
rfind	Searches a <code>string_view</code> in reverse for the first occurrence of a substring that matches a specified sequence of characters.
size	Returns the current number of elements.
substr	Returns a substring of a specified length starting at a specified index.
swap	Exchange the contents of two <code>string_views</code> .

Remarks

If a function is asked to generate a sequence longer than [max_size](#) elements, the function reports a length error by throwing an object of type [length_error](#).

Requirements

[std:c++17](#) or later

Header: `<string_view>`

Namespace: `std`

basic_string_view::at

Returns a const_reference to the character at the specified 0-based index.

```
constexpr const_reference at(size_type offset) const;
```

Parameters

offset

The index of the element to be referenced.

Return Value

A const_reference to the character at the position specified by the parameter index.

Remarks

The first element has an index of zero and the following elements are indexed consecutively by the positive integers, so that a string_view of length n has an n th element indexed by the number $n - 1$. **at** throws an exception for invalid indices, unlike [operator\[\]](#).

In general, we recommend that **at** for sequences such as `std::vector` and string_view should never be used. An invalid index passed to a sequence is a logic error that should be discovered and fixed during development. If a program isn't absolutely certain that its indices are valid, it should test them, not call `at()` and rely on exceptions to defend against careless programming.

See [basic_string_view::operator\[\]](#) for more information.

Example

```
// basic_string_view_at.cpp
// compile with: /EHsc
#include <string_view>
#include <iostream>

int main()
{
    using namespace std;

    const string_view str1("Hello world");
    string_view::const_reference refStr2 = str1.at(8); // 'r'
}
```

basic_string_view::back

Returns a const_reference to the last element.

```
constexpr const_reference back() const;
```

Return Value

A const_reference to the last element in the string_view.

Remarks

Throws an exception if the string_view is empty.

Keep in mind that after a string_view is modified, for example by calling `remove_suffix`, then the element returned by this function is no longer the last element in the underlying data.

Example

A `string_view` that is constructed with a C string literal does not include the terminating null and therefore in the following example `back` returns 'p' and not '\0'.

```
char c[] = "Help"; // char[5]
string_view sv{ c };
cout << sv.size(); // size() == 4
cout << sv.back() << endl; // p
```

Embedded nulls are treated as any other character:

```
string_view e = "embedded\0nulls"sv;
cout << boolalpha << (e.back() == 's'); // true
```

basic_string_view::basic_string_view

Constructs a `string_view`.

```
constexpr basic_string_view() noexcept;
constexpr basic_string_view(const basic_string_view&) noexcept = default;
constexpr basic_string_view(const charT* str);
constexpr basic_string_view(const charT* str, size_type len);
```

Parameters

str

The pointer to the character values.

len

The number of characters to include in the view.

Remarks

The constructors with a `charT*` parameter assume that the input is null-terminated, but the terminating null is not included in the `string_view`.

You can also construct a `string_view` with a literal. See [operator""sv](#).

basic_string_view::begin

Same as [cbegin](#).

```
constexpr const_iterator begin() const noexcept;
```

Return Value

Returns a `const_iterator` addressing the first element.

basic_string_view::cbegin

Returns a `const_iterator` that addresses the first element in the range.

```
constexpr const_iterator cbegin() const noexcept;
```

Return Value

A **const** random-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

basic_string_view::cend

Returns a `const_iterator` that addresses the location just beyond the last element in a range.

```
constexpr const_iterator cend() const noexcept;
```

Return Value

A **const** random-access iterator that points just beyond the end of the range.

Remarks

The value returned by `cend` should not be dereferenced.

basic_string_view::compare

Performs a case sensitive comparison with a specified `string_view` (or a convertible string type) to determine if the two objects are equal or if one is lexicographically less than the other. The [<string_view> operators](#) use this member function to perform comparisons.

```
constexpr int compare(basic_string_view strv) const noexcept;  
constexpr int compare(size_type pos, size_type num, basic_string_view strv) const;  
constexpr int compare(size_type pos, size_type num, basic_string_view strv, size_type offset, size_type num2) const;  
constexpr int compare(const charT* ptr) const;  
constexpr int compare(size_type pos, size_type num, const charT* ptr) const;  
constexpr int compare(size_type pos, size_type num, const charT* ptr, size_type num2) const;
```

Parameters

strv

The `string_view` that is to be compared to this `string_view`.

pos

The index of this `string_view` at which the comparison begins.

num

The maximum number of characters from this `string_view` to be compared.

num2

The maximum number of characters from *strv* to be compared.

offset

The index of *strv* at which the comparison begins.

ptr

The C string to be compared to this `string_view`.

Return Value

A negative value if this `string_view` is less than *strv* or *ptr*; zero if the two character sequences are equal; or a positive value if this `string_view` is greater than *strv* or *ptr*.

Remarks

The `compare` member functions perform a case-sensitive comparison of either all or part of each character sequence.

Example

```
// basic_string_view_compare.cpp
// compile with: /EHsc
#include <string_view>
#include <iostream>
#include <string>

using namespace std;

string to_alpha(int result)
{
    if (result < 0) return " less than ";
    else if (result == 0) return " equal to ";
    else return " greater than ";
}

int main()
{
    // The first member function compares
    // two string_views
    string_view sv_A("CAB");
    string_view sv_B("CAB");
    cout << "sv_A is " << sv_A << endl;
    cout << "sv_B is " << sv_B << endl;
    int comp1 = sv_A.compare(sv_B);
    cout << "sv_A is" << to_alpha(comp1) << "sv_B.\n";

    // The second member function compares part of
    // an operand string_view to another string_view
    string_view sv_C("AACAB");
    string_view sv_D("CAB");
    cout << "sv_C is: " << sv_C << endl;
    cout << "sv_D is: " << sv_D << endl;
    int comp2a = sv_C.compare(2, 3, sv_D);
    cout << "The last three characters of sv_C are"
        << to_alpha(comp2a) << "sv_D.\n";

    int comp2b = sv_C.compare(0, 3, sv_D);
    cout << "The first three characters of sv_C are"
        << to_alpha(comp2b) << "sv_D.\n";

    // The third member function compares part of
    // an operand string_view to part of another string_view
    string_view sv_E("AACAB");
    string_view sv_F("DCABD");
    cout << "sv_E: " << sv_E << endl;
    cout << "sv_F is: " << sv_F << endl;
    int comp3a = sv_E.compare(2, 3, sv_F, 1, 3);
    cout << "The three characters from position 2 of sv_E are"
        << to_alpha(comp3a)
        << "the 3 characters of sv_F from position 1.\n";

    // The fourth member function compares
    // an operand string_view to a C string
    string_view sv_G("ABC");
    const char* cs_A = "DEF";
    cout << "sv_G is: " << sv_G << endl;
    cout << "cs_A is: " << cs_A << endl;
    int comp4a = sv_G.compare(cs_A);
    cout << "sv_G is" << to_alpha(comp4a) << "cs_A.\n";

    // The fifth member function compares part of
    // an operand string_view to a C string
    string_view sv_H("AACAB");
    const char* cs_B = "CAB";
    cout << "sv_H is: " << sv_H << endl;
    cout << "cs_B is: " << cs_B << endl;
```

```

int comp5a = sv_H.compare(2, 3, cs_B);
cout << "The last three characters of sv_H are"
    << to_alpha(comp5a) << "cs_B.\n";

// The sixth member function compares part of
// an operand string_view to part of an equal length of
// a C string
string_view sv_I("AACAB");
const char* cs_C = "ACAB";
cout << "sv_I is: " << sv_I << endl;
cout << "cs_C: " << cs_C << endl;
int comp6a = sv_I.compare(1, 3, cs_C, 3);
cout << "The 3 characters from position 1 of sv_I are"
    << to_alpha(comp6a) << "the first 3 characters of cs_C.\n";
}

```

```

sv_A is CAB
sv_B is CAB
sv_A is equal to sv_B.
sv_C is: AACAB
sv_D is: CAB
The last three characters of sv_C are equal to sv_D.
The first three characters of sv_C are less than sv_D.
sv_E: AACAB
sv_F is: DCABD
The three characters from position 2 of sv_E are equal to the 3 characters of sv_F from position 1.
sv_G is: ABC
cs_A is: DEF
sv_G is less than cs_A.
sv_H is: AACAB
cs_B is: CAB
The last three characters of sv_H are equal to cs_B.
sv_I is: AACAB
cs_C: ACAB
The 3 characters from position 1 of sv_I are equal to the first 3 characters of cs_C.

```

basic_string_view::copy

Copies at most a specified number of characters from an indexed position in a source string_view to a target character array. We recommend that you use the secure function [basic_string_view::Copy_s](#) instead.

```

size_type copy(charT* ptr, size_type count, size_type offset = 0) const;

```

Parameters

ptr

The target character array to which the elements are to be copied.

count

The number of characters to be copied, at most, from the source string_view.

offset

The beginning position in the source string_view from which copies are to be made.

Return Value

The number of characters actually copied.

Remarks

A null character is not appended to the end of the copy.

basic_string_view::_Copy_s

Secure CRT copy function to be used instead of [copy](#).

```
size_type _Copy_s(  
    value_type* dest,  
    size_type dest_size,  
    size_type count,  
    size_type _Off = 0) const;
```

Parameters

dest

The target character array to which the elements are to be copied.

dest_size

The size of *dest*.

_Count The number of characters to be copied, at most, from the source string.

_Off

The beginning position in the source string from which copies are to be made.

Return Value

The number of characters actually copied.

Remarks

A null character is not appended to the end of the copy.

For more information, see [c-runtime-library/security-features-in-the-crt](#).

basic_string_view::crbegin

Returns a `const_reverse_iterator` that addresses the first element in a reversed `string_view`.

```
constexpr const_reverse_iterator crbegin() const noexcept;
```

Return Value

A `const_reverse_iterator` that addresses the first element in a reversed `string_view`.

basic_string_view::crend

Same as [rend](#).

```
constexpr const_reverse_iterator crend() const noexcept;
```

Return Value

Returns a `const_reverse_iterator` that addresses one past the end of a reversed `string_view`.

basic_string_view::data

Returns a raw non-owning pointer to the `const` character sequence of the object that was used to construct the `string_view`.

```
constexpr value_type *data() const noexcept;
```

Return Value

A pointer-to-const to the first element of the character sequence.

Remarks

The pointer cannot modify the characters.

A sequence of `string_view` characters is not necessarily null-terminated. The return type for `data` is not a valid C string, because no null character gets appended. The null character `'\0'` has no special meaning in an object of type `string_view` and may be a part of the `string_view` object just like any other character.

`basic_string_view::empty`

Tests whether the `string_view` contains characters or not.

```
constexpr bool empty() const noexcept;
```

Return Value

true if the `string_view` object contains no characters; **false** if it has at least one character.

Remarks

The member function is equivalent to `size() == 0`.

`basic_string_view::end`

Returns a random-access `const_iterator` that points to one past the last element.

```
constexpr const_iterator end() const noexcept;
```

Return Value

Returns a random-access `const_iterator` that points to one past the last element.

Remarks

`end` is used to test whether a `const_iterator` has reached the end of its `string_view`. The value returned by `end` should not be dereferenced.

`basic_string_view::find`

Searches a `string_view` in a forward direction for the first occurrence of a character or substring that matches a specified sequence of character(s).

```
constexpr size_type find(basic_string_view str, size_type offset = 0) const noexcept;  
constexpr size_type find(charT chVal, size_type offset = 0) const noexcept;  
constexpr size_type find(const charT* ptr, size_type offset, size_type count) const;  
constexpr size_type find(const charT* ptr, size_type offset = 0) const;
```

Parameters

str

The `string_view` for which the member function is to search.

chVal

The character value for which the member function is to search.

offset

Index at which the search is to begin.

ptr

The C string for which the member function is to search.

count

The number of characters in *ptr*, counting forward from the first character.

Return Value

The index of the first character of the substring searched for when successful; otherwise `npos`.

basic_string_view::find_first_not_of

Searches for the first character that is not an element of a specified string_view or convertible string object.

```
constexpr size_type find_first_not_of(basic_string_view str, size_type offset = 0) const noexcept;
constexpr size_type find_first_not_of(charT chVal, size_type offset = 0) const noexcept;
constexpr size_type find_first_not_of(const charT* ptr, size_type offset, size_type count) const;
constexpr size_type find_first_not_of(const charT* ptr, size_type offset = 0) const;
```

Parameters

str

The string_view for which the member function is to search.

chVal

The character value for which the member function is to search.

offset

Index at which the search is to begin.

ptr

The C string for which the member function is to search.

count

The number of characters, counting forward from the first character, in the C string for which the member function is to search.

Return Value

The index of the first character of the substring searched for when successful; otherwise `npos`.

basic_string_view::find_first_of

Searches for the first character that matches any element of a specified string_view.

```
constexpr size_type find_first_of(basic_string_view str, size_type offset = 0) const noexcept;
constexpr size_type find_first_of(charT chVal, size_type offset = 0) const noexcept;
constexpr size_type find_first_of(const charT* str, size_type offset, size_type count) const;
constexpr size_type find_first_of(const charT* str, size_type offset = 0) const;
```

Parameters

chVal

The character value for which the member function is to search.

offset

Index at which the search is to begin.

ptr

The C string for which the member function is to search.

count

The number of characters, counting forward from the first character, in the C string for which the member function is to search.

str

The string_view for which the member function is to search.

Return Value

The index of the first character of the substring searched for when successful; otherwise `npos`.

basic_string_view::find_last_not_of

Searches for the last character that is not any element of a specified string_view.

```
constexpr size_type find_last_not_of(basic_string_view str, size_type offset = npos) const noexcept;  
constexpr size_type find_last_not_of(charT chVal, size_type offset = npos) const noexcept;  
constexpr size_type find_last_not_of(const charT* ptr, size_type offset, size_type count) const;  
constexpr size_type find_last_not_of(const charT* ptr, size_type offset = npos) const;
```

Parameters

str

The string_view for which the member function is to search.

chVal

The character value for which the member function is to search.

offset

Index at which the search is to finish.

ptr

The C string for which the member function is to search.

count

The number of characters, counting forward from the first character, in *ptr*.

Return Value

The index of the first character of the substring searched for when successful; otherwise `string_view::npos`.

basic_string_view::find_last_of

Searches for the last character that matches any element of a specified string_view.

```
constexpr size_type find_last_of(basic_string_view str, size_type offset = npos) const noexcept;  
constexpr size_type find_last_of(charT chVal, size_type offset = npos) const noexcept;  
constexpr size_type find_last_of(const charT* ptr, size_type offset, size_type count) const;  
constexpr size_type find_last_of(const charT* ptr, size_type offset = npos) const;
```

Parameters

str

The string_view for which the member function is to search.

chVal

The character value for which the member function is to search.

offset

Index at which the search is to finish.

ptr

The C string for which the member function is to search.

count

The number of characters, counting forward from the first character, in the C string for which the member function is to search.

Return Value

The index of the last character of the substring searched for when successful; otherwise `npos`.

basic_string_view::front

Returns a `const_reference` to the first element.

```
constexpr const_reference front() const;
```

Return Value

A `const_reference` to the first element.

Remarks

Throws an exception if the `string_view` is empty.

basic_string_view::length

Returns the current number of elements.

```
constexpr size_type length() const noexcept;
```

Remarks

The member function is the same as [size](#).

basic_string_view::max_size

Returns the maximum number of characters a `string_view` can contain.

```
constexpr size_type max_size() const noexcept;
```

Return Value

The maximum number of characters a `string_view` can contain.

Remarks

A exception of type [length_error](#) is thrown when an operation produces a `string_view` with a length greater than `max_size()`.

basic_string_view::operator=

Assigns a `string_view` or convertible string object to another `string_view`.

```
constexpr basic_string_view& operator=(const basic_string_view&) noexcept = default;
```

Example

```
string_view s = "Hello";  
string_view s2 = s;
```

basic_string_view::operator[]

Provides a `const`_reference to the character with a specified index.

```
constexpr const_reference operator[](size_type offset) const;
```

Parameters

offset

The index of the element to be referenced.

Return Value

A `const`_reference to the character at the position specified by the parameter index.

Remarks

The first element has an index of zero, and the following elements are indexed consecutively by the positive integers, so that a `string_view` of length n has an n th element indexed by the number $n - 1$.

`operator[]` is faster than the member function [at](#) for providing read access to the elements of a `string_view`.

`operator[]` does not check whether the index passed as an argument is valid. An invalid index passed to `operator[]` results in undefined behavior.

The reference returned may be invalidated if the underlying string data is modified or deleted by the owning object.

When compiling with `_ITERATOR_DEBUG_LEVEL` set to 1 or 2, a runtime error will occur if you attempt to access an element outside the bounds of the `string_view`. For more information, see [Checked Iterators](#).

basic_string_view::rbegin

Returns a `const` iterator to the first element in a reversed `string_view`.

```
constexpr const_reverse_iterator rbegin() const noexcept;
```

Return Value

Returns a random-access iterator to the first element in a reversed `string_view`, addressing what would be the last element in the corresponding unreversed `string_view`.

Remarks

`rbegin` is used with a reversed `string_view` just as [begin](#) is used with a `string_view`. `rbegin` can be used to initialize an iteration backwards.

basic_string_view::remove_prefix

Moves the pointer forward by the specified number of elements.

```
constexpr void remove_prefix(size_type n);
```

Remarks

Leaves the underlying data unchanged. Moves the `string_view` pointer forward by `n` elements and sets the private `size` data member to `size - n`.

basic_string_view::remove_suffix

Reduces the size of the view by the specified number of elements starting from the back.

```
constexpr void remove_suffix(size_type n);
```

Remarks

Leaves the underlying data and the pointer to it unchanged. Sets the private `size` data member to `size - n`.

basic_string_view::rend

Returns a const iterator that points to one past the last element in a reversed `string_view`.

```
constexpr reverse_iterator rend() const noexcept;
```

Return Value

A const reverse random-access iterator that points to one past the last element in a reversed `string_view`.

Remarks

`rend` is used with a reversed `string_view` just as `end` is used with a `string_view`. `rend` can be used to test whether a reverse iterator has reached the end of its `string_view`. The value returned by `rend` should not be dereferenced.

basic_string_view::rfind

Searches a `string_view` in reverse for a substring that matches a specified sequence of characters.

```
constexpr size_type rfind(basic_string_view str, size_type offset = npos) const noexcept;  
constexpr size_type rfind(charT chVal, size_type offset = npos) const noexcept;  
constexpr size_type rfind(const charT* ptr, size_type offset, size_type count) const;  
constexpr size_type rfind(const charT* ptr, size_type offset = npos) const;
```

Parameters

chVal

The character value for which the member function is to search.

offset

Index at which the search is to begin.

ptr

The C string for which the member function is to search.

count

The number of characters, counting forward from the first character, in the C string for which the member function is to search.

str

The `string_view` for which the member function is to search.

Return Value

The index of the first character of the substring when successful; otherwise `npos`.

`basic_string_view::size`

Returns the number of elements in the `string_view`.

```
constexpr size_type size() const noexcept;
```

Return Value

The length of the `string_view`.

Remarks

A `string_view` can modify its length, for example by `remove_prefix` and `remove_suffix`. Because this does not modify the underlying string data, the size of a `string_view` is not necessarily the size of the underlying data.

`basic_string_view::substr`

Returns a `string_view` that represents (at most) the specified number of characters from a specified position.

```
constexpr basic_string_view substr(size_type offset = 0, size_type count = npos) const;
```

Parameters

offset

An index locating the element at the position from which the copy is made, with a default value of 0.

count

The number of characters to include in the substring, if they are present.

Return Value

A `string_view` object that represents the specified sub-sequence of elements.

`basic_string_view::swap`

Exchanges two `string_views`, in other words the pointers to the underlying string data, and the size values.

```
constexpr void swap(basic_string_view& sv) noexcept;
```

Parameters

sv

The source `string_view` whose pointer and size values are to be exchanged with that of the destination `string_view`.

See also

[<string_view>](#)

[Thread Safety in the C++ Standard Library](#)

hash<string_view> Specialization

4/24/2019 • 2 minutes to read • [Edit Online](#)

A template specialization that produces a hash value given a string_view.

```
template <class CharType, class Traits>
struct hash<basic_string_view<CharType, Traits>>
{
    typedef basic_string_view<CharType, Traits> argument_type;
    typedef size_t result_type;

    size_t operator()(const basic_string_view<CharType, Traits>) const
        noexcept;
};
```

Remarks

The hash of a string_view equals the hash of the underlying string object.

Example

```
//compile with: /std:c++17
#include <string>
#include <string_view>
#include <iostream>

using namespace std;

int main()
{
    string_view sv{ "Hello world" };
    string s{ "Hello world" };
    cout << boolalpha << (hash<string_view>{})(sv)
        == hash<string>{}(s)); // true
}
```

<strstream>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines several classes that support iostreams operations on sequences stored in an allocated array of **char** object. Such sequences are easily converted to and from C strings.

Syntax

```
#include <strstream>
```

Remarks

Objects of type `strstream` work with `char *`, which are C strings. Use `<sstream>` to work with objects of type `basic_string`.

NOTE

The classes in `<strstream>` are deprecated. Consider using the classes in `<sstream>` instead.

Classes

CLASS	DESCRIPTION
strstreambuf Class	The class describes a stream buffer that controls the transmission of elements to and from a sequence of elements stored in a char array object.
istrstream Class	The class describes an object that controls extraction of elements and encoded objects from a stream buffer of class strstreambuf .
ostrstream Class	The class describes an object that controls insertion of elements and encoded objects into a stream buffer of class strstreambuf .
strstream Class	The class describes an object that controls insertion and extraction of elements and encoded objects using a stream buffer of class strstreambuf .

strstreambuf Class

11/8/2018 • 10 minutes to read • [Edit Online](#)

Describes a stream buffer that controls the transmission of elements to and from a sequence of elements stored in a **char** array object.

Syntax

```
class strstreambuf : public streambuf
```

Remarks

Depending on how the object is constructed, it can be allocated, extended, and freed as necessary to accommodate changes in the sequence.

An object of class `strstreambuf` stores several bits of mode information as its `strstreambuf` mode. These bits indicate whether the controlled sequence:

- Has been allocated and needs to be freed eventually.
- Is modifiable.
- Is extendable by reallocating storage.
- Has been frozen and hence needs to be unfrozen before the object is destroyed, or freed (if allocated) by an agency other than the object.

A controlled sequence that is frozen cannot be modified or extended, regardless of the state of these separate mode bits.

The object also stores pointers to two functions that control `strstreambuf` allocation. If these are null pointers, the object devises its own method of allocating and freeing storage for the controlled sequence.

NOTE

This class is deprecated. Consider using [stringbuf](#) or [wstringbuf](#) instead.

Constructors

CONSTRUCTOR	DESCRIPTION
strstreambuf	Constructs an object of type <code>strstreambuf</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
freeze	Causes a stream buffer to be unavailable through stream buffer operations.

MEMBER FUNCTION	DESCRIPTION
overflow	A protected virtual function that can be called when a new character is inserted into a full buffer.
pbackfail	A protected virtual member function that tries to put back an element into the input stream, and then make it the current element (pointed to by the next pointer).
pcount	Returns a count of the number of elements written to the controlled sequence.
seekoff	A protected virtual member function that tries to alter the current positions for the controlled streams.
seekpos	A protected virtual member function that tries to alter the current positions for the controlled streams.
str	Calls freeze , and then returns a pointer to the beginning of the controlled sequence.
underflow	A protected virtual function to extract the current element from the input stream.

Requirements

Header: <strstream>

Namespace: std

strstreambuf::freeze

Causes a stream buffer to be unavailable through stream buffer operations.

```
void freeze(bool _Freezeit = true);
```

Parameters

_Freezeit

A **bool** indicating whether you want the stream to be frozen.

Remarks

If *_Freezeit* is true, the function alters the stored `strstreambuf` mode to make the controlled sequence frozen. Otherwise, it makes the controlled sequence not frozen.

[str](#) implies `freeze`.

NOTE

A frozen buffer will not be freed during `strstreambuf` destruction. You must unfreeze the buffer before it is freed to avoid a memory leak.

Example

```

// strstreambuf_freeze.cpp
// compile with: /EHsc

#include <iostream>
#include <strstream>

using namespace std;

void report(strstream &x)
{
    if (!x.good())
        cout << "stream bad" << endl;
    else
        cout << "stream good" << endl;
}

int main()
{
    strstream x;

    x << "test1";
    cout << "before freeze: ";
    report(x);

    // Calling str freezes stream.
    cout.write(x.rdbuf()->str(), 5) << endl;
    cout << "after freeze: ";
    report(x);

    // Stream is bad now, wrote on frozen stream
    x << "test1.5";
    cout << "after write to frozen stream: ";
    report(x);

    // Unfreeze stream, but it is still bad
    x.rdbuf()->freeze(false);
    cout << "after unfreezing stream: ";
    report(x);

    // Clear stream
    x.clear();
    cout << "after clearing stream: ";
    report(x);

    x << "test3";
    cout.write(x.rdbuf()->str(), 10) << endl;

    // Clean up. Failure to unfreeze stream will cause a
    // memory leak.
    x.rdbuf()->freeze(false);
}

```

```

before freeze: stream good
test1
after freeze: stream good
after write to frozen stream: stream bad
after unfreezing stream: stream bad
after clearing stream: stream good
test1test3

```

strstreambuf::overflow

A protected virtual function that can be called when a new character is inserted into a full buffer.

```
virtual int overflow(int _Meta = EOF);
```

Parameters

_Meta

The character to insert into the buffer, or `EOF`.

Return Value

If the function cannot succeed, it returns `EOF`. Otherwise, if *_Meta* == `EOF`, it returns some value other than `EOF`. Otherwise, it returns *_Meta*.

Remarks

If *_Meta* != `EOF`, the protected virtual member function tries to insert the element `(char)_Meta` into the output buffer. It can do so in various ways:

- If a write position is available, it can store the element into the write position and increment the next pointer for the output buffer.
- If the stored `strstreambuf` mode says the controlled sequence is modifiable, extendable, and not frozen, the function can make a write position available by allocating new for the output buffer. Extending the output buffer this way also extends any associated input buffer.

`strstreambuf::pbackfail`

A protected virtual member function that tries to put back an element into the input stream, and then makes it the current element (pointed to by the next pointer).

```
virtual int pbackfail(int _Meta = EOF);
```

Parameters

_Meta

The character to insert into the buffer, or `EOF`.

Return Value

If the function cannot succeed, it returns `EOF`. Otherwise, if *_Meta* == `EOF`, it returns some value other than `EOF`. Otherwise, it returns *_Meta*.

Remarks

The protected virtual member function tries to put back an element into the input buffer, and then make it the current element (pointed to by the next pointer).

If *_Meta* == `EOF`, the element to push back is effectively the one already in the stream before the current element. Otherwise, that element is replaced by `ch = (char)_Meta`. The function can put back an element in various ways:

- If a putback position is available, and the element stored there compares equal to `ch`, it can decrement the next pointer for the input buffer.
- If a putback position is available, and if the `strstreambuf` mode says the controlled sequence is modifiable, the function can store `ch` into the putback position and decrement the next pointer for the input buffer.

`strstreambuf::pcount`

Returns a count of the number of elements written to the controlled sequence.

```
streamsize pcount() const;
```

Return Value

A count of the number of elements written to the controlled sequence.

Remarks

Specifically, if `pptr` is a null pointer, the function returns zero. Otherwise, it returns `pptr` - `pbase`.

Example

```
// strstreambuf_pcount.cpp
// compile with: /EHsc
#include <iostream>
#include <strstream>
using namespace std;

int main( )
{
    strstream x;
    x << "test1";
    cout << x.rdbuf( )->pcount( ) << endl;
    x << "test2";
    cout << x.rdbuf( )->pcount( ) << endl;
}
```

strstreambuf::seekoff

A protected virtual member function that tries to alter the current positions for the controlled streams.

```
virtual streampos seekoff(streamoff _Off,
    ios_base::seekdir _Way,
    ios_base::openmode _Which = ios_base::in | ios_base::out);
```

Parameters

_Off

The position to seek for relative to *_Way*.

_Way

The starting point for offset operations. See [seekdir](#) for possible values.

_Which

Specifies the mode for the pointer position. The default is to allow you to modify the read and write positions.

Return Value

If the function succeeds in altering either or both stream positions, it returns the resultant stream position. Otherwise, it fails and returns an invalid stream position.

Remarks

The protected virtual member function endeavors to alter the current positions for the controlled streams. For an object of class `strstreambuf`, a stream position consists purely of a stream offset. Offset zero designates the first element of the controlled sequence.

The new position is determined as follows:

- If `_Way == ios_base::beg`, the new position is the beginning of the stream plus *_Off*.

- If `_Way == ios_base::cur`, the new position is the current stream position plus `_Off`.
- If `_Way == ios_base::end`, the new position is the end of the stream plus `_Off`.

If `_Which & ios_base::in` is nonzero and the input buffer exist, the function alters the next position to read in the input buffer. If `_Which & ios_base::out` is also nonzero, `_Way != ios_base::cur`, and the output buffer exists, the function also sets the next position to write to match the next position to read.

Otherwise, if `_Which & ios_base::out` is nonzero and the output buffer exists, the function alters the next position to write in the output buffer. Otherwise, the positioning operation fails. For a positioning operation to succeed, the resulting stream position must lie within the controlled sequence.

stringstream::seekpos

A protected virtual member function that tries to alter the current positions for the controlled streams.

```
virtual streampos seekpos(streampos _Sp, ios_base::openmode _Which = ios_base::in | ios_base::out);
```

Parameters

`_Sp`

The position to seek for.

`_Which`

Specifies the mode for the pointer position. The default is to allow you to modify the read and write positions.

Return Value

If the function succeeds in altering either or both stream positions, it returns the resultant stream position. Otherwise, it fails and returns an invalid stream position. To determine if the stream position is invalid, compare the return value with `pos_type(off_type(-1))`.

Remarks

The protected virtual member function endeavors to alter the current positions for the controlled streams. For an object of class `stringstream`, a stream position consists purely of a stream offset. Offset zero designates the first element of the controlled sequence. The new position is determined by `_Sp`.

If `_Which & ios_base::in` is nonzero and the input buffer exists, the function alters the next position to read in the input buffer. If `_Which & ios_base::out` is nonzero and the output buffer exists, the function also sets the next position to write to match the next position to read. Otherwise, if `_Which & ios_base::out` is nonzero and the output buffer exists, the function alters the next position to write in the output buffer. Otherwise, the positioning operation fails. For a positioning operation to succeed, the resulting stream position must lie within the controlled sequence.

stringstream::str

Calls [freeze](#), and then returns a pointer to the beginning of the controlled sequence.

```
char *str();
```

Return Value

A pointer to the beginning of the controlled sequence.

Remarks

No terminating null element exists, unless you explicitly insert one.

Example

See [strstreambuf::freeze](#) for a sample that uses **str**.

strstreambuf::strstreambuf

Constructs an object of type `strstreambuf`.

```
explicit strstreambuf(streamsize count = 0);

strstreambuf(void (* _Allocfunc)(size_t),
             void (* _Freefunc)(void*));

strstreambuf(char* _Getptr,
             streamsize count,
             char* _Putptr = 0);

strstreambuf(signed char* _Getptr,
             streamsize count,
             signed char* _Putptr = 0);

strstreambuf(unsigned char* _Getptr,
             streamsize count,
             unsigned char* _Putptr = 0);

strstreambuf(const char* _Getptr,
             streamsize count);

strstreambuf(const signed char* _Getptr,
             streamsize count);

strstreambuf(const unsigned char* _Getptr,
             streamsize count);
```

Parameters

_Allocfunc

The function used to allocate buffer memory.

count

Determines the length of the buffer pointed to by *_Getptr*. If *_Getptr* is not an argument (first constructor form), a suggested allocation size for the buffers.

_Freefunc

The function used to free buffer memory.

_Getptr

A buffer used for input.

_Putptr

A buffer used for output.

Remarks

The first constructor stores a null pointer in all the pointers controlling the input buffer, the output buffer, and `strstreambuf` allocation. It sets the stored `strstreambuf` mode to make the controlled sequence modifiable and extendable. It also accepts *count* as a suggested initial allocation size.

The second constructor behaves like the first, except that it stores *_Allocfunc* as the pointer to the function to call to allocate storage and *_Freefunc* as the pointer to the function to call to free that storage.

The three constructors:

```

strstreambuf(char *_Getptr,
             streamsize count,
             char *putptr = 0);

strstreambuf(signed char *_Getptr,
             streamsize count,
             signed char *putptr = 0);

strstreambuf(unsigned char *_Getptr,
             streamsize count,
             unsigned char *putptr = 0);

```

also behave like the first, except that `_Getptr` designates the array object used to hold the controlled sequence. (Hence, it must not be a null pointer.) The number of elements N in the array is determined as follows:

- If `(count > 0)`, then N is `count`.
- If `(count == 0)`, then N is `strlen((const char *)_Getptr)`.
- If `(count < 0)`, then N is **INT_MAX**.

If `_Putptr` is a null pointer, the function establishes just an input buffer by executing:

```

setg(_Getptr,
     _Getptr,
     _Getptr + N);

```

Otherwise, it establishes both input and output buffers by executing:

```

setg(_Getptr,
     _Getptr,
     _Putptr);

setp(_Putptr,
     _Getptr + N);

```

In this case, `_Putptr` must be in the interval `[_Getptr, _Getptr + N]`.

Finally, the three constructors:

```

strstreambuf(const char *_Getptr,
             streamsize count);

strstreambuf(const signed char *_Getptr,
             streamsize count);

strstreambuf(const unsigned char *_Getptr,
             streamsize count);

```

all behave the same as:

```

streambuf((char *)_Getptr, count);

```

except that the stored mode makes the controlled sequence neither modifiable nor extendable.

strstreambuf::underflow

A protected virtual function to extract the current element from the input stream.

```
virtual int underflow();
```

Return Value

If the function cannot succeed, it returns `EOF`. Otherwise, it returns the current element in the input stream, converted as described above.

Remarks

The protected virtual member function endeavors to extract the current element `ch` from the input buffer, then advance the current stream position, and return the element as `(int)(unsigned char)ch`. It can do so in only one way: if a read position is available, it takes `ch` as the element stored in the read position and advances the next pointer for the input buffer.

istream Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an object that controls extraction of elements and encoded objects from a stream buffer of class `strstreambuf`.

Syntax

```
class istream : public istream
```

Remarks

The object stores an object of class `strstreambuf`.

NOTE

This class is deprecated. Consider using `istream` or `wistream` instead.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>istream</code>	Constructs an object of type <code>istream</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>rdbuf</code>	Returns a pointer to the stream's associated <code>strstreambuf</code> object.
<code>str</code>	Calls <code>freeze</code> , and then returns a pointer to the beginning of the controlled sequence.

Requirements

Header: `<istream>`

Namespace: `std`

`istream::istream`

Constructs an object of type `istream`.

```
explicit istrstream(
    const char* ptr);

explicit istrstream(
    char* ptr);

istrstream(
    const char* ptr,
    streamsize count);

istrstream(
    char* ptr,
    int count);
```

Parameters

count

The length of the buffer (*ptr*).

ptr

The contents with which the buffer is initialized.

Remarks

All the constructors initialize the base class by calling [istream\(sb\)](#), where `sb` is the stored object of class [strstreambuf](#). The first two constructors also initialize `sb` by calling `strstreambuf((const char *) ptr, 0)`. The remaining two constructors instead call `strstreambuf((const char *) ptr, count)`.

istrstream::rdbuf

Returns a pointer to the stream's associated [strstreambuf](#) object.

```
strstreambuf *rdbuf() const
```

Return Value

A pointer to the stream's associated [strstreambuf](#) object.

Remarks

The member function returns the address of the stored stream buffer, of type pointer to [strstreambuf](#).

Example

See [strstreambuf::pcount](#) for a sample that uses `rdbuf`.

istrstream::str

Calls [freeze](#), and then returns a pointer to the beginning of the controlled sequence.

```
char *str();
```

Return Value

A pointer to the beginning of the controlled sequence.

Remarks

The member function returns `rdbuf` -> `str`.

Example

See [istream::str](#) for a sample that uses `str`.

ostream Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an object that controls insertion of elements and encoded objects into a stream buffer of class `strstreambuf`.

Syntax

```
class ostream : public ostream
```

Remarks

The object stores an object of class `strstreambuf`.

NOTE

This class is deprecated. Consider using `ostream` or `wostringstream` instead.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>ostream</code>	Constructs an object of type <code>ostream</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>freeze</code>	Causes a stream buffer to be unavailable through stream buffer operations.
<code>pcount</code>	Returns a count of the number of elements written to the controlled sequence.
<code>rdbuf</code>	Returns a pointer to the stream's associated <code>strstreambuf</code> object.
<code>str</code>	Calls <code>freeze</code> , and then returns a pointer to the beginning of the controlled sequence.

Requirements

Header: `<ostream>`

Namespace: `std`

`ostream::freeze`

Causes a stream buffer to be unavailable through stream buffer operations.

```
void freeze(bool _Freezeit = true);
```

Parameters

_Freezeit

A **bool** indicating whether you want the stream to be frozen.

Remarks

The member function calls `rdbuf -> freeze(_Freezeit)`.

Example

See `stringstream::freeze` for an example that uses `freeze`.

ostream::ostream

Constructs an object of type `ostream`.

```
ostream();

ostream(char* ptr,
        streamsize count,
        ios_base::openmode _Mode = ios_base::out);
```

Parameters

ptr

The buffer.

count

The size of the buffer in bytes.

_Mode

The input and output mode of the buffer. See `ios_base::openmode` for more information.

Remarks

Both constructors initialize the base class by calling `ostream(sb)`, where `sb` is the stored object of class `stringstreambuf`. The first constructor also initializes `sb` by calling `stringstreambuf`. The second constructor initializes the base class one of two ways:

- If `_Mode & ios_base::app == 0`, then `ptr` must designate the first element of an array of `count` elements, and the constructor calls `stringstreambuf(ptr, count, ptr)`.
- Otherwise, `ptr` must designate the first element of an array of count elements that contains a C string whose first element is designated by `ptr`, and the constructor calls `stringstreambuf(ptr, count, ptr + strlen(ptr))`.

ostream::pcount

Returns a count of the number of elements written to the controlled sequence.

```
streamsize pcount() const;
```

Return Value

The number of elements written to the controlled sequence.

Remarks

The member function returns [rdbuf](#) -> [pcount](#).

Example

See [stringstream::pcount](#) for a sample that uses `pcount`.

stringstream::rdbuf

Returns a pointer to the stream's associated stringstreambuf object.

```
stringstreambuf *rdbuf() const
```

Return Value

A pointer to the stream's associated stringstreambuf object.

Remarks

The member function returns the address of the stored stream buffer of type `pointer` to [stringstreambuf](#).

Example

See [stringstreambuf::pcount](#) for a sample that uses `rdbuf`.

stringstream::str

Calls [freeze](#), and then returns a pointer to the beginning of the controlled sequence.

```
char *str();
```

Return Value

A pointer to the beginning of the controlled sequence.

Remarks

The member function returns [rdbuf](#) -> [str](#).

Example

See [stringstream::str](#) for a sample that uses `str`.

stringstream Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Describes an object that controls insertion and extraction of elements and encoded objects using a stream buffer of class [stringstreambuf](#).

Syntax

```
class stringstream : public istream
```

Remarks

The object stores an object of class `stringstreambuf`.

NOTE

This class is deprecated. Consider using [stringstream](#) or [wstringstream](#) instead.

Constructors

CONSTRUCTOR	DESCRIPTION
stringstream	Constructs an object of type <code>stringstream</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
freeze	Causes a stream buffer to be unavailable through stream buffer operations.
pcount	Returns a count of the number of elements written to the controlled sequence.
rdbuf	Returns a pointer to the stream's associated <code>stringstreambuf</code> object.
str	Calls freeze , and then returns a pointer to the beginning of the controlled sequence.

Requirements

Header: <stringstream>

Namespace: std

stringstream::freeze

Causes a stream buffer to be unavailable through stream buffer operations.

```
void freeze(bool _Freezeit = true);
```

Parameters

_Freezeit

A **bool** indicating whether you want the stream to be frozen.

Remarks

The member function calls `rdbuf -> freeze(_Freezeit)`.

Example

See `stringstream::freeze` for an example that uses `freeze`.

stringstream::pcount

Returns a count of the number of elements written to the controlled sequence.

```
streamsize pcount() const;
```

Return Value

The number of elements written to the controlled sequence.

Remarks

The member function returns `rdbuf -> pcount`.

Example

See `stringstream::pcount` for a sample of using `pcount`.

stringstream::rdbuf

Returns a pointer to the stream's associated `stringstreambuf` object.

```
stringstreambuf *rdbuf() const
```

Return Value

A pointer to the stream's associated `stringstreambuf` object.

Remarks

The member function returns the address of the stored stream buffer of type `pointer` to `stringstreambuf`.

Example

See `stringstreambuf::pcount` for a sample that uses `rdbuf`.

stringstream::str

Calls `freeze`, and then returns a pointer to the beginning of the controlled sequence.

```
char *str();
```

Return Value

A pointer to the beginning of the controlled sequence.

Remarks

The member function returns `rdbuf` -> `str`.

Example

See `stringstream::str` for a sample that uses `str`.

stringstream::stringstream

Constructs an object of type `stringstream`.

```
stringstream();

stringstream(char* ptr,
             streamsize count,
             ios_base::openmode _Mode = ios_base::in | ios_base::out);
```

Parameters

count

The size of the buffer.

_Mode

The input and output mode of the buffer. See `ios_base::openmode` for more information.

ptr

The buffer.

Remarks

Both constructors initialize the base class by calling `streambuf(sb)`, where `sb` is the stored object of class `stringstream`. The first constructor also initializes `sb` by calling `stringstream`. The second constructor initializes the base class one of two ways:

- If `_Mode` & `ios_base::app` == 0, then *ptr* must designate the first element of an array of `count` elements, and the constructor calls `stringstream(ptr, count, ptr)`.
- Otherwise, *ptr* must designate the first element of an array of count elements that contains a C string whose first element is designated by *ptr*, and the constructor calls `stringstream(ptr, count, ptr + strlen(ptr))`.

<system_error>

3/18/2019 • 2 minutes to read • [Edit Online](#)

Include the header `<system_error>` to define the exception class `system_error` and related templates for processing low-level system errors.

Syntax

```
#include <system_error>
```

Objects

<code>generic_category</code>	Represents the category for generic errors.
<code>system_category</code>	Represents the category for errors caused by low-level system overflows.

Functions

FUNCTION	DESCRIPTION
<code>make_error_code</code>	Creates an <code>error_code</code> object.
<code>make_error_condition</code>	Creates an <code>error_condition</code> object.

Operators

OPERATOR	DESCRIPTION
<code>operator==</code>	Tests if the object on the left side of the operator is equal to the object on the right side.
<code>operator!=</code>	Tests if the object on the left side of the operator is not equal to the object on the right side.
<code>operator<</code>	Tests if an object is less than the object passed in for comparison.

Enumerations

<code>errc</code>	Provides symbolic names for all the error-code macros defined by Posix in <code><errno.h></code> .

Classes and Structs

--	--

error_category	Represents the abstract, common base for objects that describes a category of error codes.
error_code	Represents low-level system errors that are implementation-specific.
error_condition	Represents user-defined error codes.
is_error_code_enum	Represents a type predicate that tests for the error_code Class enumeration.
is_error_condition_enum	Represents a type predicate that tests for the error_condition Class enumeration.
system_error	Represents the base class for all exceptions thrown to report a low-level system overflow.

Requirements

Header: `<system_error>`

Namespace: `std`

[Header Files Reference](#)

<system_error> functions

3/18/2019 • 2 minutes to read • [Edit Online](#)

generic_category	make_error_code	make_error_condition
system_category		

generic_category

Represents the category for generic errors.

```
const error_category& generic_category() noexcept;
```

Remarks

The `generic_category` object is an implementation of [error_category](#).

make_error_code

Creates an error code object.

```
error_code make_error_code(std::errc error) noexcept;
```

Parameters

error

The `std::errc` enumeration value to store in the error code object.

Return Value

The error code object.

Remarks

make_error_condition

Creates an error condition object.

```
error_condition make_error_condition(std::errc error) noexcept;
```

Parameters

error

The `std::errc` enumeration value to store in the error code object.

Return Value

The error condition object.

Remarks

system_category

Represents the category for errors caused by low-level system overflows.

```
const error_category& system_category() noexcept;
```

Remarks

The `system_category` object is an implementation of [error_category](#).

See also

[<system_error>](#)

<system_error> operators

10/31/2018 • 2 minutes to read • [Edit Online](#)

operator!=

operator<

operator==

operator==

Tests if the object on the left side of the operator is equal to the object on the right side.

```
bool operator==(const error_code& left,
                const error_condition& right);

bool operator==(const error_condition& left,
                const error_code& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	The object to be tested for equality.
<i>right</i>	The object to be tested for equality.

Return Value

true if the objects are equal; **false** if objects are not equal.

Remarks

This function returns `left.category() == right.category() && left.value() == right.value()`.

operator!=

Tests if the object on the left side of the operator is not equal to the object on the right side.

```
bool operator!=(const error_code& left,
                const error_condition& right);

bool operator!=(const error_condition& left,
                const error_code& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	The object to be tested for inequality.
<i>right</i>	The object to be tested for inequality.

Return Value

true if the object passed in *left* is not equal to the object passed in *right*; otherwise **false**.

Remarks

This function returns `!(left == right)` .

operator<

Tests if an object is less than the object passed in for comparison.

```
template <class _Enum>
inline bool operator<(
    _Enum left,
    typename enable_if<is_error_code_enum<_Enum>::value,
    const error_code&>::type right);

template <class _Enum>
inline bool operator<(
    typename enable_if<is_error_code_enum<_Enum>::value,
    const error_code&>::type left, _Enum right);

template <class _Enum>
inline bool operator<(
    _Enum left,
    typename enable_if<is_error_condition_enum<_Enum>::value,
    const error_condition&>::type right);

template <class _Enum>
inline bool operator<(
    typename enable_if<is_error_condition_enum<_Enum>::value,
    const error_condition&>::type left, _Enum right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	The object to be compared.
<i>right</i>	The object to be compared.

Return Value

true if the object passed in *left* is less than the object passed in *right*; Otherwise, **false**.

Remarks

This function tests the error order.

too_many_links = EMLINK, too_many_symbolic_link_levels = ELOOP, value_too_large = EOVERFLOW,
wrong_protocol_type = EPROTOTYPE,};
```

Remarks

io_errc Enumeration

Provides symbolic names for the error conditions in `<iostream>`. Can be used to create [error_condition](#) objects to be compared with the value that's returned by the [ios_base::failure](#) `code()` function.

```
class io_errc { stream = 1 };
```

Remarks

Both [std::make_error_code\(\)](#) and [std::make_error_condition\(\)](#) are overloaded for this enum.

[ios_base::failure](#) can contain categories of error codes other than [error_condition](#).

Example

```
// io_errc.cpp
// cl.exe /nologo /W4 /EHsc /MTd

#include <iostream>

using namespace std;

int main()
{
    cin.exceptions(ios::failbit | ios::badbit);

    try {
        cin.rdbuf(nullptr); // throws io_errc::stream
    }
    catch (ios::failure& e) {
        cerr << "ios failure caught: ";
        if (e.code() == make_error_condition(io_errc::stream)) {
            cerr << "io_errc stream error condition" << endl;
        }
        else {
            cerr << "unmatched error condition code " << e.code() << endl;
        }
    }
}
```

[<system_error>](#)

error_category Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents the abstract, common base for objects that describes a category of error codes.

Syntax

```
class error_category;
```

Remarks

Two predefined objects implement `error_category`: [generic_category](#) and [system_category](#).

Typedefs

TYPE NAME	DESCRIPTION
value_type	A type that represents the stored error code value.

Member functions

MEMBER FUNCTION	DESCRIPTION
default_error_condition	Stores the error code value for an error condition object.
equivalent	Returns a value that specifies whether error objects are equivalent.
message	Returns the name of the specified error code.
name	Returns the name of the category.

Operators

OPERATOR	DESCRIPTION
operator==	Tests for equality between <code>error_category</code> objects.
operator!=	Tests for inequality between <code>error_category</code> objects.
operator<	Tests if the error_category object is less than the <code>error_category</code> object passed in for comparison.

Requirements

Header: <system_error>

Namespace: std

error_category::default_error_condition

Stores the error code value for an error condition object.

```
virtual error_condition default_error_condition(int _Errval) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>_Errval</i>	The error code value to store in the error_condition .

Return Value

Returns `error_condition(_Errval, *this)`.

Remarks

error_category::equivalent

Returns a value that specifies whether error objects are equivalent.

```
virtual bool equivalent(value_type _Errval,  
    const error_condition& _Cond) const;  
  
virtual bool equivalent(const error_code& _Code,  
    value_type _Errval) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>_Errval</i>	The error code value to compare.
<i>_Cond</i>	The error_condition object to compare.
<i>_Code</i>	The error_code object to compare.

Return Value

true if the category and value are equal; otherwise, **false**.

Remarks

The first member function returns `*this == _Cond.category() && _Cond.value() == _Errval`.

The second member function returns `*this == _Code.category() && _Code.value() == _Errval`.

error_category::message

Returns the name of the specified error code.

```
virtual string message(error_code::value_type val) const = 0;
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The error code value to describe.

Return Value

Returns a descriptive name of the error code *val* for the category.

Remarks

error_category::name

Returns the name of the category.

```
virtual const char *name() const = 0;
```

Return Value

Returns the name of the category as a null-terminated byte string.

Remarks

error_category::operator==

Tests for equality between `error_category` objects.

```
bool operator==(const error_category& right) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The object to be tested for equality.

Return Value

true if the objects are equal; **false** if the objects are not equal.

Remarks

This member operator returns `this == &right`.

error_category::operator!=

Tests for inequality between `error_category` objects.

```
bool operator!=(const error_category& right) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The object to be tested for inequality.

Return Value

true if the `error_category` object is not equal to the `error_category` object passed in *right*; otherwise **false**.

Remarks

The member operator returns `(!*this == right)`.

error_category::operator<

Tests if the [error_category](#) object is less than the `error_category` object passed in for comparison.

```
bool operator<(const error_category& right) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The <code>error_category</code> object to be compared.

Return Value

true if the `error_category` object is less than the `error_category` object passed in for comparison; Otherwise, **false**.

Remarks

The member operator returns `this < &right`.

error_category::value_type

A type that represents the stored error code value.

```
typedef int value_type;
```

Remarks

This type definition is a synonym for **int**.

See also

[<system_error>](#)

error_code Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Represents low-level system errors that are implementation-specific.

Syntax

```
class error_code;
```

Remarks

An object of type `error_code` class stores an error code value and a pointer to an object that represents a [category](#) of error codes that describe reported low-level system errors.

Constructors

CONSTRUCTOR	DESCRIPTION
error_code	Constructs an object of type <code>error_code</code> .

Typedefs

TYPE NAME	DESCRIPTION
value_type	A type that represents the stored error code value.

Member functions

MEMBER FUNCTION	DESCRIPTION
assign	Assigns an error code value and category to an error code.
category	Returns the error category.
clear	Clears the error code value and category.
default_error_condition	Returns the default error condition.
message	Returns the name of the error code.

Operators

OPERATOR	DESCRIPTION
operator==	Tests for equality between <code>error_code</code> objects.
operator!=	Tests for inequality between <code>error_code</code> objects.

OPERATOR	DESCRIPTION
<code>operator<</code>	Tests if the <code>error_code</code> object is less than the <code>error_code</code> object passed in for comparison.
<code>operator=</code>	Assigns a new enumeration value to the <code>error_code</code> object.
<code>operator bool</code>	Casts a variable of type <code>error_code</code> .

Requirements

Header: `<system_error>`

Namespace: `std`

`error_code::assign`

Assigns an error code value and category to an error code.

```
void assign(value_type val, const error_category& _Cat);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The error code value to store in the <code>error_code</code> .
<i>_Cat</i>	The error category to store in the <code>error_code</code> .

Remarks

The member function stores *val* as the error code value and a pointer to *_Cat*.

`error_code::category`

Returns the error category.

```
const error_category& category() const;
```

Remarks

`error_code::clear`

Clears the error code value and category.

```
clear();
```

Remarks

The member function stores a zero error code value and a pointer to the [generic_category](#) object.

`error_code::default_error_condition`

Returns the default error condition.

```
error_condition default_error_condition() const;
```

Return Value

The [error_condition](#) specified by [default_error_condition](#).

Remarks

This member function returns `category().default_error_condition(value())`.

error_code::error_code

Constructs an object of type `error_code`.

```
error_code();

error_code(value_type val, const error_category& _Cat);

template <class _Enum>
error_code(_Enum _Errcode,
           typename enable_if<is_error_code_enum<_Enum>::value,
                               error_code::type* = 0>);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The error code value to store in the <code>error_code</code> .
<i>_Cat</i>	The error category to store in the <code>error_code</code> .
<i>_Errcode</i>	The enumeration value to store in the <code>error_code</code> .

Remarks

The first constructor stores a zero error code value and a pointer to the [generic_category](#).

The second constructor stores *val* as the error code value and a pointer to [error_category](#).

The third constructor stores `(value_type)_Errcode` as the error code value and a pointer to the [generic_category](#).

error_code::message

Returns the name of the error code.

```
string message() const;
```

Return Value

A `string` representing the name of the error code.

Remarks

This member function returns `category().message(value())`.

error_code::operator==

Tests for equality between `error_code` objects.

```
bool operator==(const error_code& right) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The object to be tested for equality.

Return Value

true if the objects are equal; **false** if objects are not equal.

Remarks

The member operator returns `category() == right.category() && value == right.value()`.

error_code::operator!=

Tests for inequality between `error_code` objects.

```
bool operator!=(const error_code& right) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The object to be tested for inequality.

Return Value

true if the `error_code` object is not equal to the `error_code` object passed in *right*; otherwise **false**.

Remarks

The member operator returns `!(*this == right)`.

error_code::operator<

Tests if the `error_code` object is less than the `error_code` object passed in for comparison.

```
bool operator<(const error_code& right) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The <code>error_code</code> object to be compared.

Return Value

true if the `error_code` object is less than the `error_code` object passed in for comparison; Otherwise, **false**.

Remarks

The member operator returns

```
category() < right.category() || category() == right.category() && value < right.value()
```

error_code::operator=

Assigns a new enumeration value to the `error_code` object.

```
template <class _Enum>
typename enable_if<is_error_code_enum<_Enum>::value, error_code>::type&
operator=(_Enum _Errcode);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Errcode</code>	The enumeration value to assign to the <code>error_code</code> object.

Return Value

A reference to the `error_code` object that is being assigned the new enumeration value by the member function.

Remarks

The member operator stores `(value_type)_Errcode` as the error code value and a pointer to the [generic_category](#). It returns `*this`.

error_code::operator bool

Casts a variable of type `error_code`.

```
explicit operator bool() const;
```

Return Value

The Boolean value of the `error_code` object.

Remarks

The operator returns a value convertible to **true** only if [value](#) is not equal to zero. The return type is convertible only to **bool**, not to `void *` or other known scalar types.

error_code::value

Returns the stored error code value.

```
value_type value() const;
```

Return Value

The stored error code value of type [value_type](#).

Remarks

error_code::value_type

A type that represents the stored error code value.

```
typedef int value_type;
```

Remarks

This type definition is a synonym for **int**.

See also

[error_category](#) Class

[<system_error>](#)

error_condition Class

10/31/2018 • 3 minutes to read • [Edit Online](#)

Represents user-defined error codes.

Syntax

```
class error_condition;
```

Remarks

An object of type `error_condition` stores an error code value and a pointer to an object that represents a [category](#) of error codes used for reported user-defined errors.

Constructors

CONSTRUCTOR	DESCRIPTION
error_condition	Constructs an object of type <code>error_condition</code> .

Typedefs

TYPE NAME	DESCRIPTION
value_type	A type that represents the stored error code value.

Member functions

MEMBER FUNCTION	DESCRIPTION
assign	Assigns an error code value and category to an error condition.
category	Returns the error category.
clear	Clears the error code value and category.
message	Returns the name of the error code.

Operators

OPERATOR	DESCRIPTION
operator==	Tests for equality between <code>error_condition</code> objects.
operator!=	Tests for inequality between <code>error_condition</code> objects.
operator<	Tests if the <code>error_condition</code> object is less than the <code>error_code</code> object passed in for comparison.

OPERATOR	DESCRIPTION
<code>operator=</code>	Assigns a new enumeration value to the <code>error_condition</code> object.
<code>operator bool</code>	Casts a variable of type <code>error_condition</code> .

Requirements

Header: `<system_error>`

Namespace: `std`

`error_condition::assign`

Assigns an error code value and category to an error condition.

```
void assign(value_type val, const error_category& _Cat);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The error code value to store in the <code>error_code</code> .
<i>_Cat</i>	The error category to store in the <code>error_code</code> .

Remarks

The member function stores *val* as the error code value and a pointer to *_Cat*.

`error_condition::category`

Returns the error category.

```
const error_category& category() const;
```

Return Value

A reference to the stored error category

Remarks

`error_condition::clear`

Clears the error code value and category.

```
clear();
```

Remarks

The member function stores a zero error code value and a pointer to the `generic_category` object.

`error_condition::error_condition`

Constructs an object of type `error_condition` .

```
error_condition();

error_condition(value_type val, const error_category& _Cat);

template <class _Enum>
error_condition(_Enum _Errcode,
               typename enable_if<is_error_condition_enum<_Enum>::value,
               error_code>::type* = 0);
```

Parameters

PARAMETER	DESCRIPTION
<i>val</i>	The error code value to store in the <code>error_condition</code> .
<i>_Cat</i>	The error category to store in the <code>error_condition</code> .
<i>_Errcode</i>	The enumeration value to store in the <code>error_condition</code> .

Remarks

The first constructor stores a zero error code value and a pointer to the [generic_category](#).

The second constructor stores *val* as the error code value and a pointer to [error_category](#).

The third constructor stores `(value_type)_Errcode` as the error code value and a pointer to the [generic_category](#).

error_condition::message

Returns the name of the error code.

```
string message() const;
```

Return Value

A `string` representing the name of the error code.

Remarks

This member function returns `category().message(value())` .

error_condition::operator==

Tests for equality between `error_condition` objects.

```
bool operator==(const error_condition& right) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The object to be tested for equality.

Return Value

true if the objects are equal; **false** if objects are not equal.

Remarks

The member operator returns `category() == right.category() && value == right.value()` .

error_condition::operator!=

Tests for inequality between `error_condition` objects.

```
bool operator!=(const error_condition& right) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The object to be tested for inequality.

Return Value

true if the `error_condition` object is not equal to the `error_condition` object passed in *right*; otherwise **false**.

Remarks

The member operator returns `!(*this == right)` .

error_condition::operator<

Tests if the `error_condition` object is less than the `error_code` object passed in for comparison.

```
bool operator<(const error_condition& right) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The <code>error_condition</code> object to be compared.

Return Value

true if the `error_condition` object is less than the `error_condition` object passed in for comparison; Otherwise, **false**.

Remarks

The member operator returns

```
category() < right.category() || category() == right.category() && value < right.value()
```

 .

error_condition::operator=

Assigns a new enumeration value to the `error_condition` object.

```
template <class _Enum>
error_condition(_Enum error,
    typename enable_if<is_error_condition_enum<_Enum>::value,
    error_condition>::type&
    operator=(Enum _Errcode);
```

Parameters

PARAMETER	DESCRIPTION
<code>_Errcode</code>	The enumeration value to assign to the <code>error_condition</code> object.

Return Value

A reference to the `error_condition` object that is being assigned the new enumeration value by the member function.

Remarks

The member operator stores `(value_type)error` as the error code value and a pointer to the [generic_category](#). It returns `*this`.

error_condition::operator bool

Casts a variable of type `error_condition`.

```
explicit operator bool() const;
```

Return Value

The Boolean value of the `error_condition` object.

Remarks

The operator returns a value convertible to **true** only if [value](#) is not equal to zero. The return type is convertible only to **bool**, not to `void *` or other known scalar types.

error_condition::value

Returns the stored error code value.

```
value_type value() const;
```

Return Value

The stored error code value of type [value_type](#).

Remarks

error_condition::value_type

A type that represents the stored error code value.

```
typedef int value_type;
```

Remarks

The type definition is a synonym for **int**.

[error_category Class](#)

[<system_error>](#)

is_error_code_enum Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a type predicate that tests for the [error_code](#) enumeration.

Syntax

```
template <_Enum>
class is_error_code_enum;
```

Remarks

An instance of this [type predicate](#) holds true if the type `_Enum` is an enumeration value suitable for storing in an object of type `error_code`.

It is permissible to add specializations to this type for user-defined types.

Requirements

Header: `<system_error>`

Namespace: `std`

See also

[<type_traits>](#)

[<system_error>](#)

is_error_condition_enum Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents a type predicate that tests for the [error_condition](#) enumeration.

Syntax

```
template <_Enum>
class is_error_condition_enum;
```

Remarks

An instance of this [type predicate](#) holds true if the type `_Enum` is an enumeration value suitable for storing in an object of type `error_condition`.

It is permissible to add specializations to this type for user-defined types.

Requirements

Header: `<system_error>`

Namespace: `std`

See also

[<type_traits>](#)

[<system_error>](#)

system_error Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Represents the base class for all exceptions thrown to report a low-level system error.

Syntax

```
class system_error : public runtime_error {
public:
    explicit system_error(error_code _Errcode,
        const string& _Message = "");

    system_error(error_code _Errcode,
        const char *_Message);

    system_error(error_code::value_type _Errval,
        const error_category& _Errcat,
        const string& _Message);

    system_error(error_code::value_type _Errval,
        const error_category& _Errcat,
        const char *_Message);
    const error_code& code() const throw();
    const error_code& code() const throw();

};
```

Remarks

The value returned by `what` in the class `exception` is constructed from `_Message` and the stored object of type `error_code` (either `code` or `error_code(_Errval, _Errcat)`).

The member function `code` returns the stored `error_code` object.

Requirements

Header: <system_error>

Namespace: std

See also

<system_error>

<thread>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Include the standard header `<thread>` to define the class **thread** and various supporting functions.

Syntax

```
#include <thread>
```

Remarks

NOTE

In code that is compiled by using `/clr`, this header is blocked.

The `__STDCPP_THREADS__` macro is defined as a nonzero value to indicate that threads are supported by this header.

Members

Public Classes

NAME	DESCRIPTION
thread Class	Defines an object that is used to observe and manage a thread of execution in an application.

Public Structures

NAME	DESCRIPTION
hash Structure (C++ Standard Library)	Defines a member function that returns a value that is uniquely determined by a <code>thread::id</code> . The member function defines a hash function that is suitable for mapping values of type <code>thread::id</code> to a distribution of index values.

Public Functions

NAME	DESCRIPTION
get_id	Uniquely identifies the current thread of execution.
sleep_for	Blocks the calling thread.
sleep_until	Blocks the calling thread at least until the specified time.
swap	Exchanges the states of two thread objects.

[Thread Safety in the C++ Standard Library](#)

<thread> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

get_id	sleep_for	sleep_until
swap	yield	

get_id

Uniquely identifies the current thread of execution.

```
thread::id this_thread::get_id() noexcept;
```

Return Value

An object of type [thread::id](#) that uniquely identifies the current thread of execution.

sleep_for

Blocks the calling thread.

```
template <class Rep,  
class Period>  
inline void sleep_for(const chrono::duration<Rep, Period>& Rel_time);
```

Parameters

Rel_time

A [duration](#) object that specifies a time interval.

Remarks

The function blocks the calling thread for at least the time that's specified by *Rel_time*. This function does not throw any exceptions.

sleep_until

Blocks the calling thread at least until the specified time.

```
template <class Clock, class Duration>  
void sleep_until(const chrono::time_point<Clock, Duration>& Abs_time);  
  
void sleep_until(const xtime *Abs_time);
```

Parameters

Abs_time

Represents a point in time.

Remarks

This function does not throw any exceptions.

swap

Swaps the states of two **thread** objects.

```
void swap(thread& Left, thread& Right) noexcept;
```

Parameters

Left

The left **thread** object.

Right

The right **thread** object.

Remarks

The function calls `Left.swap(Right)` .

yield

Signals the operating system to run other threads, even if the current thread would ordinarily continue to run.

```
inline void yield() noexcept;
```

[<thread>](#)

<thread> operators

10/31/2018 • 2 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<<</code>	<code>operator<=</code>
<code>operator==</code>		

`operator>=`

Determines whether one `thread::id` object is greater than or equal to another.

```
bool operator>= (  
    thread::id Left,  
    thread::id Right) noexcept
```

Parameters

Left

The left `thread::id` object.

Right

The right `thread::id` object.

Return Value

```
!(Left < Right)
```

Remarks

This function does not throw any exceptions.

`operator>`

Determines whether one `thread::id` object is greater than another.

```
bool operator> (  
    thread::id Left,  
    thread::id Right) noexcept
```

Parameters

Left

The left `thread::id` object.

Right

The right `thread::id` object.

Return Value

```
Right < Left
```

Remarks

This function does not throw any exceptions.

operator<=

Determines whether one `thread::id` object is less than or equal to another.

```
bool operator<= (
    thread::id Left,
    thread::id Right) noexcept
```

Parameters

Left

The left `thread::id` object.

Right

The right `thread::id` object.

Return Value

```
!(Right < Left)
```

Remarks

This function does not throw any exceptions.

operator<

Determines whether one `thread::id` object is less than another.

```
bool operator<(
    thread::id Left,
    thread::id Right) noexcept
```

Parameters

Left

The left `thread::id` object.

Right

The right `thread::id` object.

Return Value

true if *Left* precedes *Right* in the total ordering; otherwise, **false**.

Remarks

The operator defines a total ordering on all `thread::id` objects. These objects can be used as keys in associative containers.

This function does not throw any exceptions.

operator!=

Compares two `thread::id` objects for inequality.

```
bool operator!= (
    thread::id Left,
    thread::id Right) noexcept
```

Parameters

Left

The left `thread::id` object.

Right

The right `thread::id` object.

Return Value

`!(Left == Right)`

Remarks

This function does not throw any exceptions.

operator==

Compares two `thread::id` objects for equality.

```
bool operator== (
    thread::id Left,
    thread::id Right) noexcept
```

Parameters

Left

The left `thread::id` object.

Right

The right `thread::id` object.

Return Value

true if the two objects represent the same thread of execution or if neither object represents a thread of execution; otherwise, **false**.

Remarks

This function does not throw any exceptions.

operator<<

Inserts a text representation of a `thread::id` object into a stream.

```
template <class Elem, class Tr>
basic_ostream<Elem, Tr>& operator<< (
    basic_ostream<Elem, Tr>& Ostr, thread::id Id);
```

Parameters

Ostr

A [basic_ostream](#) object.

Id

A `thread::id` object.

Return Value

Ostr.

Remarks

This function inserts *Id* into *Ostr*.

If two `thread::id` objects compare equal, the inserted text representations of those objects are the same.

See also

[<thread>](#)

hash Structure (C++ Standard Library)

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines a member function that returns a value that's uniquely determined by `val`. The member function defines a `hash` function that's suitable for mapping values of type `thread::id` to a distribution of index values.

Syntax

```
template <>
struct hash<thread::id> :
    public unary_function<thread::id, size_t>
{
    size_t operator()(thread::id Val) const;
};
```

Requirements

Header: `<thread>`

Namespace: `std`

See also

[Header Files Reference](#)

[<thread>](#)

[unary_function Struct](#)

thread Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

Defines an object that's used to observe and manage a thread of execution within an application.

Syntax

```
class thread;
```

Remarks

You can use a **thread** object to observe and manage a thread of execution within an application. A thread object that's created by using the default constructor is not associated with any thread of execution. A thread object that's constructed by using a callable object creates a new thread of execution and calls the callable object in that thread. Thread objects can be moved but not copied. Therefore, a thread of execution can be associated with only one thread object.

Every thread of execution has a unique identifier of type `thread::id`. The function `this_thread::get_id` returns the identifier of the calling thread. The member function `thread::get_id` returns the identifier of the thread that's managed by a thread object. For a default-constructed thread object, the `thread::get_id` method returns an object that has a value that's the same for all default-constructed thread objects and different from the value that's returned by `this_thread::get_id` for any thread of execution that could be joined at the time of the call.

Members

Public Classes

NAME	DESCRIPTION
<code>thread::id</code> Class	Uniquely identifies the associated thread.

Public Constructors

NAME	DESCRIPTION
<code>thread</code>	Constructs a thread object.

Public Methods

NAME	DESCRIPTION
<code>detach</code>	Detaches the associated thread from the thread object.
<code>get_id</code>	Returns the unique identifier of the associated thread.
<code>hardware_concurrency</code>	Static. Returns an estimate of the number of hardware thread contexts.
<code>join</code>	Blocks until the associated thread completes.

NAME	DESCRIPTION
<code>joinable</code>	Specifies whether the associated thread is joinable.
<code>native_handle</code>	Returns the implementation-specific type that represents the thread handle.
<code>swap</code>	Swaps the object state with a specified thread object.

Public Operators

NAME	DESCRIPTION
<code>thread::operator=</code>	Associates a thread with the current thread object.

Requirements

Header: <thread>

Namespace: std

thread::detach

Detaches the associated thread. The operating system becomes responsible for releasing thread resources on termination.

```
void detach();
```

Remarks

After a call to `detach`, subsequent calls to `get_id` return `id`.

If the thread that's associated with the calling object is not joinable, the function throws a `system_error` that has an error code of `invalid_argument`.

If the thread that's associated with the calling object is invalid, the function throws a `system_error` that has an error code of `no_such_process`.

thread::get_id

Returns a unique identifier for the associated thread.

```
id get_id() const noexcept;
```

Return Value

A `thread::id` object that uniquely identifies the associated thread, or `thread::id()` if no thread is associated with the object.

thread::hardware_concurrency

Static method that returns an estimate of the number of hardware thread contexts.

```
static unsigned int hardware_concurrency() noexcept;
```

Return Value

An estimate of the number of hardware thread contexts. If the value cannot be computed or is not well defined, this method returns 0.

thread::id Class

Provides a unique identifier for each thread of execution in the process.

```
class thread::id {  
    id() noexcept;  
};
```

Remarks

The default constructor creates an object that does not compare equal to the `thread::id` object for any existing thread.

All default-constructed `thread::id` objects compare equal.

thread::join

Blocks until the thread of execution that's associated with the calling object completes.

```
void join();
```

Remarks

If the call succeeds, subsequent calls to `get_id` for the calling object return a default `thread::id` that does not compare equal to the `thread::id` of any existing thread; if the call does not succeed, the value that's returned by `get_id` is unchanged.

thread::joinable

Specifies whether the associated thread is *joinable*.

```
bool joinable() const noexcept;
```

Return Value

true if the associated thread is *joinable*; otherwise, **false**.

Remarks

A thread object is *joinable* if `get_id() != id()`.

thread::native_handle

Returns the implementation-specific type that represents the thread handle. The thread handle can be used in implementation-specific ways.

```
native_handle_type native_handle();
```

Return Value

`native_handle_type` is defined as a `Win32 HANDLE` that's cast as `void *`.

thread::operator=

Associates the thread of a specified object with the current object.

```
thread& operator=(thread&& Other) noexcept;
```

Parameters

Other

A **thread** object.

Return Value

`*this`

Remarks

The method calls `detach` if the calling object is joinable.

After the association is made, `other` is set to a default-constructed state.

thread::swap

Swaps the object state with that of a specified **thread** object.

```
void swap(thread& Other) noexcept;
```

Parameters

Other

A **thread** object.

thread::thread Constructor

Constructs a **thread** object.

```
thread() noexcept;  
template <class Fn, class... Args>  
explicit thread(Fn&& F, Args&&... A);  
  
thread(thread&& Other) noexcept;
```

Parameters

F

An application-defined function to be executed by the thread.

A

A list of arguments to be passed to *F*.

Other

An existing **thread** object.

Remarks

The first constructor constructs an object that's not associated with a thread of execution. The value that's returned

by a call to `get_id` for the constructed object is `thread::id()` .

The second constructor constructs an object that's associated with a new thread of execution and executes the pseudo-function `INVOKE` that's defined in [<functional>](#) . If not enough resources are available to start a new thread, the function throws a [system_error](#) object that has an error code of `resource_unavailable_try_again` . If the call to *F* terminates with an uncaught exception, [terminate](#) is called.

The third constructor constructs an object that's associated with the thread that's associated with `Other` . `Other` is then set to a default-constructed state.

<tuple>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines a template `tuple` whose instances hold objects of varying types.

Syntax

```
#include <tuple>
```

Classes

CLASS	DESCRIPTION
<code>tuple</code>	Wraps a fixed-length sequence of elements.
<code>tuple_element</code> Class	Wraps the type of a <code>tuple</code> element.
<code>tuple_size</code> Class	Wraps <code>tuple</code> element count.

Operators

OPERATOR	DESCRIPTION
<code>operator==</code>	Comparison of <code>tuple</code> objects, equal
<code>operator!=</code>	Comparison of <code>tuple</code> objects, not equal
<code>operator<</code>	Comparison of <code>tuple</code> objects, less than
<code>operator<=</code>	Comparison of <code>tuple</code> objects, less than or equal
<code>operator></code>	Comparison of <code>tuple</code> objects, greater than
<code>operator>=</code>	Comparison of <code>tuple</code> objects, greater than or equal

Functions

FUNCTION	DESCRIPTION
<code>get</code>	Gets an element from a <code>tuple</code> object.
<code>make_tuple</code>	Makes a <code>tuple</code> from element values.
<code>tie</code>	Makes a <code>tuple</code> from element references.

See also

[<array>](#)

<tuple> functions

10/31/2018 • 3 minutes to read • [Edit Online](#)

get	make_tuple	tie

get

Gets an element from a `tuple` object, by index or (in C++14) by type.

```
// by index:
// get reference to Index element of tuple
template <size_t Index, class... Types>
constexpr tuple_element_t<Index, tuple<Types...>& get(tuple<Types...>& Tuple) noexcept;

// get const reference to Index element of tuple
template <size_t Index, class... Types>
constexpr const tuple_element_t<Index, tuple<Types...>& get(const tuple<Types...>& Tuple) noexcept;

// get rvalue reference to Index element of tuple
template <size_t Index, class... Types>
constexpr tuple_element_t<Index, tuple<Types...>&& get(tuple<Types...>&& Tuple) noexcept;

// (C++14) by type:
// get reference to T element of tuple
template <class T, class... Types>
constexpr T& get(tuple<Types...>& Tuple) noexcept;

// get const reference to T element of tuple
template <class T, class... Types>
constexpr const T& get(const tuple<Types...>& Tuple) noexcept;

// get rvalue reference to T element of tuple
template <class T, class... Types>
constexpr T&& get(tuple<Types...>&& Tuple) noexcept;
```

Parameters

Index

The index of the element to get.

Types

The sequence of types declared in the tuple, in declaration order.

T

The type of the element to get.

Tuple

A `std::tuple` that contains any number of elements.

Remarks

The template functions return a reference to the value at index *Index*, or of type *T* in the `tuple` object.

Calling `get<T>(Tuple)` will produce a compiler error if `Tuple` contains more or less than one element of type *T*.

Example

```
#include <tuple>
#include <iostream>
#include <string>

using namespace std;

int main() {
    tuple<int, double, string> tup(0, 1.42, "Call me Tuple");

    // get elements by index
    cout << " " << get<0>(tup);
    cout << " " << get<1>(tup);
    cout << " " << get<2>(tup) << endl;

    // get elements by type
    cout << " " << get<int>(tup);
    cout << " " << get<double>(tup);
    cout << " " << get<string>(tup) << endl;
}
```

```
0 1.42 Call me Tuple
0 1.42 Call me Tuple
```

make_tuple

Makes a `tuple` from element values.

```
template <class T1, class T2, ..., class TN>
    tuple<V1, V2, ..., VN> make_tuple(const T1& t1, const T2& t2, ..., const TN& tN);
```

Parameters

TN

The type of the Nth function parameter.

tN

The value of the Nth function parameter.

Remarks

The template function returns `tuple<V1, V2, ..., VN>(t1, t2, ..., tN)`, where each type `Vi` is `X&` when the corresponding type `Ti` is `cv reference_wrapper<X>`; otherwise, it is `Ti`.

One advantage of `make_tuple` is that the types of objects that are being stored are determined automatically by the compiler and do not have to be explicitly specified. Don't use explicit template arguments such as

`make_tuple<int, int>(1, 2)` when you use `make_tuple` because it is unnecessarily verbose and adds complex rvalue reference problems that might cause compilation failure.

Example

```

// std_tuple_make_tuple.cpp
// compile by using: /EHsc
#include <tuple>
#include <iostream>

typedef std::tuple<int, double, int, double> Mytuple;
int main() {
    Mytuple c0(0, 1, 2, 3);

    // display contents " 0 1 2 3"
    std::cout << std::get<0>(c0) << " ";
    std::cout << std::get<1>(c0) << " ";
    std::cout << std::get<2>(c0) << " ";
    std::cout << std::get<3>(c0) << std::endl;

    c0 = std::make_tuple(4, 5, 6, 7);

    // display contents " 4 5 6 7"
    std::cout << std::get<0>(c0) << " ";
    std::cout << std::get<1>(c0) << " ";
    std::cout << std::get<2>(c0) << " ";
    std::cout << std::get<3>(c0) << std::endl;

    return (0);
}

```

```

0 1 2 3
4 5 6 7

```

tie

Makes a `tuple` from element references.

```

template <class T1, class T2, ..., class TN>
tuple<T1&, T2&, ..., TN&> tie(T1& t1, T2& t2, ..., TN& tN);

```

Parameters

TN

The base type of the Nth tuple element.

Remarks

The template function returns `tuple<T1&, T2&, ..., TN&>(t1, t2, ..., tN)`.

Example

```

// std_tuple_tie.cpp
// compile with: /EHsc
#include <tuple>
#include <iostream>

typedef std::tuple<int, double, int, double> Mytuple;
int main() {
    Mytuple c0(0, 1, 2, 3);

    // display contents " 0 1 2 3"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    int v4 = 4;
    double v5 = 5;
    int v6 = 6;
    double v7 = 7;
    std::tie(v4, v5, v6, v7) = c0;

    // display contents " 0 1 2 3"
    std::cout << " " << v4;
    std::cout << " " << v5;
    std::cout << " " << v6;
    std::cout << " " << v7;
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3

```

[<tuple>](#)

<tuple> operators

10/31/2018 • 6 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<=</code>	<code>operator==</code>

operator!=

Compare `tuple` objects for inequality.

```
template <class T1, class T2, ..., class TN,  
          class U1, class U2, ..., class UN>  
bool operator!=(const tuple<T1, T2, ..., TN>& tp1,  
                const tuple<U1, U2, ..., UN>& tp2);
```

Parameters

TN

The type of the Nth tuple element.

Remarks

The function returns false when `N` is 0, otherwise

```
get<0>(tp1) != get<0>(tp2) || get<1>(tp1) != get<1>(tp2) || ... || get<N - 1>(tp1) == get<N - 1>(tp2) .
```

Example

```

// std_tuple_operator_ne.cpp
// compile with: /EHsc
#include <tuple>
#include <iostream>

typedef std::tuple<int, double, int, double> Mytuple;
int main() {
    Mytuple c0(0, 1, 2, 3);

    // display contents " 0 1 2 3"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    Mytuple c1 = std::make_tuple(4, 5, 6, 7);

    // display contents " 4 5 6 7"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 != c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c0 != c1);
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3
false
true

```

operator<

Compare `tuple` objects for less.

```

template <class T1, class T2, ..., class TN,
          class U1, class U2, ..., class UN>
bool operator<(const tuple<T1, T2, ..., TN>& tp1,
              const tuple<U1, U2, ..., UN>& tp2);

```

Parameters

TN

The type of the Nth tuple element.

Remarks

The function returns true when `N` is greater than 0 and the first differing value in `tp1` compares less than the corresponding value in `tp2`, otherwise it returns false.

Example

```

// std_tuple_operator_lt.cpp
// compile with: /EHsc
#include <tuple>
#include <iostream>

typedef std::tuple<int, double, int, double> Mytuple;
int main() {
    Mytuple c0(0, 1, 2, 3);

    // display contents " 0 1 2 3"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    Mytuple c1 = std::make_tuple(4, 5, 6, 7);

    // display contents " 4 5 6 7"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 < c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c0 < c1);
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3
false
true

```

operator<=

Compare `tuple` objects for less or equal.

```

template <class T1, class T2, ..., class TN,
          class U1, class U2, ..., class UN>
bool operator<=(const tuple<T1, T2, ..., TN>& tp1,
               const tuple<U1, U2, ..., UN>& tp2);

```

Parameters

TN

The type of the Nth tuple element.

Remarks

The function returns `!(tp2 < tp1)`.

Example

```

// std_tuple_operator_le.cpp
// compile with: /EHsc
#include <tuple>
#include <iostream>

typedef std::tuple<int, double, int, double> Mytuple;
int main() {
    Mytuple c0(0, 1, 2, 3);

    // display contents " 0 1 2 3"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    Mytuple c1 = std::make_tuple(4, 5, 6, 7);

    // display contents " 4 5 6 7"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 <= c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c1 <= c0);
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3
true
false

```

operator==

Compare `tuple` objects for equality.

```

template <class T1, class T2, ..., class TN,
          class U1, class U2, ..., class UN>
bool operator==(const tuple<T1, T2, ..., TN>& tp1,
               const tuple<U1, U2, ..., UN>& tp2);

```

Parameters

TN

The type of the Nth tuple element.

Remarks

The function returns true when `N` is 0, otherwise

```
get<0>(tp1) == get<0>(tp2) && get<1>(tp1) == get<1>(tp2) && ... && get<N - 1>(tp1) == get<N - 1>(tp2) .
```

Example

```

// std_tuple_operator_eq.cpp
// compile with: /EHsc
#include <tuple>
#include <iostream>

typedef std::tuple<int, double, int, double> Mytuple;
int main() {
    Mytuple c0(0, 1, 2, 3);

    // display contents " 0 1 2 3"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    Mytuple c1 = std::make_tuple(4, 5, 6, 7);

    // display contents " 4 5 6 7"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 == c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c0 == c1);
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3
true
false

```

operator>

Compare `tuple` objects for greater.

```

template <class T1, class T2, ..., class TN,
          class U1, class U2, ..., class UN>
bool operator>(const tuple<T1, T2, ..., TN>& tp11,
               const tuple<U1, U2, ..., UN>& tp12);

```

Parameters

TN

The type of the Nth tuple element.

Remarks

The function returns `tp12 < tp11` .

Example

```

// std_tuple_operator_gt.cpp
// compile with: /EHsc
#include <tuple>
#include <iostream>

typedef std::tuple<int, double, int, double> Mytuple;
int main() {
    Mytuple c0(0, 1, 2, 3);

    // display contents " 0 1 2 3"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    Mytuple c1 = std::make_tuple(4, 5, 6, 7);

    // display contents " 4 5 6 7"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 > c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c1 > c0);
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3
false
true

```

operator>=

Compare `tuple` objects for greater or equal.

```

template <class T1, class T2, ..., class TN,
          class U1, class U2, ..., class UN>
bool operator>=(const tuple<T1, T2, ..., TN>& tp1,
               const tuple<U1, U2, ..., UN>& tp2);

```

Parameters

TN

The type of the Nth tuple element.

Remarks

The function returns `!(tp1 < tp2)`.

Example

```

// std_tuple_operator_ge.cpp
// compile with: /EHsc
#include <tuple>
#include <iostream>

typedef std::tuple<int, double, int, double> Mytuple;
int main() {
    Mytuple c0(0, 1, 2, 3);

    // display contents " 0 1 2 3"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    Mytuple c1 = std::make_tuple(4, 5, 6, 7);

    // display contents " 4 5 6 7"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    // display results of comparisons
    std::cout << std::boolalpha << " " << (c0 >= c0);
    std::cout << std::endl;
    std::cout << std::boolalpha << " " << (c0 >= c1);
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3
true
false

```

[<tuple>](#)

tuple Class

11/9/2018 • 5 minutes to read • [Edit Online](#)

Wraps a fixed-length sequence of elements.

Syntax

```
class tuple {
public:
    tuple();
    explicit tuple(P1, P2, ..., PN); // 0 < N
    tuple(const tuple&);
    template <class U1, class U2, ..., class UN>
        tuple(const tuple<U1, U2, ..., UN>&);
    template <class U1, class U2>
        tuple(const pair<U1, U2>&); // N == 2

    void swap(tuple& right);
    tuple& operator=(const tuple&);
    template <class U1, class U2, ..., class UN>
        tuple& operator=(const tuple<U1, U2, ..., UN>&);
    template <class U1, class U2>
        tuple& operator=(const pair<U1, U2>&); // N == 2
};
```

Parameters

T_N

The type of the Nth tuple element.

Remarks

The template class describes an object that stores N objects of types *T₁*, *T₂*, ..., *T_N*, respectively, where $0 \leq N \leq N_{\max}$. The extent of a tuple instance `tuple<T1, T2, ..., TN>` is the number *N* of its template arguments. The index of the template argument *T_i* and of the corresponding stored value of that type is *i* - 1. Thus, while we number the types from 1 to N in this documentation, the corresponding index values range from 0 to N - 1.

Example

```

// tuple.cpp
// compile with: /EHsc

#include <vector>
#include <iomanip>
#include <iostream>
#include <tuple>
#include <string>

using namespace std;

typedef tuple<int, double, string> ids;

void print_ids(const ids& i)
{
    cout << "( "
        << get<0>(i) << ", "
        << get<1>(i) << ", "
        << get<2>(i) << " )." << endl;
}

int main( )
{
    // Using the constructor to declare and initialize a tuple
    ids p1(10, 1.1e-2, "one");

    // Compare using the helper function to declare and initialize a tuple
    ids p2;
    p2 = make_tuple(10, 2.22e-1, "two");

    // Making a copy of a tuple
    ids p3(p1);

    cout.precision(3);
    cout << "The tuple p1 is: ( ";
    print_ids(p1);
    cout << "The tuple p2 is: ( ";
    print_ids(p2);
    cout << "The tuple p3 is: ( ";
    print_ids(p3);

    vector<ids> v;

    v.push_back(p1);
    v.push_back(p2);
    v.push_back(make_tuple(3, 3.3e-2, "three"));

    cout << "The tuples in the vector are" << endl;
    for(vector<ids>::const_iterator i = v.begin(); i != v.end(); ++i)
    {
        print_ids(*i);
    }
}

```

```

The tuple p1 is: ( 10, 0.011, one ).
The tuple p2 is: ( 10, 0.222, two ).
The tuple p3 is: ( 10, 0.011, one ).
The tuples in the vector are
( 10, 0.011, one ).
( 10, 0.222, two ).
( 3, 0.033, three ).

```

Requirements

Header: <tuple>

Namespace: std

tuple::operator=

Assigns a `tuple` object.

```
tuple& operator=(const tuple& right);

template <class U1, class U2, ..., class UN>
    tuple& operator=(const tuple<U1, U2, ..., UN>& right);

template <class U1, class U2>
    tuple& operator=(const pair<U1, U2>& right); // N == 2

tuple& operator=(tuple&& right);

template <class U1, class U2>
    tuple& operator=(pair<U1, U2>&& right);
```

Parameters

UN

The type of the Nth copied tuple element.

right

The tuple to copy from.

Remarks

The first two member operators assign the elements of *right* to the corresponding elements of `*this`. The third member operator assigns `right.first` to the element at index 0 of `*this` and `right.second` to the element at index 1. All three member operators return `*this`.

The remaining member operators are analogs to earlier ones, but with [Rvalue Reference Declarator: &&](#).

Example

```

// std_tuple_tuple_operator_as.cpp
// compile with: /EHsc
#include <tuple>
#include <iostream>
#include <utility>

typedef std::tuple<int, double, int, double> Mytuple;
int main()
{
    Mytuple c0(0, 1, 2, 3);

    // display contents " 0 1 2 3"
    std::cout << " " << std::get<0>(c0);
    std::cout << " " << std::get<1>(c0);
    std::cout << " " << std::get<2>(c0);
    std::cout << " " << std::get<3>(c0);
    std::cout << std::endl;

    Mytuple c1;
    c1 = c0;

    // display contents " 0 1 2 3"
    std::cout << " " << std::get<0>(c1);
    std::cout << " " << std::get<1>(c1);
    std::cout << " " << std::get<2>(c1);
    std::cout << " " << std::get<3>(c1);
    std::cout << std::endl;

    std::tuple<char, int> c2;
    c2 = std::make_pair('x', 4);

    // display contents " x 4"
    std::cout << " " << std::get<0>(c2);
    std::cout << " " << std::get<1>(c2);
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3
x 4

```

tuple:swap

Exchanges the elements of two tuples.

```

template <class... Types>
void swap(tuple<Types...&> left, tuple<Types...&> right);

```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	A tuple whose elements are to be exchanged with those of the tuple <i>right</i> .
<i>right</i>	A tuple whose elements are to be exchanged with those of the tuple <i>left</i> .

Remarks

The function executes `left.swap(right)` .

tuple::tuple

Constructs a `tuple` object.

```
constexpr tuple();
explicit constexpr tuple(const Types&...);
template <class... UTypes>
    explicit constexpr tuple(UTypes&&...);

tuple(const tuple&) = default;
tuple(tuple&&) = default;

template <class... UTypes>
    constexpr tuple(const tuple<UTypes...>&);
template <class... UTypes>
    constexpr tuple(tuple<UTypes...>&&);

// only if sizeof...(Types) == 2
template <class U1, class U2>
    constexpr tuple(const pair<U1, U2>&);
template <class U1, class U2>
    constexpr tuple(pair<U1, U2>&&);
```

Parameters

UN

The type of the Nth copied tuple element.

right

The tuple to copy from.

Remarks

The first constructor constructs an object whose elements are default constructed.

The second constructor constructs an object whose elements are copy constructed from the arguments `P1` , `P2` , ..., `PN` with each `Pi` initializing the element at index `i - 1` .

The third and fourth constructors construct an object whose elements are copy constructed from the corresponding element of *right*.

The fifth constructor constructs an object whose element at index 0 is copy constructed from `right.first` and whose element at index 1 is copy constructed from `right.second` .

The remaining constructors are analogs to earlier ones, but with [Rvalue Reference Declarator: &&](#).

Example

```

// std_tuple_tuple_tuple.cpp
// compile with: /EHsc
#include <tuple>
#include <iostream>
#include <utility>

typedef std::tuple<int, double, int, double> Mytuple;
int main()
{
    Mytuple c0(0, 1, 2, 3);

    // display contents "0 1 2 3"
    std::cout << std::get<0>(c0) << " ";
    std::cout << std::get<1>(c0) << " ";
    std::cout << std::get<2>(c0) << " ";
    std::cout << std::get<3>(c0);
    std::cout << std::endl;

    Mytuple c1;
    c1 = c0;

    // display contents "0 1 2 3"
    std::cout << std::get<0>(c1) << " ";
    std::cout << std::get<1>(c1) << " ";
    std::cout << std::get<2>(c1) << " ";
    std::cout << std::get<3>(c1);
    std::cout << std::endl;

    std::tuple<char, int> c2(std::make_pair('x', 4));

    // display contents "x 4"
    std::cout << std::get<0>(c2) << " ";
    std::cout << std::get<1>(c2);
    std::cout << std::endl;

    Mytuple c3(c0);

    // display contents "0 1 2 3"
    std::cout << std::get<0>(c3) << " ";
    std::cout << std::get<1>(c3) << " ";
    std::cout << std::get<2>(c3) << " ";
    std::cout << std::get<3>(c3);
    std::cout << std::endl;

    typedef std::tuple<int, float, int, float> Mytuple2;
    Mytuple c4(Mytuple2(4, 5, 6, 7));

    // display contents "4 5 6 7"
    std::cout << std::get<0>(c4) << " ";
    std::cout << std::get<1>(c4) << " ";
    std::cout << std::get<2>(c4) << " ";
    std::cout << std::get<3>(c4);
    std::cout << std::endl;

    return (0);
}

```

```

0 1 2 3
0 1 2 3
x 4
0 1 2 3
4 5 6 7

```

[<tuple>](#)

[make_tuple](#)

tuple_element Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Wraps a `tuple` element. Specializations wrap `array` elements and `pair` elements.

Syntax

```
// CLASS tuple_element (find element by index)
template <size_t Index, class Tuple>
    struct tuple_element;

// tuple_element for const
template <size_t Index, class Tuple>
    struct tuple_element<Index, const Tuple>;

// tuple_element for volatile
template <size_t Index, class Tuple>
    struct tuple_element<Index, volatile Tuple>;

// tuple_element for const volatile
template <size_t Index, class Tuple>
    struct tuple_element<Index, const volatile Tuple>;

// Helper typedef
template <size_t Index, class Tuple>
    using tuple_element_t = typename tuple_element<Index, Tuple>::type;

// Specialization for arrays
template <size_t Index, class Elem, size_t Size>
    struct tuple_element<Index, array<Elem, Size>>;

// Specializations for pairs
// struct to determine type of element 0 in pair
template <class T1, class T2>
    struct tuple_element<0, pair<T1, T2>>;

// struct to determine type of element 1 in pair
template <class T1, class T2>
    struct tuple_element<1, pair<T1, T2>>;
```

Parameters

Index

The index of the designated element.

Tuple

The type of the tuple.

Elem

The type of an array element.

Size

The size of the array.

T1

The type of the first element in a pair.

T2

The type of the second element in a pair.

Remarks

The template class `tuple_element` has a nested typedef `type` that is a synonym for the type at index *Index* of the tuple type *Tuple*.

The typedef `tuple_element_t` is a convenient alias for `tuple_element<Index, Tuple>::type`.

The template class specialization for arrays provides an interface to an `array` as a tuple of `Size` elements, each of which has the same type. Each specialization has a nested typedef `type` that is a synonym for the type of the *Index* element of the `array`, with any const-volatile qualifications preserved.

The template specializations for `pair` types each provide a single member typedef, `type`, which is a synonym for the type of the element at the specified position in the pair, with any const and/or volatile qualifications preserved. The typedef `tuple_element_t` is a convenient alias for `tuple_element<N, pair<T1, T2>>::type`.

Use the [get Function <utility>](#) to return the element at a specified position, or of a specified type.

Example

```
#include <tuple>
#include <string>
#include <iostream>

using namespace std;
typedef tuple<int, double, string> MyTuple;

int main() {
    MyTuple c0{ 0, 1.5, "Tail" };

    tuple_element_t<0, MyTuple> val = get<0>(c0); //get by index
    tuple_element_t<1, MyTuple> val2 = get<1>(c0);
    tuple_element_t<2, MyTuple> val3 = get<string>(c0); // get by type

    cout << val << " " << val2 << " " << val3 << endl;
}
```

```
0 1.5 Tail
```

Example

```

#include <array>
#include <iostream>

using namespace std;
typedef array<int, 4> MyArray;

int main()
{
    MyArray c0 { 0, 1, 2, 3 };

    for (const auto& e : c0)
    {
        cout << e << " ";
    }
    cout << endl;

    // display first element "0"
    tuple_element<0, MyArray>::type val = c0.front();
    cout << val << endl;
}

```

```

0 1 2 3
0

```

Example

```

#include <utility>
#include <iostream>

using namespace std;

typedef pair<int, double> MyPair;
int main() {
    MyPair c0(0, 1.333);

    // display contents "0 1"
    cout << get<0>(c0) << " ";
    cout << get<1>(c0) << endl;

    // display first element "0 " by index
    tuple_element<0, MyPair>::type val = get<0>(c0);
    cout << val << " ";

    // display second element by type
    tuple_element<1, MyPair>::type val2 = get<double>(c0);
    cout << val2 << endl;
}

```

```

0 1.333
0 1.333

```

Requirements

Header: <tuple>

Header: <array> (for array specialization)

Header: <utility> (for pair specializations)

Namespace: std

[tuple](#)

tuple_size Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Reports the number of elements that a `tuple` contains.

Syntax

```
// TEMPLATE STRUCT tuple_size
template <class Tuple>
    struct tuple_size;

// number of elements in array
template <class Elem, size_t Size>
    struct tuple_size<array<Elem, Size>>
        : integral_constant<size_t, Size>;

// size of pair
template <class T1, class T2>
    struct tuple_size<pair<T1, T2>>
        : integral_constant<size_t, 2>;

// size of tuple
template <class... Types>
    struct tuple_size<tuple<Types...>>
        : integral_constant<size_t, sizeof...(Types)>;

// size of const tuple
template <class Tuple>
    struct tuple_size<const Tuple>;

// size of volatile tuple
template <class Tuple>
    struct tuple_size<volatile Tuple>;

// size of const volatile tuple
template <class Tuple>
    struct tuple_size<const volatile Tuple>;
```

Parameters

Tuple

The type of the tuple.

Elem

The type of the array elements.

Size

The size of the array.

T1

The type of the first member of the pair.

T2

The type of the second member of the pair.

Types

The types of the tuple elements.

Remarks

The template class has a member `value` that is an integral constant expression whose value is the extent of the tuple type *Tuple*.

The template specialization for arrays has a member `value` that is an integral constant expression whose value is *Size*, which is the size of the array.

The template specialization for pair has a member `value` that is an integral constant expression whose value is 2.

Example

```
#include <tuple>
#include <iostream>

using namespace std;

typedef tuple<int, double, int, double> MyTuple;
int main()
{
    MyTuple c0(0, 1.5, 2, 3.7);

    // display contents "0 1 2 3"
    cout << get<0>(c0);
    cout << " " << get<1>(c0);
    cout << " " << get<2>(c0);
    cout << " " << get<3>(c0) << endl;

    // display size "4"
    cout << " " << tuple_size<MyTuple>::value << endl;
}
```

```
0 1.5 2 3.7
4
```

Requirements

Header: `<tuple>`

Header: `<array>` (for array specialization)

Header: `<utility>` (for pair specialization)

Namespace: `std`

[<tuple>](#)

[tuple](#)

[tuple_element Class](#)

<type_traits>

2/28/2019 • 6 minutes to read • [Edit Online](#)

Defines templates for compile-time constants that give information about the properties of their type arguments, or produce transformed types.

Syntax

```
#include <type_traits>
```

Remarks

The classes and templates in <type_traits> are used to support type inference, classification, and transformation at compile time. They are also used to detect type-related errors, and to help you optimize your generic code. Unary type traits describe a property of a type, binary type traits describe a relationship between types, and transformation traits modify a property of a type.

The helper class `integral_constant` and its template specializations `true_type` and `false_type` form the base classes for type predicates. A *type predicate* is a template that takes one or more type arguments. When a type predicate *holds true*, it's publicly derived, directly or indirectly, from `true_type`. When a type predicate *holds false*, it's publicly derived, directly or indirectly, from `false_type`.

A *type modifier* or *transformation trait* is a template that takes one or more template arguments and has one member, `type`, which is a synonym for the modified type.

Alias Templates

To simplify type traits expressions, [alias templates](#) for `typename some_trait<T>::type` are provided, where *some_trait* is the template class name. For example, `add_const` has an alias template for its type, `add_const_t`, defined as:

```
template <class T>
using add_const_t = typename add_const<T>::type;
```

These are the provided aliases for the `type` members:

<code>add_const_t</code>	<code>add_cv_t</code>	<code>add_lvalue_reference_t</code>
<code>add_pointer_t</code>	<code>add_rvalue_reference_t</code>	<code>add_volatile_t</code>
<code>aligned_storage_t</code>	<code>aligned_union_t</code>	<code>common_type_t</code>
<code>conditional_t</code>	<code>decay_t</code>	<code>enable_if_t</code>
<code>invoke_result_t</code>	<code>make_signed_t</code>	<code>make_unsigned_t</code>
<code>remove_all_extents_t</code>	<code>remove_const_t</code>	<code>remove_cv_t</code>

remove_extent_t	remove_pointer_t	remove_reference_t
remove_volatile_t	result_of_t	underlying_type_t

Classes

Helper class and typedefs

integral_constant	Makes an integral constant from a type and a value.
true_type	Holds integral constant with true value.
false_type	Holds integral constant with false value.

Primary type categories

is_void	Tests whether the type is void .
is_null_pointer	Tests whether the type is <code>std::nullptr_t</code> .
is_integral	Tests whether the type is integral.
is_floating_point	Tests whether the type is floating-point.
is_array	Tests whether the type is an array.
is_pointer	Tests whether the type is a pointer.
is_lvalue_reference	Tests if type is an lvalue reference.
is_rvalue_reference	Tests if type is an rvalue reference.
is_member_object_pointer	Tests whether the type is a pointer to a member object.
is_member_function_pointer	Tests whether the type is a pointer to a member function.
is_enum	Tests whether the type is an enumeration.
is_union	Tests whether the type is a union.
is_class	Tests whether the type is a class.
is_function	Tests whether the type is a function type.

Composite type categories

is_reference	Tests whether the type is a reference.
is_arithmetic	Tests whether the type is arithmetic.
is_fundamental	Tests whether the type is void or arithmetic.
is_object	Tests whether the type is an object type.
is_scalar	Tests whether the type is scalar.
is_compound	Tests whether the type is not scalar.
is_member_pointer	Tests whether the type is a pointer to a member.

Type properties

is_const	Tests whether the type is const .
is_volatile	Tests whether the type is volatile .
is_trivial	Tests whether the type is trivial.
is_trivially_copyable	Tests whether the type is trivially copyable.
is_standard_layout	Tests if type is a standard layout type.
is_pod	Tests whether the type is a POD.
is_literal_type	Tests whether the type can be a <code>constexpr</code> variable or used in a <code>constexpr</code> function.
is_empty	Tests whether the type is an empty class.
is_polymorphic	Tests whether the type is a polymorphic class.
is_abstract	Tests whether the type is an abstract class.
is_final	Tests whether the type is a class type marked <code>final</code> .
is_signed	Tests whether the type is a signed integer.
is_unsigned	Tests whether the type is an unsigned integer.
is_constructible	Tests whether the type is constructible using the specified argument types.
is_default_constructible	Tests whether the type has a default constructor.
is_copy_constructible	Tests whether the type has a copy constructor.

<code>is_move_constructible</code>	Tests whether the type has a move constructor.
<code>is_assignable</code>	Tests whether the first type can be assigned a value of the second type.
<code>is_copy_assignable</code>	Tests whether a type can be assigned a const reference value of the type.
<code>is_move_assignable</code>	Tests whether a type can be assigned an rvalue reference of the type.
<code>is_destructible</code>	Tests whether the type is destructible.
<code>is_trivially_constructible</code>	Tests whether the type uses no non-trivial operations when constructed using the specified types.
<code>is_trivially_default_constructible</code>	Tests whether the type uses no non-trivial operations when default constructed.
<code>is_trivially_copy_constructible</code>	Tests whether the type uses no non-trivial operations when copy constructed.
<code>is_trivially_move_constructible</code>	Tests whether the type uses no non-trivial operations when move constructed.
<code>is_trivially_assignable</code>	Tests whether the types are assignable and the assignment uses no non-trivial operations.
<code>is_trivially_copy_assignable</code>	Tests whether the type is copy assignable and the assignment uses no non-trivial operations.
<code>is_trivially_move_assignable</code>	Tests whether the type is move assignable and the assignment uses no non-trivial operations.
<code>is_trivially_destructible</code>	Tests whether the type is destructible and the destructor uses no non-trivial operations.
<code>is_nothrow_constructible</code>	Tests whether the type is constructible and is known not to throw when constructed using the specified types.
<code>is_nothrow_default_constructible</code>	Tests whether the type is default constructible and is known not to throw when default constructed.
<code>is_nothrow_copy_constructible</code>	Tests whether the type is copy constructible and the copy constructor is known not to throw.
<code>is_nothrow_move_constructible</code>	Tests whether the type is move constructible and the move constructor is known not to throw.
<code>is_nothrow_assignable</code>	Tests whether the type is assignable using the specified type and the assignment is known not to throw.

is_nothrow_copy_assignable	Tests whether the type is copy assignable and the assignment is known not to throw.
is_nothrow_move_assignable	Tests whether the type is move assignable and the assignment is known not to throw.
is_nothrow_destructible	Tests whether the type is destructible and the destructor is known not to throw.
<code>has_virtual_destructor</code>	Tests whether the type has a virtual destructor.
is_invocable	Tests whether a callable type can be invoked using the specified argument types. Added in C++17.
is_invocable_r	Tests whether a callable type can be invoked using the specified argument types and the result is convertible to the specified type. Added in C++17.
is_nothrow_invocable	Tests whether a callable type can be invoked using the specified argument types and is known not to throw exceptions. Added in C++17.
is_nothrow_invocable_r	Tests whether a callable type can be invoked using the specified argument types and is known not to throw exceptions, and the result is convertible to the specified type. Added in C++17.

Type property queries

alignment_of	Gets the alignment of a type.
rank	Gets the number of array dimensions.
extent	Gets the number of elements in the specified array dimension.

Type relations

is_same	Tests whether two types are the same.
is_base_of	Tests whether one type is a base of another.
is_convertible	Tests whether one type is convertible to another.

Const-volatile modifications

add_const	Produces a const type from type.
add_volatile	Produces a volatile type from type.
add_cv	Produces a const volatile type from type.
remove_const	Produces a non-const type from type.
remove_volatile	Produces a non-volatile type from type.
remove_cv	Produces a non-const non-volatile type from type.

Reference modifications

add_lvalue_reference	Produces a reference to type from type.
add_rvalue_reference	Produces an rvalue reference to type from type
remove_reference	Produces a non-reference type from type.

Sign modifications

make_signed	Produces the type if signed, or the smallest signed type greater than or equal in size to type.
make_unsigned	Produces the type if unsigned, or the smallest unsigned type greater than or equal in size to type.

Array modifications

remove_all_extents	Produces a non-array type from an array type.
remove_extent	Produces the element type from an array type.

Pointer modifications

add_pointer	Produces a pointer to type from type.
remove_pointer	Produces a type from a pointer to type.

Other transformations

aligned_storage	Allocates uninitialized memory for an aligned type.

aligned_union	Allocates uninitialized memory for an aligned union with a non-trivial constructor or destructor.
common_type	Produces the common type of all the types of the parameter pack.
conditional	If the condition is true, produces the first specified type, otherwise the second specified type.
decay	Produces the type as passed by value. Makes non-reference, non-const, or non-volatile type, or makes a pointer to type.
enable_if	If the condition is true, produces the specified type, otherwise no type.
invoke_result	Determines the return type of the callable type that takes the specified argument types. Added in C++17.
result_of	Determines the return type of the callable type that takes the specified argument types. Added in C++14, deprecated in C++17.
underlying_type	Produces the underlying integral type for an enumeration type.

See also

[<functional>](#)

add_const Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes const type from type.

Syntax

```
template <class Ty>
struct add_const;
```

Parameters

Ty

The type to modify.

Remarks

An instance of the type modifier holds a modified-type that is *Ty* if *Ty* is a reference, a function, or a const-qualified type, otherwise `const Ty`.

Example

```
// std__type_traits__add_const.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

int main()
{
    std::add_const<int>::type *p = (const int *)0;

    p = p; // to quiet "unused" warning
    std::cout << "add_const<int> == "
              << typeid(*p).name() << std::endl;

    return (0);
}
```

```
add_const<int> == int
```

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

[remove_const Class](#)

add_cv Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes **const volatile** type from type.

Syntax

```
template <class T>
struct add_cv;

template <class T>
using add_cv_t = typename add_cv<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of the modified type `add_cv<T>` has a `type` member **typedef** equivalent to *T* modified by both [add_volatile](#) and [add_const](#), unless *T* already has the cv-qualifiers, is a reference, or is a function.

The `add_cv_t<T>` helper type is a shortcut to access the `add_cv<T>` member typedef `type`.

Example

```

// add_cv.cpp
// compile by using: cl /EHsc /W4 add_cv.cpp
#include <type_traits>
#include <iostream>

struct S {
    void f() {
        std::cout << "invoked non-cv-qualified S.f()" << std::endl;
    }
    void f() const {
        std::cout << "invoked const S.f()" << std::endl;
    }
    void f() volatile {
        std::cout << "invoked volatile S.f()" << std::endl;
    }
    void f() const volatile {
        std::cout << "invoked const volatile S.f()" << std::endl;
    }
};

template <class T>
void invoke() {
    T t;
    ((T *)&t)->f();
}

int main()
{
    invoke<S>();
    invoke<std::add_const<S>::type>();
    invoke<std::add_volatile<S>::type>();
    invoke<std::add_cv<S>::type>();
}

```

```

invoked non-cv-qualified S.f()
invoked const S.f()
invoked volatile S.f()
invoked const volatile S.f()

```

[remove_const Class](#)

[remove_volatile Class](#)

add_lvalue_reference Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes reference to type from type.

Syntax

```
template <class T>
struct add_lvalue_reference;

template <class T>
using add_lvalue_reference_t = typename add_lvalue_reference<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of the type modifier holds a modified-type that is *T* if *T* is an lvalue reference, otherwise `T&`.

Example

```
#include <type_traits>
#include <iostream>

using namespace std;
int main()
{
    int val = 0;
    add_lvalue_reference_t<int> p = (int&)val;
    p = p; // to quiet "unused" warning
    cout << "add_lvalue_reference_t<int> == "
          << typeid(p).name() << endl;

    return (0);
}
```

```
add_lvalue_reference_t<int> == int
```

Requirements

Header: <type_traits>

Namespace: std

[<type_traits>](#)

[remove_reference Class](#)

add_rvalue_reference Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Creates an rvalue reference type of the template parameter, if it is an object or function type. Otherwise, because of the semantics of reference collapsing, the type is the same as the template parameter.

Syntax

```
template <class T>
struct add_rvalue_reference;

template <class T>
using add_rvalue_reference_t = typename add_rvalue_reference<T>::type;
```

Parameters

T

The type to modify.

Remarks

The `add_rvalue_reference` class has a member named `type`, which is an alias for the type of an rvalue reference to the template parameter *T*. The semantics of reference collapsing imply that, for non-object and non-function types *T*, `T&&` is a *T*. For example, when *T* is an lvalue reference type, `add_rvalue_reference<T>::type` is the lvalue reference type, not an rvalue reference.

For convenience, `<type_traits>` defines a helper template, `add_rvalue_reference_t`, that aliases the `type` member of `add_rvalue_reference`.

Example

This code example uses `static_assert` to show how rvalue reference types are created by using `add_rvalue_reference` and `add_rvalue_reference_t`, and how the result of `add_rvalue_reference` on an lvalue reference type is not an rvalue reference, but collapses to the lvalue reference type.

```

// ex_add_rvalue_reference.cpp
// Build by using: cl /EHsc /W4 ex_add_rvalue_reference.cpp
#include <type_traits>
#include <iostream>
#include <string>

using namespace std;
int main()
{
    static_assert(is_same<add_rvalue_reference<string>::type, string&&>::value,
        "Expected add_rvalue_reference_t<string> to be string&&");
    static_assert(is_same<add_rvalue_reference_t<string*>, string*&&>::value,
        "Expected add_rvalue_reference_t<string*> to be string*&&");
    static_assert(is_same<add_rvalue_reference<string&>::type, string&>::value,
        "Expected add_rvalue_reference_t<string&> to be string&");
    static_assert(is_same<add_rvalue_reference_t<string&&>, string&&>::value,
        "Expected add_rvalue_reference_t<string&&> to be string&&");
    cout << "All static_assert tests of add_rvalue_reference passed." << endl;
    return 0;
}

/*Output:
All static_assert tests of add_rvalue_reference passed.
*/

```

Requirements

[add_lvalue_reference Class](#)

[is_rvalue_reference Class](#)

add_pointer Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes a pointer-to-type from a specified type.

Syntax

```
template <class T>
struct add_pointer;

template <class T>
using add_pointer_t = typename add_pointer<T>::type;
```

Parameters

T

The type to modify.

Remarks

The member **typedef** `type` names the same type as `remove_reference<T>::type*`. The alias `add_pointer_t` is a shortcut to access the member **typedef** `type`.

Because it is invalid to make a pointer from a reference, `add_pointer` removes the reference, if any, from the specified type before it makes a pointer-to-type. Consequently, you can use a type with `add_pointer` without being concerned about whether the type is a reference.

Example

The following example demonstrates that `add_pointer` of a type is the same as a pointer to that type.

```
#include <type_traits>
#include <iostream>

int main()
{
    std::add_pointer_t<int> *p = (int **)0;

    p = p; // to quiet "unused" warning
    std::cout << "add_pointer_t<int> == "
              << typeid(*p).name() << std::endl;

    return (0);
}
```

```
add_pointer_t<int> == int *
```

Requirements

[remove_pointer](#) Class

add_volatile Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes a **volatile** type from the specified type.

Syntax

```
template <class Ty>
struct add_volatile;

template <class T>
using add_volatile_t = typename add_volatile<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of `add_volatile<T>` has a member **typedef** `type` that is *T* if *T* is a reference, a function, or a volatile-qualified type, otherwise **volatile** *T*. The alias `add_volatile_t` is a shortcut to access the member **typedef** `type`.

Example

```
#include <type_traits>
#include <iostream>

int main()
{
    std::add_volatile_t<int> *p = (volatile int *)0;

    p = p; // to quiet "unused" warning
    std::cout << "add_volatile<int> == "
              << typeid(*p).name() << std::endl;

    return (0);
}
```

```
add_volatile<int> == int
```

Requirements

[<type_traits>](#)

[remove_volatile Class](#)

aligned_storage Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Makes suitably aligned type.

Syntax

```
template <std::size_t Len, std::size_t Align>
struct aligned_storage;

template <std::size_t Len, std::size_t Align = alignment_of<max_align_t>::value>
using aligned_storage_t = typename aligned_storage<Len, Align>::type;
```

Parameters

Len

The object size.

Align

The object alignment.

Remarks

The template member typedef `type` is a synonym for a POD type with alignment *Align* and size *Len*. *Align* must be equal to `alignment_of<T>::value` for some type `T`, or to the default alignment.

Example

```
#include <type_traits>
#include <iostream>

typedef std::aligned_storage<sizeof (int),
    std::alignment_of<double>::value>::type New_type;
int main()
{
    std::cout << "alignment_of<int> == "
        << std::alignment_of<int>::value << std::endl;
    std::cout << "aligned to double == "
        << std::alignment_of<New_type>::value << std::endl;

    return (0);
}
```

```
alignment_of<int> == 4
aligned to double == 8
```

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

[alignment_of Class](#)

aligned_union Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Provides a POD type large enough and suitably aligned to store a union type, and the size required.

Syntax

```
template <std::size_t Len, class... Types>
struct aligned_union;

template <std::size_t Len, class... Types>
using aligned_union_t = typename aligned_union<Len, Types...>::type;
```

Parameters

Len

The alignment value for the largest type in the union.

Types

The distinct types in the underlying union.

Remarks

Use the template class to get the alignment and size needed to store a union in uninitialized storage. The member typedef `type` names a POD type suitable for storage of any type listed in *Types*; the minimum size is *Len*. The static member `alignment_value` of type `std::size_t` contains the strictest alignment required of all the types listed in *Types*.

Example

The following example shows how to use `aligned_union` to allocate an aligned stack buffer to place a union.

```

// std_type_traits__aligned_union.cpp
#include <iostream>
#include <type_traits>

union U_type
{
    int i;
    float f;
    double d;
    U_type(float e) : f(e) {}
};

typedef std::aligned_union<16, int, float, double>::type aligned_U_type;

int main()
{
    // allocate memory for a U_type aligned on a 16-byte boundary
    aligned_U_type au;
    // do placement new in the aligned memory on the stack
    U_type* u = new (&au) U_type(1.0f);
    if (nullptr != u)
    {
        std::cout << "value of u->i is " << u->i << std::endl;
        // must clean up placement objects manually!
        u->~U_type();
    }
}

```

```

value of u->i is 1065353216

```

Requirements

Header: `<type_traits>`

Namespace: `std`

[<type_traits>](#)

[alignment_of Class](#)

alignment_of Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Gets alignment of the specified type. This struct is implemented in terms of [alignof](#). Use `alignof` directly when you simply need to query an alignment value. Use `alignment_of` when you need an integral constant, for example when doing tag dispatch.

Syntax

```
template <class Ty>
struct alignment_of;
```

Parameters

Ty

The type to query.

Remarks

The type query holds the value of the alignment of the type *Ty*.

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

[aligned_storage](#) Class

common_type Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Determines the common type of one or more types.

Syntax

```
template <class... T>
struct common_type;

template <class T>
struct common_type<T> {
    typedef typename decay<T>::type type;
};

template <class T, class U>
struct common_type<T, U> {
    typedef typename decay<decltype(true declval<T>() :
        declval<U>())>::type type;
};

template <class T, class U, class... V>
struct common_type<T, U, V...> {
    typedef typename common_type<typename common_type<T, U>::type, V...>::type type;
};
```

Parameters

List of types that are either [complete types](#) or void.

Remarks

The `type` member is the common type to which all types in the parameter list can be converted.

Example

The following program demonstrates some correct usage scenarios and tests for results.

```

// Compile using cl.exe /EHsc
// common_type sample
#include <iostream>
#include <type_traits>

struct Base {};
struct Derived : Base {};

int main()
{
    typedef std::common_type<unsigned char, short, int>::type NumericType;
    typedef std::common_type<float, double>::type FloatType;
    typedef std::common_type<const int, volatile int>::type ModifiedIntType;
    typedef std::common_type<Base, Derived>::type ClassType;

    std::cout << std::boolalpha;
    std::cout << "Test for typedefs of common_type int" << std::endl;
    std::cout << "NumericType: " << std::is_same<int, NumericType>::value << std::endl;
    std::cout << "FloatType: " << std::is_same<int, FloatType>::value << std::endl;
    std::cout << "ModifiedIntType: " << std::is_same<int, ModifiedIntType>::value << std::endl;
    std::cout << "ClassType: " << std::is_same<int, ClassType>::value << std::endl;
    std::cout << "-----" << std::endl;
    std::cout << "Test for typedefs of common_type double" << std::endl;
    std::cout << "NumericType: " << std::is_same<double, NumericType>::value << std::endl;
    std::cout << "FloatType: " << std::is_same<double, FloatType>::value << std::endl;
    std::cout << "ModifiedIntType: " << std::is_same<double, ModifiedIntType>::value << std::endl;
    std::cout << "ClassType: " << std::is_same<double, ClassType>::value << std::endl;
    std::cout << "-----" << std::endl;
    std::cout << "Test for typedefs of common_type Base" << std::endl;
    std::cout << "NumericType: " << std::is_same<Base, NumericType>::value << std::endl;
    std::cout << "FloatType: " << std::is_same<Base, FloatType>::value << std::endl;
    std::cout << "ModifiedIntType: " << std::is_same<Base, ModifiedIntType>::value << std::endl;
    std::cout << "ClassType: " << std::is_same<Base, ClassType>::value << std::endl;

    return 0;
}

```

Output

```

Test for typedefs of common_type int
NumericType: true
FloatType: false
ModifiedIntType: true
ClassType: false
-----
Test for typedefs of common_type double
NumericType: false
FloatType: true
ModifiedIntType: false
ClassType: false
-----
Test for typedefs of common_type Base
NumericType: false
FloatType: false
ModifiedIntType: false
ClassType: true

```

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

conditional Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Selects one of two types, depending on the specified condition.

Syntax

```
template <bool B, class T1, class T2>
struct conditional;

template <bool _Test, class _T1, class _T2>
using conditional_t = typename conditional<_Test, _T1, _T2>::type;
```

Parameters

B

The value that determines the selected type.

T1

The type result when *B* is true.

T2

The type result when *B* is false.

Remarks

The template member typedef `conditional<B, T1, T2>::type` evaluates to *T1* when *B* evaluates to **true**, and evaluates to *T2* when *B* evaluates to **false**.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

decay Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Produces the type as passed by value. Makes the type non-reference, non-const, non-volatile, or makes a pointer to the type from a function or an array type.

Syntax

```
template <class T>
struct decay;

template <class T>
using decay_t = typename decay<T>::type;
```

Parameters

T

The type to modify.

Remarks

Use the decay template to produce the resulting type as if the type was passed by value as an argument. The template class member typedef `type` holds a modified type that is defined in the following stages:

- The type `U` is defined as `remove_reference<T>::type`.
- If `is_array<U>::value` is true, the modified type `type` is `remove_extent<U>::type *`.
- Otherwise, if `is_function<U>::value` is true, the modified type `type` is `add_pointer<U>::type`.
- Otherwise, the modified type `type` is `remove_cv<U>::type`.

Requirements

Header: `<type_traits>`

Namespace: `std`

[<type_traits>](#)

enable_if Class

10/31/2018 • 4 minutes to read • [Edit Online](#)

Conditionally makes an instance of a type for SFINAE overload resolution. The nested typedef

`enable_if<Condition,Type>::type` exists—and is a synonym for `Type`—if and only if `Condition` is **true**.

Syntax

```
template <bool B, class T = void>
struct enable_if;
```

Parameters

B

The value that determines the existence of the resulting type.

T

The type to instantiate if *B* is true.

Remarks

If *B* is true, `enable_if<B, T>` has a nested typedef named "type" that's a synonym for *T*.

If *B* is false, `enable_if<B, T>` doesn't have a nested typedef named "type".

This alias template is provided:

```
template <bool B, class T = void>
using enable_if_t = typename enable_if<B,T>::type;
```

In C++, substitution failure of template parameters is not an error in itself—this is referred to as *SFINAE* (substitution failure is not an error). Typically, `enable_if` is used to remove candidates from overload resolution—that is, it culls the overload set—so that one definition can be rejected in favor of another. This conforms to SFINAE behavior. For more information about SFINAE, see [Substitution failure is not an error](#) on Wikipedia.

Here are four example scenarios:

- Scenario 1: Wrapping the return type of a function:

```
template <your_stuff>
typename enable_if<your_condition, your_return_type>::type
yourfunction(args) { // ...
}
// The alias template makes it more concise:
template <your_stuff>
enable_if_t<your_condition, your_return_type>
yourfunction(args) { // ...
}
```

- Scenario 2: Adding a function parameter that has a default argument:

```
template <your_stuff>
your_return_type_if_present
    yourfunction(args, enable_if_t<your condition, FOO> = BAR) { // ...
}
```

- Scenario 3: Adding a template parameter that has a default argument:

```
template <your_stuff, typename Dummy = enable_if_t<your_condition>>
rest_of_function_declaration_goes_here
```

- Scenario 4: If your function has a non-templated argument, you can wrap its type:

```
template <typename T>
void your_function(const T& t,
    enable_if_t<is_something<T>::value, const string&>
s) { // ...
}
```

Scenario 1 doesn't work with constructors and conversion operators because they don't have return types.

Scenario 2 leaves the parameter unnamed. You could say `::type Dummy = BAR`, but the name `Dummy` is irrelevant, and giving it a name is likely to trigger an "unreferenced parameter" warning. You have to choose a `FOO` function parameter type and `BAR` default argument. You could say `int` and `0`, but then users of your code could accidentally pass to the function an extra integer that would be ignored. Instead, we recommend that you use `void **` and either `0` or `nullptr` because almost nothing is convertible to `void **`:

```
template <your_stuff>
your_return_type_if_present
yourfunction(args, typename enable_if<your_condition, void **>::type = nullptr) { // ...
}
```

Scenario 2 also works for ordinary constructors. However, it doesn't work for conversion operators because they can't take extra parameters. It also doesn't work for [variadic](#) constructors because adding extra parameters makes the function parameter pack a non-deduced context and thereby defeats the purpose of `enable_if`.

Scenario 3 uses the name `Dummy`, but it's optional. Just "`typename = typename`" would work, but if you think that looks weird, you can use a "dummy" name—just don't use one that might also be used in the function definition. If you don't give a type to `enable_if`, it defaults to `void`, and that's perfectly reasonable because you don't care what `Dummy` is. This works for everything, including conversion operators and [variadic](#) constructors.

Scenario 4 works in constructors that don't have return types, and thereby solves the wrapping limitation of Scenario 1. However, Scenario 4 is limited to non-templated function arguments, which aren't always available. (Using Scenario 4 on a templated function argument prevents template argument deduction from working on it.)

`enable_if` is powerful, but also dangerous if it's misused. Because its purpose is to make candidates vanish before overload resolution, when it's misused, its effects can be very confusing. Here are some recommendations:

- Do not use `enable_if` to select between implementations at compile-time. Don't ever write one `enable_if` for `CONDITION` and another for `!CONDITION`. Instead, use a *tag dispatch* pattern—for example, an algorithm that selects implementations depending on the strengths of the iterators they're given.
- Do not use `enable_if` to enforce requirements. If you want to validate template parameters, and if the validation fails, cause an error instead of selecting another implementation, use [static_assert](#).
- Use `enable_if` when you have an overload set that makes otherwise good code ambiguous. Most often,

this occurs in implicitly converting constructors.

Example

This example explains how the C++ Standard Library template function `std::make_pair()` takes advantage of `enable_if`.

```
void func(const pair<int, int>&);

void func(const pair<string, string>&);

func(make_pair("foo", "bar"));
```

In this example, `make_pair("foo", "bar")` returns `pair<const char *, const char *>`. Overload resolution has to determine which `func()` you want. `pair<A, B>` has an implicitly converting constructor from `pair<X, Y>`. This isn't new—it was in C++98. However, in C++98/03, the implicitly converting constructor's signature always exists, even if it's `pair<int, int>(const pair<const char *, const char *>&)`. Overload resolution doesn't care that an attempt to instantiate that constructor explodes horribly because `const char *` isn't implicitly convertible to `int`; it's only looking at signatures, before function definitions are instantiated. Therefore, the example code is ambiguous, because signatures exist to convert `pair<const char *, const char *>` to both `pair<int, int>` and `pair<string, string>`.

C++11 solved this ambiguity by using `enable_if` to make sure `pair<A, B>(const pair<X, Y>&)` exists **only** when `const X&` is implicitly convertible to `A` and `const Y&` is implicitly convertible to `B`. This allows overload resolution to determine that `pair<const char *, const char *>` is not convertible to `pair<int, int>` and that the overload that takes `pair<string, string>` is viable.

Requirements

[`<type_traits>`](#)

extent Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Gets an array dimension.

Syntax

```
template <class Ty, unsigned I = 0>
struct extent;
```

Parameters

Ty

The type to query.

I

The array bound to query.

Remarks

If *Ty* is an array type that has at least *I* dimensions, the type query holds the number of elements in the dimension specified by *I*. If *Ty* is not an array type or its rank is less than *I*, or if *I* is zero and *Ty* is of type "array of unknown bound of `u`", the type query holds the value 0.

Example

```
// std__type_traits__extent.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

int main()
{
    std::cout << "extent 0 == "
        << std::extent<int[5][10]>::value << std::endl;
    std::cout << "extent 1 == "
        << std::extent<int[5][10], 1>::value << std::endl;

    return (0);
}
```

```
extent 0 == 5
extent 1 == 10
```

remove_all_extents Class

remove_extent Class

integer_sequence Class

11/8/2018 • 2 minutes to read • [Edit Online](#)

Represents an integer sequence. Can be used to deduce and expand parameter packs in variadic types such as `std::tuple<T...>` that are passed as arguments to a function.

Syntax

```
template <class T, T... Vals>
struct integer_sequence
```

Parameters

T

The type of the values; must be an integral type: `bool`, `char`, `char16_t`, `char32_t`, `wchar_t`, or signed or unsigned integer types.

Vals

A non-type parameter pack that represents a sequence of values of integral type `T`.

Members

<code>static size_t size() noexcept</code>	The number of elements in the sequence.
<code>typedef T value_type</code>	The type of each element in the sequence. Must be an integral type.

Remarks

A parameter pack that is passed directly to a function can be unpacked without any special library helpers. When a parameter pack is part of a type that is passed to a function, and you need indices to access the elements, then the easiest way to unpack it is to use `integer_sequence` and its related type aliases `make_integer_sequence`, `index_sequence`, `make_index_sequence`, and `index_sequence_for`.

Example

The following example is based on the original proposal [N3658](#). It shows how to use an `integer_sequence` to create a `std::tuple` from a `std::array<T,N>`, and how to use an `integer_sequence` to get at the tuple members.

In the `a2t` function, an `index_sequence` is an alias of `integer_sequence` based on the `size_t` integral type. `make_index_sequence` is an alias that at compile time creates a zero-based `index_sequence` with the same number of elements as the array that is passed in by the caller. `a2t` passes the `index_sequence` by value to `a2t_`, where the expression `a[I]...` unpacks `I`, and then the elements are being fed to `make_tuple` which consumes them as individual arguments. For example, if the sequence contains three elements, then `make_tuple` is called as `make_tuple(a[0], a[1], a[2])`. The array elements themselves can of course be any type.

The `apply` function accepts a `std::tuple`, and produces an `integer_sequence` by using the `tuple_size` helper class. Note that `std::decay_t` is necessary because `tuple_size` does not work with reference types. The `apply_` function

unpacks the tuple members and forwards them as separate arguments to a function call. In this example the function is a simple lambda expression that prints out the values.

```
#include <stddef.h>
#include <iostream>
#include <tuple>
#include <utility>
#include <array>
#include <string>

using namespace std;

// Create a tuple from the array and the index_sequence
template<typename Array, size_t... I>
auto a2t_(const Array& a, index_sequence<I...>)
{
    return make_tuple(a[I]...);
}

// Create an index sequence for the array, and pass it to the
// implementation function a2t_
template<typename T, size_t N>
auto a2t(const array<T, N>& a)
{
    return a2t_(a, make_index_sequence<N>());
}

// Call function F with the tuple members as separate arguments.
template<typename F, typename Tuple = tuple<T...>, size_t... I>
decltype(auto) apply_(F&& f, Tuple&& args, index_sequence<I...>)
{
    return forward<F>(f)(get<I>(forward<Tuple>(args))...);
}

// Create an index_sequence for the tuple, and pass it with the
// function object and the tuple to the implementation function apply_
template<typename F, typename Tuple = tuple<T...>>
decltype(auto) apply(F&& f, Tuple&& args)
{
    using Indices = make_index_sequence<tuple_size<decay_t<Tuple>>::value >;
    return apply_(forward<F>(f), forward<Tuple>(args), Indices());
}

int main()
{
    const array<string, 3> arr { "Hello", "from", "C++14" };

    //Create a tuple given a array
    auto tup = a2t(arr);

    // Extract the tuple elements
    apply([](const string& a, const string& b, const string& c) {cout << a << " " << b << " " << c << endl; },
tup);

    char c;
    cin >> c;
}
```

To make an `index_sequence` for a parameter pack, use `index_sequence_for<T...>` which is an alias for `make_index_sequence<sizeof...(T)>`

[Ellipses and Variadic Templates](#)

integral_constant Class, bool_constant Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Makes an integral constant from a type and value.

Syntax

```
template<class T, T v>
struct integral_constant {
    static constexpr T value = v;
    typedef T value_type;
    typedef integral_constant<T, v> type;
    constexpr operator value_type() const noexcept;
    constexpr value_type operator()() const noexcept;
};
```

Parameters

T

The type of the constant.

v

The value of the constant.

Remarks

The `integral_constant` template class, when specialized with an integral type *T* and a value *v* of that type, represents an object that holds a constant of that integral type with the specified value. The member named `type` is an alias for the generated template specialization type, and the `value` member holds the value *v* used to create the specialization.

The `bool_constant` template class is an explicit partial specialization of `integral_constant` that uses **bool** as the *T* argument.

Example

```
// std__type_traits__integral_constant.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

int main()
{
    std::cout << "integral_constant<int, 5> == "
               << std::integral_constant<int, 5>::value << std::endl;
    std::cout << "integral_constant<bool, false> == " << std::boolalpha
               << std::integral_constant<bool, false>::value << std::endl;

    return (0);
}
```

```
integral_constant<int, 5> == 5  
integral_constant<bool, false> == false
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[false_type](#)

[true_type](#)

invoke_result Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

Determines the return type of the callable type that takes the specified argument types at compile time. Added in C++17.

Syntax

```
template <class Callable, class... Args>
    struct invoke_result<Callable(Args...)>;

// Helper type
template<class Callable, class... Args>
    using invoke_result_t = typename invoke_result<Callable, Args...>::type;
```

Parameters

Callable

The callable type to query.

Args

The types of the argument list to the callable type to query.

Remarks

Use this template to determine the result type of *Callable(Args...)* at compile time, where *Callable* and all types in *Args* are any complete type, an array of unknown bound, or a possibly cv-qualified `void`. The `type` member of the template class names the return type of *Callable* when invoked using the arguments *Args...*. The `type` member is only defined if *Callable* can be called when invoked using the arguments *Args...* in an unevaluated context. Otherwise, the template class has no member `type`, which allows SFINAE tests on a particular set of argument types at compile time.

[invoke](#)

is_abstract Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is abstract class.

Syntax

```
template <class Ty>
struct is_abstract;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a class that has at least one pure virtual function, otherwise it holds false.

Example

```
// std__type_traits__is_abstract.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

struct abstract
{
    virtual int val() = 0;
};

int main()
{
    std::cout << "is_abstract<trivial> == " << std::boolalpha
        << std::is_abstract<trivial>::value << std::endl;
    std::cout << "is_abstract<abstract> == " << std::boolalpha
        << std::is_abstract<abstract>::value << std::endl;

    return (0);
}
```

```
is_abstract<trivial> == false
is_abstract<abstract> == true
```

[is_polymorphic](#) Class

is_arithmetic Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is arithmetic.

Syntax

```
template <class Ty>
struct is_arithmetic;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is an arithmetic type, that is, an integral type or a floating point type, or a `cv-qualified` form of one of them, otherwise it holds false.

Example

```
// std__type_traits__is_arithmetic.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_arithmetic<trivial> == " << std::boolalpha
        << std::is_arithmetic<trivial>::value << std::endl;
    std::cout << "is_arithmetic<int> == " << std::boolalpha
        << std::is_arithmetic<int>::value << std::endl;
    std::cout << "is_arithmetic<float> == " << std::boolalpha
        << std::is_arithmetic<float>::value << std::endl;

    return (0);
}
```

```
is_arithmetic<trivial> == false
is_arithmetic<int> == true
is_arithmetic<float> == true
```

[is_floating_point](#) Class

[is_integral](#) Class

is_array Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is array.

Syntax

```
template <class Ty>
struct is_array;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is an array type, otherwise it holds false.

Example

```
// std__type_traits__is_array.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_array<trivial> == " << std::boolalpha
        << std::is_array<trivial>::value << std::endl;
    std::cout << "is_array<int> == " << std::boolalpha
        << std::is_array<int>::value << std::endl;
    std::cout << "is_array<int[5]> == " << std::boolalpha
        << std::is_array<int[5]>::value << std::endl;

    return (0);
}
```

```
is_array<trivial> == false
is_array<int> == false
is_array<int[5]> == true
```

[extent Class](#)

[rank Class](#)

is_assignable Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether a value of `From` type can be assigned to a `To` type.

Syntax

```
template <class To, class From>
struct is_assignable;
```

Parameters

To

The type of the object that receives the assignment.

From

The type of the object that provides the value.

Remarks

The unevaluated expression `declval<To>() = declval<From>()` must be well-formed. Both `From` and `To` must be complete types, **void**, or arrays of unknown bound.

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

is_base_of Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether one type is base of another.

Syntax

```
template <class Base, class Derived>
struct is_base_of;
```

Parameters

Base

The base class to test for.

Derived

The derived type to test for.

Remarks

An instance of the type predicate holds true if the type *Base* is a base class of the type *Derived*, otherwise it holds false.

Example

```
#include <type_traits>
#include <iostream>

struct base
{
    int val;
};

struct derived
    : public base
{
};

int main()
{
    std::cout << "is_base_of<base, base> == " << std::boolalpha
        << std::is_base_of<base, base>::value << std::endl;
    std::cout << "is_base_of<base, derived> == " << std::boolalpha
        << std::is_base_of<base, derived>::value << std::endl;
    std::cout << "is_base_of<derived, base> == " << std::boolalpha
        << std::is_base_of<derived, base>::value << std::endl;

    return (0);
}
```

```
is_base_of<base, base> == true
is_base_of<base, derived> == true
is_base_of<derived, base> == false
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[is_convertible](#) Class

is_class Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is a class.

Syntax

```
template <class Ty>
struct is_class;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a type defined as a **class** or a **struct**, or a `cv-qualified` form of one of them, otherwise it holds false.

Example

```
// std__type_traits__is_class.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_class<trivial> == " << std::boolalpha
        << std::is_class<trivial>::value << std::endl;
    std::cout << "is_class<int> == " << std::boolalpha
        << std::is_class<int>::value << std::endl;

    return (0);
}
```

```
is_class<trivial> == true
is_class<int> == false
```

<type_traits>

is_compound Class

is_union Class

is_compound Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if the specified type is not fundamental.

Syntax

```
template <class Ty>
struct is_compound;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds **false** if the type of *Ty* is a fundamental type (that is, if [is_fundamental](#)<*Ty*> holds **true**); otherwise, it holds **true**. Thus, the predicate holds **true** if *Ty* is an array type, a function type, a pointer to **void** or an object or a function, a reference, a class, a union, an enumeration, or a pointer to non-static class member, or a *cv-qualified* form of one of them.

Example

```
// std__type_traits__is_compound.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_compound<trivial> == " << std::boolalpha
        << std::is_compound<trivial>::value << std::endl;
    std::cout << "is_compound<int[]> == " << std::boolalpha
        << std::is_compound<int[]>::value << std::endl;
    std::cout << "is_compound<int()> == " << std::boolalpha
        << std::is_compound<int()>::value << std::endl;
    std::cout << "is_compound<int*> == " << std::boolalpha
        << std::is_compound<int*>::value << std::endl;
    std::cout << "is_compound<void *> == " << std::boolalpha
        << std::is_compound<void *>::value << std::endl;
    std::cout << "is_compound<int> == " << std::boolalpha
        << std::is_compound<int>::value << std::endl;

    return (0);
}
```

```
is_compound<trivial> == true
is_compound<int[]> == true
is_compound<int()> == true
is_compound<int&> == true
is_compound<void *> == true
is_compound<int> == false
```

Requirements

[<type_traits>](#)

[is_class](#) [Class](#)

is_const Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is const.

Syntax

```
template <class Ty>
struct is_const;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if *Ty* is `const-qualified`.

Example

```
// std__type_traits__is_const.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_const<trivial> == " << std::boolalpha
        << std::is_const<trivial>::value << std::endl;
    std::cout << "is_const<const trivial> == " << std::boolalpha
        << std::is_const<const trivial>::value << std::endl;
    std::cout << "is_const<int> == " << std::boolalpha
        << std::is_const<int>::value << std::endl;
    std::cout << "is_const<const int> == " << std::boolalpha
        << std::is_const<const int>::value << std::endl;

    return (0);
}
```

```
is_const<trivial> == false
is_const<const trivial> == true
is_const<int> == false
is_const<const int> == true
```

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

[is_volatile Class](#)

is_constructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether a type is constructible when the specified argument types are used.

Syntax

```
template <class T, class... Args>
struct is_constructible;
```

Parameters

T

The type to query.

Args

The argument types to match in a constructor of *T*.

Remarks

An instance of the type predicate holds true if the type *T* is constructible by using the argument types in *Args*, otherwise it holds false. Type *T* is constructible if the variable definition `T t(std::declval<Args>()...);` is well-formed. Both *T* and all the types in *Args* must be complete types, **void**, or arrays of unknown bound.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_convertible Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if one type is convertible to another.

Syntax

```
template <class From, class To>
struct is_convertible;
```

Parameters

From

The type to convert from.

To

The type to convert to.

Remarks

An instance of the type predicate holds true if the expression `To to = from;`, where `from` is an object of type `From`, is well-formed.

Example

```
// std_type_traits_is_convertible.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_convertible<trivial, int> == " << std::boolalpha
        << std::is_convertible<trivial, int>::value << std::endl;
    std::cout << "is_convertible<trivial, trivial> == " << std::boolalpha
        << std::is_convertible<trivial, trivial>::value << std::endl;
    std::cout << "is_convertible<char, int> == " << std::boolalpha
        << std::is_convertible<char, int>::value << std::endl;

    return (0);
}
```

```
is_convertible<trivial, int> == false
is_convertible<trivial, trivial> == true
is_convertible<char, int> == true
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[is_base_of](#) `Class`

is_copy_assignable Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether type has can be copied on assignment.

Syntax

```
template <class Ty>
struct is_copy_assignable;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a class that has a copy assignment operator, otherwise it holds false. Equivalent to `is_assignable<Ty&, const Ty&>`.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_copy_constructible Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type has a copy constructor.

Syntax

```
template <class Ty>
struct is_copy_constructible;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a class that has a copy constructor, otherwise it holds false.

Example

```
#include <type_traits>
#include <iostream>

struct Copyable
{
    int val;
};

struct NotCopyable
{
    NotCopyable(const NotCopyable&) = delete;
    int val;
};

int main()
{
    std::cout << "is_copy_constructible<Copyable> == " << std::boolalpha
              << std::is_copy_constructible<Copyable>::value << std::endl;
    std::cout << "is_copy_constructible<NotCopyable> == " << std::boolalpha
              << std::is_copy_constructible<NotCopyable>::value << std::endl;

    return (0);
}
```

```
is_copy_constructible<Copyable> == true
is_copy_constructible<NotCopyable> == false
```

Requirements

Header: <type_traits>

Namespace: `std`

See also

[`<type_traits>`](#)

is_default_constructible Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if a type has a default constructor.

Syntax

```
template <class Ty>
struct is_default_constructible;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a class type that has a default constructor, otherwise it holds false. This is equivalent to the predicate `is_constructible<T>`. Type *T* must be a complete type, **void**, or an array of unknown bound.

Example

```
#include <type_traits>
#include <iostream>

struct Simple
{
    Simple() : val(0) {}
    int val;
};

struct Simple2
{
    Simple2(int v) : val(v) {}
    int val;
};

int main()
{
    std::cout << "is_default_constructible<Simple> == " << std::boolalpha
        << std::is_default_constructible<Simple>::value << std::endl;
    std::cout << "is_default_constructible<Simple2> == " << std::boolalpha
        << std::is_default_constructible<Simple2>::value << std::endl;

    return (0);
}
```

```
is_default_constructible<Simple> == true
is_default_constructible<Simple2> == false
```

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

is_destructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether the type is destructible.

Syntax

```
template <class T>
struct is_destructible;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a destructible type, otherwise it holds false. Destructible types are reference types, object types, and types where for some type `U` equal to `remove_all_extents_t<T>` the unevaluated operand `std::declval<U&>::~~U()` is well-formed. Other types, including incomplete types, **void**, and function types, are not destructible types.

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

is_empty Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is an empty class.

Syntax

```
template <class Ty>
struct is_empty;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is an empty class, otherwise it holds false.

Example

```
// std__type_traits__is_empty.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct empty
{
};

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_empty<trivial> == " << std::boolalpha
        << std::is_empty<trivial>::value << std::endl;
    std::cout << "is_empty<empty> == " << std::boolalpha
        << std::is_empty<empty>::value << std::endl;
    std::cout << "is_empty<int> == " << std::boolalpha
        << std::is_empty<int>::value << std::endl;

    return (0);
}
```

```
is_empty<trivial> == false
is_empty<empty> == true
is_empty<int> == false
```

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

is_enum Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is an enumeration.

Syntax

```
template <class Ty>
struct is_enum;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is an enumeration type or a `cv-qualified` form of an enumeration type, otherwise it holds false.

Example

```
// std__type_traits__is_enum.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

enum color {
    red, greed, blue};

int main()
{
    std::cout << "is_enum<trivial> == " << std::boolalpha
              << std::is_enum<trivial>::value << std::endl;
    std::cout << "is_enum<color> == " << std::boolalpha
              << std::is_enum<color>::value << std::endl;
    std::cout << "is_enum<int> == " << std::boolalpha
              << std::is_enum<int>::value << std::endl;

    return (0);
}
```

```
is_enum<trivial> == false
is_enum<color> == true
is_enum<int> == false
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[<type_traits>](#)

[is_integral](#) Class

is_final Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether the type is a class type marked `final`.

Syntax

```
template <class T>
struct is_final;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a class type marked `final`, otherwise it holds false. If *T* is a class type, it must be a complete type.

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

[final Specifier](#)

is_floating_point Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is floating point.

Syntax

```
template <class Ty>
struct is_floating_point;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a floating point type or a `cv-qualified` form of a floating point type, otherwise it holds false.

A floating point type is one of **float**, **double**, or **long double**.

Example

```
// std_type_traits_is_floating_point.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_floating_point<trivial> == " << std::boolalpha
        << std::is_floating_point<trivial>::value << std::endl;
    std::cout << "is_floating_point<int> == " << std::boolalpha

[is_integral](#) Class

is_function Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

Tests if type is a function type.

Syntax

```
template <class Ty>
struct is_function;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a function type, otherwise it holds false.

Example

```
// std__type_traits__is_function.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

struct functional
{
    int f();
};

int main()
{
    std::cout << "is_function<trivial> == " << std::boolalpha
        << std::is_function<trivial>::value << std::endl;
    std::cout << "is_function<functional> == " << std::boolalpha
        << std::is_function<functional>::value << std::endl;
    std::cout << "is_function<float()> == " << std::boolalpha
        << std::is_function<float()>::value << std::endl;

    return (0);
}
```

```
is_function<trivial> == false
is_function<functional> == false
is_function<float()> == true
```

[is_object Class](#)

is_fundamental Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is void or arithmetic.

Syntax

```
template <class Ty>
struct is_fundamental;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a fundamental type, that is, **void**, an integral type, an floating point type, or a `cv-qualified` form of one of them, otherwise it holds false.

Example

```
// std__type_traits__is_fundamental.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_fundamental<trivial> == " << std::boolalpha
        << std::is_fundamental<trivial>::value << std::endl;
    std::cout << "is_fundamental<int> == " << std::boolalpha
        << std::is_fundamental<int>::value << std::endl;
    std::cout << "is_fundamental<const float> == " << std::boolalpha
        << std::is_fundamental<const float>::value << std::endl;
    std::cout << "is_fundamental<void> == " << std::boolalpha
        << std::is_fundamental<void>::value << std::endl;

    return (0);
}
```

```
is_fundamental<trivial> == false
is_fundamental<int> == true
is_fundamental<const float> == true
is_fundamental<void> == true
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[<type_traits>](#)

[is_compound Class](#)

is_integral Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is integral.

Syntax

```
template <class Ty>
struct is_integral;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is one of the integral types, or a `cv-qualified` form of one of the integral types, otherwise it holds false.

An integral type is one of **bool**, **char**, **unsigned char**, **signed char**, **wchar_t**, **short**, **unsigned short**, **int**, **unsigned int**, **long**, and **unsigned long**. In addition, with compilers that provide them, an integral type can be one of **long long**, **unsigned long long**, **__int64**, and **unsigned __int64**.

Example

```
// std__type_traits__is_integral.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_integral<trivial> == " << std::boolalpha
        << std::is_integral<trivial>::value << std::endl;
    std::cout << "is_integral<int> == " << std::boolalpha
        << std::is_integral<int>::value << std::endl;
    std::cout << "is_integral<float> == " << std::boolalpha
        << std::is_integral<float>::value << std::endl;

    return (0);
}
```

```
is_integral<trivial> == false
is_integral<int> == true
is_integral<float> == false
```

[<type_traits>](#)

[is_enum](#) Class

[is_floating_point](#) Class

is_invocable, is_invocable_r, is_nothrow_invocable, is_nothrow_invocable_r classes

2/28/2019 • 2 minutes to read • [Edit Online](#)

These templates determine if a type can be invoked with the specified argument types. `is_invocable_r` and `is_nothrow_invocable_r` also determine if the result of the invocation is convertible to a specific type. `is_nothrow_invocable` and `is_nothrow_invocable_r` also determine if the invocation is known not to throw exceptions. Added in C++17.

Syntax

```
template <class Callable, class... Args>
struct is_invocable;

template <class Convertible, class Callable, class... Args>
struct is_invocable_r;

template <class Callable, class... Args>
struct is_nothrow_invocable;

template <class Convertible, class Callable, class... Args>
struct is_nothrow_invocable_r;

// Helper templates
template <class Callable, class... Args>
inline constexpr bool is_invocable_v =
    std::is_invocable<Callable, Args...>::value;

template <class Convertible, class Callable, class... Args>
inline constexpr bool is_invocable_r_v =
    std::is_invocable_r<Convertible, Callable, Args...>::value;

template <class Callable, class... Args>
inline constexpr bool is_nothrow_invocable_v =
    std::is_nothrow_invocable<Callable, Args...>::value;

template <class Convertible, class Callable, class... Args>
inline constexpr bool is_nothrow_invocable_r_v =
    std::is_nothrow_invocable_r<Convertible, Callable, Args...>::value;
```

Parameters

Callable

The callable type to query.

Args

The argument types to query.

Convertible

The type the result of *Callable* must be convertible to.

Remarks

The `is_invocable` type predicate holds true if the callable type *Callable* can be invoked using the arguments *Args* in an unevaluated context.

The `is_invocable_r` type predicate holds true if the callable type *Callable* can be invoked using the arguments *Args* in an unevaluated context to produce a result type convertible to *Convertible*.

The `is_nothrow_invocable` type predicate holds true if the callable type *Callable* can be invoked using the arguments *Args* in an unevaluated context, and that such a call is known not to throw an exception.

The `is_nothrow_invocable_r` type predicate holds true if the callable type *Callable* can be invoked using the arguments *Args* in an unevaluated context to produce a result type convertible to *Convertible*, and that such a call is known not to throw an exception.

Each of the types *Convertible*, *Callable*, and the types in the parameter pack *Args* must be a complete type, an array of unknown bound, or a possibly cv-qualified **void**. Otherwise, the behavior of the predicate is undefined.

Example

```
// std__type_traits__is_invocable.cpp
// compile using: cl /EHsc /std:c++17 std__type_traits__is_invocable.cpp
#include <type_traits>

auto test1(int) noexcept -> int (*)()
{
    return nullptr;
}

auto test2(int) -> int (*)()
{
    return nullptr;
}

int main()
{
    static_assert( std::is_invocable<decltype(test1), short>::value );

    static_assert( std::is_invocable_r<int(*)(), decltype(test1), int>::value );
    static_assert( std::is_invocable_r<long(*)(), decltype(test1), int>::value ); // fails

    static_assert( std::is_nothrow_invocable<decltype(test1), int>::value );
    static_assert( std::is_nothrow_invocable<decltype(test2), int>::value ); // fails

    static_assert( std::is_nothrow_invocable_r<int(*)(), decltype(test1), int>::value );
    static_assert( std::is_nothrow_invocable_r<int(*)(), decltype(test2), int>::value ); // fails
}
```

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[`<type_traits>`](#)

[invoke](#)

is_literal_type Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether a type can be used as a `constexpr` variable or be constructed, used by, or returned from `constexpr` functions.

Syntax

```
template <class T>
struct is_literal_type;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a *literal type*, otherwise it holds false. A literal type is either **void**, a scalar type, a reference type, an array of literal type, or a literal class type. A literal class type is a class type that has a trivial destructor, is either an aggregate type or has at least one non-move, non-copy `constexpr` constructor, and all of its base classes and non-static data members are non-volatile literal types. While the type of a literal is always a literal type, the concept of a literal type includes anything that the compiler can evaluate as a `constexpr` at compile time.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_lvalue_reference Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is an lvalue reference.

Syntax

```
template <class Ty>
struct is_lvalue_reference;
```

Parameters

Ty

The type to query.

Remarks

An instance of this type predicate holds true if the type *Ty* is a reference to an object or to a function, otherwise it holds false. Note that *Ty* may not be an rvalue reference. For more information about rvalues, see [Rvalue Reference Declarator: &&](#).

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

[Lvalues and Rvalues](#)

is_member_function_pointer Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is a pointer to member function.

Syntax

```
template <class Ty>
struct is_member_function_pointer;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a pointer to member function or a `cv-qualified` pointer to member function, otherwise it holds false.

Example

```
// std_type_traits__is_member_function_pointer.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

struct functional
{
    int f();
};

int main()
{
    std::cout << "is_member_function_pointer<trivial *> == "
        << std::boolalpha
        << std::is_member_function_pointer<trivial *>::value
        << std::endl;
    std::cout << "is_member_function_pointer<int trivial::*> == "
        << std::boolalpha
        << std::is_member_function_pointer<int trivial::*>::value
        << std::endl;
    std::cout << "is_member_function_pointer<int (functional::*)()> == "
        << std::boolalpha
        << std::is_member_function_pointer<int (functional::*)()>::value
        << std::endl;

    return (0);
}
```

```
is_member_function_pointer<trivial *> == false  
is_member_function_pointer<int trivial::*> == false  
is_member_function_pointer<int (functional::*)()> == true
```

Namespace: `std`

See also

[<type_traits>](#)

[is_member_pointer](#) Class

is_member_object_pointer Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is a pointer to member object.

Syntax

```
template <class Ty>
struct is_member_object_pointer;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a pointer to member object or a `cv-qualified` pointer to member object, otherwise it holds false. Note that `is_member_object_pointer` holds false if *Ty* is a pointer to member function.

Example

```
// std__type_traits__is_member_object_pointer.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

struct functional
{
    int f();
};

int main()
{
    std::cout << "is_member_object_pointer<trivial *> == "
        << std::boolalpha
        << std::is_member_object_pointer<trivial *>::value
        << std::endl;
    std::cout << "is_member_object_pointer<int trivial::*> == "
        << std::boolalpha
        << std::is_member_object_pointer<int trivial::*>::value
        << std::endl;
    std::cout << "is_member_object_pointer<int (functional::*)()> == "
        << std::boolalpha
        << std::is_member_object_pointer<int (functional::*)()>::value
        << std::endl;

    return (0);
}
```

```
is_member_object_pointer<trivial *> == false  
is_member_object_pointer<int trivial::*> == true  
is_member_object_pointer<int (functional::*)()> == false
```

[<type_traits>](#)

[is_member_pointer](#) Class

is_member_pointer Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is a pointer to member.

Syntax

```
template <class Ty>
struct is_member_pointer;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a pointer to member function or a pointer to member object, or a `cv-qualified` form of one of them, otherwise it holds false.

Example

```
// std_type_traits_is_member_pointer.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

struct functional
{
    int f();
};

int main()
{
    std::cout << "is_member_pointer<trivial *> == "
        << std::boolalpha
        << std::is_member_pointer<trivial *>::value
        << std::endl;
    std::cout << "is_member_pointer<int trivial::*> == "
        << std::boolalpha
        << std::is_member_pointer<int trivial::*>::value
        << std::endl;
    std::cout << "is_member_pointer<int (functional::*)()> == "
        << std::boolalpha
        << std::is_member_pointer<int (functional::*)()>::value
        << std::endl;

    return (0);
}
```

```
is_member_pointer<trivial *> == false  
is_member_pointer<int trivial::*> == true  
is_member_pointer<int (functional::*)()> == true
```

[is_member_object_pointer](#) Class

[is_pointer](#) Class

is_move_assignable Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if the type can be move assigned.

Syntax

```
template <class T>
struct is_move_assignable;
```

Parameters

T

The type to query.

Remarks

A type is move assignable if an rvalue reference to the type can be assigned to a reference to the type. The type predicate is equivalent to `is_assignable<T&, T&&>`. Move assignable types include referenceable scalar types and class types that have either compiler-generated or user-defined move assignment operators.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_move_constructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether the type has a move constructor.

Syntax

```
template <class T>
struct is_move_constructible;
```

Parameters

T

The type to be evaluated

Remarks

A type predicate that evaluates to true if the type *T* can be constructed by using a move operation. This predicate is equivalent to `is_constructible<T, T&&>`.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_nothrow_assignable Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether a value of *From* type can be assigned to *To* type and the assignment is known not to throw.

Syntax

```
template <class To, class From>
struct is_nothrow_assignable;
```

Parameters

To

The type of the object that receives the assignment.

From

The type of the object that provides the value.

Remarks

The expression `declval<To>() = declval<From>()` must be well-formed and must be known to the compiler not to throw. Both *From* and *To* must be complete types, **void**, or arrays of unknown bound.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_nothrow_constructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether a type is constructible and is known not to throw when the specified argument types are used.

Syntax

```
template <class T, class... Args>
struct is_nothrow_constructible;
```

Parameters

T

The type to query.

Args

The argument types to match in a constructor of *T*.

Remarks

An instance of the type predicate holds true if the type *T* is constructible by using the argument types in *Args*, and the constructor is known by the compiler not to throw; otherwise it holds false. Type *T* is constructible if the variable definition `T t(std::declval<Args>()...);` is well-formed. Both *T* and all the types in *Args* must be complete types, **void**, or arrays of unknown bound.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_nothrow_copy_assignable Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether type has a copy assignment operator that is known to the compiler not to throw.

Syntax

```
template <class T>
struct is_nothrow_copy_assignable;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true for a referenceable type *T* where `is_nothrow_assignable<T&, const T&>` holds true; otherwise it holds false.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

[is_nothrow_assignable Class](#)

is_nothrow_copy_constructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether type has a **nothrow** copy constructor.

Syntax

```
template <class Ty>
struct is_nothrow_copy_constructible;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* has a nothrow copy constructor, otherwise it holds false.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_nothrow_default_constructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether type has a non-throwing default constructor.

Syntax

```
template <class Ty>
struct is_nothrow_default_constructible;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* has a nothrow default constructor, otherwise it holds false. An instance of the type predicate is equivalent to `is_nothrow_constructible<Ty>`.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_nothrow_destructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether the type is destructible and the destructor is known to the compiler not to throw.

Syntax

```
template <class T>  
struct is_nothrow_destructible;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a destructible type, and the destructor is known to the compiler not to throw. Otherwise, it holds false.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_nothrow_move_assignable Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether type has a **nothrow** move assignment operator.

Syntax

```
template <class Ty>
struct is_nothrow_move_assignable;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* has a nothrow move assignment operator, otherwise it holds false.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_nothrow_move_constructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether type has a **nothrow** move constructor.

Syntax

```
template <class Ty>
struct is_nothrow_move_constructible;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* has a nothrow move constructor, otherwise it holds false.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_null_pointer Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is `std::nullptr_t`.

Syntax

```
template <class T>
struct is_null_pointer;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is `std::nullptr_t`, otherwise it holds false.

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

is_object Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is an object type.

Syntax

```
template <class Ty>
struct is_object;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds false if the type *Ty* is a reference type, a function type, or void, or a `cv-qualified` form of one of them, otherwise holds true.

Example

```
// std__type_traits__is_object.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

struct functional
{
    int f();
};

int main()
{
    std::cout << "is_object<trivial> == " << std::boolalpha
        << std::is_object<trivial>::value << std::endl;
    std::cout << "is_object<functional> == " << std::boolalpha
        << std::is_object<functional>::value << std::endl;
    std::cout << "is_object<trivial&> == " << std::boolalpha
        << std::is_object<trivial&>::value << std::endl;
    std::cout << "is_object<float()> == " << std::boolalpha
        << std::is_object<float()>::value << std::endl;
    std::cout << "is_object<void> == " << std::boolalpha
        << std::is_object<void>::value << std::endl;

    return (0);
}
```

```
is_object<trivial> == true  
is_object<functional> == true  
is_object<trivial&> == false  
is_object<float()> == false  
is_object<void> == false
```

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

[is_function](#) Class

is_pod Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is POD.

Syntax

```
template <class T>
struct is_pod;
```

Parameters

T

The type to query.

Remarks

`is_pod<T>::value` is **true** if the type *T* is Plain Old Data (POD). Otherwise it is **false**.

Arithmetic types, enumeration types, pointer types, and pointer to member types are POD.

A cv-qualified version of a POD type is itself a POD type.

An array of POD is itself POD.

A struct or union, all of whose non-static data members are POD, is itself POD if it has:

- No user-declared constructors.
- No private or protected non-static data members.
- No base classes.
- No virtual functions.
- No non-static data members of reference type.
- No user-defined copy assignment operator.
- No user-defined destructor.

Therefore, you can recursively build POD structs and arrays that contain POD structs and arrays.

Example

```

// std__type_traits__is_pod.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial {
    int val;
};

struct throws {
    throws() {} // User-declared ctor, so not POD

    int val;
};

int main() {
    std::cout << "is_pod<trivial> == " << std::boolalpha
        << std::is_pod<trivial>::value << std::endl;
    std::cout << "is_pod<int> == " << std::boolalpha
        << std::is_pod<int>::value << std::endl;
    std::cout << "is_pod<throws> == " << std::boolalpha
        << std::is_pod<throws>::value << std::endl;

    return (0);
}

```

```

is_pod<trivial> == true
is_pod<int> == true
is_pod<throws> == false

```

Requirements

[<type_traits>](#)

is_pointer Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is a pointer.

Syntax

```
template <class Ty>
struct is_pointer;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a pointer to **void**, a pointer to an object, or a pointer to a function, or a `cv-qualified` form of one of them, otherwise it holds false. Note that `is_pointer` holds false if *Ty* is a pointer to member or a pointer to member function.

Example

```
// std__type_traits__is_pointer.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_pointer<trivial> == " << std::boolalpha
        << std::is_pointer<trivial>::value << std::endl;
    std::cout << "is_pointer<int trivial::*> == " << std::boolalpha
        << std::is_pointer<int trivial::*>::value << std::endl;
    std::cout << "is_pointer<trivial *> == " << std::boolalpha
        << std::is_pointer<trivial *>::value << std::endl;
    std::cout << "is_pointer<int> == " << std::boolalpha
        << std::is_pointer<int>::value << std::endl;
    std::cout << "is_pointer<int *> == " << std::boolalpha
        << std::is_pointer<int *>::value << std::endl;

    return (0);
}
```

```
is_pointer<trivial> == false
is_pointer<int trivial::*> == false
is_pointer<trivial *> == true
is_pointer<int> == false
is_pointer<int *> == true
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[is_member_pointer](#) Class

[is_reference](#) Class

is_polymorphic Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type has a virtual function.

Syntax

```
template <class Ty>  
struct is_polymorphic;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a class that declares or inherits a virtual function, otherwise it holds false.

Example

```

// std__type_traits__is_polymorphic.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

struct throws
{
    throws() throw(int)
    {
    }

    throws(const throws&) throw(int)
    {
    }

    throws& operator=(const throws&) throw(int)
    {
    }

    virtual ~throws()
    {
    }

    int val;
};

int main()
{
    std::cout << "is_polymorphic<trivial> == " << std::boolalpha
        << std::is_polymorphic<trivial>::value << std::endl;
    std::cout << "is_polymorphic<throws> == " << std::boolalpha
        << std::is_polymorphic<throws>::value << std::endl;

    return (0);
}

```

```

is_polymorphic<trivial> == false
is_polymorphic<throws> == true

```

Requirements

Header: `<type_traits>`

Namespace: `std`

[is_abstract Class](#)

is_reference Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is a reference.

Syntax

```
template <class Ty>
struct is_reference;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a reference to an object or to a function, otherwise it holds false.

Example

```
// std__type_traits__is_reference.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_reference<trivial> == " << std::boolalpha
        << std::is_reference<trivial>::value << std::endl;
    std::cout << "is_reference<trivial&> == " << std::boolalpha
        << std::is_reference<trivial&>::value << std::endl;
    std::cout << "is_reference<int()> == " << std::boolalpha
        << std::is_reference<int()>::value << std::endl;
    std::cout << "is_reference<int(&)()> == " << std::boolalpha
        << std::is_reference<int(&)()>::value << std::endl;

    return (0);
}
```

```
is_reference<trivial> == false
is_reference<trivial&> == true
is_reference<int()> == false
is_reference<int(&)()> == true
```

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[is_pointer](#) Class

is_rvalue_reference Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is an rvalue reference.

Syntax

```
template <class Ty>
struct is_rvalue_reference;
```

Parameters

Ty

The type to query.

Remarks

An instance of this type predicate holds true if the type *Ty* is an [rvalue reference](#).

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

[Lvalues and Rvalues](#)

is_same Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if two types are the same.

Syntax

```
template <class Ty1, class Ty2>
struct is_same;
```

Parameters

Ty1

The first type to query.

Ty2

The second type to query.

Remarks

An instance of the type predicate holds true if the types *Ty1* and *Ty2* are the same type, otherwise it holds false.

Example

```
// std__type_traits__is_same.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct base
{
    int val;
};

struct derived
: public base
{
};

int main()
{
    std::cout << "is_same<base, base> == " << std::boolalpha
        << std::is_same<base, base>::value << std::endl;
    std::cout << "is_same<base, derived> == " << std::boolalpha
        << std::is_same<base, derived>::value << std::endl;
    std::cout << "is_same<derived, base> == " << std::boolalpha
        << std::is_same<derived, base>::value << std::endl;
    std::cout << "is_same<int, int> == " << std::boolalpha
        << std::is_same<int, int>::value << std::endl;
    std::cout << "is_same<int, const int> == " << std::boolalpha
        << std::is_same<int, const int>::value << std::endl;

    return (0);
}
```

```
is_same<base, base> == true  
is_same<base, derived> == false  
is_same<derived, base> == false  
is_same<int, int> == true  
is_same<int, const int> == false
```

Requirements

[is_convertible](#) Class

[is_base_of](#) Class

is_scalar Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is scalar.

Syntax

```
template <class Ty>
struct is_scalar;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is an integral type, a floating point type, an enumeration type, a pointer type, or a pointer to member type, or a `cv-qualified` form of one of them, otherwise it holds false.

Example

```
// std__type_traits__is_scalar.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_scalar<trivial> == " << std::boolalpha
        << std::is_scalar<trivial>::value << std::endl;
    std::cout << "is_scalar<trivial*> == " << std::boolalpha
        << std::is_scalar<trivial*>::value << std::endl;
    std::cout << "is_scalar<int> == " << std::boolalpha
        << std::is_scalar<int>::value << std::endl;
    std::cout << "is_scalar<float> == " << std::boolalpha
        << std::is_scalar<float>::value << std::endl;

    return (0);
}
```

```
is_scalar<trivial> == false
is_scalar<trivial*> == true
is_scalar<int> == true
is_scalar<float> == true
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[<type_traits>](#)

[is_compound](#) Class

is_signed Class

4/12/2019 • 2 minutes to read • [Edit Online](#)

Test if type is signed integer.

Syntax

```
template <class Ty>
struct is_signed;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a signed integral type or a `cv-qualified` signed integral type, otherwise it holds false.

Example

```
// std__type_traits__is_signed.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_signed<trivial> == " << std::boolalpha
        << std::is_signed<trivial>::value << std::endl;
    std::cout << "is_signed<int> == " << std::boolalpha
        << std::is_signed<int>::value << std::endl;
    std::cout << "is_signed<unsigned int> == " << std::boolalpha
        << std::is_signed<unsigned int>::value << std::endl;
    std::cout << "is_signed<float> == " << std::boolalpha
        << std::is_signed<float>::value << std::endl;

    return (0);
}
```

```
is_signed<trivial> == false
is_signed<int> == true
is_signed<unsigned int> == false
is_signed<float> == true
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[<type_traits>](#)

[is_unsigned Class](#)

is_standard_layout Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is a standard layout.

Syntax

```
template <class Ty>
struct is_standard_layout;
```

Parameters

PARAMETER	DESCRIPTION
<i>Ty</i>	The type to query

Remarks

An instance of this type predicate holds true if the type *Ty* is a class that has a standard layout of member objects in memory, otherwise it holds false.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_trivial Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether the type is a trivial type.

Syntax

```
template <class T>  
struct is_trivial;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a trivial type, otherwise it holds false. Trivial types are scalar types, trivially copyable class types, arrays of these types and cv-qualified versions of these types.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_trivially_assignable Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether a value of `From` type can be trivially assigned to `To` type

Syntax

```
template <class To, class From>
struct is_trivially_assignable;
```

Parameters

To

The type of the object that receives the assignment.

From

The type of the object that provides the value.

Remarks

The expression `declval<To>() = declval<From>()` must be well-formed, and must be known to the compiler to require no non-trivial operations. Both `From` and `To` must be complete types, **void**, or arrays of unknown bound.

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

is_trivially_constructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether a type is trivially constructible when the specified argument types are used.

Syntax

```
template <class T, class... Args>
struct is_trivially_constructible;
```

Parameters

T

The type to query.

Args

The argument types to match in a constructor of *T*.

Remarks

An instance of the type predicate holds true if the type *T* is trivially constructible by using the argument types in *Args*, otherwise it holds false. Type *T* is trivially constructible if the variable definition

`T t(std::declval<Args>()...);` is well-formed and is known to call no non-trivial operations. Both *T* and all the types in *Args* must be complete types, **void**, or arrays of unknown bound.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_trivially_copy_assignable Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether the type has a trivial copy assignment operator.

Syntax

```
template <class Ty>
struct is_trivially_copy_assignable;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a class that has a trivial copy assignment operator, otherwise it holds false.

An assignment constructor for a class *T* is trivial if it is implicitly provided, the class *T* has no virtual functions, the class *T* has no virtual bases, the classes of all the non-static data members of class type have trivial assignment operators, and the classes of all the non-static data members of type array of class have trivial assignment operators.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_trivially_copy_constructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if the type has a trivial copy constructor.

Syntax

```
template <class T>
struct is_trivially_copy_constructible;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a class that has a trivial copy constructor, otherwise it holds false.

A copy constructor for a class *T* is trivial if it is implicitly declared, the class *T* has no virtual functions or virtual bases, all the direct bases of class *T* have trivial copy constructors, the classes of all the non-static data members of class type have trivial copy constructors, and the classes of all the non-static data members of type array of class have trivial copy constructors.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_trivially_copyable Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether the type is a trivially copyable type.

Syntax

```
template <class T>  
struct is_trivially_copyable;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a trivially copyable type, otherwise it holds false. Trivially copyable types have no non-trivial copy operations, move operations, or destructors. Generally, a copy operation is considered trivial if it can be implemented as a bitwise copy. Both built-in types and arrays of trivially copyable types are trivially copyable.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_trivially_default_constructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type has trivial default constructor.

Syntax

```
template <class Ty>
struct is_trivially_default_constructible;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a class that has a trivial constructor, otherwise it holds false.

A default constructor for a class *Ty* is trivial if:

- it is an implicitly declared default constructor
- the class *Ty* has no virtual functions
- the class *Ty* has no virtual bases
- all the direct bases of the class *Ty* have trivial constructors
- the classes of all the non-static data members of class type have trivial constructors
- the classes of all the non-static data members of type array of class have trivial constructors

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_trivially_destructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether the type is trivially destructible.

Syntax

```
template <class T>
struct is_trivially_destructible;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a destructible type, and the destructor is known to the compiler to use no non-trivial operations. Otherwise, it holds false.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_trivially_move_assignable Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests whether the type has a trivial move assignment operator.

Syntax

```
template <class Ty>
struct is_trivially_move_assignable;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a class that has a trivial move assignment operator, otherwise it holds false.

A move assignment operator for a class *Ty* is trivial if:

it is implicitly provided

the class *Ty* has no virtual functions

the class *Ty* has no virtual bases

the classes of all the non-static data members of class type have trivial move assignment operators

the classes of all the non-static data members of type array of class have trivial move assignment operators

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_trivially_move_constructible Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Tests if type has trivial move constructor.

Syntax

```
template <class Ty>
struct is_trivially_move_constructible;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a class that has a trivial move constructor, otherwise it holds false.

A move constructor for a class *Ty* is trivial if:

it is implicitly declared

its parameter types are equivalent to those of an implicit declaration

the class *Ty* has no virtual functions

the class *Ty* has no virtual bases

the class has no volatile non-static data members

all the direct bases of the class *Ty* have trivial move constructors

the classes of all the non-static data members of class type have trivial move constructors

the classes of all the non-static data members of type array of class have trivial move constructors

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_union Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is a union.

Syntax

```
template <class Ty>
struct is_union;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a union type or a `cv-qualified` form of a union type, otherwise it holds false.

Example

```
// std__type_traits__is_union.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

union ints
{
    int in;
    long lo;
};

int main()
{
    std::cout << "is_union<trivial> == " << std::boolalpha
        << std::is_union<trivial>::value << std::endl;
    std::cout << "is_union<int> == " << std::boolalpha
        << std::is_union<int>::value << std::endl;
    std::cout << "is_union<ints> == " << std::boolalpha
        << std::is_union<ints>::value << std::endl;

    return (0);
}
```

```
is_union<trivial> == false
is_union<int> == false
is_union<ints> == true
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[is_class](#) [Class](#)

is_unsigned Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is unsigned integer.

Syntax

```
template <class Ty>
struct is_unsigned;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is an unsigned integral type or a `cv-qualified` unsigned integral type, otherwise it holds false.

Example

```
// std__type_traits__is_unsigned.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_unsigned<trivial> == " << std::boolalpha
        << std::is_unsigned<trivial>::value << std::endl;
    std::cout << "is_unsigned<int> == " << std::boolalpha
        << std::is_unsigned<int>::value << std::endl;
    std::cout << "is_unsigned<unsigned int> == " << std::boolalpha
        << std::is_unsigned<unsigned int>::value << std::endl;
    std::cout << "is_unsigned<float> == " << std::boolalpha
        << std::is_unsigned<float>::value << std::endl;

    return (0);
}
```

```
is_unsigned<trivial> == false
is_unsigned<int> == false
is_unsigned<unsigned int> == true
is_unsigned<float> == false
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[<type_traits>](#)

[is_signed Class](#)

is_void Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests whether the type is void.

Syntax

```
template <class T>
struct is_void;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is **void** or a cv-qualified form of **void**, otherwise it holds false.

Example

```
// std_type_traits_is_void.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_void<trivial> == " << std::boolalpha
        << std::is_void<trivial>::value << std::endl;
    std::cout << "is_void<void()> == " << std::boolalpha
        << std::is_void<void()>::value << std::endl;
    std::cout << "is_void<void> == " << std::boolalpha
        << std::is_void<void>::value << std::endl;

    return (0);
}
```

```
is_void<trivial> == false
is_void<void()> == false
is_void<void> == true
```

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

is_volatile Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Tests if type is volatile.

Syntax

```
template <class Ty>
struct is_volatile;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if *Ty* is `volatile-qualified`.

Example

```
// std__type_traits__is_volatile.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

struct trivial
{
    int val;
};

int main()
{
    std::cout << "is_volatile<trivial> == " << std::boolalpha
        << std::is_volatile<trivial>::value << std::endl;
    std::cout << "is_volatile<volatile trivial> == " << std::boolalpha
        << std::is_volatile<volatile trivial>::value << std::endl;
    std::cout << "is_volatile<int> == " << std::boolalpha
        << std::is_volatile<int>::value << std::endl;
    std::cout << "is_volatile<volatile int> == " << std::boolalpha
        << std::is_volatile<volatile int>::value << std::endl;

    return (0);
}
```

```
is_volatile<trivial> == false
is_volatile<volatile trivial> == true
is_volatile<int> == false
is_volatile<volatile int> == true
```

Requirements

Header: `<type_traits>`

Namespace: `std`

[<type_traits>](#)

[is_const](#) [Class](#)

make_signed Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes type or the smallest signed type greater than or equal in size to type.

Syntax

```
template <class T>
struct make_signed;

template <class T>
using make_signed_t = typename make_signed<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of the type modifier holds a modified-type that is *T* if `is_signed<T>` holds true. Otherwise it is the smallest unsigned type `UT` for which `sizeof (T) <= sizeof (UT)` .

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

make_unsigned Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes type or the smallest unsigned type greater than or equal in size to type.

Syntax

```
template <class T>
struct make_unsigned;

template <class T>
using make_unsigned_t = typename make_unsigned<T>::type;
```

Parameters

PARAMETER	DESCRIPTION
<i>T</i>	The type to modify.

Remarks

An instance of the type modifier holds a modified-type that is *T* if `is_unsigned<T>` holds true. Otherwise it is the smallest signed type `ST` for which `sizeof (T) <= sizeof (ST)` .

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

rank Class

11/9/2018 • 2 minutes to read • [Edit Online](#)

Gets number of array dimensions.

Syntax

```
template <class Ty>
struct rank;
```

Parameters

Ty

The type to query.

Remarks

The type query holds the value of the number of dimensions of the array type *Ty*, or 0 if *Ty* is not an array type.

Example

```
// std__type_traits__rank.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

int main()
{
    std::cout << "rank<int> == "
        << std::rank<int>::value << std::endl;
    std::cout << "rank<int[5]> == "
        << std::rank<int[5]>::value << std::endl;
    std::cout << "rank<int[5][10]> == "
        << std::rank<int[5][10]>::value << std::endl;

    return (0);
}
```

```
rank<int> == 0
rank<int[5]> == 1
rank<int[5][10]> == 2
```

Requirements

[extent Class](#)

remove_all_extents Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes non array type from array type.

Syntax

```
template <class T>
struct remove_all_extents;

template <class T>
using remove_all_extents_t = typename remove_all_extents<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of `remove_all_extents<T>` holds a modified-type that is the element type of the array type *T* with all array dimensions removed, or *T* if *T* is not an array type.

Example

```
#include <type_traits>
#include <iostream>

int main()
{
    std::cout << "remove_all_extents<int> == "
        << typeid(std::remove_all_extents_t<int>).name()
        << std::endl;
    std::cout << "remove_all_extents_t<int[5]> == "
        << typeid(std::remove_all_extents_t<int[5]>).name()
        << std::endl;
    std::cout << "remove_all_extents_t<int[5][10]> == "
        << typeid(std::remove_all_extents_t<int[5][10]>).name()
        << std::endl;

    return (0);
}
```

[remove_extent Class](#)

remove_const Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes a non const type from type.

Syntax

```
template <class T>
struct remove_const;
```

```
template <class T>
using remove_const_t = typename remove_const<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of `remove_const<T>` holds a modified-type that is `T1` when *T* is of the form `const T1`, otherwise *T*.

Example

```
#include <type_traits>
#include <iostream>

int main()
{
    int *p = (std::remove_const_t<const int>*)0;

    p = p; // to quiet "unused" warning
    std::cout << "remove_const_t<const int> == "
              << typeid(*p).name() << std::endl;

    return (0);
}
```

```
remove_const_t<const int> == int
```

Requirements

remove_cv Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes non const/volatile type from type.

Syntax

```
template <class T>
struct remove_cv;

template <class T>
using remove_cv_t = typename remove_cv<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of `remove_cv<T>` holds a modified-type that is `T1` when *T* is of the form `const T1`, `volatile T1`, or `const volatile T1`, otherwise *T*.

Example

```
#include <type_traits>
#include <iostream>

int main()
{
    int *p = (std::remove_cv_t<const volatile int> *)0;

    p = p; // to quiet "unused" warning
    std::cout << "remove_cv_t<const volatile int> == "
              << typeid(*p).name() << std::endl;

    return (0);
}
```

```
remove_cv_t<const volatile int> == int
```

Requirements

remove_volatile Class

remove_extent Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes element type from array type.

Syntax

```
template <class T>
struct remove_extent;

template <class T>
using remove_extent_t = typename remove_extent<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of `remove_extent<T>` holds a modified-type that is `T1` when *T* is of the form `T1[N]`, otherwise *T*.

Example

```
#include <type_traits>
#include <iostream>

int main()
{
    std::cout << "remove_extent_t<int> == "
              << typeid(std::remove_extent_t<int>).name()
              << std::endl;
    std::cout << "remove_extent_t<int[5]> == "
              << typeid(std::remove_extent_t<int[5]>).name()
              << std::endl;
    std::cout << "remove_extent_t<int[5][10]> == "
              << typeid(std::remove_extent_t<int[5][10]>).name()
              << std::endl;
    return (0);
}
```

```
remove_extent_t<int> == int
remove_extent_t<int[5]> == int
remove_extent_t<int[5][10]> == int [10]
```

`remove_all_extents` Class

remove_pointer Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes type from pointer to type.

Syntax

```
template <class T>
struct remove_pointer;

template <class T>
using remove_pointer_t = typename remove_pointer<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of `remove_pointer<T>` holds a modified-type that is `T1` when *T* is of the form `T1*`, `T1* const`, `T1* volatile`, or `T1* const volatile`, otherwise *T*.

Example

```
#include <type_traits>
#include <iostream>

int main()
{
    int *p = (std::remove_pointer_t<int *> *)0;

    p = p; // to quiet "unused" warning
    std::cout << "remove_pointer_t<int *> == "
              << typeid(*p).name() << std::endl;

    return (0);
}
```

```
remove_pointer_t<int *> == int
```

Requirements

remove_reference Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes non reference type from type.

Syntax

```
template <class T>
struct remove_reference;

template <class T>
using remove_reference_t = typename remove_reference<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of `remove_reference<T>` holds a modified-type that is `T1` when *T* is of the form `T1&`, otherwise *T*.

Example

```
#include <type_traits>
#include <iostream>

int main()
{
    int *p = (std::remove_reference_t<int&> *)0;

    p = p; // to quiet "unused" warning
    std::cout << "remove_reference_t<int&> == "
              << typeid(*p).name() << std::endl;

    return (0);
}
```

```
remove_reference_t<int&> == int
```

remove_volatile Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Makes non volatile type from type.

Syntax

```
template <class T>
struct remove_volatile;

template <class T>
using remove_volatile_t = typename remove_volatile<T>::type;
```

Parameters

T

The type to modify.

Remarks

An instance of `remove_volatile<T>` holds a modified-type that is `T1` when *T* is of the form `volatile T1`, otherwise *T*.

Example

```
#include <type_traits>
#include <iostream>

int main()
{
    int *p = (std::remove_volatile_t<volatile int> *)0;

    p = p; // to quiet "unused" warning
    std::cout << " remove_volatile_t<volatile int> == "
              << typeid(*p).name() << std::endl;

    return (0);
}
```

```
remove_volatile_t<volatile int> == int
```

Requirements

[<type_traits>](#)

[add_volatile Class](#)

result_of Class

2/28/2019 • 2 minutes to read • [Edit Online](#)

Determines the return type of the callable type that takes the specified argument types. Added in C++14, deprecated in C++17.

Syntax

```
template<class>
struct result_of; // Causes a static assert

template <class Fn, class... ArgTypes>
struct result_of<Fn(ArgTypes...)>;

// Helper type
template<class T>
    using result_of_t = typename result_of<T>::type;
```

Parameters

Fn

The callable type to query.

ArgTypes

The types of the argument list to the callable type to query.

Remarks

Use this template to determine at compile time the result type of `Fn (ArgTypes)`, where *Fn* is a callable type, reference to function, or reference to callable type, invoked using an argument list of the types in *ArgTypes*. The

`type` member of the template class names the result type of

`decltype(std::invoke(declval<Fn>(), declval<ArgTypes>()...))` if the unevaluated expression

`std::invoke(declval<Fn>(), declval<ArgTypes>()...)` is well-formed. Otherwise, the template class has no member

`type`. The type *Fn* and all types in the parameter pack *ArgTypes* must be complete types, **void**, or arrays of unknown bound. Deprecated in favor of [invoke_result](#) in C++17.

Requirements

Header: <type_traits>

Namespace: std

See also

[<type_traits>](#)

[invoke_result class](#)

underlying_type Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

Produces the underlying integral type for an enumeration type.

Syntax

```
template <class T>
struct underlying_type;
```

Parameters

T

The type to modify.

Remarks

The `type` member typedef of the template class names the underlying integral type of *T*, when *T* is an enumeration type, otherwise there is no member typedef `type`.

Requirements

Header: `<type_traits>`

Namespace: `std`

See also

[<type_traits>](#)

<type_traits> functions

11/9/2018 • 4 minutes to read • [Edit Online](#)

is_assignable	is_copy_assignable	is_copy_constructible
is_default_constructible	is_move_assignable	is_move_constructible
is_nothrow_move_assignable	is_trivially_copy_assignable	is_trivially_move_assignable
is_trivially_move_constructible		

is_assignable

Tests whether a value of *From* type can be assigned to a *To* type.

```
template <class To, class From>
struct is_assignable;
```

Parameters

To

The type of the object that receives the assignment.

From

The type of the object that provides the value.

Remarks

The unevaluated expression `declval<To>() = declval<From>()` must be well-formed. Both *From* and *To* must be complete types, **void**, or arrays of unknown bound.

is_copy_assignable

Tests whether type has can be copied on assignment.

```
template <class Ty>
struct is_copy_assignable;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a class that has a copy assignment operator, otherwise it holds false. Equivalent to `is_assignable<Ty&, const Ty&>`.

is_copy_constructible

Tests if type has a copy constructor.

```
template <class Ty>
struct is_copy_constructible;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a class that has a copy constructor, otherwise it holds false.

Example

```
#include <type_traits>
#include <iostream>

struct Copyable
{
    int val;
};

struct NotCopyable
{
    NotCopyable(const NotCopyable&) = delete;
    int val;
};

int main()
{
    std::cout << "is_copy_constructible<Copyable> == " << std::boolalpha
        << std::is_copy_constructible<Copyable>::value << std::endl;
    std::cout << "is_copy_constructible<NotCopyable> == " << std::boolalpha
        << std::is_copy_constructible<NotCopyable>::value << std::endl;

    return (0);
}
```

```
is_copy_constructible<Copyable> == true
is_copy_constructible<NotCopyable> == false
```

is_default_constructible

Tests if a type has a default constructor.

```
template <class Ty>
struct is_default_constructible;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type *T* is a class type that has a default constructor, otherwise it holds false. This is equivalent to the predicate `is_constructible<T>`. Type *T* must be a complete type, **void**, or an array of unknown bound.

Example

```
#include <type_traits>
#include <iostream>

struct Simple
{
    Simple() : val(0) {}
    int val;
};

struct Simple2
{
    Simple2(int v) : val(v) {}
    int val;
};

int main()
{
    std::cout << "is_default_constructible<Simple> == " << std::boolalpha
        << std::is_default_constructible<Simple>::value << std::endl;
    std::cout << "is_default_constructible<Simple2> == " << std::boolalpha
        << std::is_default_constructible<Simple2>::value << std::endl;

    return (0);
}
```

```
is_default_constructible<Simple> == true
is_default_constructible<Simple2> == false
```

is_move_assignable

Tests if the type can be move assigned.

```
template <class T>
struct is_move_assignable;
```

Parameters

T

The type to query.

Remarks

A type is move assignable if an rvalue reference to the type can be assigned to a reference to the type. The type predicate is equivalent to `is_assignable<T&, T&&>`. Move assignable types include referenceable scalar types and class types that have either compiler-generated or user-defined move assignment operators.

is_move_constructible

Tests whether the type has a move constructor.

```
template <class T>
struct is_move_constructible;
```

Parameters

T

The type to be evaluated

Remarks

A type predicate that evaluates to true if the type T can be constructed by using a move operation. This predicate is equivalent to `is_constructible<T, T&&>`.

is_nothrow_move_assignable

Tests whether type has a **nothrow** move assignment operator.

```
template <class Ty>
struct is_nothrow_move_assignable;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type Ty has a nothrow move assignment operator, otherwise it holds false.

is_trivially_copy_assignable

Tests whether the type has a trivial copy assignment operator.

```
template <class Ty>
struct is_trivially_copy_assignable;
```

Parameters

T

The type to query.

Remarks

An instance of the type predicate holds true if the type T is a class that has a trivial copy assignment operator, otherwise it holds false.

An assignment constructor for a class T is trivial if it is implicitly provided, the class T has no virtual functions, the class T has no virtual bases, the classes of all the non-static data members of class type have trivial assignment operators, and the classes of all the non-static data members of type array of class have trivial assignment operators.

is_trivially_move_assignable

Tests whether the type has a trivial move assignment operator.

```
template <class Ty>
struct is_trivially_move_assignable;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type Ty is a class that has a trivial move assignment operator,

otherwise it holds false.

A move assignment operator for a class *Ty* is trivial if:

it is implicitly provided

the class *Ty* has no virtual functions

the class *Ty* has no virtual bases

the classes of all the non-static data members of class type have trivial move assignment operators

the classes of all the non-static data members of type array of class have trivial move assignment operators

is_trivially_move_constructible

Tests if type has trivial move constructor.

```
template <class Ty>
struct is_trivially_move_constructible;
```

Parameters

Ty

The type to query.

Remarks

An instance of the type predicate holds true if the type *Ty* is a class that has a trivial move constructor, otherwise it holds false.

A move constructor for a class *Ty* is trivial if:

it is implicitly declared

its parameter types are equivalent to those of an implicit declaration

the class *Ty* has no virtual functions

the class *Ty* has no virtual bases

the class has no volatile non-static data members

all the direct bases of the class *Ty* have trivial move constructors

the classes of all the non-static data members of class type have trivial move constructors

the classes of all the non-static data members of type array of class have trivial move constructors

[<type_traits>](#)

<type_traits> typedefs

10/31/2018 • 2 minutes to read • [Edit Online](#)

false_type

true_type

false_type Typedef

Holds integral constant with false value.

```
typedef integral_constant<bool, false> false_type;
```

Remarks

The type is a synonym for a specialization of the template `integral_constant`.

Example

```
#include <type_traits>
#include <iostream>

int main() {
    std::cout << "false_type == " << std::boolalpha
               << std::false_type::value << std::endl;
    std::cout << "true_type == " << std::boolalpha
               << std::true_type::value << std::endl;

    return (0);
}
```

```
false_type == false
true_type == true
```

true_type Typedef

Holds integral constant with true value.

```
typedef integral_constant<bool, true> true_type;
```

Remarks

The type is a synonym for a specialization of the template `integral_constant`.

Example

```
// std__type_traits__true_type.cpp
// compile with: /EHsc
#include <type_traits>
#include <iostream>

int main() {
    std::cout << "false_type == " << std::boolalpha
        << std::false_type::value << std::endl;
    std::cout << "true_type == " << std::boolalpha
        << std::true_type::value << std::endl;

    return (0);
}
```

```
false_type == false
true_type == true
```

See also

[`<type_traits>`](#)

<typeindex>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Include the standard header <typeindex> to define a class and function that support the indexing of objects of class `type_info`.

Syntax

```
#include <typeindex>
```

Remarks

The [hash Structure](#) defines a `hash function` that's suitable for mapping values of type `type_index` to a distribution of index values.

The `type_index` class wraps a pointer to a `type_info` object to assist in indexing.

See also

[Header Files Reference](#)

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

hash Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

The template class defines its method as returning `val.hash_code()`. The method defines a hash function that is used to map values of type `type_index` to a distribution of index values.

Syntax

```
template <>
struct hash<type_index>
: public unary_function<type_index, size_t>
{ // hashes a typeinfo object
    size_t operator()(type_index val) const;

};
```

See also

[<typeindex>](#)

type_index Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

The `type_index` class wraps a pointer to [type_info Class](#) to assist in indexing by such objects.

```
class type_index { public: type_index(const type_info& tinfo); const char *name() const; size_t hash_code() const;
bool operator==(const type_info& right) const; bool operator!=(const type_info& right) const; bool
operator<(const type_info& right) const; bool operator<=(const type_info& right) const; bool operator>(const
type_info& right) const; bool operator>=(const type_info& right) const; };
```

The constructor initializes `ptr` to `&tinfo`.

`name` returns `ptr->name()`.

`hash_code` returns `ptr->hash_code()`.

`operator==` returns `*ptr == right.ptr`.

`operator!=` returns `!(*this == right)`.

`operator<` returns `*ptr->before(*right.ptr)`.

`operator<=` returns `!(right < *this)`.

`operator>` returns `right < *this`.

`operator>=` returns `!(*this < right)`.

[Run-Time Type Information](#)

[<typeindex>](#)

<typeinfo>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Include the standard header <typeinfo> to define several types associated with the type-identification operator [typeid Operator](#), which yields information about both static and dynamic types.

Syntax

```
#include <typeinfo>
```

Remarks

For information on classes defined in <typeinfo>, see the following topics:

- [bad_cast Exception](#)
- [bad_typeid Exception](#)
- [type_info Class](#)

<unordered_map>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template classes [unordered_map](#) and [unordered_multimap](#) and their supporting templates.

Syntax

```
#include <unordered_map>
```

Classes

CLASS	DESCRIPTION
unordered_map Class	Stores hash table of {key, mapped} pairs.
unordered_multimap Class	Stores hash table of {key, mapped} pairs.

Functions

FUNCTION	DESCRIPTION
operator!=	Tests if the unordered_map object on the left side of the operator is not equal to the unordered_map object on the right side.
operator==	Tests if the unordered_map object on the left side of the operator is equal to the unordered_map object on the right side.
swap Function (unordered_map)	Swaps two maps.
operator!=	Tests if the unordered_multimap object on the left side of the operator is not equal to the unordered_multimap object on the right side.
operator==	Tests if the unordered_multimap object on the left side of the operator is equal to the unordered_multimap object on the right side.
swap Function (unordered_map)	Swaps two multimaps.

[unordered_multiset Class](#)

[unordered_set Class](#)

<unordered_map> functions

11/9/2018 • 2 minutes to read • [Edit Online](#)

[swap \(unordered_map\)](#)

[swap \(unordered_multimap\)](#)

swap (unordered_map)

Swaps the contents of two containers.

```
template <class Key, class Ty, class Hash, class Pred, class Alloc>
void swap(
    unordered_map <Key, Ty, Hash, Pred, Alloc>& left,
    unordered_map <Key, Ty, Hash, Pred, Alloc>& right);
```

Parameters

Key

The key type.

Ty

The mapped type.

Hash

The hash function object type.

Pred

The equality comparison function object type.

Alloc

The allocator class.

left

The first container to swap.

right

The second container to swap.

Remarks

The template function executes `left.unordered_map::swap(right)`.

Example

```

// std__unordered_map__u_m_swap.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    Mymap c2;

    c2.insert(Mymap::value_type('d', 4));
    c2.insert(Mymap::value_type('e', 5));
    c2.insert(Mymap::value_type('f', 6));

    c1.swap(c2);

    // display contents " [f 6] [e 5] [d 4]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    swap(c1, c2);

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[f, 6] [e, 5] [d, 4]
[c, 3] [b, 2] [a, 1]

```

swap (unordered_multimap)

Swaps the contents of two containers.

```

template <class Key, class Ty, class Hash, class Pred, class Alloc>
void swap(
    unordered_multimap <Key, Ty, Hash, Pred, Alloc>& left,
    unordered_multimap <Key, Ty, Hash, Pred, Alloc>& right);

```

Parameters

Key

The key type.

Ty

The mapped type.

Hash

The hash function object type.

Pred

The equality comparison function object type.

Alloc

The allocator class.

left

The first container to swap.

right

The second container to swap.

Remarks

The template function executes `left. unordered_multimap::swap (right) .`

Example

```

// std__unordered_map__u__mm_swap.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    Mymap c2;

    c2.insert(Mymap::value_type('d', 4));
    c2.insert(Mymap::value_type('e', 5));
    c2.insert(Mymap::value_type('f', 6));

    c1.swap(c2);

    // display contents " [f 6] [e 5] [d 4]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    swap(c1, c2);

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[f, 6] [e, 5] [d, 4]
[c, 3] [b, 2] [a, 1]

```

[<unordered_map>](#)

<unordered_map> operators

11/9/2018 • 4 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator==</code>	<code>operator!=</code>	<code>operator==</code>

operator!=

Tests whether the `unordered_map` object on the left side of the operator is not equal to the `unordered_map` object on the right side.

```
bool operator!=(const unordered_map <Key, Type, Hash, Pred, Allocator>& left, const unordered_map <Key, Type, Hash, Pred, Allocator>& right);
```

Parameters

left

An object of type `unordered_map`.

right

An object of type `unordered_map`.

Return Value

true if the `unordered_maps` are not equal; **false** if they are equal.

Remarks

The comparison between `unordered_map` objects is not affected by the arbitrary order in which they store their elements. Two `unordered_maps` are equal if they have the same number of elements and the elements in one container are a permutation of the elements in the other container. Otherwise, they are unequal.

Example

```
// unordered_map_op_ne.cpp
// compile by using: cl.exe /EHsc /nologo /W4 /MTd
#include <unordered_map>
#include <iostream>
#include <ios>

int main( )
{
    using namespace std;
    unordered_map<int, int> um1, um2, um3;

    for ( int i = 0 ; i < 3 ; ++i ) {
        um1.insert( make_pair( i+1, i ) );
        um1.insert( make_pair( i, i ) );

        um2.insert( make_pair( i, i+1 ) );
        um2.insert( make_pair( i, i ) );

        um3.insert( make_pair( i, i ) );
        um3.insert( make_pair( i+1, i ) );
    }

    cout << boolalpha;
    cout << "um1 != um2: " << (um1 != um2) << endl;
    cout << "um1 != um3: " << (um1 != um3) << endl;
    cout << "um2 != um3: " << (um2 != um3) << endl;
}
```

Output:

```
um1 != um2: true
```

```
um1 != um3: false
```

```
um2 != um3: true
```

operator==

Tests whether the [unordered_map](#) object on the left side of the operator is equal to the `unordered_map` object on the right side.

```
bool operator==(const unordered_map <Key, Type, Hash, Pred, Allocator>& left, const unordered_map <Key, Type, Hash, Pred, Allocator>& right);
```

Parameters

left

An object of type `unordered_map`.

right

An object of type `unordered_map`.

Return Value

true if the `unordered_maps` are equal; **false** if they are not equal.

Remarks

The comparison between `unordered_map` objects is not affected by the arbitrary order in which they store their elements. Two `unordered_maps` are equal if they have the same number of elements and the elements in one container are a permutation of the elements in the other container. Otherwise, they are unequal.

Example

```

// unordered_map_op_eq.cpp
// compile by using: cl.exe /EHsc /nologo /W4 /MTd
#include <unordered_map>
#include <iostream>
#include <ios>

int main( )
{
    using namespace std;
    unordered_map<int, int> um1, um2, um3;

    for ( int i = 0 ; i < 3 ; ++i ) {
        um1.insert( make_pair( i+1, i ) );
        um1.insert( make_pair( i, i ) );

        um2.insert( make_pair( i, i+1 ) );
        um2.insert( make_pair( i, i ) );

        um3.insert( make_pair( i, i ) );
        um3.insert( make_pair( i+1, i ) );
    }

    cout << boolalpha;
    cout << "um1 == um2: " << (um1 == um2) << endl;
    cout << "um1 == um3: " << (um1 == um3) << endl;
    cout << "um2 == um3: " << (um2 == um3) << endl;
}

```

Output:

```
um1 == um2: false
```

```
um1 == um3: true
```

```
um2 == um3: false
```

operator!=

Tests whether the [unordered_multimap](#) object on the left side of the operator is not equal to the [unordered_multimap](#) object on the right side.

```

bool operator!=(const unordered_multimap<Key, Type, Hash, Pred, Allocator>& left, const unordered_multimap<Key, Type, Hash, Pred, Allocator>& right);

```

Parameters

left

An object of type `unordered_multimap` .

right

An object of type `unordered_multimap` .

Return Value

true if the [unordered_multimaps](#) are not equal; **false** if they are equal.

Remarks

The comparison between [unordered_multimap](#) objects is not affected by the arbitrary order in which they store their elements. Two [unordered_multimaps](#) are equal if they have the same number of elements and the elements in one container are a permutation of the elements in the other container. Otherwise, they are not equal.

Example

```
// unordered_multimap_op_ne.cpp
// compile by using: cl.exe /EHsc /nologo /W4 /MTd
#include <unordered_map>
#include <iostream>
#include <ios>

int main( )
{
    using namespace std;
    unordered_multimap<int, int> um1, um2, um3;

    for ( int i = 0 ; i < 3 ; ++i ) {
        um1.insert( make_pair( i, i ) );
        um1.insert( make_pair( i, i ) );

        um2.insert( make_pair( i, i ) );
        um2.insert( make_pair( i, i ) );
        um2.insert( make_pair( i, i ) );

        um3.insert( make_pair( i, i ) );
        um3.insert( make_pair( i, i ) );
    }

    cout << boolalpha;
    cout << "um1 != um2: " << (um1 != um2) << endl;
    cout << "um1 != um3: " << (um1 != um3) << endl;
    cout << "um2 != um3: " << (um2 != um3) << endl;
}
```

Output:

```
um1 != um2: true
```

```
um1 != um3: false
```

```
um2 != um3: true
```

operator==

Tests whether the [unordered_multimap](#) object on the left side of the operator is equal to the `unordered_multimap` object on the right side.

```
bool operator==(const unordered_multimap <Key, Type, Hash, Pred, Allocator>& left, const unordered_multimap
<Key, Type, Hash, Pred, Allocator>& right);
```

Parameters

left

An object of type `unordered_multimap` .

right

An object of type `unordered_multimap` .

Return Value

true if the `unordered_multimaps` are equal; **false** if they are not equal.

Remarks

The comparison between `unordered_multimap` objects is not affected by the arbitrary order in which they store their elements. Two `unordered_multimaps` are equal if they have the same number of elements and the elements in one container are a permutation of the elements in the other container. Otherwise, they are unequal.

Example

```
// unordered_multimap_op_eq.cpp
// compile by using: cl.exe /EHsc /nologo /W4 /MTd
#include <unordered_map>
#include <iostream>
#include <ios>

int main( )
{
    using namespace std;
    unordered_multimap<int, int> um1, um2, um3;

    for ( int i = 0 ; i < 3 ; ++i ) {
        um1.insert( make_pair( i, i ) );
        um1.insert( make_pair( i, i ) );

        um2.insert( make_pair( i, i ) );
        um2.insert( make_pair( i, i ) );
        um2.insert( make_pair( i, i ) );

        um3.insert( make_pair( i, i ) );
        um3.insert( make_pair( i, i ) );
    }

    cout << boolalpha;
    cout << "um1 == um2: " << (um1 == um2) << endl;
    cout << "um1 == um3: " << (um1 == um3) << endl;
    cout << "um2 == um3: " << (um2 == um3) << endl;
}
```

Output:

```
um1 == um2: false
```

```
um1 == um3: true
```

```
um2 == um3: false
```

[<unordered_map>](#)

unordered_map Class

11/9/2018 • 45 minutes to read • [Edit Online](#)

The template class describes an object that controls a varying-length sequence of elements of type `std::pair<const Key, Ty>`. The sequence is weakly ordered by a hash function, which partitions the sequence into an ordered set of subsequences called buckets. Within each bucket a comparison function determines whether any pair of elements has equivalent ordering. Each element stores two objects, a sort key and a value. The sequence is represented in a way that permits lookup, insertion, and removal of an arbitrary element with a number of operations that can be independent of the number of elements in the sequence (constant time), at least when all buckets are of roughly equal length. In the worst case, when all of the elements are in one bucket, the number of operations is proportional to the number of elements in the sequence (linear time). Moreover, inserting an element invalidates no iterators, and removing an element invalidates only those iterators which point at the removed element.

Syntax

```
template <class Key,  
          class Ty,  
          class Hash = std::hash<Key>,  
          class Pred = std::equal_to<Key>,  
          class Alloc = std::allocator<std::pair<const Key, Ty>>>  
class unordered_map;
```

Parameters

PARAMETER	DESCRIPTION
<i>Key</i>	The key type.
<i>Ty</i>	The mapped type.
<i>Hash</i>	The hash function object type.
<i>Pred</i>	The equality comparison function object type.
<i>Alloc</i>	The allocator class.

Members

TYPE DEFINITION	DESCRIPTION
allocator_type	The type of an allocator for managing storage.
const_iterator	The type of a constant iterator for the controlled sequence.
const_local_iterator	The type of a constant bucket iterator for the controlled sequence.

TYPE DEFINITION	DESCRIPTION
<code>const_pointer</code>	The type of a constant pointer to an element.
<code>const_reference</code>	The type of a constant reference to an element.
<code>difference_type</code>	The type of a signed distance between two elements.
<code>hasher</code>	The type of the hash function.
<code>iterator</code>	The type of an iterator for the controlled sequence.
<code>key_equal</code>	The type of the comparison function.
<code>key_type</code>	The type of an ordering key.
<code>local_iterator</code>	The type of a bucket iterator for the controlled sequence.
<code>mapped_type</code>	The type of a mapped value associated with each key.
<code>pointer</code>	The type of a pointer to an element.
<code>reference</code>	The type of a reference to an element.
<code>size_type</code>	The type of an unsigned distance between two elements.
<code>value_type</code>	The type of an element.
MEMBER FUNCTION	DESCRIPTION
<code>at</code>	Finds an element with the specified key.
<code>begin</code>	Designates the beginning of the controlled sequence.
<code>bucket</code>	Gets the bucket number for a key value.
<code>bucket_count</code>	Gets the number of buckets.
<code>bucket_size</code>	Gets the size of a bucket.
<code>cbegin</code>	Designates the beginning of the controlled sequence.
<code>cend</code>	Designates the end of the controlled sequence.
<code>clear</code>	Removes all elements.
<code>count</code>	Finds the number of elements matching a specified key.
<code>emplace</code>	Adds an element constructed in place.

MEMBER FUNCTION	DESCRIPTION
<code>emplace_hint</code>	Adds an element constructed in place, with hint.
<code>empty</code>	Tests whether no elements are present.
<code>end</code>	Designates the end of the controlled sequence.
<code>equal_range</code>	Finds range that matches a specified key.
<code>erase</code>	Removes elements at specified positions.
<code>find</code>	Finds an element that matches a specified key.
<code>get_allocator</code>	Gets the stored allocator object.
<code>hash_function</code>	Gets the stored hash function object.
<code>insert</code>	Adds elements.
<code>key_eq</code>	Gets the stored comparison function object.
<code>load_factor</code>	Counts the average elements per bucket.
<code>max_bucket_count</code>	Gets the maximum number of buckets.
<code>max_load_factor</code>	Gets or sets the maximum elements per bucket.
<code>max_size</code>	Gets the maximum size of the controlled sequence.
<code>rehash</code>	Rebuilds the hash table.
<code>size</code>	Counts the number of elements.
<code>swap</code>	Swaps the contents of two containers.
<code>unordered_map</code>	Constructs a container object.

OPERATOR	DESCRIPTION
<code>unordered_map::operator[]</code>	Finds or inserts an element with the specified key.
<code>unordered_map::operator=</code>	Copies a hash table.

Remarks

The object orders the sequence it controls by calling two stored objects, a comparison function object of type `unordered_map::key_equal` and a hash function object of type `unordered_map::hasher`. You access the first stored object by calling the member function `unordered_map::key_eq()`; and you access the second stored object by calling the member function `unordered_map::hash_function()`. Specifically, for all values `x` and `y` of type `key`, the call `key_eq()(x, y)` returns true only if the two argument values have equivalent ordering; the call `hash_function()(keyval)` yields a distribution of

values of type `size_t`. Unlike template class [unordered_multimap Class](#), an object of template class `unordered_map` ensures that `key_eq()(X, Y)` is always false for any two elements of the controlled sequence. (Keys are unique.)

The object also stores a maximum load factor, which specifies the maximum desired average number of elements per bucket. If inserting an element causes `unordered_map::load_factor()` to exceed the maximum load factor, the container increases the number of buckets and rebuilds the hash table as needed.

The actual order of elements in the controlled sequence depends on the hash function, the comparison function, the order of insertion, the maximum load factor, and the current number of buckets. You cannot in general predict the order of elements in the controlled sequence. You can always be assured, however, that any subset of elements that have equivalent ordering are adjacent in the controlled sequence.

The object allocates and frees storage for the sequence it controls through a stored allocator object of type `unordered_map::allocator_type`. Such an allocator object must have the same external interface as an object of template class `allocator`. Note that the stored allocator object is not copied when the container object is assigned.

Requirements

Header: `<unordered_map>`

Namespace: `std`

`unordered_map::allocator_type`

The type of an allocator for managing storage.

```
typedef Alloc allocator_type;
```

Remarks

The type is a synonym for the template parameter `Alloc`.

Example

```
// std__unordered_map__unordered_map_allocator_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
typedef std::allocator<std::pair<const char, int> > Myalloc;
int main()
{
    Mymap c1;

    Mymap::allocator_type al = c1.get_allocator();
    std::cout << "al == std::allocator() is "
        << std::boolalpha << (al == Myalloc()) << std::endl;

    return (0);
}
```

```
al == std::allocator() is true
```

unordered_map::at

Finds an element in a unordered_map with a specified key value.

```
Ty& at(const Key& key);  
const Ty& at(const Key& key) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>key</i>	The key value to find.

Return Value

A reference to the data value of the element found.

Remarks

If the argument key value is not found, then the function throws an object of class `out_of_range`.

Example

```
// unordered_map_at.cpp  
// compile with: /EHsc  
#include <unordered_map>  
#include <iostream>  
  
typedef std::unordered_map<char, int> Mymap;  
typedef std::unordered_map<char, int> Mymap;  
int main()  
{  
    Mymap c1;  
  
    c1.insert(Mymap::value_type('a', 1));  
    c1.insert(Mymap::value_type('b', 2));  
    c1.insert(Mymap::value_type('c', 3));  
  
    // find and show elements  
    std::cout << "c1.at('a') == " << c1.at('a') << std::endl;  
    std::cout << "c1.at('b') == " << c1.at('b') << std::endl;  
    std::cout << "c1.at('c') == " << c1.at('c') << std::endl;  
  
    return (0);  
}
```

unordered_map::begin

Designates the beginning of the controlled sequence or a bucket.

```
iterator begin();  
const_iterator begin() const;  
local_iterator begin(size_type nbucket);  
const_local_iterator begin(size_type nbucket) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>nbucket</i>	The bucket number.

Remarks

The first two member functions return a forward iterator that points at the first element of the sequence (or just beyond the end of an empty sequence). The last two member functions return a forward iterator that points at the first element of bucket *nbucket* (or just beyond the end of an empty bucket).

Example

```
// std__unordered_map__unordered_map_begin.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    // inspect first two items " [c 3] [b 2]"
    Mymap::iterator it2 = c1.begin();
    std::cout << " [" << it2->first << ", " << it2->second << "]\n";
    ++it2;
    std::cout << " [" << it2->first << ", " << it2->second << "]\n";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Mymap::const_local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << " [" << lit->first << ", " << lit->second << "]\n";

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
[c, 3] [b, 2]
[a, 1]
```

unordered_map::bucket

Gets the bucket number for a key value.

```
size_type bucket(const Key& keyval) const;
```

Parameters

keyval

The key value to map.

Remarks

The member function returns the bucket number currently corresponding to the key value *keyval*.

Example

```
// std__unordered_map__unordered_map_bucket.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // display buckets for keys
    Mymap::size_type bs = c1.bucket('a');
    std::cout << "bucket('a') == " << bs << std::endl;
    std::cout << "bucket_size(" << bs << ") == " << c1.bucket_size(bs)
               << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
bucket('a') == 7
bucket_size(7) == 1
```

unordered_map::bucket_count

Gets the number of buckets.

```
size_type bucket_count() const;
```

Remarks

The member function returns the current number of buckets.

Example

```

// std_unordered_map__unordered_map_bucket_count.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```

[c, 3][b, 2][a, 1]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1

```

unordered_map::bucket_size

Gets the size of a bucket

```
size_type bucket_size(size_type nbucket) const;
```

Parameters

nbucket

The bucket number.

Remarks

The member functions returns the size of bucket number *nbucket*.

Example

```

// std__unordered_map__unordered_map_bucket_size.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    // display buckets for keys
    Mymap::size_type bs = c1.bucket('a');
    std::cout << "bucket('a') == " << bs << std::endl;
    std::cout << "bucket_size(" << bs << ") == " << c1.bucket_size(bs)
        << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
bucket('a') == 7
bucket_size(7) == 1
```

unordered_map::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** forward-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin`, the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

unordered_map::cend

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A **const** forward-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();
// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

unordered_map::clear

Removes all elements.

```
void clear();
```

Remarks

The member function calls `unordered_map::erase` (`unordered_map::begin` (), `unordered_map::end` ()) .

Example

```
// std_unordered_map_unordered_map_clear.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]" ;
    std::cout << std::endl;

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert(Mymap::value_type('d', 4));
    c1.insert(Mymap::value_type('e', 5));

    // display contents " [e 5] [d 4]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]" ;
    std::cout << std::endl;

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
size == 0
empty() == true

[e, 5] [d, 4]
size == 2
empty() == false
```

unordered_map::const_iterator

The type of a constant iterator for the controlled sequence.

```
typedef T1 const_iterator;
```

Remarks

The type describes an object that can serve as a constant forward iterator for the controlled sequence. It is described here as a synonym for the implementation-defined type `T1`.

Example

```
// std_unordered_map_unordered_map_const_iterator.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";
    std::cout << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
```

unordered_map::const_local_iterator

The type of a constant bucket iterator for the controlled sequence.

```
typedef T5 const_local_iterator;
```

Remarks

The type describes an object that can serve as a constant forward iterator for a bucket. It is described here as a synonym for the implementation-defined type `T5`.

Example

```

// std__unordered_map__unordered_map_const_local_iterator.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<
        std::cout << std::endl;

    // inspect bucket containing 'a'
    Mymap::const_local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << " [" << lit->first << ", " << lit->second << "]"<

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[a, 1]

```

unordered_map::const_pointer

The type of a constant pointer to an element.

```

typedef Alloc::const_pointer const_pointer;

```

Remarks

The type describes an object that can serve as a constant pointer to an element of the controlled sequence.

Example

```

// std__unordered_map__unordered_map_const_pointer.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Mymap::const_pointer p = &*it;
        std::cout << " [" << p->first << ", " << p->second << "]"<< "\n";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
```

unordered_map::const_reference

The type of a constant reference to an element.

```
typedef Alloc::const_reference const_reference;
```

Remarks

The type describes an object that can serve as a constant reference to an element of the controlled sequence.

Example

```

// std__unordered_map__unordered_map_const_reference.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Mymap::const_reference ref = *it;
        std::cout << " [" << ref.first << ", " << ref.second << "]"<< "\n";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
```

unordered_map::count

Finds the number of elements matching a specified key.

```
size_type count(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns the number of elements in the range delimited by [unordered_map::equal_range](#) (`keyval`) .

Example

```

// std__unordered_map__unordered_map_count.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    std::cout << "count('A') == " << c1.count('A') << std::endl;
    std::cout << "count('b') == " << c1.count('b') << std::endl;
    std::cout << "count('C') == " << c1.count('C') << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
count('A') == 0
count('b') == 1
count('C') == 0

```

unordered_map::difference_type

The type of a signed distance between two elements.

```
typedef T3 difference_type;
```

Remarks

The signed integer type describes an object that can represent the difference between the addresses of any two elements in the controlled sequence. It is described here as a synonym for the implementation-defined type `T3`.

Example

```

// std_unordered_map_unordered_map_difference_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // compute positive difference
    Mymap::difference_type diff = 0;
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        ++diff;
    std::cout << "end()-begin() == " << diff << std::endl;

    // compute negative difference
    diff = 0;
    for (Mymap::const_iterator it = c1.end();
         it != c1.begin(); --it)
        --diff;
    std::cout << "begin()-end() == " << diff << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
end()-begin() == 3
begin()-end() == -3

```

unordered_map::emplace

Inserts an element constructed in place (no copy or move operations are performed) into an unordered_map.

```

template <class... Args>
pair<iterator, bool> emplace( Args&&... args);

```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the unordered_map unless it already contains an element whose value is equivalently ordered.

Return Value

A `pair` whose **bool** component returns true if an insertion was made and false if the `unordered_map` already contained an element whose key had an equivalent value in the ordering, and whose iterator component returns the address where a new element was inserted or where the element was already located.

To access the iterator component of a pair `pr` returned by this member function, use `pr.first`, and to dereference it, use `*(pr.first)`. To access the **bool** component of a pair `pr` returned by this member function, use `pr.second`.

Remarks

No iterators or references are invalidated by this function.

During the insertion, if an exception is thrown but does not occur in the container's hash function, the container is not modified. If the exception is thrown in the hash function, the result is undefined.

For a code example, see [map::emplace](#).

unordered_map::emplace_hint

Inserts an element constructed in place (no copy or move operations are performed), with a placement hint.

```
template <class... Args>
iterator emplace_hint(const_iterator where, Args&&... args);
```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the <code>unordered_map</code> unless the <code>unordered_map</code> already contains that element or, more generally, unless it already contains an element whose key is equivalently ordered.
<i>where</i>	A hint regarding the place to start searching for the correct point of insertion.

Return Value

An iterator to the newly inserted element.

If the insertion failed because the element already exists, returns an iterator to the existing element.

Remarks

No references are invalidated by this function.

During the insertion, if an exception is thrown but does not occur in the container's hash function, the container is not modified. If the exception is thrown in the hash function, the result is undefined.

The [value_type](#) of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

For a code example, see [map::emplace_hint](#).

unordered_map::empty

Tests whether no elements are present.

```
bool empty() const;
```

Remarks

The member function returns true for an empty controlled sequence.

Example

```
// std__unordered_map__unordered_map_empty.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << "\n";
    std::cout << "empty() == " << std::boolalpha << c1.empty() << "\n";
    std::cout << "\n";

    c1.insert(Mymap::value_type('d', 4));
    c1.insert(Mymap::value_type('e', 5));

    // display contents " [e 5] [d 4]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    std::cout << "size == " << c1.size() << "\n";
    std::cout << "empty() == " << std::boolalpha << c1.empty() << "\n";

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
size == 0
empty() == true

[e, 5] [d, 4]
size == 2
empty() == false
```

unordered_map::end

Designates the end of the controlled sequence.

```
iterator end();
const_iterator end() const;
local_iterator end(size_type nbucket);
const_local_iterator end(size_type nbucket) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>nbucket</i>	The bucket number.

Remarks

The first two member functions return a forward iterator that points just beyond the end of the sequence. The last two member functions return a forward iterator that points just beyond the end of bucket *nbucket*.

unordered_map::equal_range

Finds range that matches a specified key.

```
std::pair<iterator, iterator> equal_range(const Key& keyval);
std::pair<const_iterator, const_iterator> equal_range(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns a pair of iterators `x` such that `[x.first, x.second)` delimits just those elements of the controlled sequence that have equivalent ordering with *keyval*. If no such elements exist, both iterators are `end()` .

Example

```

// std_unordered_map__unordered_map_equal_range.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // display results of failed search
    std::pair<Mymap::iterator, Mymap::iterator> pair1 =
        c1.equal_range('x');
    std::cout << "equal_range('x'):";
    for (; pair1.first != pair1.second; ++pair1.first)
        std::cout << " [" << pair1.first->first
        << ", " << pair1.first->second << "]"
        std::cout << std::endl;

    // display results of successful search
    pair1 = c1.equal_range('b');
    std::cout << "equal_range('b'):";
    for (; pair1.first != pair1.second; ++pair1.first)
        std::cout << " [" << pair1.first->first
        << ", " << pair1.first->second << "]"
        std::cout << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
equal_range('x'):
equal_range('b'): [b, 2]

```

unordered_map::erase

Removes an element or a range of elements in a unordered_map from specified positions or removes elements that match a specified key.

```

iterator erase(const_iterator Where);
iterator erase(const_iterator First, const_iterator Last);
size_type erase(const key_type& Key);

```

Parameters

Where

Position of the element to be removed.

First

Position of the first element to be removed.

Last

Position just beyond the last element to be removed.

Key

The key value of the elements to be removed.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or an element that is the end of the map if no such element exists.

For the third member function, returns the number of elements that have been removed from the `unordered_map`.

Remarks

For a code example, see [map::erase](#).

`unordered_map::find`

Finds an element that matches a specified key.

```
const_iterator find(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns [unordered_map::equal_range](#)(`keyval`).first .

Example

```

// std__unordered_map__unordered_map_find.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // try to find and fail
    std::cout << "find('A') == "
        << std::boolalpha << (c1.find('A') != c1.end()) << std::endl;

    // try to find and succeed
    Mymap::iterator it = c1.find('b');
    std::cout << "find('b') == "
        << std::boolalpha << (it != c1.end())
        << ": [" << it->first << ", " << it->second << "]" << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
find('A') == false
find('b') == true: [b, 2]

```

unordered_map::get_allocator

Gets the stored allocator object.

```

Alloc get_allocator() const;

```

Remarks

The member function returns the stored allocator object.

Example

```
// std__unordered_map__unordered_map_get_allocator.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
typedef std::allocator<std::pair<const char, int> > Myalloc;
int main()
{
    Mymap c1;

    Mymap::allocator_type al = c1.get_allocator();
    std::cout << "al == std::allocator() is "
        << std::boolalpha << (al == Myalloc()) << std::endl;

    return (0);
}
```

```
al == std::allocator() is true
```

unordered_map::hash_function

Gets the stored hash function object.

```
Hash hash_function() const;
```

Remarks

The member function returns the stored hash function object.

Example

```
// std__unordered_map__unordered_map_hash_function.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    Mymap::hasher hfn = c1.hash_function();
    std::cout << "hfn('a') == " << hfn('a') << std::endl;
    std::cout << "hfn('b') == " << hfn('b') << std::endl;

    return (0);
}
```

```
hfn('a') == 1630279
hfn('b') == 1647086
```

unordered_map::hasher

The type of the hash function.

```
typedef Hash hasher;
```

Remarks

The type is a synonym for the template parameter `Hash`.

Example

```
// std_unordered_map_unordered_map_hasher.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    Mymap::hasher hfn = c1.hash_function();
    std::cout << "hfn('a') == " << hfn('a') << std::endl;
    std::cout << "hfn('b') == " << hfn('b') << std::endl;

    return (0);
}
```

```
hfn('a') == 1630279
hfn('b') == 1647086
```

unordered_map::insert

Inserts an element or a range of elements into an unordered_map.

```
// (1) single element
pair<iterator, bool> insert(    const value_type& Val);

// (2) single element, perfect forwarded
template <class ValTy>
pair<iterator, bool>
insert(    ValTy&& Val);

// (3) single element with hint
iterator insert(    const_iterator Where,
    const value_type& Val);

// (4) single element, perfect forwarded, with hint
template <class ValTy>
iterator insert(    const_iterator Where,
    ValTy&& Val);

// (5) range
template <class InputIterator>
void insert(InputIterator First,
    InputIterator Last);

// (6) initializer list
void insert(initializer_list<value_type>
    IList);
```

Parameters

PARAMETER	DESCRIPTION
<i>Val</i>	The value of an element to be inserted into the <code>unordered_map</code> unless it already contains an element whose key is equivalently ordered.
<i>Where</i>	The place to start searching for the correct point of insertion.
<i>ValTy</i>	Template parameter that specifies the argument type that the <code>unordered_map</code> can use to construct an element of <code>value_type</code> , and perfect-forwards <i>Val</i> as an argument.
<i>First</i>	The position of the first element to be copied.
<i>Last</i>	The position just beyond the last element to be copied.
<i>InputIterator</i>	Template function argument that meets the requirements of an <code>input iterator</code> that points to elements of a type that can be used to construct <code>value_type</code> objects.
<i>lList</i>	The <code>initializer_list</code> from which to copy the elements.

Return Value

The single-element member functions, (1) and (2), return a `pair` whose `bool` component is true if an insertion was made, and false if the `unordered_map` already contained an element whose key had an equivalent value in the ordering. The iterator component of the return-value pair points to the newly inserted element if the `bool` component is true, or to the existing element if the `bool` component is false.

The single-element-with-hint member functions, (3) and (4), return an iterator that points to the position where the new element was inserted into the `unordered_map` or, if an element with an equivalent key already exists, to the existing element.

Remarks

No iterators, pointers, or references are invalidated by this function.

During the insertion of just one element, if an exception is thrown but does not occur in the container's hash function, the container's state is not modified. If the exception is thrown in the hash function, the result is undefined. During the insertion of multiple elements, if an exception is thrown, the container is left in an unspecified but valid state.

To access the iterator component of a `pair` `pr` that's returned by the single-element member functions, use `pr.first`; to dereference the iterator within the returned pair, use `*pr.first`, giving you an element. To access the `bool` component, use `pr.second`. For an example, see the sample code later in this article.

The `value_type` of a container is a typedef that belongs to the container, and for `map`, `map<K, V>::value_type` is `pair<const K, V>`. The value of an element is an ordered pair in which the first component is equal to the key value and the second component is equal to the data value of the element.

The range member function (5) inserts the sequence of element values into an `unordered_map` that

corresponds to each element addressed by an iterator in the range `[First, Last)`; therefore, `Last` does not get inserted. The container member function `end()` refers to the position just after the last element in the container—for example, the statement `m.insert(v.begin(), v.end());` attempts to insert all elements of `v` into `m`. Only elements that have unique values in the range are inserted; duplicates are ignored. To observe which elements are rejected, use the single-element versions of `insert`.

The initializer list member function (6) uses an [initializer_list](#) to copy elements into the `unordered_map`.

For insertion of an element constructed in place—that is, no copy or move operations are performed—see [unordered_map::emplace](#) and [unordered_map::emplace_hint](#).

For a code example, see [map::insert](#).

unordered_map::iterator

The type of an iterator for the controlled sequence.

```
typedef T0 iterator;
```

Remarks

The type describes an object that can serve as a forward iterator for the controlled sequence. It is described here as a synonym for the implementation-defined type `T0`.

Example

```
// std__unordered_map__unordered_map_iterator.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";
    std::cout << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
```

unordered_map::key_eq

Gets the stored comparison function object.

```
Pred key_eq() const;
```

Remarks

The member function returns the stored comparison function object.

Example

```
// std_unordered_map_unordered_map_key_eq.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    Mymap::key_equal cmpfn = c1.key_eq();
    std::cout << "cmpfn('a', 'a') == "
        << std::boolalpha << cmpfn('a', 'a') << std::endl;
    std::cout << "cmpfn('a', 'b') == "
        << std::boolalpha << cmpfn('a', 'b') << std::endl;

    return (0);
}
```

```
cmpfn('a', 'a') == true
cmpfn('a', 'b') == false
```

unordered_map::key_equal

The type of the comparison function.

```
typedef Pred key_equal;
```

Remarks

The type is a synonym for the template parameter `Pred`.

Example

```
// std__unordered_map__unordered_map_key_equal.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    Mymap::key_equal cmpfn = c1.key_eq();
    std::cout << "cmpfn('a', 'a') == "
        << std::boolalpha << cmpfn('a', 'a') << std::endl;
    std::cout << "cmpfn('a', 'b') == "
        << std::boolalpha << cmpfn('a', 'b') << std::endl;

    return (0);
}
```

```
cmpfn('a', 'a') == true
cmpfn('a', 'b') == false
```

unordered_map::key_type

The type of an ordering key.

```
typedef Key key_type;
```

Remarks

The type is a synonym for the template parameter `Key`.

Example

```

// std__unordered_map__unordered_map_key_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // add a value and reinspect
    Mymap::key_type key = 'd';
    Mymap::mapped_type mapped = 4;
    Mymap::value_type val = Mymap::value_type(key, mapped);
    c1.insert(val);

    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[d, 4] [c, 3] [b, 2] [a, 1]

```

unordered_map::load_factor

Counts the average elements per bucket.

```
float load_factor() const;
```

Remarks

The member function returns `(float) unordered_map::size() / (float) unordered_map::bucket_count()`, the average number of elements per bucket.

Example

```

// std_unordered_map_unordered_map_load_factor.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1

```

unordered_map::local_iterator

The type of a bucket iterator.

```
typedef T4 local_iterator;
```

Remarks

The type describes an object that can serve as a forward iterator for a bucket. It is described here as a synonym for the implementation-defined type `T4`.

Example

```

// std_unordered_map_unordered_map_local_iterator.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Mymap::local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << " [" << lit->first << ", " << lit->second << "]\n";

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[a, 1]

```

unordered_map::mapped_type

The type of a mapped value associated with each key.

```
typedef Ty mapped_type;
```

Remarks

The type is a synonym for the template parameter `Ty`.

Example

```
// std__unordered_map__unordered_map_mapped_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";

    // add a value and reinspect
    Mymap::key_type key = 'd';
    Mymap::mapped_type mapped = 4;
    Mymap::value_type val = Mymap::value_type(key, mapped);
    c1.insert(val);

    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
[d, 4] [c, 3] [b, 2] [a, 1]
```

unordered_map::max_bucket_count

Gets the maximum number of buckets.

```
size_type max_bucket_count() const;
```

Remarks

The member function returns the maximum number of buckets currently permitted.

Example

```

// std_unordered_map_unordered_map_max_bucket_count.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1
```

unordered_map::max_load_factor

Gets or sets the maximum elements per bucket.

```
float max_load_factor() const;

void max_load_factor(float factor);
```

Parameters

factor

The new maximum load factor.

Remarks

The first member function returns the stored maximum load factor. The second member function replaces the stored maximum load factor with *factor*.

Example

```

// std_unordered_map_unordered_map_max_load_factor.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]" << "\n";

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1

```

unordered_map::max_size

Gets the maximum size of the controlled sequence.

```
size_type max_size() const;
```

Remarks

The member function returns the length of the longest sequence that the object can control.

Example

```

// std_unordered_map_unordered_map_max_size.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    std::cout << "max_size() == " << c1.max_size() << std::endl;

    return (0);
}

```

```
max_size() == 536870911
```

unordered_map::operator[]

Finds or inserts an element with the specified key.

```

Ty& operator[](const Key& keyval);

Ty& operator[](Key&& keyval);

```

Parameters

PARAMETER	DESCRIPTION
<i>Keyval</i>	The key value to find or insert.

Return Value

A reference to the data value of the inserted element.

Remarks

If the argument key value is not found, then it is inserted along with the default value of the data type.

`operator[]` may be used to insert elements into a map *m* using `m[Key] = DataValue`; where `DataValue` is the value of the `mapped_type` of the element with a key value of *Key*.

When using `operator[]` to insert elements, the returned reference does not indicate whether an insertion is changing a pre-existing element or creating a new one. The member functions [find](#) and [insert](#) can be used to determine whether an element with a specified key is already present before an insertion.

Example

```
// std_unordered_map_unordered_map_operator_sub.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>
#include <string>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // try to find and fail
    std::cout << "c1['A'] == " << c1['A'] << std::endl;

    // try to find and succeed
    std::cout << "c1['a'] == " << c1['a'] << std::endl;

    // redisplay contents
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // insert by moving key
    std::unordered_map<string, int> c2;
    std::string str("abc");
    std::cout << "c2[std::move(str)] == " << c2[std::move(str)] << std::endl;
    std::cout << "c2[\"abc\"] == " << c2["abc"] << std::endl;

    return (0);
}
```

```

[c, 3] [b, 2] [a, 1]
c1['A'] == 0
c1['a'] == 1
[c, 3] [b, 2] [A, 0] [a, 1]
c2[move(str)] == 0
c2["abc"] == 1

```

Remarks

The member function determines the iterator `where` as the return value of `unordered_map::insert` (`unordered_map::value_type` (`keyval`, `Ty()`)). (It inserts an element with the specified key if no such element exists.) It then returns a reference to `(*where).second`.

unordered_map::operator=

Replaces the elements of this `unordered_map` using the elements from another `unordered_map`.

```

unordered_map& operator=(const unordered_map& right);

unordered_map& operator=(unordered_map&& right);

```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The <code>unordered_map</code> that the operator function assigns content from.

Remarks

The first version copies all of the elements from *right* to this `unordered_map`.

The second version moves all of the elements from *right* to this `unordered_map`.

Any elements that are in this `unordered_map` before `operator =` executes are discarded.

Example

```

// unordered_map_operator_as.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

int main( )
{
    using namespace std;
    unordered_map<int, int> v1, v2, v3;
    unordered_map<int, int>::iterator iter;

    v1.insert(pair<int, int>(1, 10));

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;
}

```

unordered_map::pointer

The type of a pointer to an element.

```
typedef Alloc::pointer pointer;
```

Remarks

The type describes an object that can serve as a pointer to an element of the controlled sequence.

Example

```

// std__unordered_map__unordered_map_pointer.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Mymap::pointer p = &*it;
        std::cout << " [" << p->first << ", " << p->second << "]"<< "\n";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
```

unordered_map::reference

The type of a reference to an element.

```
typedef Alloc::reference reference;
```

Remarks

The type describes an object that can serve as a reference to an element of the controlled sequence.

Example

```

// std__unordered_map__unordered_map_reference.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Mymap::reference ref = *it;
        std::cout << " [" << ref.first << ", " << ref.second << "]"<< "\n";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
```

unordered_map::rehash

Rebuilds the hash table.

```
void rehash(size_type nbuckets);
```

Parameters

nbuckets

The requested number of buckets.

Remarks

The member function alters the number of buckets to be at least *nbuckets* and rebuilds the hash table as needed.

Example

```

// std_unordered_map__unordered_map_rehash.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_load_factor() == " << c1.max_load_factor() << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_load_factor() == " << c1.max_load_factor() << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_load_factor() == " << c1.max_load_factor() << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
bucket_count() == 8
load_factor() == 0.375
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_load_factor() == 0.1

```

unordered_map::size

Counts the number of elements.

```
size_type size() const;
```

Remarks

The member function returns the length of the controlled sequence.

Example

```
// std__unordered_map__unordered_map_size.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<endl;

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert(Mymap::value_type('d', 4));
    c1.insert(Mymap::value_type('e', 5));

    // display contents " [e 5] [d 4]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<endl;

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
size == 0
empty() == true

[e, 5] [d, 4]
size == 2
empty() == false
```

unordered_map::size_type

The type of an unsigned distance between two elements.

```
typedef T2 size_type;
```

Remarks

The unsigned integer type describes an object that can represent the length of any controlled

sequence. It is described here as a synonym for the implementation-defined type `T2`.

Example

```
// std__unordered_map__unordered_map_size_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;
    Mymap::size_type sz = c1.size();

    std::cout << "size == " << sz << std::endl;

    return (0);
}
```

```
size == 0
```

unordered_map::swap

Swaps the contents of two containers.

```
void swap(unordered_map& right);
```

Parameters

right

The container to swap with.

Remarks

The member function swaps the controlled sequences between `*this` and *right*. If `unordered_map::get_allocator()` `() == right.get_allocator()`, it does so in constant time, it throws an exception only as a result of copying the stored traits object of type `Tr`, and it invalidates no references, pointers, or iterators that designate elements in the two controlled sequences. Otherwise, it performs a number of element assignments and constructor calls proportional to the number of elements in the two controlled sequences.

Example

```

// std__unordered_map__unordered_map_swap.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<
    std::cout << std::endl;

    Mymap c2;

    c2.insert(Mymap::value_type('d', 4));
    c2.insert(Mymap::value_type('e', 5));
    c2.insert(Mymap::value_type('f', 6));

    c1.swap(c2);

    // display contents " [f 6] [e 5] [d 4]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<
    std::cout << std::endl;

    swap(c1, c2);

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<
    std::cout << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[f, 6] [e, 5] [d, 4]
[c, 3] [b, 2] [a, 1]

```

unordered_map::unordered_map

Constructs a container object.

```

unordered_map(const unordered_map& Right);

explicit unordered_map(
    size_type Bucket_count = N0,
    const Hash& Hash = Hash(),
    const Comp& Comp = Comp(),
    const Allocator& Al = Allocator());

unordered_map(unordered_map&& Right);
unordered_map(initializer_list<Type> IList);
unordered_map(initializer_list<Type> IList, size_type Bucket_count);

unordered_map(
    initializer_list<Type> IList,
    size_type Bucket_count,
    const Hash& Hash);

unordered_map(
    initializer_list<Type> IList,
    size_type Bucket_count,
    const Hash& Hash,
    KeyEqual& equal);

unordered_map(
    initializer_list<Type> IList,
    size_type Bucket_count,
    const Hash& Hash,
    KeyEqual& Equal
    const Allocator& Al);

template <class InIt>
unordered_map(
    InputIterator First,
    InputIterator Last,
    size_type Bucket_count = N0,
    const Hash& Hash = Hash(),
    const Comp& Comp = Comp(),
    const Allocator& Al = Alloc());

```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The allocator object to store.
<i>Comp</i>	The comparison function object to store.
<i>Hash</i>	The hash function object to store.
<i>Bucket_count</i>	The minimum number of buckets.
<i>Right</i>	The container to copy.
<i>First</i>	
<i>Last</i>	
<i>IList</i>	The initializer_list that contains the elements to be copied.

Remarks

The first constructor specifies a copy of the sequence controlled by `right`. The second constructor specifies an empty controlled sequence. The third constructor inserts the sequence of element values `[first, last)`. The fourth constructor specifies a copy of the sequence by moving `right`.

All constructors also initialize several stored values. For the copy constructor, the values are obtained from *Right*. Otherwise:

the minimum number of buckets is the argument *Bucket_count*, if present; otherwise it is a default value described here as the implementation-defined value `N0`.

the hash function object is the argument *Hash*, if present; otherwise it is `Hash()`.

The comparison function object is the argument *Comp*, if present; otherwise it is `Pred()`.

The allocator object is the argument *Al*, if present; otherwise, it is `Alloc()`.

Example

```
// std__unordered_map__unordered_map_construct.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>
#include <initializer_list>

using namespace std;

using Mymap = unordered_map<char, int>;

int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (const auto& c : c1) {
        cout << " [" << c.first << ", " << c.second << "]"<< endl;
    }

    Mymap c2(8,
        hash<char>(),
        equal_to<char>(),
        allocator<pair<const char, int> >());

    c2.insert(Mymap::value_type('d', 4));
    c2.insert(Mymap::value_type('e', 5));
    c2.insert(Mymap::value_type('f', 6));

    // display contents " [f 6] [e 5] [d 4]"
    for (const auto& c : c2) {
        cout << " [" << c.first << ", " << c.second << "]"<< endl;
    }

    Mymap c3(c1.begin(),
        c1.end(),
        8,
        hash<char>(),
        equal_to<char>(),
        allocator<pair<const char, int> >());

    // display contents " [c 3] [b 2] [a 1]"
    for (const auto& c : c3) {
```

```

        cout << " [" << c.first << ", " << c.second << "]\n";
    }
    cout << endl;

    Mymap c4(move(c3));

    // display contents " [c 3] [b 2] [a 1]"
    for (const auto& c : c4) {
        cout << " [" << c.first << ", " << c.second << "]\n";
    }
    cout << endl;
    cout << endl;

    // Construct with an initializer_list
    unordered_map<int, char> c5({ { 5, 'g' }, { 6, 'h' }, { 7, 'i' }, { 8, 'j' } });
    for (const auto& c : c5) {
        cout << " [" << c.first << ", " << c.second << "]\n";
    }
    cout << endl;

    // Initializer_list plus size
    unordered_map<int, char> c6({ { 5, 'g' }, { 6, 'h' }, { 7, 'i' }, { 8, 'j' } }, 4);
    for (const auto& c : c6) {
        cout << " [" << c.first << ", " << c.second << "]\n";
    }
    cout << endl;
    cout << endl;

    // Initializer_list plus size and hash
    unordered_map<int, char, hash<char>> c7(
        { { 5, 'g' }, { 6, 'h' }, { 7, 'i' }, { 8, 'j' } },
        4,
        hash<char>()
    );

    for (const auto& c : c7) {
        cout << " [" << c.first << ", " << c.second << "]\n";
    }
    cout << endl;

    // Initializer_list plus size, hash, and key_equal
    unordered_map<int, char, hash<char>, equal_to<char>> c8(
        { { 5, 'g' }, { 6, 'h' }, { 7, 'i' }, { 8, 'j' } },
        4,
        hash<char>(),
        equal_to<char>()
    );

    for (const auto& c : c8) {
        cout << " [" << c.first << ", " << c.second << "]\n";
    }
    cout << endl;

    // Initializer_list plus size, hash, key_equal, and allocator
    unordered_map<int, char, hash<char>, equal_to<char>>, allocator<pair<const char, int>> c9(
        { { 5, 'g' }, { 6, 'h' }, { 7, 'i' }, { 8, 'j' } },
        4,
        hash<char>(),
        equal_to<char>(),
        allocator<pair<const char, int>>()
    );

    for (const auto& c : c9) {
        cout << " [" << c.first << ", " << c.second << "]\n";
    }
    cout << endl;
}

```

```
[a, 1] [b, 2] [c, 3]
[d, 4] [e, 5] [f, 6]
[a, 1] [b, 2] [c, 3]
[a, 1] [b, 2] [c, 3]

[5, g] [6, h] [7, i] [8, j]
[a, 1] [b, 2] [c, 3]

[a, 1] [b, 2] [c, 3]
[a, 1] [b, 2] [c, 3]
[a, 1] [b, 2] [c, 3]
```

unordered_map::value_type

The type of an element.

```
typedef std::pair<const Key, Ty> value_type;
```

Remarks

The type describes an element of the controlled sequence.

Example

```
// std__unordered_map__unordered_map_value_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_map<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // add a value and reinspect
    Mymap::key_type key = 'd';
    Mymap::mapped_type mapped = 4;
    Mymap::value_type val = Mymap::value_type(key, mapped);
    c1.insert(val);

    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
[d, 4] [c, 3] [b, 2] [a, 1]
```

unordered_multimap Class

11/9/2018 • 42 minutes to read • [Edit Online](#)

The template class describes an object that controls a varying-length sequence of elements of type `std::pair<const Key, Ty>`. The sequence is weakly ordered by a hash function, which partitions the sequence into an ordered set of subsequences called buckets. Within each bucket a comparison function determines whether any pair of elements has equivalent ordering. Each element stores two objects, a sort key and a value. The sequence is represented in a way that permits lookup, insertion, and removal of an arbitrary element with a number of operations that can be independent of the number of elements in the sequence (constant time), at least when all buckets are of roughly equal length. In the worst case, when all of the elements are in one bucket, the number of operations is proportional to the number of elements in the sequence (linear time). Moreover, inserting an element invalidates no iterators, and removing an element invalidates only those iterators which point at the removed element.

Syntax

```
template <class Key,  
          class Ty,  
          class Hash = std::hash<Key>,  
          class Pred = std::equal_to<Key>,  
          class Alloc = std::allocator<Key>>  
class unordered_multimap;
```

Parameters

PARAMETER	DESCRIPTION
<i>Key</i>	The key type.
<i>Ty</i>	The mapped type.
<i>Hash</i>	The hash function object type.
<i>Pred</i>	The equality comparison function object type.
<i>Alloc</i>	The allocator class.

Members

TYPE DEFINITION	DESCRIPTION
allocator_type	The type of an allocator for managing storage.
const_iterator	The type of a constant iterator for the controlled sequence.
const_local_iterator	The type of a constant bucket iterator for the controlled sequence.

TYPE DEFINITION	DESCRIPTION
<code>const_pointer</code>	The type of a constant pointer to an element.
<code>const_reference</code>	The type of a constant reference to an element.
<code>difference_type</code>	The type of a signed distance between two elements.
<code>hasher</code>	The type of the hash function.
<code>iterator</code>	The type of an iterator for the controlled sequence.
<code>key_equal</code>	The type of the comparison function.
<code>key_type</code>	The type of an ordering key.
<code>local_iterator</code>	The type of a bucket iterator for the controlled sequence.
<code>mapped_type</code>	The type of a mapped value associated with each key.
<code>pointer</code>	The type of a pointer to an element.
<code>reference</code>	The type of a reference to an element.
<code>size_type</code>	The type of an unsigned distance between two elements.
<code>value_type</code>	The type of an element.
MEMBER FUNCTION	DESCRIPTION
<code>begin</code>	Designates the beginning of the controlled sequence.
<code>bucket</code>	Gets the bucket number for a key value.
<code>bucket_count</code>	Gets the number of buckets.
<code>bucket_size</code>	Gets the size of a bucket.
<code>cbegin</code>	Designates the beginning of the controlled sequence.
<code>cend</code>	Designates the end of the controlled sequence.
<code>clear</code>	Removes all elements.
<code>count</code>	Finds the number of elements matching a specified key.
<code>emplace</code>	Adds an element constructed in place.
<code>emplace_hint</code>	Adds an element constructed in place, with hint.

MEMBER FUNCTION	DESCRIPTION
<code>empty</code>	Tests whether no elements are present.
<code>end</code>	Designates the end of the controlled sequence.
<code>equal_range</code>	Finds range that matches a specified key.
<code>erase</code>	Removes elements at specified positions.
<code>find</code>	Finds an element that matches a specified key.
<code>get_allocator</code>	Gets the stored allocator object.
<code>hash_function</code>	Gets the stored hash function object.
<code>insert</code>	Adds elements.
<code>key_eq</code>	Gets the stored comparison function object.
<code>load_factor</code>	Counts the average elements per bucket.
<code>max_bucket_count</code>	Gets the maximum number of buckets.
<code>max_load_factor</code>	Gets or sets the maximum elements per bucket.
<code>max_size</code>	Gets the maximum size of the controlled sequence.
<code>rehash</code>	Rebuilds the hash table.
<code>size</code>	Counts the number of elements.
<code>swap</code>	Swaps the contents of two containers.
<code>unordered_multimap</code>	Constructs a container object.

OPERATOR	DESCRIPTION
<code>unordered_multimap::operator=</code>	Copies a hash table.

Remarks

The object orders the sequence it controls by calling two stored objects, a comparison function object of type `unordered_multimap::key_equal` and a hash function object of type `unordered_multimap::hasher`. You access the first stored object by calling the member function `unordered_multimap::key_eq()`; and you access the second stored object by calling the member function `unordered_multimap::hash_function()`. Specifically, for all values `x` and `y` of type `Key`, the call `key_eq()(x, y)` returns true only if the two argument values have equivalent ordering; the call `hash_function()(keyval)` yields a distribution of values of type `size_t`. Unlike template class `unordered_map Class`, an object of template class `unordered_multimap` does not ensure that `key_eq()(x, y)` is always false for any two elements of the controlled sequence. (Keys need not be unique.)

The object also stores a maximum load factor, which specifies the maximum desired average number of elements per bucket. If inserting an element causes `unordered_multimap::load_factor()` to exceed the maximum load factor, the container increases the number of buckets and rebuilds the hash table as needed.

The actual order of elements in the controlled sequence depends on the hash function, the comparison function, the order of insertion, the maximum load factor, and the current number of buckets. You cannot in general predict the order of elements in the controlled sequence. You can always be assured, however, that any subset of elements that have equivalent ordering are adjacent in the controlled sequence.

The object allocates and frees storage for the sequence it controls through a stored allocator object of type `unordered_multimap::allocator_type`. Such an allocator object must have the same external interface as an object of template class `allocator`. Note that the stored allocator object is not copied when the container object is assigned.

Requirements

Header: `<unordered_map>`

Namespace: `std`

`unordered_multimap::allocator_type`

The type of an allocator for managing storage.

```
typedef Alloc allocator_type;
```

Remarks

The type is a synonym for the template parameter `Alloc`.

Example

```
// std__unordered_map__unordered_multimap_allocator_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
typedef std::allocator<std::pair<const char, int> > Myalloc;
int main()
{
    Mymap c1;

    Mymap::allocator_type al = c1.get_allocator();
    std::cout << "al == std::allocator() is "
        << std::boolalpha << (al == Myalloc()) << std::endl;

    return (0);
}
```

```
al == std::allocator() is true
```

`unordered_multimap::begin`

Designates the beginning of the controlled sequence or a bucket.

```

iterator begin();

const_iterator begin() const;

local_iterator begin(size_type nbucket);

const_local_iterator begin(size_type nbucket) const;

```

Parameters

PARAMETER	DESCRIPTION
<i>nbucket</i>	The bucket number.

Remarks

The first two member functions return a forward iterator that points at the first element of the sequence (or just beyond the end of an empty sequence). The last two member functions return a forward iterator that points at the first element of bucket *nbucket* (or just beyond the end of an empty bucket).

Example

```

// std__unordered_map__unordered_multimap_begin.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]" << "\n";

    // inspect first two items " [c 3] [b 2]"
    Mymap::iterator it2 = c1.begin();
    std::cout << " [" << it2->first << ", " << it2->second << "]" << "\n";
    ++it2;
    std::cout << " [" << it2->first << ", " << it2->second << "]" << "\n";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Mymap::const_local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << " [" << lit->first << ", " << lit->second << "]" << "\n";

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[c, 3] [b, 2]
[a, 1]

```

unordered_multimap::bucket

Gets the bucket number for a key value.

```
size_type bucket(const Key& keyval) const;
```

Parameters

keyval

The key value to map.

Remarks

The member function returns the bucket number currently corresponding to the key value *keyval*.

Example

```
// std__unordered_map__unordered_multimap_bucket.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]\n";
    std::cout << std::endl;

    // display buckets for keys
    Mymap::size_type bs = c1.bucket('a');
    std::cout << "bucket('a') == " << bs << std::endl;
    std::cout << "bucket_size(" << bs << ") == " << c1.bucket_size(bs)
        << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
bucket('a') == 7
bucket_size(7) == 1
```

unordered_multimap::bucket_count

Gets the number of buckets.

```
size_type bucket_count() const;
```

Remarks

The member function returns the current number of buckets.

Example

```
// std__unordered_map__unordered_multimap_bucket_count.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}
```

```

[c, 3] [b, 2] [a, 1]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1

```

unordered_multimap::bucket_size

Gets the size of a bucket

```
size_type bucket_size(size_type nbucket) const;
```

Parameters

nbucket

The bucket number.

Remarks

The member functions returns the size of bucket number *nbucket*.

Example

```

// std__unordered_map__unordered_multimap_bucket_size.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << it->first << ", " << it->second << "]"<< "\n";

    // display buckets for keys
    Mymap::size_type bs = c1.bucket('a');
    std::cout << "bucket('a') == " << bs << std::endl;
    std::cout << "bucket_size(" << bs << ") == " << c1.bucket_size(bs)
        << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
bucket('a') == 7
bucket_size(7) == 1
```

unordered_multimap::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** forward-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin`, the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

unordered_multimap::cend

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A **const** forward-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

unordered_multimap::clear

Removes all elements.

```
void clear();
```

Remarks

The member function calls `unordered_multimap::erase (unordered_multimap::begin (), unordered_multimap::end ())`.

Example

```
// std_unordered_map_unordered_multimap_clear.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert(Mymap::value_type('d', 4));
    c1.insert(Mymap::value_type('e', 5));

    // display contents " [e 5] [d 4]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
size == 0
empty() == true

[e, 5] [d, 4]
size == 2
empty() == false
```

unordered_multimap::const_iterator

The type of a constant iterator for the controlled sequence.

```
typedef T1 const_iterator;
```

Remarks

The type describes an object that can serve as a constant forward iterator for the controlled sequence. It is described here as a synonym for the implementation-defined type `T1`.

Example

```
// std__unordered_map__unordered_multimap_const_iterator.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";
    std::cout << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
```

unordered_multimap::const_local_iterator

The type of a constant bucket iterator for the controlled sequence.

```
typedef T5 const_local_iterator;
```

Remarks

The type describes an object that can serve as a constant forward iterator for a bucket. It is described here as a synonym for the implementation-defined type `T5`.

Example

```
// std__unordered_map__unordered_multimap_const_local_iterator.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // inspect bucket containing 'a'
    Mymap::const_local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << " [" << lit->first << ", " << lit->second << "]"

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
[a, 1]
```

unordered_multimap::const_pointer

The type of a constant pointer to an element.

```
typedef Alloc::const_pointer const_pointer;
```

Remarks

The type describes an object that can serve as a constant pointer to an element of the controlled sequence.

Example

```

// std__unordered_map__unordered_multimap_const_pointer.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Mymap::const_pointer p = &*it;
        std::cout << " [" << p->first << ", " << p->second << "]"<< "\n";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
```

unordered_multimap::const_reference

The type of a constant reference to an element.

```
typedef Alloc::const_reference const_reference;
```

Remarks

The type describes an object that can serve as a constant reference to an element of the controlled sequence.

Example

```

// std_unordered_map__unordered_multimap_const_reference.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Mymap::const_reference ref = *it;
        std::cout << " [" << ref.first << ", " << ref.second << "]"<< "\n";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
```

unordered_multimap::count

Finds the number of elements matching a specified key.

```
size_type count(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns the number of elements in the range delimited by [unordered_multimap::equal_range](#) (`keyval`).

Example

```

// std_unordered_map_unordered_multimap_count.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    std::cout << "count('A') == " << c1.count('A') << std::endl;
    std::cout << "count('b') == " << c1.count('b') << std::endl;
    std::cout << "count('C') == " << c1.count('C') << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
count('A') == 0
count('b') == 1
count('C') == 0

```

unordered_multimap::difference_type

The type of a signed distance between two elements.

```
typedef T3 difference_type;
```

Remarks

The signed integer type describes an object that can represent the difference between the addresses of any two elements in the controlled sequence. It is described here as a synonym for the implementation-defined type `T3`.

Example

```

// std_unordered_map_unordered_multimap_difference_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<
        std::cout << std::endl;

    // compute positive difference
    Mymap::difference_type diff = 0;
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        ++diff;
    std::cout << "end()-begin() == " << diff << std::endl;

    // compute negative difference
    diff = 0;
    for (Mymap::const_iterator it = c1.end();
         it != c1.begin(); --it)
        --diff;
    std::cout << "begin()-end() == " << diff << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
end()-begin() == 3
begin()-end() == -3

```

unordered_multimap::emplace

Inserts an element constructed in place (no copy or move operations are performed), with a placement hint.

```

template <class... Args>
iterator emplace(Args&&... args);

```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the unordered_multimap.

Return Value

An iterator to the newly inserted element.

Remarks

No references to container elements are invalidated by this function, but it may invalidate all iterators to the container.

The [value_type](#) of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

During the insertion, if an exception is thrown but does not occur in the container's hash function, the container is not modified. If the exception is thrown in the hash function, the result is undefined.

For a code example, see [multimap::emplace](#).

unordered_multimap::emplace_hint

Inserts an element constructed in place (no copy or move operations are performed), with a placement hint.

```
template <class... Args>
iterator emplace_hint(
    const_iterator where,
    Args&&... args);
```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the unordered.
<i>where</i>	A hint regarding the place to start searching for the correct point of insertion.

Return Value

An iterator to the newly inserted element.

Remarks

No references to container elements are invalidated by this function, but it may invalidate all iterators to the container.

During the insertion, if an exception is thrown but does not occur in the container's hash function, the container is not modified. If the exception is thrown in the hash function, the result is undefined.

The [value_type](#) of an element is a pair, so that the value of an element will be an ordered pair with the first component equal to the key value and the second component equal to the data value of the element.

For a code example, see [map::emplace_hint](#).

unordered_multimap::empty

Tests whether no elements are present.

```
bool empty() const;
```

Remarks

The member function returns true for an empty controlled sequence.

Example

```
// std__unordered_map__unordered_multimap_empty.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert(Mymap::value_type('d', 4));
    c1.insert(Mymap::value_type('e', 5));

    // display contents " [e 5] [d 4]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
size == 0
empty() == true

[e, 5] [d, 4]
size == 2
empty() == false
```

unordered_multimap::end

Designates the end of the controlled sequence.

```

iterator end();

const_iterator end() const;

local_iterator end(size_type nbucket);

const_local_iterator end(size_type nbucket) const;

```

Parameters

PARAMETER	DESCRIPTION
<i>nbucket</i>	The bucket number.

Remarks

The first two member functions return a forward iterator that points just beyond the end of the sequence. The last two member functions return a forward iterator that points just beyond the end of bucket *nbucket*.

Example

```

// std_unordered_map_unordered_multimap_end.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // inspect last two items " [a 1] [b 2]"
    Mymap::iterator it2 = c1.end();
    --it2;
    std::cout << " [" << it2->first << ", " << it2->second << "]"<< "\n";
    --it2;
    std::cout << " [" << it2->first << ", " << it2->second << "]"<< "\n";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Mymap::const_local_iterator lit = c1.end(c1.bucket('a'));
    --lit;
    std::cout << " [" << lit->first << ", " << lit->second << "]"<< "\n";

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[a, 1] [b, 2]
[a, 1]

```

unordered_multimap::equal_range

Finds range that matches a specified key.

```
std::pair<iterator, iterator>
    equal_range(const Key& keyval);

std::pair<const_iterator, const_iterator>
    equal_range(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns a pair of iterators `x` such that `[x.first, x.second)` delimits just those elements of the controlled sequence that have equivalent ordering with *keyval*. If no such elements exist, both iterators are `end()`.

Example

```
// std__unordered_map__unordered_multimap_equal_range.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // display results of failed search
    std::pair<Mymap::iterator, Mymap::iterator> pair1 =
        c1.equal_range('x');
    std::cout << "equal_range('x'):";
    for (; pair1.first != pair1.second; ++pair1.first)
        std::cout << " [" << pair1.first->first
            << ", " << pair1.first->second << "]"
        std::cout << std::endl;

    // display results of successful search
    pair1 = c1.equal_range('b');
    std::cout << "equal_range('b'):";
    for (; pair1.first != pair1.second; ++pair1.first)
        std::cout << " [" << pair1.first->first
            << ", " << pair1.first->second << "]"
        std::cout << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
equal_range('x'):
equal_range('b'): [b, 2]
```

unordered_multimap::erase

Removes an element or a range of elements in a `unordered_multimap` from specified positions or removes elements that match a specified key.

```
iterator erase(
    const_iterator Where);

iterator erase(
    const_iterator First,
    const_iterator Last);

size_type erase(
    const key_type& Key);
```

Parameters

Where

Position of the element to be removed.

First

Position of the first element to be removed.

Last

Position just beyond the last element to be removed.

Key

The key value of the elements to be removed.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or an element that is the end of the map if no such element exists.

For the third member function, returns the number of elements that have been removed from the `unordered_multimap`.

Remarks

For a code example, see [map::erase](#).

unordered_multimap::find

Finds an element that matches a specified key.

```
const_iterator find(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns `unordered_multimap::equal_range` `(keyval).first` .

Example

```
// std__unordered_map__unordered_multimap_find.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<
        std::cout << std::endl;

    // try to find and fail
    std::cout << "find('A') == "
        << std::boolalpha << (c1.find('A') != c1.end()) << std::endl;

    // try to find and succeed
    Mymap::iterator it = c1.find('b');
    std::cout << "find('b') == "
        << std::boolalpha << (it != c1.end())
        << ": [" << it->first << ", " << it->second << "]" << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
find('A') == false
find('b') == true: [b, 2]
```

unordered_multimap::get_allocator

Gets the stored allocator object.

```
Alloc get_allocator() const;
```

Remarks

The member function returns the stored allocator object.

Example

```
// std__unordered_map__unordered_multimap_get_allocator.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
typedef std::allocator<std::pair<const char, int> > Myalloc;
int main()
{
    Mymap c1;

    Mymap::allocator_type al = c1.get_allocator();
    std::cout << "al == std::allocator() is "
        << std::boolalpha << (al == Myalloc()) << std::endl;

    return (0);
}
```

```
al == std::allocator() is true
```

unordered_multimap::hash_function

Gets the stored hash function object.

```
Hash hash_function() const;
```

Remarks

The member function returns the stored hash function object.

Example

```
// std__unordered_map__unordered_multimap_hash_function.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    Mymap::hasher hfn = c1.hash_function();
    std::cout << "hfn('a') == " << hfn('a') << std::endl;
    std::cout << "hfn('b') == " << hfn('b') << std::endl;

    return (0);
}
```

```
hfn('a') == 1630279
hfn('b') == 1647086
```

unordered_multimap::hasher

The type of the hash function.

```
typedef Hash hasher;
```

Remarks

The type is a synonym for the template parameter `Hash`.

Example

```
// std__unordered_map__unordered_multimap_hasher.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    Mymap::hasher hfn = c1.hash_function();
    std::cout << "hfn('a') == " << hfn('a') << std::endl;
    std::cout << "hfn('b') == " << hfn('b') << std::endl;

    return (0);
}
```

```
hfn('a') == 1630279
hfn('b') == 1647086
```

unordered_multimap::insert

Inserts an element or a range of elements into an unordered_multimap.

```

// (1) single element
pair<iterator, bool> insert(
    const value_type& Val);

// (2) single element, perfect forwarded
template <class ValTy>
pair<iterator, bool>
insert(
    ValTy&& Val);

// (3) single element with hint
iterator insert(
    const_iterator Where,
    const value_type& Val);

// (4) single element, perfect forwarded, with hint
template <class ValTy>
iterator insert(
    const_iterator Where,
    ValTy&& Val);

// (5) range
template <class InputIterator>
void insert(
    InputIterator First,
    InputIterator Last);

// (6) initializer list
void insert(
    initializer_list<value_type>
    IList);

```

Parameters

PARAMETER	DESCRIPTION
<i>Val</i>	The value of an element to be inserted into the <code>unordered_multimap</code> .
<i>Where</i>	The place to start searching for the correct point of insertion.
<i>ValTy</i>	Template parameter that specifies the argument type that the <code>unordered_multimap</code> can use to construct an element of value_type , and perfect-forwards <i>Val</i> as an argument.
<i>First</i>	The position of the first element to be copied.
<i>Last</i>	The position just beyond the last element to be copied.
<i>InputIterator</i>	Template function argument that meets the requirements of an input iterator that points to elements of a type that can be used to construct value_type objects.
<i>IList</i>	The initializer_list from which to copy the elements.

Return Value

The single-element-insert member functions, (1) and (2), return an iterator to the position where the new element was inserted into the `unordered_multimap`.

The single-element-with-hint member functions, (3) and (4), return an iterator that points to the position where the new element was inserted into the `unordered_multimap`.

Remarks

No pointers or references are invalidated by this function, but it may invalidate all iterators to the container.

During the insertion of just one element, if an exception is thrown but does not occur in the container's hash function, the container's state is not modified. If the exception is thrown in the hash function, the result is undefined. During the insertion of multiple elements, if an exception is thrown, the container is left in an unspecified but valid state.

The [value_type](#) of a container is a typedef that belongs to the container, and for `map`,

`map<K, V>::value_type` is `pair<const K, V>`. The value of an element is an ordered pair in which the first component is equal to the key value and the second component is equal to the data value of the element.

The range member function (5) inserts the sequence of element values into an `unordered_multimap` that corresponds to each element addressed by an iterator in the range `[First, Last)`; therefore, *Last* does not get inserted. The container member function `end()` refers to the position just after the last element in the container—for example, the statement `m.insert(v.begin(), v.end());` inserts all elements of `v` into `m`.

The initializer list member function (6) uses an [initializer_list](#) to copy elements into the `unordered_multimap`.

For insertion of an element constructed in place—that is, no copy or move operations are performed—see [unordered_multimap::emplace](#) and [unordered_multimap::emplace_hint](#).

For a code example, see [multimap::insert](#).

unordered_multimap::iterator

The type of an iterator for the controlled sequence.

```
typedef T0 iterator;
```

Remarks

The type describes an object that can serve as a forward iterator for the controlled sequence. It is described here as a synonym for the implementation-defined type `T0`.

Example

```

// std__unordered_map__unordered_multimap_iterator.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
```

unordered_multimap::key_eq

Gets the stored comparison function object.

```
Pred key_eq() const;
```

Remarks

The member function returns the stored comparison function object.

Example

```

// std__unordered_map__unordered_multimap_key_eq.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    Mymap::key_equal cmpfn = c1.key_eq();
    std::cout << "cmpfn('a', 'a') == "
        << std::boolalpha << cmpfn('a', 'a') << std::endl;
    std::cout << "cmpfn('a', 'b') == "
        << std::boolalpha << cmpfn('a', 'b') << std::endl;

    return (0);
}

```

```

cmpfn('a', 'a') == true
cmpfn('a', 'b') == false

```

unordered_multimap::key_equal

The type of the comparison function.

```
typedef Pred key_equal;
```

Remarks

The type is a synonym for the template parameter `Pred`.

Example

```
// std__unordered_map__unordered_multimap_key_equal.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    Mymap::key_equal cmpfn = c1.key_eq();
    std::cout << "cmpfn('a', 'a') == "
        << std::boolalpha << cmpfn('a', 'a') << std::endl;
    std::cout << "cmpfn('a', 'b') == "
        << std::boolalpha << cmpfn('a', 'b') << std::endl;

    return (0);
}
```

```
cmpfn('a', 'a') == true
cmpfn('a', 'b') == false
```

unordered_multimap::key_type

The type of an ordering key.

```
typedef Key key_type;
```

Remarks

The type is a synonym for the template parameter `Key`.

Example

```

// std_unordered_map_unordered_multimap_key_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    // add a value and reinspect
    Mymap::key_type key = 'd';
    Mymap::mapped_type mapped = 4;
    Mymap::value_type val = Mymap::value_type(key, mapped);
    c1.insert(val);

    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<< "\n";

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[d, 4] [c, 3] [b, 2] [a, 1]

```

unordered_multimap::load_factor

Counts the average elements per bucket.

```
float load_factor() const;
```

Remarks

The member function returns `(float) unordered_multimap::size() / (float) unordered_multimap::bucket_count()`, the average number of elements per bucket.

Example

```

// std_unordered_map_unordered_multimap_load_factor.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

unordered_multimap::local_iterator

The type of a bucket iterator.

```
typedef T4 local_iterator;
```

Remarks

The type describes an object that can serve as a forward iterator for a bucket. It is described here as a synonym for the implementation-defined type `T4`.

Example

```
// std__unordered_map__unordered_multimap_local_iterator.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // inspect bucket containing 'a'
    Mymap::local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << " [" << lit->first << ", " << lit->second << "]"
    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
[a, 1]
```

unordered_multimap::mapped_type

The type of a mapped value associated with each key.

```
typedef Ty mapped_type;
```

Remarks

The type is a synonym for the template parameter `Ty`.

Example

```

// std_unordered_map_unordered_multimap_mapped_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // add a value and reinspect
    Mymap::key_type key = 'd';
    Mymap::mapped_type mapped = 4;
    Mymap::value_type val = Mymap::value_type(key, mapped);
    c1.insert(val);

    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[d, 4] [c, 3] [b, 2] [a, 1]

```

unordered_multimap::max_bucket_count

Gets the maximum number of buckets.

```
size_type max_bucket_count() const;
```

Remarks

The member function returns the maximum number of buckets currently permitted.

Example

```

// std_unordered_map_unordered_multimap_max_bucket_count.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1
```

unordered_multimap::max_load_factor

Gets or sets the maximum elements per bucket.

```
float max_load_factor() const;

void max_load_factor(float factor);
```

Parameters

factor

The new maximum load factor.

Remarks

The first member function returns the stored maximum load factor. The second member function replaces the stored maximum load factor with *factor*.

Example

```

// std_unordered_map_unordered_multimap_max_load_factor.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1

```

unordered_multimap::max_size

Gets the maximum size of the controlled sequence.

```
size_type max_size() const;
```

Remarks

The member function returns the length of the longest sequence that the object can control.

Example

```

// std__unordered_map__unordered_multimap_max_size.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    std::cout << "max_size() == " << c1.max_size() << std::endl;

    return (0);
}

```

```
max_size() == 536870911
```

unordered_multimap::operator=

Copies a hash table.

```

unordered_multimap& operator=(const unordered_multimap& right);

unordered_multimap& operator=(unordered_multimap&& right);

```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The unordered_multimap being copied into the unordered_multimap.

Remarks

After erasing any existing elements in a unordered_multimap, `operator=` either copies or moves the contents of *right* into the unordered_multimap.

Example

```
// unordered_multimap_operator_as.cpp
// compile with: /EHsc
#include <unordered_multimap>
#include <iostream>

int main( )
{
    using namespace std;
    unordered_multimap<int, int> v1, v2, v3;
    unordered_multimap<int, int>::iterator iter;

    v1.insert(pair<int, int>(1, 10));

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << iter->second << " ";
    cout << endl;
}
```

unordered_multimap::pointer

The type of a pointer to an element.

```
typedef Alloc::pointer pointer;
```

Remarks

The type describes an object that can serve as a pointer to an element of the controlled sequence.

Example

```

// std__unordered_map__unordered_multimap_pointer.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Mymap::pointer p = &*it;
        std::cout << " [" << p->first << ", " << p->second << "]"<< "\n";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
```

unordered_multimap::reference

The type of a reference to an element.

```
typedef Alloc::reference reference;
```

Remarks

The type describes an object that can serve as a reference to an element of the controlled sequence.

Example

```

// std__unordered_map__unordered_multimap_reference.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Mymap::reference ref = *it;
        std::cout << " [" << ref.first << ", " << ref.second << "]"<< "\n";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c, 3] [b, 2] [a, 1]
```

unordered_multimap::rehash

Rebuilds the hash table.

```
void rehash(size_type nbuckets);
```

Parameters

nbuckets

The requested number of buckets.

Remarks

The member function alters the number of buckets to be at least *nbuckets* and rebuilds the hash table as needed.

Example

```

// std_unordered_map_unordered_multimap_rehash.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]" << "\n";

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << "\n";
    std::cout << "load_factor() == " << c1.load_factor() << "\n";
    std::cout << "max_load_factor() == " << c1.max_load_factor() << "\n";

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << "\n";
    std::cout << "load_factor() == " << c1.load_factor() << "\n";
    std::cout << "max_load_factor() == " << c1.max_load_factor() << "\n";

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << "\n";
    std::cout << "load_factor() == " << c1.load_factor() << "\n";
    std::cout << "max_load_factor() == " << c1.max_load_factor() << "\n";

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
bucket_count() == 8
load_factor() == 0.375
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_load_factor() == 0.1

```

unordered_multimap::size

Counts the number of elements.

```
size_type size() const;
```

Remarks

The member function returns the length of the controlled sequence.

Example

```
// std__unordered_map__unordered_multimap_size.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert(Mymap::value_type('d', 4));
    c1.insert(Mymap::value_type('e', 5));

    // display contents " [e 5] [d 4]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"
        std::cout << std::endl;

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}
```

```
[c, 3] [b, 2] [a, 1]
size == 0
empty() == true

[e, 5] [d, 4]
size == 2
empty() == false
```

unordered_multimap::size_type

The type of an unsigned distance between two elements.

```
typedef T2 size_type;
```

Remarks

The unsigned integer type describes an object that can represent the length of any controlled

sequence. It is described here as a synonym for the implementation-defined type `T2`.

Example

```
// std__unordered_map__unordered_multimap_size_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;
    Mymap::size_type sz = c1.size();

    std::cout << "size == " << sz << std::endl;

    return (0);
}
```

```
size == 0
```

unordered_multimap::swap

Swaps the contents of two containers.

```
void swap(unordered_multimap& right);
```

Parameters

right

The container to swap with.

Remarks

The member function swaps the controlled sequences between `*this` and *right*. If `unordered_multimap::get_allocator()` `() == right.get_allocator()`, it does so in constant time, it throws an exception only as a result of copying the stored traits object of type `Tr`, and it invalidates no references, pointers, or iterators that designate elements in the two controlled sequences. Otherwise, it performs a number of element assignments and constructor calls proportional to the number of elements in the two controlled sequences.

Example

```

// std__unordered_map__unordered_multimap_swap.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<
        std::cout << std::endl;

    Mymap c2;

    c2.insert(Mymap::value_type('d', 4));
    c2.insert(Mymap::value_type('e', 5));
    c2.insert(Mymap::value_type('f', 6));

    c1.swap(c2);

    // display contents " [f 6] [e 5] [d 4]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<
        std::cout << std::endl;

    swap(c1, c2);

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]"<
        std::cout << std::endl;

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[f, 6] [e, 5] [d, 4]
[c, 3] [b, 2] [a, 1]

```

unordered_multimap::unordered_multimap

Constructs a container object.

```

unordered_multimap(
    const unordered_multimap& Right);

explicit unordered_multimap(
    size_type Bucket_count = N0,
    const Hash& Hash = Hash(),
    const Comp& Comp = Pred(),
    const Allocator& Al = Alloc());

unordered_multimap(
    unordered_multimap&& Right);

unordered_multimap(
    initializer_list<Type> IList);

unordered_multimap(
    initializer_list<Type> IList,
    size_type Bucket_count);

unordered_multimap(
    initializer_list<Type> IList,
    size_type Bucket_count,
    const Hash& Hash);

unordered_multimap(
    initializer_list<Type> IList,
    size_type Bucket_count,
    const Hash& Hash,
    const Key& Key);

unordered_multimap(
    initializer_list<Type> IList,
    size_type Bucket_count,
    const Hash& Hash,
    const Key& Key,
    const Allocator& Al);

template <class InputIterator>
unordered_multimap(
    InputIterator first,
    InputIterator last,
    size_type Bucket_count = N0,
    const Hash& Hash = Hash(),
    const Comp& Comp = Pred(),
    const Allocator& Al = Alloc());

```

Parameters

PARAMETER	DESCRIPTION
<i>InputIterator</i>	The iterator type.
<i>Al</i>	The allocator object to store.
<i>Comp</i>	The comparison function object to store.
<i>Hash</i>	The hash function object to store.
<i>Bucket_count</i>	The minimum number of buckets.
<i>Right</i>	The container to copy.

PARAMETER	DESCRIPTION
<i>lList</i>	The initializer_list from which to copy the elements.

Remarks

The first constructor specifies a copy of the sequence controlled by *Right*. The second constructor specifies an empty controlled sequence. The third constructor. specifies a copy of the sequence by moving *Right*. The fourth, fifth, sixth, seventh, and eighth constructors use an initializer_list for the members. The ninth constructor inserts the sequence of element values `[First, Last)`.

All constructors also initialize several stored values. For the copy constructor, the values are obtained from *Right*. Otherwise:

The minimum number of buckets is the argument *Bucket_count*, if present; otherwise it is a default value described here as the implementation-defined value `N0`.

The hash function object is the argument *Hash*, if present; otherwise it is `Hash()`.

The comparison function object is the argument *Comp*, if present; otherwise it is `Pred()`.

The allocator object is the argument *Al*, if present; otherwise, it is `Alloc()`.

Example

```
// std__unordered_map__unordered_multimap_construct.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

using namespace std;

using Mymap = unordered_multimap<char, int> ;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (const auto& c : c1) {
        cout << " [" << c.first << ", " << c.second << "]" ;
    }
    cout << endl;

    Mymap c2(8,
        hash<char>(),
        equal_to<char>(),
        allocator<pair<const char, int> >());

    c2.insert(Mymap::value_type('d', 4));
    c2.insert(Mymap::value_type('e', 5));
    c2.insert(Mymap::value_type('f', 6));

    // display contents " [f 6] [e 5] [d 4]"
    for (const auto& c : c2) {
        cout << " [" << c.first << ", " << c.second << "]" ;
    }
    cout << endl;

    Mymap c3(c1.begin(),
        c1.end(),
        8.
```

```

~,
hash<char>(),
equal_to<char>(),
allocator<pair<const char, int> >());

// display contents " [c 3] [b 2] [a 1]"
for (const auto& c : c3) {
    cout << " [" << c.first << ", " << c.second << "]"<endl;
}

Mymap c4(move(c3));

// display contents " [c 3] [b 2] [a 1]"
for (const auto& c : c4) {
    cout << " [" << c.first << ", " << c.second << "]"<endl;
}

// Construct with an initializer_list
unordered_multimap<int, char> c5({ { 5, 'g' }, { 6, 'h' }, { 7, 'i' }, { 8, 'j' } });
for (const auto& c : c5) {
    cout << " [" << c.first << ", " << c.second << "]"<endl;
}

// Initializer_list plus size
unordered_multimap<int, char> c6({ { 5, 'g' }, { 6, 'h' }, { 7, 'i' }, { 8, 'j' } }, 4);
for (const auto& c : c1) {
    cout << " [" << c.first << ", " << c.second << "]"<endl;
}

// Initializer_list plus size and hash
unordered_multimap<int, char, hash<char>> c7(
    { { 5, 'g' }, { 6, 'h' }, { 7, 'i' }, { 8, 'j' } },
    4,
    hash<char>()
);

for (const auto& c : c1) {
    cout << " [" << c.first << ", " << c.second << "]"<endl;
}

// Initializer_list plus size, hash, and key_equal
unordered_multimap<int, char, hash<char>, equal_to<char>> c8(
    { { 5, 'g' }, { 6, 'h' }, { 7, 'i' }, { 8, 'j' } },
    4,
    hash<char>(),
    equal_to<char>()
);

for (const auto& c : c1) {
    cout << " [" << c.first << ", " << c.second << "]"<endl;
}

// Initializer_list plus size, hash, key_equal, and allocator
unordered_multimap<int, char, hash<char>, equal_to<char>,
    allocator<pair<const char, int> >()
);

for (const auto& c : c1) {
    cout << " [" << c.first << ", " << c.second << "]"<endl;
}

```

```

    }
    cout << endl;
}

```

```

[a, 1] [b, 2] [c, 3] [d, 4] [e, 5] [f, 6] [a, 1] [b, 2] [c, 3] [a, 1] [b, 2] [c, 3] [5, g] [6, h]
[7, i] [8, j] [a, 1] [b, 2] [c, 3] [a, 1] [b, 2] [c, 3] [a, 1] [b, 2] [c, 3] [a, 1] [b, 2] [c, 3]
[c, 3] [b, 2] [a, 1]
[f, 6] [e, 5] [d, 4]
[c, 3] [b, 2] [a, 1]
[c, 3] [b, 2] [a, 1]

```

unordered_multimap::value_type

The type of an element.

```

typedef std::pair<const Key, Ty> value_type;

```

Remarks

The type describes an element of the controlled sequence.

Example

```

// std_unordered_map_unordered_multimap_value_type.cpp
// compile with: /EHsc
#include <unordered_map>
#include <iostream>

typedef std::unordered_multimap<char, int> Mymap;
int main()
{
    Mymap c1;

    c1.insert(Mymap::value_type('a', 1));
    c1.insert(Mymap::value_type('b', 2));
    c1.insert(Mymap::value_type('c', 3));

    // display contents " [c 3] [b 2] [a 1]"
    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]" << "\n";

    // add a value and reinspect
    Mymap::key_type key = 'd';
    Mymap::mapped_type mapped = 4;
    Mymap::value_type val = Mymap::value_type(key, mapped);
    c1.insert(val);

    for (Mymap::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << it->first << ", " << it->second << "]" << "\n";

    return (0);
}

```

```

[c, 3] [b, 2] [a, 1]
[d, 4] [c, 3] [b, 2] [a, 1]

```

[C++ Standard Library Reference](#)

<unordered_set>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template classes [unordered_multiset](#) and [unordered_set](#) and their supporting templates.

Syntax

```
#include <unordered_set>
```

Classes

CLASS	DESCRIPTION
unordered_multiset Class	Stores hash table of keys.
unordered_set Class	Stores hash table of keys.

Functions

FUNCTION	DESCRIPTION
operator!=	Tests if the unordered_multiset object on the left side of the operator is not equal to the unordered_multiset object on the right side.
operator==	Tests if the unordered_multiset object on the left side of the operator is equal to the unordered_multiset object on the right side.
swap	Swaps two multisets.
operator!=	Tests if the unordered_set object on the left side of the operator is not equal to the unordered_set object on the right side.
operator==	Tests if the unordered_set object on the left side of the operator is equal to the unordered_set object on the right side.
swap	Swaps two sets.

<unordered_set> functions

11/9/2018 • 2 minutes to read • [Edit Online](#)

`swap (set)`

`swap (unordered_multiset)`

swap (unordered_set)

Swaps the contents of two containers.

```
template <class Key, class Hash, class Pred, class Alloc>
void swap(
    unordered_set <Key, Hash, Pred, Alloc>& left,
    unordered_set <Key, Hash, Pred, Alloc>& right);
```

Parameters

Key

The key type.

Hash

The hash function object type.

Pred

The equality comparison function object type.

Alloc

The allocator class.

left

The first container to swap.

right

The second container to swap.

Remarks

The template function executes `left.unordered_set::swap (right)`.

Example

```

#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents " [c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << *it << " ]";
    std::cout << std::endl;

    Myset c2;

    c2.insert('d');
    c2.insert('e');
    c2.insert('f');

    c1.swap(c2);

    // display contents " [f] [e] [d]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << *it << " ]";
    std::cout << std::endl;

    swap(c1, c2);

    // display contents " [c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << *it << " ]";
    std::cout << std::endl;

    return (0);
}

```

```

[c] [b] [a]
[f] [e] [d]
[c] [b] [a]

```

swap (unordered_multiset)

Swaps the contents of two containers.

```

template <class Key, class Hash, class Pred, class Alloc>
void swap(
    unordered_multiset <Key, Hash, Pred, Alloc>& left,
    unordered_multiset <Key, Hash, Pred, Alloc>& right);

```

Parameters

Key

The key type.

Hash

The hash function object type.

Pred

The equality comparison function object type.

Alloc

The allocator class.

left

The first container to swap.

right

The second container to swap.

Remarks

The template function executes `left. unordered_multiset::swap (right)`.

Example

```
// std__unordered_set__u_ms_swap.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents " [c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << *it << "]\n";
    std::cout << std::endl;

    Myset c2;

    c2.insert('d');
    c2.insert('e');
    c2.insert('f');

    c1.swap(c2);

    // display contents " [f] [e] [d]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << *it << "]\n";
    std::cout << std::endl;

    swap(c1, c2);

    // display contents " [c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << " [" << *it << "]\n";
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]  
[f] [e] [d]  
[c] [b] [a]
```

[`<unordered_set>`](#)

<unordered_set> operators

11/9/2018 • 4 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator==</code>	<code>operator!=</code>	<code>operator==</code>

operator!=

Tests whether the `unordered_set` object on the left side of the operator is not equal to the `unordered_set` object on the right side.

```
bool operator!=(const unordered_set <Key, Hash, Pred, Allocator>& left, const unordered_set <Key, Hash, Pred, Allocator>& right);
```

Parameters

left

An object of type `unordered_set`.

right

An object of type `unordered_set`.

Return Value

true if the `unordered_sets` are not equal; **false** if they are equal.

Remarks

The comparison between `unordered_set` objects is not affected by the arbitrary order in which they store their elements. Two `unordered_sets` are equal if they have the same number of elements and the elements in one container are a permutation of the elements in the other container. Otherwise, they are unequal.

Example

```

// unordered_set_ne.cpp
// compile by using: cl.exe /EHsc /nologo /W4 /MTd
#include <unordered_set>
#include <iostream>
#include <ios>

int main()
{
    using namespace std;

    unordered_set<char> c1, c2, c3;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    c2.insert('c');
    c2.insert('a');
    c2.insert('d');

    c3.insert('c');
    c3.insert('a');
    c3.insert('b');

    cout << boolalpha;
    cout << "c1 != c2: " << (c1 != c2) << endl;
    cout << "c1 != c3: " << (c1 != c3) << endl;
    cout << "c2 != c3: " << (c2 != c3) << endl;

    return (0);
}

```

Output:

```
c1 != c2: true
```

```
c1 != c3: false
```

```
c2 != c3: true
```

operator==

Tests whether the [unordered_set](#) object on the left side of the operator is equal to the `unordered_set` object on the right side.

```
bool operator==(const unordered_set <Key, Hash, Pred, Allocator>& left, const unordered_set <Key, Hash, Pred, Allocator>& right);
```

Parameters

left

An object of type `unordered_set`.

right

An object of type `unordered_set`.

Return Value

true if the `unordered_sets` are equal; **false** if they are not equal.

Remarks

The comparison between `unordered_set` objects is not affected by the arbitrary order in which they store their

elements. Two `unordered_sets` are equal if they have the same number of elements and the elements in one container are a permutation of the elements in the other container. Otherwise, they are unequal.

Example

```
// unordered_set_eq.cpp
// compile by using: cl.exe /EHsc /nologo /W4 /MTd
#include <unordered_set>
#include <iostream>
#include <ios>

int main()
{
    using namespace std;

    unordered_set<char> c1, c2, c3;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    c2.insert('c');
    c2.insert('a');
    c2.insert('d');

    c3.insert('c');
    c3.insert('a');
    c3.insert('b');

    cout << boolalpha;
    cout << "c1 == c2: " << (c1 == c2) << endl;
    cout << "c1 == c3: " << (c1 == c3) << endl;
    cout << "c2 == c3: " << (c2 == c3) << endl;

    return (0);
}
```

Output:

```
c1 == c2: false
```

```
c1 == c3: true
```

```
c2 == c3: false
```

operator!=

Tests whether the [unordered_multiset](#) object on the left side of the operator is not equal to the `unordered_multiset` object on the right side.

```
bool operator!=(const unordered_multiset <Key, Hash, Pred, Allocator>& left, const unordered_multiset <Key, Hash, Pred, Allocator>& right);
```

Parameters

left

An object of type `unordered_multiset`.

right

An object of type `unordered_multiset`.

Return Value

true if the unordered_multisets are not equal; **false** if they are equal.

Remarks

The comparison between unordered_multiset objects is not affected by the arbitrary order in which they store their elements. Two unordered_multisets are equal if they have the same number of elements and the elements in one container are a permutation of the elements in the other container. Otherwise, they are unequal.

Example

```
// unordered_multiset_ne.cpp
// compile by using: cl.exe /EHsc /nologo /W4 /MTd
#include <unordered_set>
#include <iostream>
#include <ios>

int main()
{
    using namespace std;

    unordered_multiset<char> c1, c2, c3;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');
    c1.insert('c');

    c2.insert('c');
    c2.insert('c');
    c2.insert('a');
    c2.insert('d');

    c3.insert('c');
    c3.insert('c');
    c3.insert('a');
    c3.insert('b');

    cout << boolalpha;
    cout << "c1 != c2: " << (c1 != c2) << endl;
    cout << "c1 != c3: " << (c1 != c3) << endl;
    cout << "c2 != c3: " << (c2 != c3) << endl;

    return (0);
}
```

Output:

```
c1 != c2: true
```

```
c1 != c3: false
```

```
c2 != c3: true
```

operator==

Tests whether the [unordered_multiset](#) object on the left side of the operator is equal to the unordered_multiset object on the right side.

```
bool operator==(const unordered_multiset <Key, Hash, Pred, Allocator>& left, const unordered_multiset <Key, Hash, Pred, Allocator>& right);
```

Parameters

left

An object of type `unordered_multiset`.

right

An object of type `unordered_multiset`.

Return Value

true if the `unordered_multisets` are equal; **false** if they are not equal.

Remarks

The comparison between `unordered_multiset` objects is not affected by the arbitrary order in which they store their elements. Two `unordered_multisets` are equal if they have the same number of elements and the elements in one container are a permutation of the elements in the other container. Otherwise, they are unequal.

Example

```
// unordered_multiset_eq.cpp
// compile by using: cl.exe /EHsc /nologo /W4 /MTd
#include <unordered_set>
#include <iostream>
#include <ios>

int main()
{
    using namespace std;

    unordered_multiset<char> c1, c2, c3;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');
    c1.insert('c');

    c2.insert('c');
    c2.insert('c');
    c2.insert('a');
    c2.insert('d');

    c3.insert('c');
    c3.insert('c');
    c3.insert('a');
    c3.insert('b');

    cout << boolalpha;
    cout << "c1 == c2: " << (c1 == c2) << endl;
    cout << "c1 == c3: " << (c1 == c3) << endl;
    cout << "c2 == c3: " << (c2 == c3) << endl;

    return (0);
}
```

Output:

```
c1 == c2: false
```

```
c1 == c3: true
```

```
c2 == c3: false
```

[<unordered_set>](#)

unordered_set Class

10/31/2018 • 36 minutes to read • [Edit Online](#)

The template class describes an object that controls a varying-length sequence of elements of type `const Key`. The sequence is weakly ordered by a hash function, which partitions the sequence into an ordered set of subsequences called buckets. Within each bucket a comparison function determines whether any pair of elements has equivalent ordering. Each element serves as both a sort key and a value. The sequence is represented in a way that permits lookup, insertion, and removal of an arbitrary element with a number of operations that can be independent of the number of elements in the sequence (constant time), at least when all buckets are of roughly equal length. In the worst case, when all of the elements are in one bucket, the number of operations is proportional to the number of elements in the sequence (linear time). Moreover, inserting an element invalidates no iterators, and removing an element invalidates only those iterators which point at the removed element.

Syntax

```
template <
    class Key,
    class Hash = std::hash<Key>,
    class Pred = std::equal_to<Key>,
    class Alloc = std::allocator<Key>>
class unordered_set;
```

Parameters

PARAMETER	DESCRIPTION
<i>Key</i>	The key type.
<i>Hash</i>	The hash function object type.
<i>Pred</i>	The equality comparison function object type.
<i>Alloc</i>	The allocator class.

Members

TYPE DEFINITION	DESCRIPTION
allocator_type	The type of an allocator for managing storage.
const_iterator	The type of a constant iterator for the controlled sequence.
const_local_iterator	The type of a constant bucket iterator for the controlled sequence.
const_pointer	The type of a constant pointer to an element.

TYPE DEFINITION	DESCRIPTION
<code>const_reference</code>	The type of a constant reference to an element.
<code>difference_type</code>	The type of a signed distance between two elements.
<code>hasher</code>	The type of the hash function.
<code>iterator</code>	The type of an iterator for the controlled sequence.
<code>key_equal</code>	The type of the comparison function.
<code>key_type</code>	The type of an ordering key.
<code>local_iterator</code>	The type of a bucket iterator for the controlled sequence.
<code>pointer</code>	The type of a pointer to an element.
<code>reference</code>	The type of a reference to an element.
<code>size_type</code>	The type of an unsigned distance between two elements.
<code>value_type</code>	The type of an element.
MEMBER FUNCTION	DESCRIPTION
<code>begin</code>	Designates the beginning of the controlled sequence.
<code>bucket</code>	Gets the bucket number for a key value.
<code>bucket_count</code>	Gets the number of buckets.
<code>bucket_size</code>	Gets the size of a bucket.
<code>cbegin</code>	Designates the beginning of the controlled sequence.
<code>cend</code>	Designates the end of the controlled sequence.
<code>clear</code>	Removes all elements.
<code>count</code>	Finds the number of elements matching a specified key.
<code>emplace</code>	Adds an element constructed in place.
<code>emplace_hint</code>	Adds an element constructed in place, with hint.
<code>empty</code>	Tests whether no elements are present.
<code>end</code>	Designates the end of the controlled sequence.

MEMBER FUNCTION	DESCRIPTION
<code>equal_range</code>	Finds range that matches a specified key.
<code>erase</code>	Removes elements at specified positions.
<code>find</code>	Finds an element that matches a specified key.
<code>get_allocator</code>	Gets the stored allocator object.
<code>hash_function</code>	Gets the stored hash function object.
<code>insert</code>	Adds elements.
<code>key_eq</code>	Gets the stored comparison function object.
<code>load_factor</code>	Counts the average elements per bucket.
<code>max_bucket_count</code>	Gets the maximum number of buckets.
<code>max_load_factor</code>	Gets or sets the maximum elements per bucket.
<code>max_size</code>	Gets the maximum size of the controlled sequence.
<code>rehash</code>	Rebuilds the hash table.
<code>size</code>	Counts the number of elements.
<code>swap</code>	Swaps the contents of two containers.
<code>unordered_set</code>	Constructs a container object.

OPERATORS	DESCRIPTION
<code>unordered_set::operator=</code>	Copies a hash table.

Remarks

The object orders the sequence it controls by calling two stored objects, a comparison function object of type `unordered_set::key_equal` and a hash function object of type `unordered_set::hasher`. You access the first stored object by calling the member function `unordered_set::key_eq()`; and you access the second stored object by calling the member function `unordered_set::hash_function()`. Specifically, for all values `x` and `y` of type `key`, the call `key_eq()(x, y)` returns true only if the two argument values have equivalent ordering; the call `hash_function()(keyval)` yields a distribution of values of type `size_t`. Unlike template class `unordered_multiset` Class, an object of template class `unordered_set` ensures that `key_eq()(x, y)` is always false for any two elements of the controlled sequence. (Keys are unique.)

The object also stores a maximum load factor, which specifies the maximum desired average number of elements per bucket. If inserting an element causes `unordered_set::load_factor()` to exceed the maximum load factor, the container increases the number of buckets and rebuilds the hash table as needed.

The actual order of elements in the controlled sequence depends on the hash function, the comparison function, the order of insertion, the maximum load factor, and the current number of buckets. You cannot in general predict the order of elements in the controlled sequence. You can always be assured, however, that any subset of elements that have equivalent ordering are adjacent in the controlled sequence.

The object allocates and frees storage for the sequence it controls through a stored allocator object of type `unordered_set::allocator_type`. Such an allocator object must have the same external interface as an object of template class `allocator`. Note that the stored allocator object is not copied when the container object is assigned.

Requirements

Header: `<unordered_set>`

Namespace: `std`

`unordered_set::allocator_type`

The type of an allocator for managing storage.

```
typedef Alloc allocator_type;
```

Remarks

The type is a synonym for the template parameter `Alloc`.

Example

```
// std__unordered_set__unordered_set_allocator_type.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
typedef std::allocator<std::pair<const char, int> > Myalloc;
int main()
{
    Myset c1;

    Myset::allocator_type al = c1.get_allocator();
    std::cout << "al == std::allocator() is "
    << std::boolalpha << (al == Myalloc()) << std::endl;

    return (0);
}
```

```
al == std::allocator() is true
```

`unordered_set::begin`

Designates the beginning of the controlled sequence or a bucket.

```
iterator begin();

const_iterator begin() const;

local_iterator begin(size_type nbucket);

const_local_iterator begin(size_type nbucket) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>nbucket</i>	The bucket number.

Remarks

The first two member functions return a forward iterator that points at the first element of the sequence (or just beyond the end of an empty sequence). The last two member functions return a forward iterator that points at the first element of bucket *nbucket* (or just beyond the end of an empty bucket).

Example

```

// unordered_set_begin.cpp
// compile using: cl.exe /EHsc /nologo /W4 /MTd
#include <unordered_set>
#include <iostream>

using namespace std;

typedef unordered_set<char> MySet;

int main()
{
    MySet c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents using range-based for
    for (auto it : c1) {
        cout << "[" << it << "]" ";
    }

    cout << endl;

    // display contents using explicit for
    for (MySet::const_iterator it = c1.begin(); it != c1.end(); ++it) {
        cout << "[" << *it << "]" ";
    }

    cout << std::endl;

    // display first two items
    MySet::iterator it2 = c1.begin();
    cout << "[" << *it2 << "]" ";
    ++it2;
    cout << "[" << *it2 << "]" ";
    cout << endl;

    // display bucket containing 'a'
    MySet::const_local_iterator lit = c1.begin(c1.bucket('a'));
    cout << "[" << *lit << "]" ";

    return (0);
}

```

```

[a] [b] [c]
[a] [b] [c]
[a] [b]
[a]

```

unordered_set::bucket

Gets the bucket number for a key value.

```
size_type bucket(const Key& keyval) const;
```

Parameters

keyval

The key value to map.

Remarks

The member function returns the bucket number currently corresponding to the key value *keyval*.

Example

```
// std__unordered_set__unordered_set_bucket.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // display buckets for keys
    Myset::size_type bs = c1.bucket('a');
    std::cout << "bucket('a') == " << bs << std::endl;
    std::cout << "bucket_size(" << bs << ") == " << c1.bucket_size(bs)
    << std::endl;

    return (0);
}
```

```
[c] [b] [a]
bucket('a') == 7
bucket_size(7) == 1
```

unordered_set::bucket_count

Gets the number of buckets.

```
size_type bucket_count() const;
```

Remarks

The member function returns the current number of buckets.

Example

```

// std_unordered_set_unordered_set_bucket_count.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```

[c] [b] [a]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1

```

unordered_set::bucket_size

Gets the size of a bucket

```
size_type bucket_size(size_type nbucket) const;
```

Parameters

nbucket

The bucket number.

Remarks

The member functions returns the size of bucket number *nbucket*.

Example

```

// std__unordered_set__unordered_set_bucket_size.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << " ] ";
    std::cout << std::endl;

    // display buckets for keys
    Myset::size_type bs = c1.bucket('a');
    std::cout << "bucket('a') == " << bs << std::endl;
    std::cout << "bucket_size(" << bs << ") == " << c1.bucket_size(bs)
    << std::endl;

    return (0);
}

```

```
[c] [b] [a]
bucket('a') == 7
bucket_size(7) == 1
```

unordered_set::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** forward-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin`, the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 isContainer<T>::iterator
auto i2 = Container.cbegin();

// i2 isContainer<T>::const_iterator
```

unordered_set::cend

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A **const** forward-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 isContainer<T>::iterator
auto i2 = Container.cend();

// i2 isContainer<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

unordered_set::clear

Removes all elements.

```
void clear();
```

Remarks

The member function calls `unordered_set::erase` (`unordered_set::begin` (), `unordered_set::end` ()).

Example

```
// std__unordered_set__unordered_set_clear.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert('d');
    c1.insert('e');

    // display contents "[e] [d] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}
```

```
[c] [b] [a]
size == 0
empty() == true
[e] [d]
size == 2
empty() == false
```

unordered_set::const_iterator

The type of a constant iterator for the controlled sequence.

```
typedef T1 const_iterator;
```

Remarks

The type describes an object that can serve as a constant forward iterator for the controlled sequence. It is described here as a synonym for the implementation-defined type `T1`.

Example

```
// std__unordered_set__unordered_set_const_iterator.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << " ] ";
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
```

unordered_set::const_local_iterator

The type of a constant bucket iterator for the controlled sequence.

```
typedef T5 const_local_iterator;
```

Remarks

The type describes an object that can serve as a constant forward iterator for a bucket. It is described here as a synonym for the implementation-defined type `T5`.

Example

```

// std__unordered_set__unordered_set_const_local_iterator.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Myset::const_local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << "[" << *lit << "]" ";

    return (0);
}

```

```

[c] [b] [a]
[a]

```

unordered_set::const_pointer

The type of a constant pointer to an element.

```

typedef Alloc::const_pointer const_pointer;

```

Remarks

The type describes an object that can serve as a constant pointer to an element of the controlled sequence.

Example

```
// std__unordered_set__unordered_set_const_pointer.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::iterator it = c1.begin(); it != c1.end(); ++it)
    {
        Myset::const_pointer p = &*it;
        std::cout << "[" << *p << " ] ";
    }
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
```

unordered_set::const_reference

The type of a constant reference to an element.

```
typedef Alloc::const_reference const_reference;
```

Remarks

The type describes an object that can serve as a constant reference to an element of the controlled sequence.

Example

```
// std__unordered_set__unordered_set_const_reference.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::iterator it = c1.begin(); it != c1.end(); ++it)
    {
        Myset::const_reference ref = *it;
        std::cout << "[" << ref << "]" ";
    }
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
```

unordered_set::count

Finds the number of elements matching a specified key.

```
size_type count(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns the number of elements in the range delimited by [unordered_set::equal_range](#) (`keyval`) .

Example

```

// std__unordered_set__unordered_set_count.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << " ] ";
    std::cout << std::endl;

    std::cout << "count('A') == " << c1.count('A') << std::endl;
    std::cout << "count('b') == " << c1.count('b') << std::endl;
    std::cout << "count('C') == " << c1.count('C') << std::endl;

    return (0);
}

```

```

[c] [b] [a]
count('A') == 0
count('b') == 1
count('C') == 0

```

unordered_set::difference_type

The type of a signed distance between two elements.

```
typedef T3 difference_type;
```

Remarks

The signed integer type describes an object that can represent the difference between the addresses of any two elements in the controlled sequence. It is described here as a synonym for the implementation-defined type `T3`.

Example

```
// std__unordered_set__unordered_set_difference_type.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // compute positive difference
    Myset::difference_type diff = 0;
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        ++diff;
    std::cout << "end()-begin() == " << diff << std::endl;

    // compute negative difference
    diff = 0;
    for (Myset::const_iterator it = c1.end(); it != c1.begin(); --it)
        --diff;
    std::cout << "begin()-end() == " << diff << std::endl;

    return (0);
}
```

```
[c] [b] [a]
end()-begin() == 3
begin()-end() == -3
```

unordered_set::emplace

Inserts an element constructed in place (no copy or move operations are performed).

```
template <class... Args>
pair<iterator, bool>
emplace(
    Args&&... args);
```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the <code>unordered_set</code> unless it already contains an element whose value is equivalently ordered.

Return Value

A `pair` whose **bool** component returns true if an insertion was made and false if the `unordered_set` already contained an element whose key had an equivalent value in the ordering,

and whose iterator component returns the address where a new element was inserted or where the element was already located.

To access the iterator component of a pair `pr` returned by this member function, use `pr.first`, and to dereference it, use `*(pr.first)`. To access the **bool** component of a pair `pr` returned by this member function, use `pr.second`.

Remarks

No iterators or references are invalidated by this function.

During the insertion, if an exception is thrown but does not occur in the container's hash function, the container is not modified. If the exception is thrown in the hash function, the result is undefined.

For a code example, see [set::emplace](#).

unordered_set::emplace_hint

Inserts an element constructed in place (no copy or move operations are performed), with a placement hint.

```
template <class... Args>
iterator emplace_hint(
    const_iteratorwhere,
    Args&&... args);
```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the unordered_set unless the unordered_set already contains that element or, more generally, unless it already contains an element whose key is equivalently ordered.
<i>where</i>	A hint regarding the place to start searching for the correct point of insertion.

Return Value

An iterator to the newly inserted element.

If the insertion failed because the element already exists, returns an iterator to the existing element.

Remarks

No iterators or references are invalidated by this function.

During the insertion, if an exception is thrown but does not occur in the container's hash function, the container is not modified. If the exception is thrown in the hash function, the result is undefined.

For a code example, see [set::emplace_hint](#).

unordered_set::empty

Tests whether no elements are present.

```
bool empty() const;
```

Remarks

The member function returns true for an empty controlled sequence.

Example

```
// std__unordered_set__unordered_set_empty.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << " ";
    std::cout << std::endl;

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert('d');
    c1.insert('e');

    // display contents "[e] [d] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << " ";
    std::cout << std::endl;

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}
```

```
[c] [b] [a]
size == 0
empty() == true
[e] [d]
size == 2
empty() == false
```

unordered_set::end

Designates the end of the controlled sequence.

```

iterator end();

const_iterator end() const;

local_iterator end(size_type nbucket);

const_local_iterator end(size_type nbucket) const;

```

Parameters

PARAMETER	DESCRIPTION
<i>nbucket</i>	The bucket number.

Remarks

The first two member functions return a forward iterator that points just beyond the end of the sequence. The last two member functions return a forward iterator that points just beyond the end of bucket *nbucket*.

Example

```

// std__unordered_set__unordered_set_end.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << " ] ";
    std::cout << std::endl;

    // inspect last two items "[a] [b] "
    Myset::iterator it2 = c1.end();
    --it2;
    std::cout << "[" << *it2 << " ] ";
    --it2;
    std::cout << "[" << *it2 << " ] ";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Myset::const_local_iterator lit = c1.end(c1.bucket('a'));
    --lit;
    std::cout << "[" << *lit << " ] ";

    return (0);
}

```

```

[c] [b] [a]
[a] [b]
[a]

```

unordered_set::equal_range

Finds range that matches a specified key.

```
std::pair<iterator, iterator>
equal_range(const Key& keyval);

std::pair<const_iterator, const_iterator>
equal_range(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns a pair of iterators `x` such that `[x.first, x.second)` delimits just those elements of the controlled sequence that have equivalent ordering with *keyval*. If no such elements exist, both iterators are `end()`.

Example

```
// std__unordered_set__unordered_set_equal_range.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << " ] ";
    std::cout << std::endl;

    // display results of failed search
    std::pair<Myset::iterator, Myset::iterator> pair1 =
        c1.equal_range('x');
    std::cout << "equal_range('x'):";
    for (; pair1.first != pair1.second; ++pair1.first)
        std::cout << "[" << *pair1.first << " ] ";
    std::cout << std::endl;

    // display results of successful search
    pair1 = c1.equal_range('b');
    std::cout << "equal_range('b'):";
    for (; pair1.first != pair1.second; ++pair1.first)
        std::cout << "[" << *pair1.first << " ] ";
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
equal_range('x'):
equal_range('b'): [b]
```

unordered_set::erase

Removes an element or a range of elements in a `unordered_set` from specified positions or removes elements that match a specified key.

```
iterator erase(const_iterator Where);

iterator erase(const_iterator First, const_iterator Last);

size_type erase(const key_type& Key);
```

Parameters

Where

Position of the element to be removed.

First

Position of the first element to be removed.

Last

Position just beyond the last element to be removed.

Key

The key value of the elements to be removed.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or an element that is the end of the `unordered_set` if no such element exists.

For the third member function, returns the number of elements that have been removed from the `unordered_set`.

Remarks

For a code example, see [set::erase](#).

unordered_set::find

Finds an element that matches a specified key.

```
const_iterator find(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns `unordered_set::equal_range` `(keyval).first`.

Example

```

// std__unordered_set__unordered_set_find.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // try to find and fail
    std::cout << "find('A') == "
    << std::boolalpha << (c1.find('A') != c1.end()) << std::endl;

    // try to find and succeed
    Myset::iterator it = c1.find('b');
    std::cout << "find('b') == "
    << std::boolalpha << (it != c1.end())
    << ": [" << *it << "]" " << std::endl;

    return (0);
}

```

```

[c] [b] [a]
find('A') == false
find('b') == true: [b]

```

unordered_set::get_allocator

Gets the stored allocator object.

```

Alloc get_allocator() const;

```

Remarks

The member function returns the stored allocator object.

Example

```
// std__unordered_set__unordered_set_get_allocator.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
typedef std::allocator<std::pair<const char, int> > Myalloc;
int main()
{
    Myset c1;

    Myset::allocator_type al = c1.get_allocator();
    std::cout << "al == std::allocator() is "
    << std::boolalpha << (al == Myalloc()) << std::endl;

    return (0);
}
```

```
al == std::allocator() is true
```

unordered_set::hash_function

Gets the stored hash function object.

```
Hash hash_function() const;
```

Remarks

The member function returns the stored hash function object.

Example

```
// std__unordered_set__unordered_set_hash_function.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    Myset::hasher hfn = c1.hash_function();
    std::cout << "hfn('a') == " << hfn('a') << std::endl;
    std::cout << "hfn('b') == " << hfn('b') << std::endl;

    return (0);
}
```

```
hfn('a') == 1630279
hfn('b') == 1647086
```

unordered_set::hasher

The type of the hash function.

```
typedef Hash hasher;
```

Remarks

The type is a synonym for the template parameter `Hash`.

Example

```
// std__unordered_set__unordered_set_hasher.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    Myset::hasher hfn = c1.hash_function();
    std::cout << "hfn('a') == " << hfn('a') << std::endl;
    std::cout << "hfn('b') == " << hfn('b') << std::endl;

    return (0);
}
```

```
hfn('a') == 1630279
hfn('b') == 1647086
```

unordered_set::insert

Inserts an element or a range of elements into an unordered_set.

```
// (1) single element
pair<iterator, bool> insert(const value_type& Val);

// (2) single element, perfect forwarded
template <class ValTy>
pair<iterator, bool> insert(ValTy&& Val);

// (3) single element with hint
iterator insert(const_iterator Where, const value_type& Val);

// (4) single element, perfect forwarded, with hint
template <class ValTy>
iterator insert(const_iterator Where, ValTy&& Val);

// (5) range
template <class InputIterator>
void insert(InputIterator First, InputIterator Last);

// (6) initializer list
void insert(initializer_list<value_type> IList);
```

Parameters

PARAMETER	DESCRIPTION
-----------	-------------

PARAMETER	DESCRIPTION
<i>Val</i>	The value of an element to be inserted into the <code>unordered_set</code> unless it already contains an element whose key is equivalently ordered.
<i>Where</i>	The place to start searching for the correct point of insertion.
<i>ValTy</i>	Template parameter that specifies the argument type that the <code>unordered_set</code> can use to construct an element of <code>value_type</code> , and perfect-forwards <i>Val</i> as an argument.
<i>First</i>	The position of the first element to be copied.
<i>Last</i>	The position just beyond the last element to be copied.
<i>InputIterator</i>	Template function argument that meets the requirements of an <code>input iterator</code> that points to elements of a type that can be used to construct <code>value_type</code> objects.
<i>lList</i>	The <code>initializer_list</code> from which to copy the elements.

Return Value

The single-element member functions, (1) and (2), return a `pair` whose **bool** component is true if an insertion was made, and false if the `unordered_set` already contained an element whose key had an equivalent value in the ordering. The iterator component of the return-value pair points to the newly inserted element if the **bool** component is true, or to the existing element if the **bool** component is false.

The single-element-with-hint member functions, (3) and (4), return an iterator that points to the position where the new element was inserted into the `unordered_set` or, if an element with an equivalent key already exists, to the existing element.

Remarks

No iterators, pointers, or references are invalidated by this function.

During the insertion of just one element, if an exception is thrown but does not occur in the container's hash function, the container's state is not modified. If the exception is thrown in the hash function, the result is undefined. During the insertion of multiple elements, if an exception is thrown, the container is left in an unspecified but valid state.

To access the iterator component of a `pair` `pr` that's returned by the single-element member functions, use `pr.first`; to dereference the iterator within the returned pair, use `*pr.first`, giving you an element. To access the **bool** component, use `pr.second`. For an example, see the sample code later in this article.

The `value_type` of a container is a typedef that belongs to the container, and, for set,

```
unordered_set<V>::value_type is type const V.
```

The range member function (5) inserts the sequence of element values into an `unordered_set` that corresponds to each element addressed by an iterator in the range `[First, Last)`; therefore, *Last* does not get inserted. The container member function `end()` refers to the position just after the last

element in the container—for example, the statement `s.insert(v.begin(), v.end());` attempts to insert all elements of `v` into `s`. Only elements that have unique values in the range are inserted; duplicates are ignored. To observe which elements are rejected, use the single-element versions of `insert`.

The initializer list member function (6) uses an [initializer_list](#) to copy elements into the `unordered_set`.

For insertion of an element constructed in place—that is, no copy or move operations are performed—see [set::emplace](#) and [set::emplace_hint](#).

For a code example, see [set::insert](#).

unordered_set::iterator

A type that provides a constant [forward iterator](#) that can read elements in an `unordered_set`.

```
typedef implementation-defined iterator;
```

Example

See the example for [begin](#) for an example of how to declare and use an **iterator**.

unordered_set::key_eq

Gets the stored comparison function object.

```
Pred key_eq() const;
```

Remarks

The member function returns the stored comparison function object.

Example

```
// std__unordered_set__unordered_set_key_eq.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    Myset::key_equal cmpfn = c1.key_eq();
    std::cout << "cmpfn('a', 'a') == "
    << std::boolalpha << cmpfn('a', 'a') << std::endl;
    std::cout << "cmpfn('a', 'b') == "
    << std::boolalpha << cmpfn('a', 'b') << std::endl;

    return (0);
}
```

```
cmpfn('a', 'a') == true
cmpfn('a', 'b') == false
```

unordered_set::key_equal

The type of the comparison function.

```
typedef Pred key_equal;
```

Remarks

The type is a synonym for the template parameter `Pred`.

Example

```
// std__unordered_set__unordered_set_key_equal.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    Myset::key_equal cmpfn = c1.key_eq();
    std::cout << "cmpfn('a', 'a') == "
    << std::boolalpha << cmpfn('a', 'a') << std::endl;
    std::cout << "cmpfn('a', 'b') == "
    << std::boolalpha << cmpfn('a', 'b') << std::endl;

    return (0);
}
```

```
cmpfn('a', 'a') == true
cmpfn('a', 'b') == false
```

unordered_set::key_type

The type of an ordering key.

```
typedef Key key_type;
```

Remarks

The type is a synonym for the template parameter `Key`.

Example

```

// std__unordered_set__unordered_set_key_type.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // add a value and reinspect
    Myset::key_type key = 'd';
    Myset::value_type val = key;
    c1.insert(val);

    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    return (0);
}

```

```

[c] [b] [a]
[d] [c] [b] [a]

```

unordered_set::load_factor

Counts the average elements per bucket.

```
float load_factor() const;
```

Remarks

The member function returns `(float) unordered_set::size () / (float) unordered_set::bucket_count ()`, the average number of elements per bucket.

Example

```

// std_unordered_set_unordered_set_load_factor.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```

[c] [b] [a]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1

```

unordered_set::local_iterator

The type of a bucket iterator.

```
typedef T4 local_iterator;
```

Remarks

The type describes an object that can serve as a forward iterator for a bucket. It is described here as a synonym for the implementation-defined type `T4`.

Example

```

// std__unordered_set__unordered_set_local_iterator.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Myset::local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << "[" << *lit << "]" ";

    return (0);
}

```

```

[c] [b] [a]
[a]

```

unordered_set::max_bucket_count

Gets the maximum number of buckets.

```
size_type max_bucket_count() const;
```

Remarks

The member function returns the maximum number of buckets currently permitted.

Example

```
// std__unordered_set__unordered_set_max_bucket_count.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "] ";
    std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1
```

unordered_set::max_load_factor

Gets or sets the maximum elements per bucket.

```
float max_load_factor() const;

void max_load_factor(float factor);
```

Parameters

factor

The new maximum load factor.

Remarks

The first member function returns the stored maximum load factor. The second member function replaces the stored maximum load factor with *factor*.

Example

```

// std__unordered_set__unordered_set_max_load_factor.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
    << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
    << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```

[c] [b] [a]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1

```

unordered_set::max_size

Gets the maximum size of the controlled sequence.

```
size_type max_size() const;
```

Remarks

The member function returns the length of the longest sequence that the object can control.

Example

```

// std__unordered_set__unordered_set_max_size.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    std::cout << "max_size() == " << c1.max_size() << std::endl;

    return (0);
}

```

```
max_size() == 4294967295
```

unordered_set::operator=

Copies a hash table.

```

unordered_set& operator=(const unordered_set& right);

unordered_set& operator=(unordered_set&& right);

```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The <code>unordered_set</code> being copied into the <code>unordered_set</code> .

Remarks

After erasing any existing elements in an `unordered_set`, `operator=` either copies or moves the contents of *right* into the `unordered_set`.

Example

```
// unordered_set_operator_as.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

int main( )
{
    using namespace std;
    unordered_set<int> v1, v2, v3;
    unordered_set<int>::iterator iter;

    v1.insert(10);

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;
}
```

unordered_set::pointer

The type of a pointer to an element.

```
typedef Alloc::pointer pointer;
```

Remarks

The type describes an object that can serve as a pointer to an element of the controlled sequence.

Example

```

// std__unordered_set__unordered_set_pointer.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::iterator it = c1.begin(); it != c1.end(); ++it)
    {
        Myset::key_type key = *it;
        Myset::pointer p = &key;
        std::cout << "[" << *p << "]" ";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c] [b] [a]
```

unordered_set::reference

The type of a reference to an element.

```
typedef Alloc::reference reference;
```

Remarks

The type describes an object that can serve as a reference to an element of the controlled sequence.

Example

```

// std__unordered_set__unordered_set_reference.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::iterator it = c1.begin(); it != c1.end(); ++it)
    {
        Myset::key_type key = *it;
        Myset::reference ref = key;
        std::cout << "[" << ref << "]" ";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c] [b] [a]
```

unordered_set::rehash

Rebuilds the hash table.

```
void rehash(size_type nbuckets);
```

Parameters

nbuckets

The requested number of buckets.

Remarks

The member function alters the number of buckets to be at least *nbuckets* and rebuilds the hash table as needed.

Example

```

// std__unordered_set__unordered_set_rehash.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_load_factor() == " << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_load_factor() == " << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_load_factor() == " << c1.max_load_factor() << std::endl;

    return (0);
}

```

```

[c] [b] [a]
bucket_count() == 8
load_factor() == 0.375
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_load_factor() == 0.1

```

unordered_set::size

Counts the number of elements.

```
size_type size() const;
```

Remarks

The member function returns the length of the controlled sequence.

Example

```
// std__unordered_set__unordered_set_size.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert('d');
    c1.insert('e');

    // display contents "[e] [d] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}
```

```
[c] [b] [a]
size == 0
empty() == true

[e] [d]
size == 2
empty() == false
```

unordered_set::size_type

The type of an unsigned distance between two elements.

```
typedef T2 size_type;
```

Remarks

The unsigned integer type describes an object that can represent the length of any controlled sequence. It is described here as a synonym for the implementation-defined type `T2`.

Example

```
// std__unordered_set__unordered_set_size_type.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;
    Myset::size_type sz = c1.size();

    std::cout << "size == " << sz << std::endl;

    return (0);
}
```

```
size == 0
```

unordered_set::swap

Swaps the contents of two containers.

```
void swap(unordered_set& right);
```

Parameters

right

The container to swap with.

Remarks

The member function swaps the controlled sequences between `*this` and *right*. If `unordered_set::get_allocator()` `() == right.get_allocator()`, it does so in constant time, it throws an exception only as a result of copying the stored traits object of type `Tr`, and it invalidates no references, pointers, or iterators that designate elements in the two controlled sequences. Otherwise, it performs a number of element assignments and constructor calls proportional to the number of elements in the two controlled sequences.

Example

```

// std__unordered_set__unordered_set_swap.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    Myset c2;

    c2.insert('d');
    c2.insert('e');
    c2.insert('f');

    c1.swap(c2);

    // display contents "[f] [e] [d] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    swap(c1, c2);

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    return (0);
}

```

```

[c] [b] [a]
[f] [e] [d]
[c] [b] [a]

```

unordered_set::unordered_set

Constructs a container object.

```

unordered_set(const unordered_set& Right);

explicit unordered_set(
    size_type bucket_count = N0,
    const Hash& Hash = Hash(),
    const Comp& Comp = Comp(),
    const Allocator& Al = Alloc());

unordered_set(unordered_set&& Right);

unordered_set(initializer_list<Type> IList);

unordered_set(initializer_list<Type> IList, size_type bucket_count);

unordered_set(
    initializer_list<Type> IList,
    size_type bucket_count,
    const Hash& Hash);

unordered_set(
    initializer_list<Type> IList,
    size_type bucket_count,
    const Hash& Hash,
    const Comp& Comp);

unordered_set(
    initializer_list<Type> IList,
    size_type bucket_count,
    const Hash& Hash,
    const Comp& Comp,
    const Allocator& Al);

template <class InputIterator>
unordered_set(
    InputIterator first,
    InputIterator last,
    size_type bucket_count = N0,
    const Hash& Hash = Hash(),
    const Comp& Comp = Comp(),
    const Allocator& Al = Alloc());

```

Parameters

PARAMETER	DESCRIPTION
<i>InputIterator</i>	The iterator type.
<i>Al</i>	The allocator object to store.
<i>Comp</i>	The comparison function object to store.
<i>Hash</i>	The hash function object to store.
<i>bucket_count</i>	The minimum number of buckets.
<i>Right</i>	The container to copy.
<i>IList</i>	The initializer_list containing the elements to copy.

Remarks

The first constructor specifies a copy of the sequence controlled by *Right*. The second constructor

specifies an empty controlled sequence. The third constructor specifies a copy of the sequence by moving *Right*. The fourth through eighth constructors use an `initializer_list` to specify the elements to copy. The ninth constructor inserts the sequence of element values `[first, last)`.

All constructors also initialize several stored values. For the copy constructor, the values are obtained from *Right*. Otherwise:

The minimum number of buckets is the argument *bucket_count*, if present; otherwise it is a default value described here as the implementation-defined value `NO`.

The hash function object is the argument *Hash*, if present; otherwise it is `Hash()`.

The comparison function object is the argument *Comp*, if present; otherwise it is `Comp()`.

The allocator object is the argument *Al*, if present; otherwise, it is `Alloc()`.

unordered_set::value_type

The type of an element.

```
typedef Key value_type;
```

Remarks

The type describes an element of the controlled sequence.

Example

```
// std__unordered_set__unordered_set_value_type.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_set<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // add a value and reinspect
    Myset::key_type key = 'd';
    Myset::value_type val = key;
    c1.insert(val);

    for (Myset::const_iterator it = c1.begin(); it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
[d] [c] [b] [a]
```

unordered_multiset Class

11/9/2018 • 35 minutes to read • [Edit Online](#)

The template class describes an object that controls a varying-length sequence of elements of type `const Key`. The sequence is weakly ordered by a hash function, which partitions the sequence into an ordered set of subsequences called buckets. Within each bucket a comparison function determines whether any pair of elements has equivalent ordering. Each element serves as both a sort key and a value. The sequence is represented in a way that permits lookup, insertion, and removal of an arbitrary element with a number of operations that can be independent of the number of elements in the sequence (constant time), at least when all buckets are of roughly equal length. In the worst case, when all of the elements are in one bucket, the number of operations is proportional to the number of elements in the sequence (linear time). Moreover, inserting an element invalidates no iterators, and removing an element invalidates only those iterators which point at the removed element.

Syntax

```
template <class Key,  
          class Hash = std::hash<Key>,  
          class Pred = std::equal_to<Key>,  
          class Alloc = std::allocator<Key>>  
class unordered_multiset;
```

Parameters

PARAMETER	DESCRIPTION
<i>Key</i>	The key type.
<i>Hash</i>	The hash function object type.
<i>Pred</i>	The equality comparison function object type.
<i>Alloc</i>	The allocator class.

Members

TYPE DEFINITION	DESCRIPTION
allocator_type	The type of an allocator for managing storage.
const_iterator	The type of a constant iterator for the controlled sequence.
const_local_iterator	The type of a constant bucket iterator for the controlled sequence.
const_pointer	The type of a constant pointer to an element.
const_reference	The type of a constant reference to an element.

TYPE DEFINITION	DESCRIPTION
difference_type	The type of a signed distance between two elements.
hasher	The type of the hash function.
iterator	The type of an iterator for the controlled sequence.
key_equal	The type of the comparison function.
key_type	The type of an ordering key.
local_iterator	The type of a bucket iterator for the controlled sequence.
pointer	The type of a pointer to an element.
reference	The type of a reference to an element.
size_type	The type of an unsigned distance between two elements.
value_type	The type of an element.
MEMBER FUNCTION	DESCRIPTION
begin	Designates the beginning of the controlled sequence.
bucket	Gets the bucket number for a key value.
bucket_count	Gets the number of buckets.
bucket_size	Gets the size of a bucket.
cbegin	Designates the beginning of the controlled sequence.
cend	Designates the end of the controlled sequence.
clear	Removes all elements.
count	Finds the number of elements matching a specified key.
emplace	Adds an element constructed in place.
emplace_hint	Adds an element constructed in place, with hint.
empty	Tests whether no elements are present.
end	Designates the end of the controlled sequence.
equal_range	Finds range that matches a specified key.

MEMBER FUNCTION	DESCRIPTION
<code>erase</code>	Removes elements at specified positions.
<code>find</code>	Finds an element that matches a specified key.
<code>get_allocator</code>	Gets the stored allocator object.
<code>hash_function</code>	Gets the stored hash function object.
<code>insert</code>	Adds elements.
<code>key_eq</code>	Gets the stored comparison function object.
<code>load_factor</code>	Counts the average elements per bucket.
<code>max_bucket_count</code>	Gets the maximum number of buckets.
<code>max_load_factor</code>	Gets or sets the maximum elements per bucket.
<code>max_size</code>	Gets the maximum size of the controlled sequence.
<code>rehash</code>	Rebuilds the hash table.
<code>size</code>	Counts the number of elements.
<code>swap</code>	Swaps the contents of two containers.
<code>unordered_multiset</code>	Constructs a container object.

OPERATOR	DESCRIPTION
<code>unordered_multiset::operator=</code>	Copies a hash table.

Remarks

The object orders the sequence it controls by calling two stored objects, a comparison function object of type `unordered_multiset::key_equal` and a hash function object of type `unordered_multiset::hasher`. You access the first stored object by calling the member function `unordered_multiset::key_eq()`; and you access the second stored object by calling the member function `unordered_multiset::hash_function()`. Specifically, for all values `x` and `y` of type `key`, the call `key_eq()(X, Y)` returns true only if the two argument values have equivalent ordering; the call `hash_function()(keyval)` yields a distribution of values of type `size_t`. Unlike template class `unordered_set` Class, an object of template class `unordered_multiset` does not ensure that `key_eq()(X, Y)` is always false for any two elements of the controlled sequence. (Keys need not be unique.)

The object also stores a maximum load factor, which specifies the maximum desired average number of elements per bucket. If inserting an element causes `unordered_multiset::load_factor()` to exceed the maximum load factor, the container increases the number of buckets and rebuilds the hash table as needed.

The actual order of elements in the controlled sequence depends on the hash function, the comparison function, the order of insertion, the maximum load factor, and the current number of buckets. You cannot in general predict the order of elements in the controlled sequence. You can always be assured, however, that any subset of elements that have equivalent ordering are adjacent in the controlled sequence.

The object allocates and frees storage for the sequence it controls through a stored allocator object of type `unordered_multiset::allocator_type`. Such an allocator object must have the same external interface as an object of template class `allocator`. Note that the stored allocator object is not copied when the container object is assigned.

Requirements

Header: `<unordered_set>`

Namespace: `std`

`unordered_multiset::allocator_type`

The type of an allocator for managing storage.

```
typedef Alloc allocator_type;
```

Remarks

The type is a synonym for the template parameter `Alloc`.

Example

```
// std__unordered_set__unordered_multiset_allocator_type.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
typedef std::allocator<std::pair<const char, int> > Myalloc;
int main()
{
    Myset c1;

    Myset::allocator_type al = c1.get_allocator();
    std::cout << "al == std::allocator() is "
        << std::boolalpha << (al == Myalloc()) << std::endl;

    return (0);
}
```

```
al == std::allocator() is true
```

`unordered_multiset::begin`

Designates the beginning of the controlled sequence or a bucket.

```

iterator begin();

const_iterator begin() const;

local_iterator begin(size_type nbucket);

const_local_iterator begin(size_type nbucket) const;

```

Parameters

PARAMETER	DESCRIPTION
<i>nbucket</i>	The bucket number.

Remarks

The first two member functions return a forward iterator that points at the first element of the sequence (or just beyond the end of an empty sequence). The last two member functions return a forward iterator that points at the first element of bucket *nbucket* (or just beyond the end of an empty bucket).

Example

```

// std__unordered_set__unordered_multiset_begin.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect first two items "[c] [b]"
    Myset::iterator it2 = c1.begin();
    std::cout << "[" << *it2 << "]" ";
    ++it2;
    std::cout << "[" << *it2 << "]" ";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Myset::const_local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << "[" << *lit << "]" ";

    return (0);
}

```

```

[c] [b] [a]
[c] [b]
[a]

```

unordered_multiset::bucket

Gets the bucket number for a key value.

```
size_type bucket(const Key& keyval) const;
```

Parameters

keyval

The key value to map.

Remarks

The member function returns the bucket number currently corresponding to the key value `keyval`.

Example

```
// std__unordered_set__unordered_multiset_bucket.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // display buckets for keys
    Myset::size_type bs = c1.bucket('a');
    std::cout << "bucket('a') == " << bs << std::endl;
    std::cout << "bucket_size(" << bs << ") == " << c1.bucket_size(bs)
        << std::endl;

    return (0);
}
```

```
[c] [b] [a]
bucket('a') == 7
bucket_size(7) == 1
```

unordered_multiset::bucket_count

Gets the number of buckets.

```
size_type bucket_count() const;
```

Remarks

The member function returns the current number of buckets.

Example

```
// std_unordered_set_unordered_multiset_bucket_count.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;

    return (0);
}
```

```

[c] [b] [a]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1

```

unordered_multiset::bucket_size

Gets the size of a bucket

```
size_type bucket_size(size_type nbucket) const;
```

Parameters

nbucket

The bucket number.

Remarks

The member functions returns the size of bucket number *nbucket*.

Example

```

// std__unordered_set__unordered_multiset_bucket_size.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // display buckets for keys
    Myset::size_type bs = c1.bucket('a');
    std::cout << "bucket('a') == " << bs << std::endl;
    std::cout << "bucket_size(" << bs << ") == " << c1.bucket_size(bs)
        << std::endl;

    return (0);
}

```

```
[c] [b] [a]
bucket('a') == 7
bucket_size(7) == 1
```

unordered_multiset::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** forward-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin` , the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator` . Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()` .

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator

auto i2 = Container.cbegin();
// i2 is Container<T>::const_iterator
```

unordered_multiset::cend

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A **const** forward-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator` . Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `end()` and `cend()` .

```
auto i1 = Container.end();
// i1 is Container<T>::iterator

auto i2 = Container.cend();
// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

`unordered_multiset::clear`

Removes all elements.

```
void clear();
```

Remarks

The member function calls `unordered_multiset::erase` (`unordered_multiset::begin` (), `unordered_multiset::end` ()).

Example

```
// std__unordered_set__unordered_multiset_clear.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a] "
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert('d');
    c1.insert('e');

    // display contents "[e] [d] "
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}
```

```
[c] [b] [a]
size == 0
empty() == true

[e] [d]
size == 2
empty() == false
```

unordered_multiset::const_iterator

The type of a constant iterator for the controlled sequence.

```
typedef T1 const_iterator;
```

Remarks

The type describes an object that can serve as a constant forward iterator for the controlled sequence. It is described here as a synonym for the implementation-defined type `T1`.

Example

```
// std__unordered_set__unordered_multiset_const_iterator.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << " ] ";
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
```

unordered_multiset::const_local_iterator

The type of a constant bucket iterator for the controlled sequence.

```
typedef T5 const_local_iterator;
```

Remarks

The type describes an object that can serve as a constant forward iterator for a bucket. It is described here as a synonym for the implementation-defined type `T5`.

Example

```
// std__unordered_set__unordered_multiset_const_local_iterator.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Myset::const_local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << "[" << *lit << "]" ";

    return (0);
}
```

```
[c] [b] [a]
[a]
```

unordered_multiset::const_pointer

The type of a constant pointer to an element.

```
typedef Alloc::const_pointer const_pointer;
```

Remarks

The type describes an object that can serve as a constant pointer to an element of the controlled sequence.

Example

```

// std__unordered_set__unordered_multiset_const_pointer.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Myset::const_pointer p = &*it;
        std::cout << "[" << *p << "]" ";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c] [b] [a]
```

unordered_multiset::const_reference

The type of a constant reference to an element.

```
typedef Alloc::const_reference const_reference;
```

Remarks

The type describes an object that can serve as a constant reference to an element of the controlled sequence.

Example

```
// std__unordered_set__unordered_multiset_const_reference.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Myset::const_reference ref = *it;
        std::cout << "[" << ref << "]" ";
    }
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
```

unordered_multiset::count

Finds the number of elements matching a specified key.

```
size_type count(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns the number of elements in the range delimited by [unordered_multiset::equal_range](#) (`keyval`) .

Example

```

// std__unordered_set__unordered_multiset_count.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    std::cout << "count('A') == " << c1.count('A') << std::endl;
    std::cout << "count('b') == " << c1.count('b') << std::endl;
    std::cout << "count('C') == " << c1.count('C') << std::endl;

    return (0);
}

```

```

[c] [b] [a]
count('A') == 0
count('b') == 1
count('C') == 0

```

unordered_multiset::difference_type

The type of a signed distance between two elements.

```
typedef T3 difference_type;
```

Remarks

The signed integer type describes an object that can represent the difference between the addresses of any two elements in the controlled sequence. It is described here as a synonym for the implementation-defined type `T3`.

Example

```

// std__unordered_set__unordered_multiset_difference_type.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // compute positive difference
    Myset::difference_type diff = 0;
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        ++diff;
    std::cout << "end()-begin() == " << diff << std::endl;

    // compute negative difference
    diff = 0;
    for (Myset::const_iterator it = c1.end();
         it != c1.begin(); --it)
        --diff;
    std::cout << "begin()-end() == " << diff << std::endl;

    return (0);
}

```

```

[c] [b] [a]
end()-begin() == 3
begin()-end() == -3

```

unordered_multiset::emplace

Inserts an element constructed in place (no copy or move operations are performed).

```

template <class... Args>
iterator emplace(Args&&... args);

```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the unordered_multiset.

Return Value

An iterator to the newly inserted element.

Remarks

No references to container elements are invalidated by this function, but it may invalidate all iterators to the container.

During the insertion, if an exception is thrown but does not occur in the container's hash function, the container is not modified. If the exception is thrown in the hash function, the result is undefined.

For a code example, see [multiset::emplace](#).

unordered_multiset::emplace_hint

Inserts an element constructed in place (no copy or move operations are performed), with a placement hint.

```
template <class... Args>
iterator emplace_hint(
    const_iterator where,
    Args&&... args);
```

Parameters

PARAMETER	DESCRIPTION
<i>args</i>	The arguments forwarded to construct an element to be inserted into the unordered_multiset.
<i>where</i>	A hint regarding the place to start searching for the correct point of insertion.

Return Value

An iterator to the newly inserted element.

Remarks

No references to container elements are invalidated by this function, but it may invalidate all iterators to the container.

During the insertion, if an exception is thrown but does not occur in the container's hash function, the container is not modified. If the exception is thrown in the hash function, the result is undefined.

For a code example, see [set::emplace_hint](#).

unordered_multiset::empty

Tests whether no elements are present.

```
bool empty() const;
```

Remarks

The member function returns true for an empty controlled sequence.

Example

```

// std__unordered_set__unordered_multiset_empty.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert('d');
    c1.insert('e');

    // display contents "[e] [d]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}

```

```

[c] [b] [a]
size == 0
empty() == true

[e] [d]
size == 2
empty() == false

```

unordered_multiset::end

Designates the end of the controlled sequence.

```

iterator end();
const_iterator end() const;
local_iterator end(size_type nbucket);
const_local_iterator end(size_type nbucket) const;

```

Parameters

nbucket

The bucket number.

Remarks

The first two member functions return a forward iterator that points just beyond the end of the sequence. The last two member functions return a forward iterator that points just beyond the end of bucket *nbucket*.

Example

```
// std__unordered_set__unordered_multiset_end.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect last two items "[a] [b]"
    Myset::iterator it2 = c1.end();
    --it2;
    std::cout << "[" << *it2 << "]" ";
    --it2;
    std::cout << "[" << *it2 << "]" ";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Myset::const_local_iterator lit = c1.end(c1.bucket('a'));
    --lit;
    std::cout << "[" << *lit << "]" ";

    return (0);
}
```

```
[c] [b] [a]
[a] [b]
[a]
```

unordered_multiset::equal_range

Finds range that matches a specified key.

```
std::pair<iterator, iterator>
    equal_range(const Key& keyval);

std::pair<const_iterator, const_iterator>
    equal_range(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns a pair of iterators `x` such that `[x.first, x.second)` delimits just those elements of the controlled sequence that have equivalent ordering with *keyval*. If no such elements exist, both iterators are `end()`.

Example

```
// std__unordered_set__unordered_multiset_equal_range.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // display results of failed search
    std::pair<Myset::iterator, Myset::iterator> pair1 =
        c1.equal_range('x');
    std::cout << "equal_range('x'):";
    for (; pair1.first != pair1.second; ++pair1.first)
        std::cout << "[" << *pair1.first << "]" ";
    std::cout << std::endl;

    // display results of successful search
    pair1 = c1.equal_range('b');
    std::cout << "equal_range('b'):";
    for (; pair1.first != pair1.second; ++pair1.first)
        std::cout << "[" << *pair1.first << "]" ";
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
equal_range('x'):
equal_range('b'): [b]
```

unordered_multiset::erase

Removes an element or a range of elements in a `unordered_multiset` from specified positions or removes elements that match a specified key.

```
iterator erase(
    const_iterator Where);

iterator erase(
    const_iterator First,
    const_iterator Last);

size_type erase(
    const key_type& Key);
```

Parameters

Where

Position of the element to be removed.

First

Position of the first element to be removed.

Last

Position just beyond the last element to be removed.

Key

The key value of the elements to be removed.

Return Value

For the first two member functions, a bidirectional iterator that designates the first element remaining beyond any elements removed, or an element that is the end of the `unordered_multiset` if no such element exists.

For the third member function, returns the number of elements that have been removed from the `unordered_multiset`.

Remarks

For a code example, see [set::erase](#).

unordered_multiset::find

Finds an element that matches a specified key.

```
const_iterator find(const Key& keyval) const;
```

Parameters

keyval

Key value to search for.

Remarks

The member function returns [unordered_multiset::equal_range](#) `(keyval).first`.

Example

```

// std__unordered_set__unordered_multiset_find.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // try to find and fail
    std::cout << "find('A') == "
        << std::boolalpha << (c1.find('A') != c1.end()) << std::endl;

    // try to find and succeed
    Myset::iterator it = c1.find('b');
    std::cout << "find('b') == "
        << std::boolalpha << (it != c1.end())
        << ": [" << *it << "]" " << std::endl;

    return (0);
}

```

```

[c] [b] [a]
find('A') == false
find('b') == true: [b]

```

unordered_multiset::get_allocator

Gets the stored allocator object.

```

Alloc get_allocator() const;

```

Remarks

The member function returns the stored allocator object.

Example

```
// std__unordered_set__unordered_multiset_get_allocator.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
typedef std::allocator<std::pair<const char, int> > Myalloc;
int main()
{
    Myset c1;

    Myset::allocator_type al = c1.get_allocator();
    std::cout << "al == std::allocator() is "
        << std::boolalpha << (al == Myalloc()) << std::endl;

    return (0);
}
```

```
al == std::allocator() is true
```

unordered_multiset::hash_function

Gets the stored hash function object.

```
Hash hash_function() const;
```

Remarks

The member function returns the stored hash function object.

Example

```
// std__unordered_set__unordered_multiset_hash_function.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    Myset::hasher hfn = c1.hash_function();
    std::cout << "hfn('a') == " << hfn('a') << std::endl;
    std::cout << "hfn('b') == " << hfn('b') << std::endl;

    return (0);
}
```

```
hfn('a') == 1630279
hfn('b') == 1647086
```

unordered_multiset::hasher

The type of the hash function.

```
typedef Hash hasher;
```

Remarks

The type is a synonym for the template parameter `Hash`.

Example

```
// std__unordered_set__unordered_multiset_hasher.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    Myset::hasher hfn = c1.hash_function();
    std::cout << "hfn('a') == " << hfn('a') << std::endl;
    std::cout << "hfn('b') == " << hfn('b') << std::endl;

    return (0);
}
```

```
hfn('a') == 1630279
hfn('b') == 1647086
```

unordered_multiset::insert

Inserts an element or a range of elements into an `unordered_multiset`.

```

// (1) single element
pair<iterator, bool> insert(
    const value_type& Val);

// (2) single element, perfect forwarded
template <class ValTy>
pair<iterator, bool>
insert(
    ValTy&& Val);

// (3) single element with hint
iterator insert(
    const_iterator Where,
    const value_type& Val);

// (4) single element, perfect forwarded, with hint
template <class ValTy>
iterator insert(
    const_iterator Where,
    ValTy&& Val);

// (5) range
template <class InputIterator>
void insert(
    InputIterator First,
    InputIterator Last);

// (6) initializer list
void insert(
    initializer_list<value_type>
    IList);

```

Parameters

PARAMETER	DESCRIPTION
<i>Val</i>	The value of an element to be inserted into the <code>unordered_multiset</code> .
<i>Where</i>	The place to start searching for the correct point of insertion.
<i>ValTy</i>	Template parameter that specifies the argument type that the <code>unordered_multiset</code> can use to construct an element of value_type , and perfect-forwards <i>Val</i> as an argument.
<i>First</i>	The position of the first element to be copied.
<i>Last</i>	The position just beyond the last element to be copied.
<i>InputIterator</i>	Template function argument that meets the requirements of an input iterator that points to elements of a type that can be used to construct value_type objects.
<i>IList</i>	The initializer_list from which to copy the elements.

Return Value

The single-element-insert member functions, (1) and (2), return an iterator to the position where the

new element was inserted into the `unordered_multiset`.

The single-element-with-hint member functions, (3) and (4), return an iterator that points to the position where the new element was inserted into the `unordered_multiset`.

Remarks

No pointers or references are invalidated by this function, but it may invalidate all iterators to the container.

During the insertion of just one element, if an exception is thrown but does not occur in the container's hash function, the container's state is not modified. If the exception is thrown in the hash function, the result is undefined. During the insertion of multiple elements, if an exception is thrown, the container is left in an unspecified but valid state.

The `value_type` of a container is a typedef that belongs to the container, and, for set,

```
unordered_multiset<V>::value_type is type const V .
```

The range member function (5) inserts the sequence of element values into an `unordered_multiset` that corresponds to each element addressed by an iterator in the range `[First, Last)`; therefore, `Last` does not get inserted. The container member function `end()` refers to the position just after the last element in the container—for example, the statement `m.insert(v.begin(), v.end());` inserts all elements of `v` into `m`.

The initializer list member function (6) uses an `initializer_list` to copy elements into the `unordered_multiset`.

For insertion of an element constructed in place—that is, no copy or move operations are performed—see `unordered_multiset::emplace` and `unordered_multiset::emplace_hint`.

For a code example, see `multiset::insert`.

unordered_multiset::iterator

A type that provides a constant `forward iterator` that can read elements in an `unordered_multiset`.

```
typedef implementation-defined iterator;
```

Example

See the example for `begin` for an example of how to declare and use an **iterator**.

unordered_multiset::key_eq

Gets the stored comparison function object.

```
Pred key_eq() const;
```

Remarks

The member function returns the stored comparison function object.

Example

```
// std__unordered_set__unordered_multiset_key_eq.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    Myset::key_equal cmpfn = c1.key_eq();
    std::cout << "cmpfn('a', 'a') == "
        << std::boolalpha << cmpfn('a', 'a') << std::endl;
    std::cout << "cmpfn('a', 'b') == "
        << std::boolalpha << cmpfn('a', 'b') << std::endl;

    return (0);
}
```

```
cmpfn('a', 'a') == true
cmpfn('a', 'b') == false
```

unordered_multiset::key_equal

The type of the comparison function.

```
typedef Pred key_equal;
```

Remarks

The type is a synonym for the template parameter `Pred`.

Example

```
// std__unordered_set__unordered_multiset_key_equal.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    Myset::key_equal cmpfn = c1.key_eq();
    std::cout << "cmpfn('a', 'a') == "
        << std::boolalpha << cmpfn('a', 'a') << std::endl;
    std::cout << "cmpfn('a', 'b') == "
        << std::boolalpha << cmpfn('a', 'b') << std::endl;

    return (0);
}
```

```
cmpfn('a', 'a') == true
cmpfn('a', 'b') == false
```

unordered_multiset::key_type

The type of an ordering key.

```
typedef Key key_type;
```

Remarks

The type is a synonym for the template parameter `Key`.

Example

```
// std_unordered_set_unordered_multiset_key_type.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // add a value and reinspect
    Myset::key_type key = 'd';
    Myset::value_type val = key;
    c1.insert(val);

    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
[d] [c] [b] [a]
```

unordered_multiset::load_factor

Counts the average elements per bucket.

```
float load_factor() const;
```

Remarks

The member function returns `(float) unordered_multiset::size() / (float) unordered_multiset::bucket_count()`, the average number of elements per bucket.

Example

```

// std__unordered_set__unordered_multiset_load_factor.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

unordered_multiset::local_iterator

The type of a bucket iterator.

```
typedef T4 local_iterator;
```

Remarks

The type describes an object that can serve as a forward iterator for a bucket. It is described here as a synonym for the implementation-defined type `T4`.

Example

```
// std__unordered_set__unordered_multiset_local_iterator.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect bucket containing 'a'
    Myset::local_iterator lit = c1.begin(c1.bucket('a'));
    std::cout << "[" << *lit << "]" ";

    return (0);
}
```

```
[c] [b] [a]
[a]
```

unordered_multiset::max_bucket_count

Gets the maximum number of buckets.

```
size_type max_bucket_count() const;
```

Remarks

The member function returns the maximum number of buckets currently permitted.

Example

```

// std__unordered_set__unordered_multiset_max_bucket_count.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```
[c] [b] [a]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1
```

unordered_multiset::max_load_factor

Gets or sets the maximum elements per bucket.

```
float max_load_factor() const;

void max_load_factor(float factor);
```

Parameters

factor

The new maximum load factor.

Remarks

The first member function returns the stored maximum load factor. The second member function replaces the stored maximum load factor with *factor*.

Example

```

// std__unordered_set__unordered_multiset_max_load_factor.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_bucket_count() == "
        << c1.max_bucket_count() << std::endl;
    std::cout << "max_load_factor() == "
        << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    return (0);
}

```

```

[c] [b] [a]
bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_bucket_count() == 8
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_bucket_count() == 128
max_load_factor() == 0.1

```

unordered_multiset::max_size

Gets the maximum size of the controlled sequence.

```
size_type max_size() const;
```

Remarks

The member function returns the length of the longest sequence that the object can control.

Example

```

// std__unordered_set__unordered_multiset_max_size.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    std::cout << "max_size() == " << c1.max_size() << std::endl;

    return (0);
}

```

```
max_size() == 4294967295
```

unordered_multiset::operator=

Copies a hash table.

```

unordered_multiset& operator=(const unordered_multiset& right);

unordered_multiset& operator=(unordered_multiset&& right);

```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The <code>unordered_multiset</code> being copied into the <code>unordered_multiset</code> .

Remarks

After erasing any existing elements in an `unordered_multiset`, `operator=` either copies or moves the contents of *right* into the `unordered_multiset`.

Example

```
// unordered_multiset_operator_as.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

int main( )
{
    using namespace std;
    unordered_multiset<int> v1, v2, v3;
    unordered_multiset<int>::iterator iter;

    v1.insert(10);

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;
}
```

unordered_multiset::pointer

The type of a pointer to an element.

```
typedef Alloc::pointer pointer;
```

Remarks

The type describes an object that can serve as a pointer to an element of the controlled sequence.

Example

```

// std__unordered_set__unordered_multiset_pointer.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Myset::key_type key = *it;
        Myset::pointer p = &key;
        std::cout << "[" << *p << "]" ";
    }
    std::cout << std::endl;

    return (0);
}

```

```
[c] [b] [a]
```

unordered_multiset::reference

The type of a reference to an element.

```
typedef Alloc::reference reference;
```

Remarks

The type describes an object that can serve as a reference to an element of the controlled sequence.

Example

```
// std__unordered_set__unordered_multiset_reference.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::iterator it = c1.begin();
         it != c1.end(); ++it)
    {
        Myset::key_type key = *it;
        Myset::reference ref = key;
        std::cout << "[" << ref << "]" ";
    }
    std::cout << std::endl;

    return (0);
}
```

```
[c] [b] [a]
```

unordered_multiset::rehash

Rebuilds the hash table.

```
void rehash(size_type nbuckets);
```

Parameters

nbuckets

The requested number of buckets.

Remarks

The member function alters the number of buckets to be at least *nbuckets* and rebuilds the hash table as needed.

Example

```

// std__unordered_set__unordered_multiset_rehash.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // inspect current parameters
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_load_factor() == " << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // change max_load_factor and redisplay
    c1.max_load_factor(0.10f);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_load_factor() == " << c1.max_load_factor() << std::endl;
    std::cout << std::endl;

    // rehash and redisplay
    c1.rehash(100);
    std::cout << "bucket_count() == " << c1.bucket_count() << std::endl;
    std::cout << "load_factor() == " << c1.load_factor() << std::endl;
    std::cout << "max_load_factor() == " << c1.max_load_factor() << std::endl;

    return (0);
}

```

```

[c] [b] [a]
bucket_count() == 8
load_factor() == 0.375
max_load_factor() == 4

bucket_count() == 8
load_factor() == 0.375
max_load_factor() == 0.1

bucket_count() == 128
load_factor() == 0.0234375
max_load_factor() == 0.1

```

unordered_multiset::size

Counts the number of elements.

```
size_type size() const;
```

Remarks

The member function returns the length of the controlled sequence.

Example

```
// std__unordered_set__unordered_multiset_size.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // clear the container and reinspect
    c1.clear();
    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;
    std::cout << std::endl;

    c1.insert('d');
    c1.insert('e');

    // display contents "[e] [d]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    std::cout << "size == " << c1.size() << std::endl;
    std::cout << "empty() == " << std::boolalpha << c1.empty() << std::endl;

    return (0);
}
```

```
[c] [b] [a]
size == 0
empty() == true

[e] [d]
size == 2
empty() == false
```

unordered_multiset::size_type

The type of an unsigned distance between two elements.

```
typedef T2 size_type;
```

Remarks

The unsigned integer type describes an object that can represent the length of any controlled

sequence. It is described here as a synonym for the implementation-defined type `T2`.

Example

```
// std__unordered_set__unordered_multiset_size_type.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;
    Myset::size_type sz = c1.size();

    std::cout << "size == " << sz << std::endl;

    return (0);
}
```

```
size == 0
```

unordered_multiset::swap

Swaps the contents of two containers.

```
void swap(unordered_multiset& right);
```

Parameters

right

The container to swap with.

Remarks

The member function swaps the controlled sequences between `*this` and *right*. If `unordered_multiset::get_allocator() == right.get_allocator()`, it does so in constant time, it throws an exception only as a result of copying the stored traits object of type `Tr`, and it invalidates no references, pointers, or iterators that designate elements in the two controlled sequences. Otherwise, it performs a number of element assignments and constructor calls proportional to the number of elements in the two controlled sequences.

Example

```

// std__unordered_set__unordered_multiset_swap.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    Myset c2;

    c2.insert('d');
    c2.insert('e');
    c2.insert('f');

    c1.swap(c2);

    // display contents "[f] [e] [d]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    swap(c1, c2);

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    return (0);
}

```

```

[c] [b] [a]
[f] [e] [d]
[c] [b] [a]

```

unordered_multiset::unordered_multiset

Constructs a container object.

```

unordered_multiset(
    const unordered_multiset& Right);

explicit unordered_multiset(
    size_type Bucket_count = N0,
    const Hash& Hash = Hash(),
    const Comp& Comp = Comp(),
    const Allocator& Al = Alloc());

unordered_multiset(
    unordered_multiset&& Right);

unordered_set(
    initializer_list<Type> IList);

unordered_set(
    initializer_list<Typ> IList,
    size_type Bucket_count);

unordered_set(
    initializer_list<Type> IList,
    size_type Bucket_count,
    const Hash& Hash);

unordered_set(
    initializer_list<Type> IList,
    size_type Bucket_count,
    const Hash& Hash,
    const Key& Key);

unordered_set(
    initializer_list<Type> IList,
    size_type Bucket_count,
    const Hash& Hash,
    const Key& Key,
    const Allocator& Al);

template <class InputIterator>
unordered_multiset(
    InputIterator First,
    InputIterator Last,
    size_type Bucket_count = N0,
    const Hash& Hash = Hash(),
    const Comp& Comp = Comp(),
    const Allocator& Al = Alloc());

```

Parameters

PARAMETER	DESCRIPTION
<i>InputIterator</i>	The iterator type.
<i>Al</i>	The allocator object to store.
<i>Comp</i>	The comparison function object to store.
<i>Hash</i>	The hash function object to store.
<i>Bucket_count</i>	The minimum number of buckets.
<i>Right</i>	The container to copy.

PARAMETER	DESCRIPTION
<i>lList</i>	The initializer_list from which to copy.

Remarks

The first constructor specifies a copy of the sequence controlled by *Right*. The second constructor specifies an empty controlled sequence. The third constructor inserts the sequence of element values `[First, Last)`. The fourth constructor specifies a copy of the sequence by moving *Right*.

All constructors also initialize several stored values. For the copy constructor, the values are obtained from *Right*. Otherwise:

The minimum number of buckets is the argument *Bucket_count*, if present; otherwise it is a default value described here as the implementation-defined value `N0`.

The hash function object is the argument *Hash*, if present; otherwise it is `Hash()`.

The comparison function object is the argument *Comp*, if present; otherwise it is `Comp()`.

The allocator object is the argument *Al*, if present; otherwise, it is `Alloc()`.

unordered_multiset::value_type

The type of an element.

```
typedef Key value_type;
```

Remarks

The type describes an element of the controlled sequence.

Example

```

// std__unordered_set__unordered_multiset_value_type.cpp
// compile with: /EHsc
#include <unordered_set>
#include <iostream>

typedef std::unordered_multiset<char> Myset;
int main()
{
    Myset c1;

    c1.insert('a');
    c1.insert('b');
    c1.insert('c');

    // display contents "[c] [b] [a]"
    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    // add a value and reinspect
    Myset::key_type key = 'd';
    Myset::value_type val = key;
    c1.insert(val);

    for (Myset::const_iterator it = c1.begin();
         it != c1.end(); ++it)
        std::cout << "[" << *it << "]" ";
    std::cout << std::endl;

    return (0);
}

```

```

[c] [b] [a]
[d] [c] [b] [a]

```

[Containers](#)

[Thread Safety in the C++ Standard Library](#)

[C++ Standard Library Reference](#)

<utility>

11/9/2018 • 2 minutes to read • [Edit Online](#)

Defines C++ Standard Library types, functions, and operators that help to construct and manage pairs of objects, which are useful whenever two objects need to be treated as if they were one.

Syntax

```
#include <utility>
```

Remarks

Pairs are widely used in the C++ Standard Library. They are required both as the arguments and return values for various functions and as element types for containers such as [map class](#) and [multimap class](#). The <utility> header is automatically included by <map> to assist in managing their key/value pair type elements.

Classes

CLASS	DESCRIPTION
tuple_element	A class that wraps the type of a <code>pair</code> element.
tuple_size	A class that wraps <code>pair</code> element count.

Functions

FUNCTION	DESCRIPTION
forward	Preserves the reference type (either <code>lvalue</code> or <code>rvalue</code>) of the argument from being obscured by perfect forwarding.
get	A function that gets an element from a <code>pair</code> object.
make_pair	A template helper function used to construct objects of type <code>pair</code> , where the component types are based on the data types passed as parameters.
move	Returns the passed in argument as an <code>rvalue</code> reference.
swap	Exchanges the elements of two <code>pair</code> objects.

Operators

OPERATOR	DESCRIPTION
operator!=	Tests if the pair object on the left side of the operator is not equal to the pair object on the right side.

OPERATOR	DESCRIPTION
<code>operator==</code>	Tests if the pair object on the left side of the operator is equal to the pair object on the right side.
<code>operator<</code>	Tests if the pair object on the left side of the operator is less than the pair object on the right side.
<code>operator<=</code>	Tests if the pair object on the left side of the operator is less than or equal to the pair object on the right side.
<code>operator></code>	Tests if the pair object on the left side of the operator is greater than the pair object on the right side.
<code>operator>=</code>	Tests if the pair object on the left side of the operator is greater than or equal to the pair object on the right side.

Structs

<code>identity</code>	
<code>pair</code>	A type that provides for the ability to treat two objects as a single object.

<utility> functions

10/31/2018 • 7 minutes to read • [Edit Online](#)

exchange	forward	get Function <utility>
make_pair	move	swap

exchange

(C++14) Assigns a new value to an object and returns its old value.

```
template <class T, class Other = T>  
T exchange(T& val, Other&& new_val)
```

Parameters

val

The object that will receive the value of new_val.

new_val

The object whose value is copied or moved into val.

Remarks

For complex types, `exchange` avoids copying the old value when a move constructor is available, avoids copying the new value if it's a temporary object or is moved, and accepts any type as the new value, using any available converting assignment operator. The exchange function is different from `std::swap` in that the left argument is not moved or copied to the right argument.

Example

The following example shows how to use `exchange`. In the real world, `exchange` is most useful with large objects that are expensive to copy:

```

#include <utility>
#include <iostream>

using namespace std;

struct C
{
    int i;
    //...
};

int main()
{
    // Use brace initialization
    C c1{ 1 };
    C c2{ 2 };
    C result = exchange(c1, c2);
    cout << "The old value of c1 is: " << result.i << endl;
    cout << "The new value of c1 after exchange is: " << c1.i << endl;

    return 0;
}

```

```

The old value of c1 is: 1
The new value of c1 after exchange is: 2

```

forward

Conditionally casts its argument to an rvalue reference if the argument is an rvalue or rvalue reference. This restores the rvalue-ness of an argument to the forwarding function in support of perfect forwarding.

```

template <class Type>    // accepts lvalues
constexpr Type&& forward(typename remove_reference<Type>::type& Arg) noexcept

template <class Type>    // accepts everything else
constexpr Type&& forward(typename remove_reference<Type>::type&& Arg) noexcept

```

Parameters

PARAMETER	DESCRIPTION
<i>Type</i>	The type of the value passed in <i>Arg</i> , which might be different than the type of <i>Arg</i> . Typically determined by a template argument of the forwarding function.
<i>Arg</i>	The argument to cast.

Return Value

Returns an rvalue reference to *Arg* if the value passed in *Arg* was originally an rvalue or a reference to an rvalue; otherwise, returns *Arg* without modifying its type.

Remarks

You must specify an explicit template argument to call `forward`.

`forward` does not forward its argument. Instead, by conditionally casting its argument to an rvalue reference if it was originally an rvalue or rvalue reference, `forward` enables the compiler to perform overload resolution with knowledge of the forwarded argument's original type. The apparent type of an argument to a forwarding function

might be different than its original type—for example, when an rvalue is used as an argument to a function and is bound to a parameter name; having a name makes it an lvalue, regardless of whether the value actually exists as an rvalue— `forward` restores the rvalue-ness of the argument.

Restoring the rvalue-ness of an argument's original value in order to perform overload resolution is known as *perfect forwarding*. Perfect forwarding enables a template function to accept an argument of either reference type and to restore its rvalue-ness when it's necessary for correct overload resolution. By using perfect forwarding, you can preserve move semantics for rvalues and avoid having to provide overloads for functions that vary only by the reference type of their arguments.

get

Gets an element from a `pair` object by index position, or by type.

```
// get reference to element at Index in pair Pr
template <size_t Index, class T1, class T2>
constexpr tuple_element_t<Index, pair<T1, T2>>&
get(pair<T1, T2>& Pr) noexcept;

// get reference to element T1 in pair Pr
template <class T1, class T2>
constexpr T1& get(pair<T1, T2>& Pr) noexcept;

// get reference to element T2 in pair Pr
template <class T2, class T1>
constexpr T2& get(pair<T1, T2>& Pr) noexcept;

// get const reference to element at Index in pair Pr
template <size_t Index, class T1, class T2>
constexpr const tuple_element_t<Index, pair<T1, T2>>&
get(const pair<T1, T2>& Pr) noexcept;

// get const reference to element T1 in pair Pr
template <class T1, class T2>
constexpr const T1& get(const pair<T1, T2>& Pr) noexcept;

// get const reference to element T2 in pair Pr
template <class T2, class T1>
constexpr const T2& get(const pair<T1, T2>& Pr) noexcept;

// get rvalue reference to element at Index in pair Pr
template <size_t Index, class T1, class T2>
constexpr tuple_element_t<Index, pair<T1, T2>>&&
get(pair<T1, T2>&& Pr) noexcept;

// get rvalue reference to element T1 in pair Pr
template <class T1, class T2>
constexpr T1&& get(pair<T1, T2>&& Pr) noexcept;

// get rvalue reference to element T2 in pair Pr
template <class T2, class T1>
constexpr T2&& get(pair<T1, T2>&& Pr) noexcept;
```

Parameters

Index

The 0-based index of the designated element.

T1

The type of the first pair element.

T2

The type of the second pair element.

pr

The pair to select from.

Remarks

The template functions each return a reference to an element of its `pair` argument.

For the indexed overloads, if the value of *Index* is 0 the functions return `pr.first` and if the value of *Index* is 1 the functions return `pr.second`. The type `RI` is the type of the returned element.

For the overloads that do not have an *Index* parameter, the element to return is deduced by the type argument. Calling `get<T>(Tuple)` will produce a compiler error if *pr* contains more or less than one element of type *T*.

Example

```
#include <utility>
#include <iostream>
using namespace std;
int main()
{

    typedef pair<int, double> MyPair;

    MyPair c0(9, 3.14);

    // get elements by index
    cout << " " << get<0>(c0);
    cout << " " << get<1>(c0) << endl;

    // get elements by type (C++14)
    MyPair c1(1, 0.27);
    cout << " " << get<int>(c1);
    cout << " " << get<double>(c1) << endl;

    /*
    Output:
    9 3.14
    1 0.27
    */

}
```

make_pair

A template function that you can use to construct objects of type `pair`, where the component types are automatically chosen based on the data types that are passed as parameters.

```
template <class T, class U>
pair<T, U> make_pair(T& Val1, U& Val2);

template <class T, class U>
pair<T, U> make_pair(T& Val1, U&& Val2);

template <class T, class U>
pair<T, U> make_pair(T&& Val1, U& Val2);

template <class T, class U>
pair<T, U> make_pair(T&& Val1, U&& Val2);
```

Parameters

Val1

Value that initializes the first element of `pair`.

`Val2`

Value that initializes the second element of `pair`.

Return Value

The pair object that's constructed: `pair < T, U >(Val1, Val2)`.

Remarks

`make_pair` converts object of type [reference_wrapper Class](#) to reference types and converts decaying arrays and functions to pointers.

In the returned `pair` object, `T` is determined as follows:

- If the input type `T` is `reference_wrapper<X>`, the returned type `T` is `X&`.
- Otherwise, the returned type `T` is `decay<T>::type`. If [decay Class](#) is not supported, the returned type `T` is the same as the input type `T`.

The returned type `U` is similarly determined from the input type `U`.

One advantage of `make_pair` is that the types of objects that are being stored are determined automatically by the compiler and do not have to be explicitly specified. Don't use explicit template arguments such as `make_pair<int, int>(1, 2)` when you use `make_pair` because it is unnecessarily verbose and adds complex rvalue reference problems that might cause compilation failure. For this example, the correct syntax would be

`make_pair(1, 2)`

The `make_pair` helper function also makes it possible to pass two values to a function that requires a pair as an input parameter.

Example

For an example about how to use the helper function `make_pair` to declare and initialize a pair, see [pair Structure](#).

move

Unconditionally casts its argument to an rvalue reference, and thereby signals that it can be moved if its type is move-enabled.

```
template <class Type>
constexpr typename remove_reference<Type>::type&& move(Type&& Arg) noexcept;
```

Parameters

PARAMETER	DESCRIPTION
<i>Type</i>	A type deduced from the type of the argument passed in <i>Arg</i> , together with the reference collapsing rules.
<i>Arg</i>	The argument to cast. Although the type of <i>Arg</i> appears to be specified as an rvalue reference, <code>move</code> also accepts lvalue arguments because lvalue references can bind to rvalue references.

Return Value

`Arg` as an rvalue reference, whether or not its type is a reference type.

Remarks

The template argument *Type* is not intended to be specified explicitly, but to be deduced from the type of the value passed in *Arg*. The type of *Type* is further adjusted according to the reference collapsing rules.

`move` does not move its argument. Instead, by unconditionally casting its argument—which might be an lvalue—to an rvalue reference, it enables the compiler to subsequently move, rather than copy, the value passed in *Arg* if its type is move-enabled. If its type is not move-enabled, it is copied instead.

If the value passed in *Arg* is an lvalue—that is, it has a name or its address can be taken—it's invalidated when the move occurs. Do not refer to the value passed in *Arg* by its name or address after it's been moved.

swap

Exchanges the elements of two [pair Structure](#) objects.

```
template <class T, class U>
void swap(pair<T, U>& left, pair<T, U>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	An object of type <code>pair</code> .
<i>right</i>	An object of type <code>pair</code> .

Remarks

One advantage of `swap` is that the types of objects that are being stored are determined automatically by the compiler and do not have to be explicitly specified. Don't use explicit template arguments such as

`swap<int, int>(1, 2)` when you use `swap` because it is unnecessarily verbose and adds complex rvalue reference problems that might cause compilation failure.

[<utility>](#)

<utility> operators

10/31/2018 • 12 minutes to read • [Edit Online](#)

operator!=	operator>	operator>=
operator<	operator<=	operator==

operator!=

Tests if the pair object on the left side of the operator is not equal to the pair object on the right side.

```
template <class Type>
constexpr bool operator!=(const Type& left, const Type& right);

template <class T, class U>
constexpr bool operator!=(const pair<T, U>& left, const pair<T, U>& right);
```

Parameters

left

An object of type `pair`.

right

An object of type `pair`.

Return Value

true if the pairs are not equal; **false** if the pairs are equal.

Remarks

One pair is equal to another pair if each of their respective elements is equal. Two pairs are unequal if either the first or the second element of one is not equal to the corresponding element of the other pair.

Example

```

// utility_op_ne.cpp
// compile with: /EHsc
#include <utility>
#include <iomanip>
#include <iostream>

int main( )
{
    using namespace std;
    pair <int, double> p1, p2, p3;

    p1 = make_pair ( 10, 1.11e-1 );
    p2 = make_pair ( 1000, 1.11e-3 );
    p3 = make_pair ( 10, 1.11e-1 );

    cout.precision ( 3 );
    cout << "The pair p1 is: ( " << p1.first << ", "
        << p1.second << " )." << endl;
    cout << "The pair p2 is: ( " << p2.first << ", "
        << p2.second << " )." << endl;
    cout << "The pair p3 is: ( " << p3.first << ", "
        << p3.second << " )." << endl << endl;

    if ( p1 != p2 )
        cout << "The pairs p1 and p2 are not equal." << endl;
    else
        cout << "The pairs p1 and p2 are equal." << endl;

    if ( p1 != p3 )
        cout << "The pairs p1 and p3 are not equal." << endl;
    else
        cout << "The pairs p1 and p3 are equal." << endl;
}

```

```

The pair p1 is: ( 10, 0.111 ).
The pair p2 is: ( 1000, 0.00111 ).
The pair p3 is: ( 10, 0.111 ).

The pairs p1 and p2 are not equal.
The pairs p1 and p3 are equal.

```

operator==

Tests if the pair object on the left side of the operator is equal to the pair object on the right side.

```

template <class T, class U>
constexpr bool operator==(const pair<T, U>& left, const pair<T, U>& right);

```

Parameters

left

An object of type `pair`.

right

An object of type `pair`.

Return Value

true if the pairs are equal; **false** if the `pair`s are not equal.

Remarks

One pair is equal to another pair if each of their respective elements is equal. The function returns `left.first == right.first && left.second == right.second`. Two pairs are unequal if either the first or the second element of one is not equal to the corresponding element of the other pair.

Example

```
// utility_op_eq.cpp
// compile with: /EHsc
#include <utility>
#include <iomanip>
#include <iostream>

int main( )
{
    using namespace std;
    pair <int, double> p1, p2, p3;

    p1 = make_pair ( 10, 1.11e-1 );
    p2 = make_pair ( 1000, 1.11e-3 );
    p3 = make_pair ( 10, 1.11e-1 );

    cout.precision ( 3 );
    cout << "The pair p1 is: ( " << p1.first << ", "
        << p1.second << " )." << endl;
    cout << "The pair p2 is: ( " << p2.first << ", "
        << p2.second << " )." << endl;
    cout << "The pair p3 is: ( " << p3.first << ", "
        << p3.second << " )." << endl << endl;

    if ( p1 == p2 )
        cout << "The pairs p1 and p2 are equal." << endl;
    else
        cout << "The pairs p1 and p2 are not equal." << endl;

    if ( p1 == p3 )
        cout << "The pairs p1 and p3 are equal." << endl;
    else
        cout << "The pairs p1 and p3 are not equal." << endl;
}
```

operator<

Tests if the pair object on the left side of the operator is less than the pair object on the right side.

```
template <class T, class U>
constexpr bool operator<(const pair<T, U>& left, const pair<T, U>& right);
```

Parameters

left

An object of type `pair` on the left side of the operator.

right

An object of type `pair` on the right side of the operator.

Return Value

true if the `pair` on the left side of the operator is strictly less than the `pair` on the right side of the operator; otherwise **false**.

Remarks

The `left` `pair` object is said to be strictly less than the `right` `pair` object if *left* is less than and not equal to

right.

In a comparison of pairs, the values' first elements of the two pairs have the highest priority. If they differ, then the result of their comparison is taken as the result of the comparison of the pair. If the values of the first elements are not different, then the values of the second elements are compared and the result of their comparison is taken as the result of the comparison of the pair.

Example

```
// utility_op_lt.cpp
// compile with: /EHsc
#include <utility>
#include <iomanip>
#include <iostream>

int main( )
{
    using namespace std;
    pair <int, double> p1, p2, p3;

    p1 = make_pair ( 10, 2.22e-1 );
    p2 = make_pair ( 100, 1.11e-1 );
    p3 = make_pair ( 10, 1.11e-1 );

    cout.precision ( 3 );
    cout << "The pair p1 is: ( " << p1.first << ", "
        << p1.second << " )." << endl;
    cout << "The pair p2 is: ( " << p2.first << ", "
        << p2.second << " )." << endl;
    cout << "The pair p3 is: ( " << p3.first << ", "
        << p3.second << " )." << endl << endl;

    if ( p1 < p2 )
        cout << "The pair p1 is less than the pair p2." << endl;
    else
        cout << "The pair p1 is not less than the pair p2." << endl;

    if ( p1 < p3 )
        cout << "The pair p1 is less than the pair p3." << endl;
    else
        cout << "The pair p1 is not less than the pair p3." << endl;
}
```

```
The pair p1 is: ( 10, 0.222 ).
The pair p2 is: ( 100, 0.111 ).
The pair p3 is: ( 10, 0.111 ).
```

```
The pair p1 is less than the pair p2.
The pair p1 is not less than the pair p3.
```

operator<=

Tests if the pair object on the left side of the operator is less than or equal to the pair object on the right side.

```
template <class Type>
constexpr bool operator<=(const Type& left, const Type& right);

template <class T, class U>
constexpr bool operator<=(const pair<T, U>& left, const pair<T, U>& right);
```

Parameters

left

An object of type `pair` on the left side of the operator.

right

An object of type `pair` on the right side of the operator.

Return Value

true if the `pair` on the left side of the operator is less than or equal to the `pair` on the right side of the operator; otherwise **false**.

Remarks

In a comparison of pairs, the values' first elements of the two pairs have the highest priority. If they differ, then the result of their comparison is taken as the result of the comparison of the pair. If the values of the first elements are not different, then the values of the second elements are compared and the result of their comparison is taken as the result of the comparison of the pair.

Example

```
// utility_op_le.cpp
// compile with: /EHsc
#include <utility>
#include <iomanip>
#include <iostream>

int main( )
{
    using namespace std;
    pair <int, double> p1, p2, p3, p4;

    p1 = make_pair ( 10, 2.22e-1 );
    p2 = make_pair ( 100, 1.11e-1 );
    p3 = make_pair ( 10, 1.11e-1 );
    p4 = make_pair ( 10, 2.22e-1 );

    cout.precision ( 3 );
    cout << "The pair p1 is: ( " << p1.first << ", "
        << p1.second << " )." << endl;
    cout << "The pair p2 is: ( " << p2.first << ", "
        << p2.second << " )." << endl;
    cout << "The pair p3 is: ( " << p3.first << ", "
        << p3.second << " )." << endl;
    cout << "The pair p4 is: ( " << p4.first << ", "
        << p4.second << " )." << endl << endl;

    if ( p1 <= p2 )
        cout << "The pair p1 is less than or equal to the pair p2." << endl;
    else
        cout << "The pair p1 is greater than the pair p2." << endl;

    if ( p1 <= p3 )
        cout << "The pair p1 is less than or equal to the pair p3." << endl;
    else
        cout << "The pair p1 is greater than the pair p3." << endl;

    if ( p1 <= p4 )
        cout << "The pair p1 is less than or equal to the pair p4." << endl;
    else
        cout << "The pair p1 is greater than the pair p4." << endl;
}
```

```
The pair p1 is: ( 10, 0.222 ).  
The pair p2 is: ( 100, 0.111 ).  
The pair p3 is: ( 10, 0.111 ).  
The pair p4 is: ( 10, 0.222 ).
```

```
The pair p1 is less than or equal to the pair p2.  
The pair p1 is greater than the pair p3.  
The pair p1 is less than or equal to the pair p4.
```

operator>

Tests if the pair object on the left side of the operator is greater than the pair object on the right side.

```
template <class Type>  
constexpr bool operator>(const Type& left, const Type& right);  
  
template <class T, class U>  
constexpr bool operator>(const pair<T, U>& left, const pair<T, U>& right);
```

Parameters

left

An object of type `pair` on the left side of the operator.

right

An object of type `pair` on the right side of the operator.

Return Value

true if the `pair` on the left side of the operator is strictly greater than the `pair` on the right side of the operator; otherwise **false**.

Remarks

The `left` `pair` object is said to be strictly greater than the `right` `pair` object if *left* is greater than and not equal to *right*.

In a comparison of pairs, the values' first elements of the two pairs have the highest priority. If they differ, then the result of their comparison is taken as the result of the comparison of the pair. If the values of the first elements are not different, then the values of the second elements are compared and the result of their comparison is taken as the result of the comparison of the pair.

Example

```

// utility_op_gt.cpp
// compile with: /EHsc
#include <utility>
#include <iomanip>
#include <iostream>

int main( )
{
    using namespace std;
    pair <int, double> p1, p2, p3, p4;

    p1 = make_pair ( 10, 2.22e-1 );
    p2 = make_pair ( 100, 1.11e-1 );
    p3 = make_pair ( 10, 1.11e-1 );
    p4 = make_pair ( 10, 2.22e-1 );

    cout.precision ( 3 );
    cout << "The pair p1 is: ( " << p1.first << ", "
        << p1.second << " )." << endl;
    cout << "The pair p2 is: ( " << p2.first << ", "
        << p2.second << " )." << endl;
    cout << "The pair p3 is: ( " << p3.first << ", "
        << p3.second << " )." << endl;
    cout << "The pair p4 is: ( " << p4.first << ", "
        << p4.second << " )." << endl << endl;

    if ( p1 > p2 )
        cout << "The pair p1 is greater than the pair p2." << endl;
    else
        cout << "The pair p1 is not greater than the pair p2." << endl;

    if ( p1 > p3 )
        cout << "The pair p1 is greater than the pair p3." << endl;
    else
        cout << "The pair p1 is not greater than the pair p3." << endl;

    if ( p1 > p4 )
        cout << "The pair p1 is greater than the pair p4." << endl;
    else
        cout << "The pair p1 is not greater than the pair p4." << endl;
}

```

```

The pair p1 is: ( 10, 0.222 ).
The pair p2 is: ( 100, 0.111 ).
The pair p3 is: ( 10, 0.111 ).
The pair p4 is: ( 10, 0.222 ).

```

```

The pair p1 is not greater than the pair p2.
The pair p1 is greater than the pair p3.
The pair p1 is not greater than the pair p4.

```

operator>=

Tests if the pair object on the left side of the operator is greater than or equal to the pair object on the right side.

```

template <class Type>
constexpr bool operator>=(const Type& left, const Type& right);

template <class T, class U>
constexpr bool operator>=(const pair<T, U>& left, const pair<T, U>& right);

```

Parameters

left

An object of type `pair` on the left side of the operator.

right

An object of type `pair` on the right side of the operator.

Return Value

true if the `pair` on the left side of the operator is greater than or equal to the `pair` on the right side of the operator; otherwise **false**.

Remarks

In a comparison of pairs, the values' first elements of the two pairs have the highest priority. If they differ, then the result of their comparison is taken as the result of the comparison of the pair. If the values of the first elements are not different, then the values of the second elements are compared and the result of their comparison is taken as the result of the comparison of the pair.

Example

```
// utility_op_ge.cpp
// compile with: /EHsc
#include <utility>
#include <iomanip>
#include <iostream>

int main( )
{
    using namespace std;
    pair <int, double> p1, p2, p3, p4;

    p1 = make_pair ( 10, 2.22e-1 );
    p2 = make_pair ( 100, 1.11e-1 );
    p3 = make_pair ( 10, 1.11e-1 );
    p4 = make_pair ( 10, 2.22e-1 );

    cout.precision ( 3 );
    cout << "The pair p1 is: ( " << p1.first << ", "
        << p1.second << " )." << endl;
    cout << "The pair p2 is: ( " << p2.first << ", "
        << p2.second << " )." << endl;
    cout << "The pair p3 is: ( " << p3.first << ", "
        << p3.second << " )." << endl;
    cout << "The pair p4 is: ( " << p4.first << ", "
        << p4.second << " )." << endl << endl;

    if ( p1 >= p2 )
        cout << "Pair p1 is greater than or equal to pair p2." << endl;
    else
        cout << "The pair p1 is less than the pair p2." << endl;

    if ( p1 >= p3 )
        cout << "Pair p1 is greater than or equal to pair p3." << endl;
    else
        cout << "The pair p1 is less than the pair p3." << endl;

    if ( p1 >= p4 )
        cout << "Pair p1 is greater than or equal to pair p4." << endl;
    else
        cout << "The pair p1 is less than the pair p4." << endl;
}
```

```
The pair p1 is: ( 10, 0.222 ).  
The pair p2 is: ( 100, 0.111 ).  
The pair p3 is: ( 10, 0.111 ).  
The pair p4 is: ( 10, 0.222 ).
```

```
The pair p1 is less than the pair p2.  
Pair p1 is greater than or equal to pair p3.  
Pair p1 is greater than or equal to pair p4.
```

See also

[<utility>](#)

identity Structure

10/31/2018 • 2 minutes to read • [Edit Online](#)

A struct that provides a type definition as the template parameter.

Syntax

```
struct identity {  
    typedef Type type;  
    Type operator()(const Type& left) const;  
};
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	The value to identify.

Remarks

The class contains the public type definition `type`, which is the same as the template parameter `Type`. It is used in conjunction with template function [forward](#) to ensure that a function parameter has the desired type.

For compatibility with older code, the class also defines the identity function `operator()` which returns its argument *left*.

Requirements

Header: <utility>

Namespace: std

See also

[<utility>](#)

pair Structure

10/31/2018 • 3 minutes to read • [Edit Online](#)

A struct that provides for the ability to treat two objects as a single object.

Syntax

```
struct pair
{
    typedef T1 first_type;
    typedef T2 second_type;
    T1 first;
    T2 second;
    constexpr pair();
    constexpr pair(
        const T1& Val1,
        const T2& Val2);

    template <class Other1, class Other2>
    constexpr pair(const pair<Other1, Other2>& Right);

    template <class Other1, class Other2>
    constexpr pair(const pair <Other1 Val1, Other2 Val2>&& Right);

    template <class Other1, class Other2>
    constexpr pair(Other1&& Val1, Other2&& Val2);
};
```

Parameters

Val1

Value initializing the first element of `pair`.

Val2

Value initializing the second element of `pair`.

Right

A pair whose values are to be used to initialize the elements of another pair.

Return Value

The first (default) constructor initializes first element of the pair to the default of type `T1` and second element to default of type `T2`.

The second constructor initializes first element of the pair to *Val1* and second to *Val2*.

The third (template) constructor initializes first element of the pair to `Right`, **first** and second to `Right`, **second**.

The fourth constructor initializes first element of the pair to *Val1* and second to *Val2* using [Rvalue Reference Declarator: &&](#).

Remarks

The template struct stores a pair of objects of type `T1` and `T2`, respectively. The type `first_type` is the same as the template parameter `T1` and the type `second_type` is the same as the template parameter `T2`. `T1` and `T2`

each need supply only a default constructor, a single-argument constructor, and a destructor. All members of the type `pair` are public, because the type is declared as a `struct` rather than as a **class**. The two most common uses for a pair are as return types for functions that return two values and as elements for the associative container classes [map Class](#) and [multimap Class](#) that have both a key and a value type associated with each element. The latter satisfies the requirements for a pair associative container and has a value type of the form `pair < const key_type, mapped_type >`.

Example

```
// utility_pair.cpp
// compile with: /EHsc
#include <utility>
#include <map>
#include <iomanip>
#include <iostream>

int main( )
{
    using namespace std;

    // Using the constructor to declare and initialize a pair
    pair <int, double> p1 ( 10, 1.1e-2 );

    // Compare using the helper function to declare and initialize a pair
    pair <int, double> p2;
    p2 = make_pair ( 10, 2.22e-1 );

    // Making a copy of a pair
    pair <int, double> p3 ( p1 );

    cout.precision ( 3 );
    cout << "The pair p1 is: ( " << p1.first << ", "
          << p1.second << " )." << endl;
    cout << "The pair p2 is: ( " << p2.first << ", "
          << p2.second << " )." << endl;
    cout << "The pair p3 is: ( " << p3.first << ", "
          << p3.second << " )." << endl;

    // Using a pair for a map element
    map <int, int> m1;
    map <int, int>::iterator m1_Iter;

    typedef pair <int, int> Map_Int_Pair;

    m1.insert ( Map_Int_Pair ( 1, 10 ) );
    m1.insert ( Map_Int_Pair ( 2, 20 ) );
    m1.insert ( Map_Int_Pair ( 3, 30 ) );

    cout << "The element pairs of the map m1 are:";
    for ( m1_Iter = m1.begin( ); m1_Iter != m1.end( ); m1_Iter++ )
        cout << " ( " << m1_Iter->first << ", "
              << m1_Iter->second << " )";
    cout << "." << endl;

    // Using pair as a return type for a function
    pair< map<int,int>::iterator, bool > pr1, pr2;
    pr1 = m1.insert ( Map_Int_Pair ( 4, 40 ) );
    pr2 = m1.insert ( Map_Int_Pair ( 1, 10 ) );

    if( pr1.second == true )
    {
        cout << "The element (4,40) was inserted successfully in m1."
              << endl;
    }
    else
```

```

    cout << "The element with a key value of\n"
        << " ( (pr1.first) -> first ) = " << ( pr1.first ) -> first
        << " is already in m1,\n so the insertion failed." << endl;
}

if( pr2.second == true )
{
    cout << "The element (1,10) was inserted successfully in m1."
        << endl;
}
else
{
    cout << "The element with a key value of\n"
        << " ( (pr2.first) -> first ) = " << ( pr2.first ) -> first
        << " is already in m1,\n so the insertion failed." << endl;
}
}
/* Output:
The pair p1 is: ( 10, 0.011 ).
The pair p2 is: ( 10, 0.222 ).
The pair p3 is: ( 10, 0.011 ).
The element pairs of the map m1 are: ( 1, 10 ) ( 2, 20 ) ( 3, 30 ).
The element (4,40) was inserted successfully in m1.
The element with a key value of
( (pr2.first) -> first ) = 1 is already in m1,
so the insertion failed.

<valarray>

11/8/2018 • 6 minutes to read • [Edit Online](#)

Defines the template class `valarray` and numerous supporting template classes and functions.

Syntax

```
#include <valarray>
```

Remarks

These template classes and functions are permitted unusual latitude in the interest of improved performance. Specifically, any function returning type `valarray<T1>` may return an object of some other type `T2`. In that case, any function that accepts one or more arguments of type `valarray<T2>` must have overloads that accept arbitrary combinations of those arguments, each replaced with an argument of type `T2`.

Functions

FUNCTION	DESCRIPTION
abs	Operates on the elements of an input <code>valarray</code> , returning a <code>valarray</code> whose elements are equal to the absolute value of the elements of the input <code>valarray</code> .
acos	Operates on the elements of an input <code>valarray</code> , returning a <code>valarray</code> whose elements are equal to the arccosine of the elements of the input <code>valarray</code> .
asin	Operates on the elements of an input <code>valarray</code> , returning a <code>valarray</code> whose elements are equal to the arcsine of the elements of the input <code>valarray</code> .
atan	Operates on the elements of an input <code>valarray</code> , returning a <code>valarray</code> whose elements are equal to the principal value of the arctangent of the elements of the input <code>valarray</code> .
atan2	Returns a <code>valarray</code> whose elements are equal to the arctangent of the Cartesian components specified by a combination of constants and elements of <code>valarrays</code> .
cos	Operates on the elements of an input <code>valarray</code> , returning a <code>valarray</code> whose elements are equal to the cosine of the elements of the input <code>valarray</code> .
cosh	Operates on the elements of an input <code>valarray</code> , returning a <code>valarray</code> whose elements are equal to the hyperbolic cosine of the elements of the input <code>valarray</code> .
exp	Operates on the elements of an input <code>valarray</code> , returning a <code>valarray</code> whose elements are equal to the natural exponential of the elements of the input <code>valarray</code> .

FUNCTION	DESCRIPTION
<code>log</code>	Operates on the elements of an input valarray, returning a valarray whose elements are equal to the natural logarithm of the elements of the input valarray.
<code>log10</code>	Operates on the elements of an input valarray, returning a valarray whose elements are equal to the base 10 or common logarithm of the elements of the input valarray.
<code>pow</code>	Operates on the elements of input valarrays and constants, returning a valarray whose elements are equal to a base specified either by the elements of an input valarray or a constant raised to an exponent specified either by the elements of an input valarray or a constant.
<code>sin</code>	Operates on the elements of an input valarray, returning a valarray whose elements are equal to the sine of the elements of the input valarray.
<code>sinh</code>	Operates on the elements of an input valarray, returning a valarray whose elements are equal to the hyperbolic sine of the elements of the input valarray.
<code>sqrt</code>	Operates on the elements of an input valarray, returning a valarray whose elements are equal to the square root of the elements of the input valarray.
<code>swap</code>	
<code>tan</code>	Operates on the elements of an input valarray, returning a valarray whose elements are equal to the tangent of the elements of the input valarray.
<code>tanh</code>	Operates on the elements of an input valarray, returning a valarray whose elements are equal to the hyperbolic tangent of the elements of the input valarray.

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests whether the corresponding elements of two equally sized valarrays are unequal or whether all the elements of a valarray are unequal a specified value of the valarray's element type.
<code>operator%</code>	Obtains the remainder of dividing the corresponding elements of two equally sized valarrays or of dividing a valarray by a specified value of the valarray's element type or of dividing a specified value by a valarray.
<code>operator&</code>	Obtains the bitwise <code>AND</code> between corresponding elements of two equally sized valarrays or between a valarray and a specified value of the element type.

OPERATOR	DESCRIPTION
<code>operator&&</code>	Obtains the logical <code>AND</code> between corresponding elements of two equally sized valarrays or between a valarray and a specified value of the valarray's element type.
<code>operator></code>	Tests whether the elements of one valarray are greater than the elements of an equally sized valarray or whether all the elements of a valarray are greater or less than a specified value of the valarray's element type.
<code>operator>=</code>	Tests whether the elements of one valarray are greater than or equal to the elements of an equally sized valarray or whether all the elements of a valarray are greater than or equal to or less than or equal to a specified value.
<code>operator>></code>	Right-shifts the bits for each element of a valarray a specified number of positions or by an element-wise amount specified by a second valarray.
<code>operator<</code>	Tests whether the elements of one valarray are less than the elements of an equally sized valarray or whether all the elements of a valarray are greater or less than a specified value.
<code>operator<=</code>	Tests whether the elements of one valarray are less than or equal to the elements of an equally sized valarray or whether all the elements of a valarray are greater than or equal to or less than or equal to a specified value.
<code>operator<<</code>	Left shifts the bits for each element of a valarray a specified number of positions or by an element-wise amount specified by a second valarray.
<code>operator*</code>	Obtains the element-wise product between corresponding elements of two equally sized valarrays or of between a valarray a specified value of the valarray's element type.
<code>operator+</code>	Obtains the element-wise sum between corresponding elements of two equally sized valarrays or of between a valarray a specified value of the valarray's element type.
<code>operator-</code>	Obtains the element-wise difference between corresponding elements of two equally sized valarrays or of between a valarray a specified value of the valarray's element type.
<code>operator/</code>	Obtains the element-wise quotient between corresponding elements of two equally sized valarrays or of between a valarray a specified value of the valarray's element type.
<code>operator==</code>	Tests whether the corresponding elements of two equally sized valarrays are equal or whether all the elements of a valarray are equal a specified value of the valarray's element type.
<code>operator^</code>	Obtains the bitwise exclusive <code>OR</code> between corresponding elements of two equally sized valarrays or between a valarray and a specified value of the element type.

OPERATOR	DESCRIPTION
operator 	Obtains the bitwise <code>OR</code> between corresponding elements of two equally sized valarrays or between a valarray and a specified value of the element type.
operator 	Obtains the logical <code>OR</code> between corresponding elements of two equally sized valarrays or between a valarray and a specified value of the valarray's element type.

Classes

CLASS	DESCRIPTION
gslice Class	A utility class to valarray that is used to define multi-dimensional slices of a valarray.
gslice_array Class	An internal, auxiliary template class that supports general slice objects by providing operations between subset arrays defined by the general slice of a valarray.
indirect_array Class	An internal, auxiliary template class that supports objects that are subsets of valarrays by providing operations between subset arrays defined by specifying a subset of indices of a parent valarray.
mask_array Class	An internal, auxiliary template class that supports objects that are subsets of parent valarrays, specified with a Boolean expression, by providing operations between the subset arrays.
slice Class	A utility class to valarray that is used to define one-dimensional, vector-like subsets of a valarray.
slice_array Class	An internal, auxiliary template class that supports slice objects by providing operations between subset arrays defined by the slice of a valarray.
valarray Class	The template class describes an object that controls a sequence of elements of type <code>Type</code> that are stored as an array and designed for performing high-speed mathematical operations, optimized for computational performance.

Specializations

valarray<bool> Class	A specialized version of the template class <code>valarray<Type></code> to elements of type bool .

abs	acos	asin
atan	atan2	cos
cosh	exp	log
log10	pow	sin
sinh	sqrt	swap
tan	tanh	

abs

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the absolute value of the elements of the input valarray.

```
template <class Type>
valarray<Type> abs(const valarray<Type>& left);
```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the absolute value of the elements of the input valarray.

Example

```

// valarray_abs.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> va1 ( 9 ), va2 ( 9 );
    for ( i = 0 ; i < 4 ; i++ )
        va1 [ i ] = -i;
    for ( i = 4 ; i < 9 ; i++ )
        va1 [ i ] = i;

    cout << "The initial valarray is: ";
    for (i = 0 ; i < 9 ; i++ )
        cout << va1 [ i ] << " ";
    cout << "." << endl;

    va2 = abs ( va1 );
    cout << "The absolute value of the initial valarray is: ";
    for (i = 0 ; i < 9 ; i++ )
        cout << va2 [ i ] << " ";
    cout << "." << endl;
}

```

```

The initial valarray is: 0 -1 -2 -3 4 5 6 7 8 .
The absolute value of the initial valarray is: 0 1 2 3 4 5 6 7 8 .

```

acos

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the arccosine of the elements of the input valarray.

```

template <class Type>
valarray<Type> acos(const valarray<Type>& left);

```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the arccosine of the elements of the input valarray.

Remarks

The units of the returned elements are in radians.

The return value is a principal value between 0 and +pi that is consistent with the cosine value input.

Example

```

// valarray_acos.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> va1 ( 9 );
    for ( i = 0 ; i < 9 ; i++ )
        va1 [ i ] = 0.25 * i - 1;
    valarray<double> va2 ( 9 );

    cout << "The initial valarray is:";
    for (i = 0 ; i < 9 ; i++ )
        cout << " " << va1 [ i ];
    cout << endl;

    va2 = acos ( va1 );
    cout << "The arccosine of the initial valarray is:\n";
    for (i = 0 ; i < 9 ; i++ )
        cout << setw(10) << va2 [ i ]
            << " radians, which is "
            << setw(11) << (180/pi) * va2 [ i ]
            << " degrees" << endl;
}

```

```

The initial valarray is: -1 -0.75 -0.5 -0.25 0 0.25 0.5 0.75 1
The arccosine of the initial valarray is:
 3.14159 radians, which is      180 degrees
 2.41886 radians, which is     138.59 degrees
 2.0944 radians, which is      120 degrees
 1.82348 radians, which is     104.478 degrees
 1.5708 radians, which is       90 degrees
 1.31812 radians, which is      75.5225 degrees
 1.0472 radians, which is       60 degrees
 0.722734 radians, which is     41.4096 degrees
 0 radians, which is           0 degrees

```

asin

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the arcsine of the elements of the input valarray.

```

template <class Type>
valarray<Type> asin(const valarray<Type>& left);

```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the arcsine of the elements of the input valarray.

Remarks

The units of the returned elements are in radians.

The return value is a principal value between $+\pi/2$ and $-\pi/2$ that is consistent with the sine value input.

Example

```
// valarray_asin.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> va1 ( 9 );
    for ( i = 0 ; i < 9 ; i++ )
        va1 [ i ] = 0.25 * i - 1;
    valarray<double> va2 ( 9 );

    cout << "The initial valarray is:";
    for ( i = 0 ; i < 9 ; i++ )
        cout << " " << va1 [ i ];
    cout << endl;

    va2 = asin ( va1 );
    cout << "The arcsine of the initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << setw(10) << va2 [ i ]
            << " radians, which is "
            << setw(11) << (180/pi) * va2 [ i ]
            << " degrees" << endl;
}
```

```
The initial valarray is: -1 -0.75 -0.5 -0.25 0 0.25 0.5 0.75 1
The arcsine of the initial valarray is:
-1.5708 radians, which is -90 degrees
-0.848062 radians, which is -48.5904 degrees
-0.523599 radians, which is -30 degrees
-0.25268 radians, which is -14.4775 degrees
0 radians, which is 0 degrees
0.25268 radians, which is 14.4775 degrees
0.523599 radians, which is 30 degrees
0.848062 radians, which is 48.5904 degrees
1.5708 radians, which is 90 degrees
```

atan

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the principal value of the arctangent of the elements of the input valarray.

```
template <class Type>
valarray<Type> atan(const valarray<Type>& left);
```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the arctangent of the elements of the input valarray.

Remarks

The units of the returned elements are in radians.

The return value is a principal value between $+\pi/2$ and $-\pi/2$ that is consistent with the tangent value input.

Example

```
// valarray_atan.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> va1 ( 9 );
    va1 [ 0 ] = -100;
    for ( i = 1 ; i < 8 ; i++ )
        va1 [ i ] = 5 * ( 0.25 * i - 1 );
    va1 [ 8 ] = 100;
    valarray<double> va2 ( 9 );

    cout << "The initial valarray is: ";
    for ( i = 0 ; i < 9 ; i++ )
        cout << va1 [ i ] << " ";
    cout << "." << endl;

    va2 = atan ( va1 );
    cout << "The arcsine of the initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << setw(10) << va2 [ i ]
            << " radians, which is "
            << setw(11) << (180/pi) * va2 [ i ]
            << " degrees" << endl;
    cout << endl;
}
```

```
The initial valarray is: -100 -3.75 -2.5 -1.25 0 1.25 2.5 3.75 100 .
The arcsine of the initial valarray is:
-1.5608 radians, which is -89.4271 degrees
-1.31019 radians, which is -75.0686 degrees
-1.19029 radians, which is -68.1986 degrees
-0.896055 radians, which is -51.3402 degrees
0 radians, which is 0 degrees
0.896055 radians, which is 51.3402 degrees
1.19029 radians, which is 68.1986 degrees
1.31019 radians, which is 75.0686 degrees
1.5608 radians, which is 89.4271 degrees
```

atan2

Returns a valarray whose elements are equal to the arctangent of the Cartesian components specified by a combination of constants and elements of valarrays.

```
template <class Type>
valarray<Type> atan2(const valarray<Type>& left, const valarray<Type>& right);

template <class Type>
valarray<Type> atan2(const valarray<Type> left, const Type& right);

template <class Type>
valarray<Type> atan2(const Type& left, const valarray<Type>& right);
```

Parameters

left

The constant numerical data type or input valarray whose elements provide the values for the y-coordinate of the arctangent argument.

right

The constant numerical data type or input valarray whose elements provide the values for the x-coordinate of the arctangent argument.

Return Value

A valarray whose elements `I` are equal to the arctangent of:

- `left [I] / _Right [I]` for the first template function.
- `left [I] / right` for the second template function.
- `left / right [I]` for the third template function.

Remarks

The units of the returned elements are in radians.

This function preserves information about the signs of the components in the argument that is lost by the standard tangent function, and this knowledge of the quadrant enables the return value to be assigned a unique angle between +pi and -pi.

If *left* and *right* have a different number of elements, the result is undefined.

Example

```

// valarray_atan2.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> va1y ( 1 , 4 ), va1x ( 1 , 4 );
    va1x [ 1 ] = -1;
    va1x [ 2 ] = -1;
    va1y [ 2 ] = -1;
    va1y [ 3 ] = -1;
    valarray<double> va2 ( 4 );

    cout << "The initial valarray for the x coordinate is: ( ";
    for ( i = 0 ; i < 4 ; i++ )
        cout << va1x [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial valarray for the y coordinate is: ( ";
    for ( i = 0 ; i < 4 ; i++ )
        cout << va1y [ i ] << " ";
    cout << ")." << endl;

    va2 = atan2 ( va1y , va1x );
    cout << "The atan2 ( y / x ) of the initial valarrays is:\n";
    for ( i = 0 ; i < 4 ; i++ )
        cout << setw( 10 ) << va2 [ i ]
            << " radians, which is "
            << setw( 11 ) << ( 180/pi ) * va2 [ i ]
            << "degrees" << endl;
    cout << endl;
}

```

```

The initial valarray for the x coordinate is: ( 1 -1 -1 1 ).
The initial valarray for the y coordinate is: ( 1 1 -1 -1 ).
The atan2 ( y / x ) of the initial valarrays is:
0.785398 radians, which is      45degrees
2.35619 radians, which is     135degrees
-2.35619 radians, which is    -135degrees
-0.785398 radians, which is    -45degrees

```

COS

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the cosine of the elements of the input valarray.

```

template <class Type>
valarray<Type> cos(const valarray<Type>& left);

```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the absolute value of the elements of the input valarray.

Example

```
// valarray_cos.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> va1 ( 9 );
    for ( i = 0 ; i < 9 ; i++ )
        va1 [ i ] = ( pi ) * ( 0.25 * i - 1 );
    valarray<double> va2 ( 9 );

    cout << "The initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << setw( 10 ) << va1 [ i ]
            << " radians, which is "
            << setw( 5 ) << ( 180/pi ) * va1 [ i ]
            << " degrees" << endl;
    cout << endl;

    va2 = cos ( va1 );
    cout << "The cosine of the initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << va2 [ i ] << endl;
}
```

```
The initial valarray is:
-3.14159 radians, which is -180 degrees
-2.35619 radians, which is -135 degrees
-1.5708 radians, which is -90 degrees
-0.785398 radians, which is -45 degrees
0 radians, which is 0 degrees
0.785398 radians, which is 45 degrees
1.5708 radians, which is 90 degrees
2.35619 radians, which is 135 degrees
3.14159 radians, which is 180 degrees
```

```
The cosine of the initial valarray is:
-1
-0.707107
-1.03412e-013
0.707107
1
0.707107
-1.03412e-013
-0.707107
-1
```

cosh

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the hyperbolic cosine of the elements of the input valarray.

```
template <class Type>
valarray<Type> cosh(const valarray<Type>& left);
```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the hyperbolic cosine of the elements of the input valarray.

Remarks

Identities defining the hyperbolic cosine in terms of exponential function:

$$\cosh(z) = (\exp(z) + \exp(-z)) / 2$$

Example

```
// valarray_cosh.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> va1 ( 9 );
    for ( i = 0 ; i < 9 ; i++ )
        va1 [ i ] = pi * ( 0.25 * i - 1 );
    valarray<double> va2 ( 9 );

    cout << "The initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << setw( 10 ) << va1 [ i ]
        << " radians, which is "
        << setw( 5 ) << ( 180/pi ) * va1 [ i ]
        << " degrees" << endl;
    cout << endl;

    va2 = cosh ( va1 );
    cout << "The hyperbolic cosine of the initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << va2 [ i ] << endl;
}
```

The initial valarray is:

-3.14159	radians, which is	-180	degrees
-2.35619	radians, which is	-135	degrees
-1.5708	radians, which is	-90	degrees
-0.785398	radians, which is	-45	degrees
0	radians, which is	0	degrees
0.785398	radians, which is	45	degrees
1.5708	radians, which is	90	degrees
2.35619	radians, which is	135	degrees
3.14159	radians, which is	180	degrees

The hyperbolic cosine of the initial valarray is:

11.592
5.32275
2.50918
1.32461
1
1.32461
2.50918
5.32275
11.592

exp

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the natural exponential of the elements of the input valarray.

```
template <class Type>
valarray<Type> exp(const valarray<Type>& left);
```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the natural exponential of the elements of the input valarray.

Example

```

// valarray_exp.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    int i;

    valarray<double> va1 ( 9 );
    for ( i = 0 ; i < 9 ; i++ )
        va1 [ i ] = 10 * ( 0.25 * i - 1 );
    valarray<double> va2 ( 9 );

    cout << "Initial valarray:";
    for ( i = 0 ; i < 9 ; i++ )
        cout << " " << va1 [ i ];
    cout << endl;

    va2 = exp ( va1 );
    cout << "The natural exponential of the initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << va2 [ i ] << endl;
}

```

```

Initial valarray: -10 -7.5 -5 -2.5 0 2.5 5 7.5 10
The natural exponential of the initial valarray is:
4.53999e-005
0.000553084
0.00673795
0.082085
1
12.1825
148.413
1808.04
22026.5

```

log

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the natural logarithm of the elements of the input valarray.

```

template <class Type>
valarray<Type> log(const valarray<Type>& left);

```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the absolute value of the elements of the input valarray.

Example

```
// valarray_log.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    int i;

    valarray<double> va1 ( 9 );
    for ( i = 0 ; i < 9 ; i++ )
        va1 [ i ] = 10 * i;
    valarray<double> va2 ( 9 );

    cout << "Initial valarray:";
    for ( i = 0 ; i < 9 ; i++ )
        cout << " " << va1 [ i ];
    cout << endl;

    va2 = log ( va1 );
    cout << "The natural logarithm of the initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << va2 [ i ] << endl;
}
```

```
Initial valarray: 0 10 20 30 40 50 60 70 80
The natural logarithm of the initial valarray is:
-inf
2.30259
2.99573
3.4012
3.68888
3.91202
4.09434
4.2485
4.38203
```

log10

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the base 10 or common logarithm of the elements of the input valarray.

```
template <class Type>
valarray<Type> log10(const valarray<Type>& left);
```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the common logarithm of the elements of the input valarray.

Example

```

// valarray_log10.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    int i;

    valarray<double> va1 ( 11 );
    for ( i = 0 ; i < 11 ; i++ )
        va1 [ i ] = 10 * i;
    valarray<double> va2 ( 9 );

    cout << "Initial valarray:";
    for (i = 0 ; i < 11 ; i++ )
        cout << " " << va1 [ i ];
    cout << endl;

    va2 = log10 ( va1 );
    cout << "The common logarithm of the initial valarray is:\n";
    for (i = 0 ; i < 11 ; i++ )
        cout << va2 [ i ] << endl;
}

```

```

Initial valarray: 0 10 20 30 40 50 60 70 80 90 100
The common logarithm of the initial valarray is:
-inf
1
1.30103
1.47712
1.60206
1.69897
1.77815
1.8451
1.90309
1.95424
2

```

pow

Operates on the elements of input valarrays and constants, returning a valarray whose elements are equal to a base specified either by the elements of an input valarray or a constant raised to an exponent specified either by the elements of an input valarray or a constant.

```

template <class Type>
valarray<Type>
pow(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<Type>
pow(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<Type>
pow(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The input valarray whose elements supply the base for each element to be exponentiated.

right

The input valarray whose elements supply the power for each element to be exponentiated.

Return Value

A valarray whose elements `I` are equal to:

- `left` `[/]` raised to the power `right` `[/]` for the first template function.
- `left` `[/]` raised to the power `right` for the second template function.
- `left` raised to the power `right` `[/]` for the third template function.

Remarks

If *left* and *right* have a different number of elements, the result is undefined.

Example

```

#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> vabase ( 6 );
    for ( i = 0 ; i < 6 ; i++ )
        vabase [ i ] = i/2;
    valarray<double> vaexp ( 6 );
    for ( i = 0 ; i < 6 ; i++ )
        vaexp [ i ] = 2 * i;

    valarray<double> va2 ( 6 );

    cout << "The initial valarray for the base is: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vabase [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial valarray for the exponent is: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vaexp[ i ] << " ";
    cout << ")." << endl;

    va2 = pow ( vabase , vaexp );
    cout << "The power of (n/2) * exp (2n) for n = 0 to n = 5 is: \n";
    for ( i = 0 ; i < 6 ; i++ )
        cout << "n = " << i << "\tgives " << va2 [ i ] << endl;
}

```

```

The initial valarray for the base is: ( 0 0 1 1 2 2 ).
The initial valarray for the exponent is: ( 0 2 4 6 8 10 ).
The power of (n/2) * exp (2n) for n = 0 to n = 5 is:
n = 0   gives 1
n = 1   gives 0
n = 2   gives 1
n = 3   gives 1
n = 4   gives 256
n = 5   gives 1024

```

sin

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the sine of the elements of the input valarray.

```

template <class Type>
valarray<Type> sin(const valarray<Type>& left);

```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the sine of the elements of the input valarray.

Example

```
// valarray_sin.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> va1 ( 9 );
    for ( i = 0 ; i < 9 ; i++ )
        va1 [ i ] = pi * ( 0.25 * i - 1 );
    valarray<double> va2 ( 9 );

    cout << "The initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << setw(10) << va1 [ i ]
            << " radians, which is "
            << setw(5) << ( 180/pi ) * va1 [ i ]
            << " degrees" << endl;
    cout << endl;

    va2 = sin ( va1 );
    cout << "The sine of the initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << va2 [ i ] << endl;
}
```

```
The initial valarray is:
-3.14159 radians, which is -180 degrees
-2.35619 radians, which is -135 degrees
-1.5708 radians, which is -90 degrees
-0.785398 radians, which is -45 degrees
0 radians, which is 0 degrees
0.785398 radians, which is 45 degrees
1.5708 radians, which is 90 degrees
2.35619 radians, which is 135 degrees
3.14159 radians, which is 180 degrees
```

```
The sine of the initial valarray is:
2.06823e-013
-0.707107
-1
-0.707107
0
0.707107
1
0.707107
-2.06823e-013
```

sinh

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the hyperbolic sine of the elements of the input valarray.

```
template <class Type>
valarray<Type> sinh(const valarray<Type>& left);
```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the hyperbolic sine of the elements of the input valarray.

Remarks

Identities defining the hyperbolic sine in terms of exponential function:

$$\sinh (z) = (\exp (z) - \exp (- z)) / 2$$

Example

```
// valarray_sinh.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> va1 ( 9 );
    for ( i = 0 ; i < 9 ; i++ )
        va1 [ i ] = pi * ( 0.25 * i - 1 );
    valarray<double> va2 ( 9 );

    cout << "The initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << setw( 10 ) << va1 [ i ]
            << " radians, which is "
            << setw( 5 ) << ( 180/pi ) * va1 [ i ]
            << " degrees" << endl;
    cout << endl;

    va2 = sinh ( va1 );
    cout << "The hyperbolic sine of the initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << va2 [ i ] << endl;
}
```

The initial valarray is:

-3.14159	radians, which is	-180	degrees
-2.35619	radians, which is	-135	degrees
-1.5708	radians, which is	-90	degrees
-0.785398	radians, which is	-45	degrees
0	radians, which is	0	degrees
0.785398	radians, which is	45	degrees
1.5708	radians, which is	90	degrees
2.35619	radians, which is	135	degrees
3.14159	radians, which is	180	degrees

The hyperbolic sine of the initial valarray is:

-11.5487
-5.22797
-2.3013
-0.868671
0
0.868671
2.3013
5.22797
11.5487

sqrt

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the square root of the elements of the input valarray.

```
template <class Type>
valarray<Type> sqrt(const valarray<Type>& left);
```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the square root of the elements of the input valarray.

Example

```
// valarray_sqrt.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <cmath>

int main( )
{
    using namespace std;
    int i;

    valarray<double> va1 ( 6 );
    for ( i = 0 ; i < 5 ; i++ )
        va1 [ i ] = i * i;

    cout << "The initial valarray is: ( ";
    for ( i = 0 ; i < 5 ; i++ )
        cout << va1 [ i ] << " ";
    cout << ")." << endl;

    valarray<double> va2 = sqrt ( va1 );
    cout << "The square root of the initial valarray is: ( ";
    for ( i = 0 ; i < 5 ; i++ )
        cout << va2 [ i ] << " ";
    cout << ")." << endl;
}
```

```
The initial valarray is: ( 0 1 4 9 16 ).
The square root of the initial valarray is: ( 0 1 2 3 4 ).
```

swap

Exchanges the elements of two valarrays.

```
template <class Type>
void swap(
    valarray<Type>& left,
    valarray<Type>& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>left</i>	An object of type <code>valarray</code> .
<i>right</i>	An object of type <code>valarray</code> .

Remarks

The template function executes `left.swap(right)` .

tan

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the tangent of the elements of the input valarray.

```
template <class Type>
valarray<Type> tan(const valarray<Type>& left);
```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the tangent of the elements of the input valarray.

Example

```
// valarray_tan.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> va1 ( 9 );
    for ( i = 0 ; i < 9 ; i++ )
        va1 [ i ] = ( pi/2 ) * ( 0.25 * i - 1 );
    valarray<double> va2 ( 9 );

    cout << "The initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << setw( 10 ) << va1 [ i ]
        << "      radians, which is "
        << setw( 5 ) << ( 180/pi ) * va1 [ i ]
        << "      degrees" << endl;
    cout << endl;

    va2 = tan ( va1 );
    cout << "The tangent of the initial valarray is:\n ";
    for ( i = 0 ; i < 9 ; i++ )
        cout << va2 [ i ] << endl;
}
```

```
The initial valarray is:
-1.5708      radians, which is    -90    degrees
-1.1781      radians, which is   -67.5   degrees
-0.785398    radians, which is   -45    degrees
-0.392699    radians, which is   -22.5   degrees
      0      radians, which is      0    degrees
 0.392699    radians, which is    22.5   degrees
 0.785398    radians, which is    45    degrees
 1.1781      radians, which is    67.5   degrees
 1.5708      radians, which is    90    degrees
```

```
The tangent of the initial valarray is:
9.6701e+012
-2.41421
-1
-0.414214
0
0.414214
1
2.41421
-9.6701e+012
```

tanh

Operates on the elements of an input valarray, returning a valarray whose elements are equal to the hyperbolic tangent of the elements of the input valarray.

```
template <class Type>
valarray<Type> tanh(const valarray<Type>& left);
```

Parameters

left

The input valarray whose elements are to be operated on by the member function.

Return Value

A valarray whose elements are equal to the hyperbolic cosine of the elements of the input valarray.

Remarks

Identities defining the hyperbolic tangent in terms of the exponential function:

$$\tanh (z)=\sinh (z) / \cosh (z)=(\exp (z)-\exp (-z)) /(\exp (z)+\exp (-z))$$

Example

```

// valarray_tanh.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>
#include <iomanip>

int main( )
{
    using namespace std;
    double pi = 3.14159265359;
    int i;

    valarray<double> va1 ( 9 );
    for ( i = 0 ; i < 9 ; i++ )
        va1 [ i ] = pi * ( 0.25 * i - 1 );
    valarray<double> va2 ( 9 );

    cout << "The initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << setw( 10 ) << va1 [ i ]
            << " radians, which is "
                << setw( 5 ) << ( 180/pi ) * va1 [ i ]
                << " degrees" << endl;
    cout << endl;

    va2 = tanh ( va1 );
    cout << "The hyperbolic tangent of the initial valarray is:\n";
    for ( i = 0 ; i < 9 ; i++ )
        cout << va2 [ i ] << endl;
}

```

```

The initial valarray is:
-3.14159 radians, which is -180 degrees
-2.35619 radians, which is -135 degrees
-1.5708 radians, which is -90 degrees
-0.785398 radians, which is -45 degrees
0 radians, which is 0 degrees
0.785398 radians, which is 45 degrees
1.5708 radians, which is 90 degrees
2.35619 radians, which is 135 degrees
3.14159 radians, which is 180 degrees

```

```

The hyperbolic tangent of the initial valarray is:
-0.996272
-0.982193
-0.917152
-0.655794
0
0.655794
0.917152
0.982193
0.996272

```

<valarray> operators

3/28/2019 • 35 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator%</code>	<code>operator&</code>
<code>operator&&</code>	<code>operator></code>	<code>operator>></code>
<code>operator>=</code>	<code>operator<</code>	<code>operator<<</code>
<code>operator<=</code>	<code>operator*</code>	<code>operator+</code>
<code>operator-</code>	<code>operator/</code>	<code>operator==</code>
<code>operator^</code>	<code>operator </code>	<code>operator </code>

operator!=

Tests whether the corresponding elements of two equally sized valarrays are unequal or whether all the elements of a valarray are unequal a specified value.

```
template <class Type>
valarray<bool>
operator!=(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<bool>
operator!=(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<bool>
operator!=(
    const Type& left,
    const valarray<Type>& right);
```

Parameters

left

The first of the two valarrays whose elements are to be tested for inequality.

right

The second of the two valarrays whose elements are to be tested for inequality.

Return Value

A valarray of Boolean values, each of which is:

- **true** if the corresponding elements are unequal.
- **false** if the corresponding elements are not unequal.

Remarks

The first template operator returns an object of class `valarray<bool>`, each of whose elements `I` is `left[I] != right[I]`.

The second template operator stores in element `I` `left[I] != right`.

The third template operator stores in element `I` `left != right[I]`.

Example

```
// valarray_op_ne.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<bool> vaNE ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = -i;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = i;
    for ( i = 0 ; i < 10 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL != vaR );
    cout << "The element-by-element result of "
        << "the not equal comparison test is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 0 1 -2 3 -4 5 -6 7 -8 9 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 8 9 ).
The element-by-element result of the not equal comparison test is the
valarray: ( 0 0 1 0 1 0 1 0 1 0 ).
*/
```

operator%

Obtains the remainder of dividing the corresponding elements of two equally sized valarrays or of dividing a valarray by a specified value or of dividing a specified value by a valarray.

```
template <class Type>
valarray<Type>
operator%(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<Type>
operator%(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<Type>
operator%(
    const Type& left,
    const valarray<Type>& right);
```

Parameters

left

A value or valarray that serves as the dividend into which another value or valarray is to be divided.

right

A value or valarray that serves as the divisor and that divides another value or valarray.

Return Value

A valarray whose elements are the element-wise remainders of *left* divided by *right*.

Example

```

// valarray_op_rem.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 6 ), vaR ( 6 );
    valarray<int> vaREM ( 6 );
    for ( i = 0 ; i < 6 ; i += 2 )
        vaL [ i ] = 53;
    for ( i = 1 ; i < 6 ; i += 2 )
        vaL [ i ] = -67;
    for ( i = 0 ; i < 6 ; i++ )
        vaR [ i ] = 3*i+1;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaREM = ( vaL % vaR );
    cout << "The remainders from the element-by-element "
        << "division is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vaREM [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 53 -67 53 -67 53 -67 ).
The initial Right valarray is: ( 1 4 7 10 13 16 ).
The remainders from the element-by-element division is the
valarray: ( 0 -3 4 -7 1 -3 ).
*/

```

operator&

Obtains the bitwise **AND** between corresponding elements of two equally sized valarrays or between a valarray and a specified value of the element type.

```

template <class Type>
valarray<Type>
operator&(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<Type>
operator&(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<Type>
operator&(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The first of the two valarrays whose respective elements are to be combined with the bitwise `AND` or a specified value of the element type to be combined bitwise with each element of a valarray.

right

The second of the two valarrays whose respective elements are to be combined with the bitwise `AND` or a specified value of the element type to be combined bitwise with each element of a valarray.

Return Value

A valarray whose elements are the element-wise combination of the bitwise AND operation of *left* and *right*.

Remarks

A bitwise operation can only be used to manipulate bits in **char** and **int** data types and variants and not on **float**, **double**, **longdouble**, **void**, **bool** or other, more complex data types.

The bitwise `AND` has the same truth table as the logical `AND` but applies to the data type on the level of the individual bits. The `operator&&` applies on an element level, counting all nonzero values as true, and the result is a valarray of Boolean values. The bitwise `AND` `operator&`, by contrast, can result in a valarray of values other than 0 or 1, depending on outcome of the bitwise operation.

Example

```

// valarray_op_bitand.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<int> vaBWA ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = 0;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = i+1;
    for ( i = 0 ; i < 10 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaBWA = ( vaL & vaR );
    cout << "The element-by-element result of "
        << "the bitwise operator & is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaBWA [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 0 2 0 4 0 6 0 8 0 10 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 8 9 ).
The element-by-element result of the bitwise operator & is the
valarray: ( 0 0 0 0 0 4 0 0 0 8 ).
*/

```

operator&&

Obtains the logical **AND** between corresponding elements of two equally sized valarrays or between a valarray and a specified value of the valarray's element type.

```

template <class Type>
valarray<bool>
operator&&(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<bool>
operator&&(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<bool>
operator&&(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The first of the two valarrays whose respective elements are to be combined with the logical `AND` or a specified value of the element type to be combined with each element of a valarray.

right

The second of the two valarrays whose respective elements are to be combined with the logical `AND` or a specified value of the element type to be combined with each element of a valarray.

Return Value

A valarray whose elements are of type `bool` and are the element-wise combination of the logical `AND` operation of *left* and *right*.

Remarks

The logical `ANDoperator&&` applies on an element level, counting all nonzero values as true, and the result is a valarray of Boolean values. The bitwise version of `AND`, `operator&`, by contrast, can result in a valarray of values other than 0 or 1, depending on the outcome of the bitwise operation.

Example

```

// valarray_op_logand.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<bool> vaLAA ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = 0;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = i-1;
    for ( i = 0 ; i < 10 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for (i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for (i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaLAA = ( vaL && vaR );
    cout << "The element-by-element result of "
        << "the logical AND operator&& is the\n"
        << "valarray: ( ";
    for (i = 0 ; i < 10 ; i++ )
        cout << vaLAA [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 0 0 0 2 0 4 0 6 0 8 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 8 9 ).
The element-by-element result of the logical AND operator&& is the
valarray: ( 0 0 0 1 0 1 0 1 0 1 ).
*/

```

operator>

Tests whether the elements of one valarray are greater than the elements of an equally sized valarray or whether all the elements of a valarray are greater or less than a specified value.

```

template <class Type>
valarray<bool>
operator>(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<bool>
operator>(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<bool>
operator>(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The first of the two valarrays whose elements are to be compared or a specified value to be compared with each element of a valarray.

right

The second of the two valarrays whose elements are to be compared or a specified value to be compared with each element of a valarray.

Return Value

A valarray of Boolean values, each of which is:

- **true** if the *left* element or value is greater than the corresponding *right* element or value.
- **false** if the *left* element or value is not greater than the corresponding *right* element or value.

Remarks

If the number of elements in two valarrays is not equal, the result is undefined.

Example

```

// valarray_op_gt.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<bool> vaNE ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = -i;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = i;
    for ( i = 0 ; i < 10 ; i++ )
        vaR [ i ] = i - 1;

    cout << "The initial Left valarray is: ( ";
    for (i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL > vaR );
    cout << "The element-by-element result of "
        << "the greater than comparison test is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 0 1 -2 3 -4 5 -6 7 -8 9 ).
The initial Right valarray is: ( -1 0 1 2 3 4 5 6 7 8 ).
The element-by-element result of the greater than comparison test is the
valarray: ( 1 1 0 1 0 1 0 1 0 1 ).
*/

```

operator>=

Tests whether the elements of one valarray are greater than or equal to the elements of an equally sized valarray or whether all the elements of a valarray are greater than or equal to or less than or equal to a specified value.

```

template <class Type>
valarray<bool>
operator>=(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<bool>
operator>=(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<bool>
operator>=(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The first of the two valarrays whose elements are to be compared or a specified value to be compared with each element of a valarray.

right

The second of the two valarrays whose elements are to be compared or a specified value to be compared with each element of a valarray.

Return Value

A valarray of Boolean values, each of which is:

- **true** if the *left* element or value is greater than or equal to the corresponding *right* element or value.
- **false** if the *left* element or value is less than the corresponding *right* element or value.

Remarks

If the number of elements in two valarrays is not equal, the result is undefined.

Example

```

// valarray_op_ge.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<bool> vaNE ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = -i;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = i;
    for ( i = 0 ; i < 10 ; i++ )
        vaR [ i ] = i - 1;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL >= vaR );
    cout << "The element-by-element result of "
        << "the greater than or equal test is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 0 1 -2 3 -4 5 -6 7 -8 9 ).
The initial Right valarray is: ( -1 0 1 2 3 4 5 6 7 8 ).
The element-by-element result of the greater than or equal test is the
valarray: ( 1 1 0 1 0 1 0 1 0 1 ).
*/

```

operator>>

Right-shifts the bits for each element of a valarray a specified number of positions or by an element-wise amount specified by a second valarray.

```
template <class Type>
valarray<Type>
operator>>(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<Type>
operator>>(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<Type>
operator>>(
    const Type& left,
    const valarray<Type>& right);
```

Parameters

left

The value to be shifted or the valarray whose elements are to be shifted.

right

The value indicating the amount of right shift or valarray whose elements indicate the element-wise amount of right shift.

Return Value

A valarray whose elements have been shifted right by the specified amount.

Remarks

Signed numbers have their signs preserved.

Example

```

// valarray_op_rs.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 8 ), vaR ( 8 );
    valarray<int> vaNE ( 8 );
    for ( i = 0 ; i < 8 ; i += 2 )
        vaL [ i ] = 64;
    for ( i = 1 ; i < 8 ; i += 2 )
        vaL [ i ] = -64;
    for ( i = 0 ; i < 8 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL >> vaR );
    cout << "The element-by-element result of "
        << "the right shift is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 64 -64 64 -64 64 -64 64 -64 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 ).
The element-by-element result of the right shift is the
valarray: ( 64 -32 16 -8 4 -2 1 -1 ).
*/

```

operator<

Tests whether the elements of one valarray are less than the elements of an equally sized valarray or whether all the elements of a valarray are greater or less than a specified value.

```

template <class Type>
valarray<bool>
operator<(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<bool>
operator<(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<bool>
operator<(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The first of the two valarrays whose elements are to be compared or a specified value to be compared with each element of a valarray.

right

The second of the two valarrays whose elements are to be compared or a specified value to be compared with each element of a valarray.

Return Value

A valarray of Boolean values, each of which is:

- **true** if the *left* element or value is less than the corresponding *right* element or value.
- **false** if the *left* element or value is not less than the corresponding *right* element or value.

Remarks

If the number of elements two valarrays is not equal, the result is undefined.

Example

```

// valarray_op_lt.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<bool> vaNE ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = -i;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = i;
    for ( i = 0 ; i < 10 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL < vaR );
    cout << "The element-by-element result of "
        << "the less-than comparison test is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 0 1 -2 3 -4 5 -6 7 -8 9 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 8 9 ).
The element-by-element result of the less-than comparison test is the
valarray: ( 0 0 1 0 1 0 1 0 1 0 ).
*/

```

operator<=

Tests whether the elements of one valarray are less than or equal to the elements of an equally sized valarray or whether all the elements of a valarray are greater than or equal to or less than or equal to a specified value.

```

template <class Type>
valarray<bool>
operator<=(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<bool>
operator<=(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<bool>
operator<=(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The first of the two valarrays whose elements are to be compared or a specified value to be compared with each element of a valarray.

right

The second of the two valarrays whose elements are to be compared or a specified value to be compared with each element of a valarray.

Return Value

A valarray of Boolean values, each of which is:

- **true** if the *left* element or value is less than or equal to the corresponding *right* element or value.
- **false** if the *left* element or value is greater than the corresponding *right* element or value.

Remarks

If the number of elements two valarrays is not equal, the result is undefined.

Example

```

// valarray_op_le.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<bool> vaNE ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = -i;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = i;
    for ( i = 0 ; i < 10 ; i++ )
        vaR [ i ] = i - 1;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL <= vaR );
    cout << "The element-by-element result of "
        << "the less than or equal test is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 0 1 -2 3 -4 5 -6 7 -8 9 ).
The initial Right valarray is: ( -1 0 1 2 3 4 5 6 7 8 ).
The element-by-element result of the less than or equal test is the
valarray: ( 0 0 1 0 1 0 1 0 1 0 ).
*/

```

operator<<

Left shifts the bits for each element of a valarray a specified number of positions or by an element-wise amount specified by a second valarray.

```
template <class Type>
valarray<Type>
operator<<(  
    const valarray<Type>& left,  
    const valarray<Type>& right);  
  
template <class Type>  
valarray<Type>  
operator<<(  
    const valarray<Type>& left,  
    const Type& right);  
  
template <class Type>  
valarray<Type>  
operator<<(  
    const Type& left,  
    const valarray<Type>& right);
```

Parameters

left

The value to be shifted or the valarray whose elements are to be shifted.

right

The value indicating the amount of left shift or valarray whose elements indicate the element-wise amount of left shift.

Return Value

A valarray whose elements have been shifted left by the specified amount.

Remarks

Signed numbers have their signs preserved.

Example

```

// valarray_op_ls.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 8 ), vaR ( 8 );
    valarray<int> vaNE ( 8 );
    for ( i = 0 ; i < 8 ; i += 2 )
        vaL [ i ] = 1;
    for ( i = 1 ; i < 8 ; i += 2 )
        vaL [ i ] = -1;
    for ( i = 0 ; i < 8 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL << vaR );
    cout << "The element-by-element result of "
        << "the left shift is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 1 -1 1 -1 1 -1 1 -1 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 ).
The element-by-element result of the left shift is the
valarray: ( 1 -2 4 -8 16 -32 64 -128 ).
*/

```

operator*

Obtains the element-wise product between corresponding elements of two equally sized valarrays or of between a valarray a specified value.

```
template <class Type>
valarray<Type>
operator*(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<Type>
operator*(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<Type>
operator*(
    const Type& left,
    const valarray<Type>& right);
```

Parameters

left

The first of the two valarrays whose elements are to be multiplied or a specified value to be multiplied with each element of a valarray.

right

The second of the two valarrays whose elements are to be multiplied or a specified value to be multiplied with each element of a valarray.

Return Value

A valarray whose elements are the element-wise product of *left* and *right*.

Example

```

// valarray_op_eprod.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 8 ), vaR ( 8 );
    valarray<int> vaNE ( 8 );
    for ( i = 0 ; i < 8 ; i += 2 )
        vaL [ i ] = 2;
    for ( i = 1 ; i < 8 ; i += 2 )
        vaL [ i ] = -1;
    for ( i = 0 ; i < 8 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for (i = 0 ; i < 8 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for (i = 0 ; i < 8 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL * vaR );
    cout << "The element-by-element result of "
        << "the multiplication is the\n"
        << "valarray: ( ";
    for (i = 0 ; i < 8 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 2 -1 2 -1 2 -1 2 -1 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 ).
The element-by-element result of the multiplication is the
valarray: ( 0 -1 4 -3 8 -5 12 -7 ).
*/

```

operator+

Obtains the element-wise sum between corresponding elements of two equally sized valarrays or of between a valarray a specified value.

```
template <class Type>
valarray<Type>
operator+(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<Type>
operator+(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<Type>
operator+(
    const Type& left,
    const valarray<Type>& right);
```

Parameters

left

The first of the two valarrays whose elements are to be added or a specified value to be added with each element of a valarray.

right

The second of the two valarrays whose elements are to be added or a specified value to be added with each element of a valarray.

Return Value

A valarray whose elements are the element-wise sum of *left* and *right*.

Example

```

// valarray_op_esum.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 8 ), vaR ( 8 );
    valarray<int> vaNE ( 8 );
    for ( i = 0 ; i < 8 ; i += 2 )
        vaL [ i ] = 2;
    for ( i = 1 ; i < 8 ; i += 2 )
        vaL [ i ] = -1;
    for ( i = 0 ; i < 8 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL + vaR );
    cout << "The element-by-element result of "
        << "the sum is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 2 -1 2 -1 2 -1 2 -1 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 ).
The element-by-element result of the sum is the
valarray: ( 2 0 4 2 6 4 8 6 ).
*/

```

operator-

Obtains the element-wise difference between corresponding elements of two equally sized valarrays or of between a valarray a specified value.

```
template <class Type>
valarray<Type>
operator-(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<Type>
operator-(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<Type>
operator-(
    const Type& left,
    const valarray<Type>& right);
```

Parameters

left

A value or valarray that serves as the minuend from which other values or valarrays are to be subtracted in forming the difference.

right

A value or valarray that serves as the subtrahend that is to be subtracted from other values or valarrays in forming the difference.

Return Value

A valarray whose elements are the element-wise difference of *left* and *right*.

Remarks

The arithmetic terminology used in describing a subtraction:

difference = minuend - subtrahend

Example

```

// valarray_op_ediff.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 8 ), vaR ( 8 );
    valarray<int> vaNE ( 8 );
    for ( i = 0 ; i < 8 ; i += 2 )
        vaL [ i ] = 10;
    for ( i = 1 ; i < 8 ; i += 2 )
        vaL [ i ] = 0;
    for ( i = 0 ; i < 8 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL - vaR );
    cout << "The element-by-element result of "
        << "the difference is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 10 0 10 0 10 0 10 0 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 ).
The element-by-element result of the difference is the
valarray: ( 10 -1 8 -3 6 -5 4 -7 ).
*/

```

operator/

Obtains the element-wise quotient between corresponding elements of two equally sized valarrays or of between a valarray a specified value.

```
template <class Type>
valarray<Type>
operator/(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<Type>
operator/(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<Type>
operator/(
    const Type& left,
    const valarray<Type>& right);
```

Parameters

left

A value or valarray that serves as the dividend into which another value or valarray is to be divided in forming the quotient.

right

A value or valarray that serves as the divisor and that divides another value or valarray in forming the quotient.

Return Value

A valarray whose elements are the element-wise quotient of *left* divided by *right*.

Remarks

The arithmetic terminology used in describing a division:

quotient = dividend / divisor

Example

```

// valarray_op_equo.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<double> vaL ( 6 ), vaR ( 6 );
    valarray<double> vaNE ( 6 );
    for ( i = 0 ; i < 6 ; i += 2 )
        vaL [ i ] = 100;
    for ( i = 1 ; i < 6 ; i += 2 )
        vaL [ i ] = -100;
    for ( i = 0 ; i < 6 ; i++ )
        vaR [ i ] = 2*i;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL / vaR );
    cout << "The element-by-element result of "
        << "the quotient is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 100 -100 100 -100 100 -100 ).
The initial Right valarray is: ( 0 2 4 6 8 10 ).
The element-by-element result of the quotient is the
valarray: ( inf -50 25 -16.6667 12.5 -10 ).
*/

```

operator==

Tests whether the corresponding elements of two equally sized valarrays are equal or whether all the elements of a valarray are equal a specified value.

```

template <class Type>
valarray<bool>
operator==(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<bool>
operator==(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<bool>
operator==(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The first of the two valarrays whose elements are to be tested for equality.

right

The second of the two valarrays whose elements are to be tested for equality.

Return Value

A valarray of Boolean values, each of which is:

- **true** if the corresponding elements are equal.
- **false** if the corresponding elements are not equal.

Remarks

The first template operator returns an object of class `valarray<bool>`, each of whose elements `I` is `left[I] == right[I]`. The second template operator stores in element `I` `left[I] == right`. The third template operator stores in element `I` `left == right[I]`.

Example

```

// valarray_op_eq.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<bool> vaNE ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = -i;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = i;
    for ( i = 0 ; i < 10 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for (i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaNE = ( vaL == vaR );
    cout << "The element-by-element result of "
        << "the equality comparison test is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaNE [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 0 1 -2 3 -4 5 -6 7 -8 9 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 8 9 ).
The element-by-element result of the equality comparison test is the
valarray: ( 1 1 0 1 0 1 0 1 0 1 ).
*/

```

operator^

Obtains the bitwise exclusive OR (**XOR**) between corresponding elements of two equally sized valarrays or between a valarray and a specified value of the element type.

```

template <class Type>
valarray<Type>
operator^(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<Type>
operator^(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<Type>
operator^(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The first of the two valarrays whose respective elements are to be combined with the bitwise **XOR** or a specified value of the element type to be combined bitwise with each element of a valarray.

right

The second of the two valarrays whose respective elements are to be combined with the bitwise **XOR** or a specified value of the element type to be combined bitwise with each element of a valarray.

Return Value

A valarray whose elements are the element-wise combination of the bitwise **XOR** operation of *left* and *right*.

Remarks

A bitwise operation can only be used to manipulate bits in **char** and **int** data types and variants and not on **float**, **double**, **long double**, **void**, **bool** or other, more complex data types.

The bitwise exclusive OR (**XOR**) has the following semantics: Given bits *b1* and *b2*, *b1 XOR b2* is **true** if exactly one of the bits is true; **false** if both bits are false or if both bits are true.

Example

```

// valarray_op_xor.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<int> vaLAA ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = 1;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = 0;
    for ( i = 0 ; i < 10 ; i += 3 )
        vaR [ i ] = i;
    for ( i = 1 ; i < 10 ; i += 3 )
        vaR [ i ] = i-1;
    for ( i = 2 ; i < 10 ; i += 3 )
        vaR [ i ] = i-1;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaLAA = ( vaL ^ vaR );
    cout << "The element-by-element result of "
        << "the bitwise XOR operator^ is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaLAA [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 1 0 1 0 1 0 1 0 1 0 ).
The initial Right valarray is: ( 0 0 1 3 3 4 6 6 7 9 ).
The element-by-element result of the bitwise XOR operator^ is the
valarray: ( 1 0 0 3 2 4 7 6 6 9 ).
*/

```

operator|

Obtains the bitwise OR between corresponding elements of two equally sized valarrays or between a valarray and a specified value of the element type.

```

template <class Type>
valarray<Type>
operator|(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<Type>
operator|(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<Type>
operator|(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The first of the two valarrays whose respective elements are to be combined with the bitwise `OR` or a specified value of the element type to be combined bitwise with each element of a valarray.

right

The second of the two valarrays whose respective elements are to be combined with the bitwise `OR` or a specified value of the element type to be combined bitwise with each element of a valarray.

Return Value

A valarray whose elements are the element-wise combination of the bitwise `OR` operation of *left* and *right*.

Remarks

A bitwise operation can only be used to manipulate bits in **char** and **int** data types and variants and not on **float**, **double**, **longdouble**, **void**, **bool** or other, more complex data types.

The bitwise OR has the same truth table as the logical `OR`, but applies to the data type on the level of the individual bits. Given bits *b1* and *b2*, *b1 OR b2* is **true** if at least one of the bits is true or **false** if both bits are false. The logical `OR operator||` applies on an element level, counting all nonzero values as **true**, and the result is a valarray of Boolean values. The bitwise OR `operator|`, by contrast, can result in a valarray of values other than 0 or 1, depending on the outcome of the bitwise operation.

Example

```

// valarray_op_bitor.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<int> vaLAA ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = 1;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = 0;
    for ( i = 0 ; i < 10 ; i += 3 )
        vaR [ i ] = i;
    for ( i = 1 ; i < 10 ; i += 3 )
        vaR [ i ] = i-1;
    for ( i = 2 ; i < 10 ; i += 3 )
        vaR [ i ] = i-1;

    cout << "The initial Left valarray is: ( ";
    for (i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for (i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaLAA = ( vaL | vaR );
    cout << "The element-by-element result of "
        << "the bitwise OR operator| is the\n"
        << "valarray: ( ";
    for (i = 0 ; i < 10 ; i++ )
        cout << vaLAA [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 1 0 1 0 1 0 1 0 1 0 ).
The initial Right valarray is: ( 0 0 1 3 3 4 6 6 7 9 ).
The element-by-element result of the bitwise OR operator| is the
valarray: ( 1 0 1 3 3 4 7 6 7 9 ).
*/

```

operator||

Obtains the logical `OR` between corresponding elements of two equally sized valarrays or between a valarray and a specified value of the valarray element type.

```

template <class Type>
valarray<bool>
operator||(
    const valarray<Type>& left,
    const valarray<Type>& right);

template <class Type>
valarray<bool>
operator||(
    const valarray<Type>& left,
    const Type& right);

template <class Type>
valarray<bool>
operator||(
    const Type& left,
    const valarray<Type>& right);

```

Parameters

left

The first of the two valarrays whose respective elements are to be combined with the logical `OR` or a specified value of the element type to be combined with each element of a valarray.

right

The second of the two valarrays whose respective elements are to be combined with the logical `OR` or a specified value of the element type to be combined with each element of a valarray.

Return Value

A valarray whose elements are of type **bool** and are the element-wise combination of the logical OR operation of *left* and *right*.

Remarks

The logical `OR` `operator||` applies on an element level, counting all nonzero values as **true**, and the result is a valarray of Boolean values. The bitwise version of `OR`, `operator|` by contrast, can result in a valarray of values other than 0 or 1, depending on outcome of the bitwise operation.

Example

```

// valarray_op_logor.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<bool> vaLOR ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = 0;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = i-1;
    for ( i = 0 ; i < 10 ; i += 3 )
        vaR [ i ] = i;
    for ( i = 1 ; i < 10 ; i += 3 )
        vaR [ i ] = 0;
    for ( i = 2 ; i < 10 ; i += 3 )
        vaR [ i ] = 0;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaLOR = ( vaL || vaR );
    cout << "The element-by-element result of "
        << "the logical OR operator|| is the\n"
        << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaLOR [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial Left valarray is: ( 0 0 0 2 0 4 0 6 0 8 ).
The initial Right valarray is: ( 0 0 0 3 0 0 6 0 0 9 ).
The element-by-element result of the logical OR operator|| is the
valarray: ( 0 0 0 1 0 1 1 1 0 1 ).
*/

[<valarray>](#)

gslice Class

10/31/2018 • 7 minutes to read • [Edit Online](#)

A utility class to valarray that is used to define multidimensional subsets of a valarray. If a valarray is regarded as a multidimensional matrix with all elements in an array, then the slice extracts a vector out of the multidimensional array.

Remarks

The class stores the parameters that characterize an object of type [gslice_array](#). The subset of a valarray is indirectly constructed when an object of class gslice appears as an argument for an object of class [valarray<Type>](#). The stored values that specify the subset selected from the parent valarray include:

- A starting index.
- A length vector of class `valarray<size_t>`.
- A stride vector of class `valarray<size_t>`.

The two vectors must have the same length.

If the set defined by a gslice is the subset of a constant valarray, then the gslice is a new valarray. If the set defined by a gslice is the subset of a nonconstant valarray, then the gslice has reference semantics to the original valarray. The evaluation mechanism for nonconstant valarrays saves time and memory.

Operations on valarrays are guaranteed only if the source and destination subsets defined by the gslices are distinct and all indices are valid.

Constructors

CONSTRUCTOR	DESCRIPTION
gslice	Defines a subset of a <code>valarray</code> that consists of multiple slices of the <code>valarray</code> that all start at a specified element.

Member functions

MEMBER FUNCTION	DESCRIPTION
size	Finds the array values specifying the numbers of elements in a general slice of a <code>valarray</code> .
start	Finds the starting index of a general slice of a <code>valarray</code> .
stride	Finds the distance between elements in a general slice of a <code>valarray</code> .

Requirements

Header: <valarray>

Namespace: std

gslice::gslice

A utility class to valarray that is used to define multi-dimensional slices of a valarray.

```
gslice();

gslice(
    size_t _StartIndex,
    const valarray<size_t>& _LenArray,
    const valarray<size_t>& _IncArray);
```

Parameters

_StartIndex

The valarray index of the first element in the subset.

_LenArray

An array specifying the number of elements in each slice.

_IncArray

An array specifying the stride in each slice.

Return Value

The default constructor stores zero for the starting index, and zero-length vectors for the length and stride vectors. The second constructor stores *_StartIndex* for the starting index, *_LenArray* for the length array, and *_IncArray* for the stride array.

Remarks

gslice defines a subset of a valarray that consists of multiple slices of the valarray that each start at the same specified element. The ability to use arrays to define multiple slices is the only difference between `gslice` and `slice::slice`. The first slice has a first element with an index of *_StartIndex*, a number of elements specified by the first element of *_LenArray*, and a stride given by the first element of *_IncArray*. The next set of orthogonal slices has first elements given by the first slice. The second element of *_LenArray* specifies the number of elements. The stride is given by the second element of *_IncArray*. A third dimension of slices would take the elements of the two-dimensional array as the starting elements and proceed analogously

Example

```

// gslice_ctor.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> va ( 20 ), vaResult;
    for ( i = 0 ; i < 20 ; i+=1 )
        va [ i ] = i;

    cout << "The operand valarray va is:" << endl << "(";
    for ( i = 0 ; i < 20 ; i++ )
        cout << " " << va [ i ];
    cout << " )" << endl;

    valarray<size_t> Len ( 2 ), Stride ( 2 );
    Len [0] = 4;
    Len [1] = 4;
    Stride [0] = 7;
    Stride [1] = 4;

    gslice vaGSlice ( 0, Len, Stride );
    vaResult = va [ vaGSlice ];

    cout << "The valarray for vaGSlice is vaResult:" << endl
        << "va[vaGSlice] = (";

    for ( i = 0 ; i < 8 ; i++ )
        cout << " " << vaResult [ i ];
    cout << ")" << endl;
}

```

```

The operand valarray va is:
( 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 )
The valarray for vaGSlice is vaResult:
va[vaGSlice] = ( 0 4 8 12 7 11 15 19)

```

gslice::size

Finds the array values specifying the numbers of elements in a general slice of a valarray.

```
valarray<size_t> size() const;
```

Return Value

A valarray specifying the number of elements in each slice of a general slice of a valarray.

Remarks

The member function returns the stored lengths of slices.

Example

```

// gslice_size.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    size_t sizeVA;

    valarray<int> va ( 20 ), vaResult;
    for ( i = 0 ; i < 20 ; i+=1 )
        va [ i ] = i;

    cout << "The operand valarray va is:\n ( ";
    for ( i = 0 ; i < 20 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;

    sizeVA = va.size ( );
    cout << "The size of the valarray is: "
        << sizeVA << "." << endl << endl;

    valarray<size_t> Len ( 2 ), Stride ( 2 );
    Len [0] = 4;
    Len [1] = 4;
    Stride [0] = 7;
    Stride [1] = 4;

    gslice vaGSlice ( 0, Len, Stride );
    vaResult = va [ vaGSlice ];
    const valarray <size_t> sizeGS = vaGSlice.size ( );

    cout << "The valarray for vaGSlice is vaResult:"
        << "\n va[vaGSlice] = ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaResult [ i ] << " ";
    cout << ")." << endl;

    cout << "The size of vaResult is:"
        << "\n vaGSlice.size ( ) = ( ";
    for ( i = 0 ; i < 2 ; i++ )
        cout << sizeGS[ i ] << " ";
    cout << ")." << endl;
}

```

```

The operand valarray va is:
( 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 ).
The size of the valarray is: 20.

The valarray for vaGSlice is vaResult:
va[vaGSlice] = ( 0 4 8 12 7 11 15 19 ).
The size of vaResult is:
vaGSlice.size ( ) = ( 4 4 ).

```

gslice::start

Finds the starting index of a general slice of a valarray.

```
size_t start() const;
```

Return Value

The starting index of a general slice of a valarray.

Example

```
// gslice_start.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> va ( 20 ), vaResult;
    for (i = 0 ; i < 20 ; i+=1 )
        va [ i ] = i;

    cout << "The operand valarray va is:\n ( ";
    for ( i = 0 ; i < 20 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;

    valarray<size_t> Len ( 2 ), Stride ( 2 );
    Len [0] = 4;
    Len [1] = 4;
    Stride [0] = 7;
    Stride [1] = 4;

    gslice vaGSlice ( 0, Len, Stride );
    vaResult = va [ vaGSlice ];
    size_t vaGSstart = vaGSlice.start ( );

    cout << "The valarray for vaGSlice is vaResult:"
        << "\n va[vaGSlice] = ( ";
    for (i = 0 ; i < 8 ; i++ )
        cout << vaResult [ i ] << " ";
    cout << ")." << endl;

    cout << "The index of the first element of vaResult is: "
        << vaGSstart << "." << endl;
}
```

```
The operand valarray va is:
( 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 ).
The valarray for vaGSlice is vaResult:
va[vaGSlice] = ( 0 4 8 12 7 11 15 19 ).
The index of the first element of vaResult is: 0.
```

gslice::stride

Finds the distance between elements in a general slice of a valarray.

```
valarray<size_t> stride() const;
```

Return Value

A valarray specifying the distances between elements in each slice of a general slice of a valarray.

Example

```

// gslice_stride.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> va ( 20 ), vaResult;
    for (i = 0 ; i < 20 ; i+=1 )
        va [ i ] = i;

    cout << "The operand valarray va is:\n ( ";
        for (i = 0 ; i < 20 ; i++ )
            cout << va [ i ] << " ";
    cout << ")." << endl;

    valarray<size_t> Len ( 2 ), Stride ( 2 );
    Len [0] = 4;
    Len [1] = 4;
    Stride [0] = 7;
    Stride [1] = 4;

    gslice vaGSlice ( 0, Len, Stride );
    vaResult = va [ vaGSlice ];
    const valarray <size_t> strideGS = vaGSlice.stride ( );

    cout << "The valarray for vaGSlice is vaResult:"
        << "\n va[vaGSlice] = ( ";
        for ( i = 0 ; i < 8 ; i++ )
            cout << vaResult [ i ] << " ";
    cout << ")." << endl;

    cout << "The strides of vaResult are:"
        << "\n vaGSlice.stride ( ) = ( ";
        for ( i = 0 ; i < 2 ; i++ )
            cout << strideGS[ i ] << " ";
    cout << ")." << endl;
}

```

```

The operand valarray va is:
( 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 ).
The valarray for vaGSlice is vaResult:
va[vaGSlice] = ( 0 4 8 12 7 11 15 19 ).
The strides of vaResult are:
vaGSlice.stride ( ) = ( 7 4 ).

```

gslice_array Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

An internal, auxiliary template class that supports general slice objects by providing operations between subset arrays defined by the general slice of a valarray.

Syntax

```
template <class Type>
class gslice_array : public gsplce {
public:
    typedef Type value_type;
    void operator=(const valarray<Type>& x) const;

    void operator=(const Type& x) const;

    void operator*=(const valarray<Type>& x) const;

    void operator/=(const valarray<Type>& x) const;

    void operator%=(const valarray<Type>& x) const;

    void operator+=(const valarray<Type>& x) const;

    void operator-=(const valarray<Type>& x) const;

    void operator^=(const valarray<Type>& x) const;

    void operator&=(const valarray<Type>& x) const;

    void operator|=(const valarray<Type>& x) const;

    void operator<<=(const valarray<Type>& x) const;

    void operator>>=(const valarray<Type>& x) const;

    // The rest is private or implementation defined
}
```

Remarks

The class describes an object that stores a reference to an object `va` of class `valarray<Type>`, along with an object `gs` of class `gslice` which describes the sequence of elements to select from the `valarray<Type>` object.

You construct a `gslice_array<Type>` object only by writing an expression of the form `va[gs]`. The member functions of class `gslice_array` then behave like the corresponding function signatures defined for `valarray<Type>`, except that only the sequence of selected elements is affected.

The template class is created indirectly by certain `valarray` operations and cannot be used directly in the program. An internal auxiliary template class instead is used by the slice subscript operator:

```
gslice_array< Type> valarray< Type>::operator[] ( constgslice&).
```

You construct a `gslice_array<Type>` object only by writing an expression of the form `va[gs1]`, for a slice `gs1` of `valarray va`. The member functions of class `gslice_array` then behave like the corresponding function signatures defined for `valarray<Type>`, except that only the sequence of selected elements is affected. The sequence

controlled by the `gslice_array` is defined by the three parameters of the slice constructor, the index of the first element in the first slice, the number of elements in each slice, and the distance between the elements in each slice.

In the following example:

```
const size_t lv[] = {2, 3};
const size_t dv[] = {7, 2};
const valarray<size_t> len(lv, 2), str(dv, 2);

// va[gslice(3, len, str)] selects elements with
//   indices 3, 5, 7, 10, 12, 14
```

The indices must be valid for the procedure to be valid.

Example

See the example for [gslice::gslice](#) for an example of how to declare and use a `slice_array`.

Requirements

Header: `<valarray>`

Namespace: `std`

[Thread Safety in the C++ Standard Library](#)

indirect_array Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

An internal, auxiliary template class that supports objects that are subsets of valarrays by providing operations between subset arrays defined by specifying a subset of indices of a parent valarray.

Syntax

Remarks

The class describes an object that stores a reference to an object `va` of class `valarray<Type>`, along with an object `xa` of class `valarray<size_t>`, which describes the sequence of elements to select from the `valarray<Type>` object.

You construct an `indirect_array<Type>` object only by writing an expression of the form `va[xa]`. The member functions of class `indirect_array` then behave like the corresponding function signatures defined for `valarray<Type>`, except that only the sequence of selected elements is affected.

The sequence consists of `xa.size` elements, where element `I` becomes the index `xa[I]` within `va`.

Example:

```
// indirect_array.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> va ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        va [ i ] = i;
    for ( i = 1 ; i < 10 ; i += 2 )
        va [ i ] = -1;

    cout << "The initial operand valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;

    // Select 2nd, 4th & 6th elements
    // and assign a value of 10 to them
    valarray<size_t> indx ( 3 );
    indx [0] = 2;
    indx [1] = 4;
    indx [2] = 6;
    va[indx] = 10;

    cout << "The modified operand valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;
}
```

Output

```
The initial operand valarray is: (0 -1 2 -1 4 -1 6 -1 8 -1).  
The modified operand valarray is: (0 -1 10 -1 10 -1 10 -1 8 -1).
```

Requirements

Header: <valarray>

Namespace: std

[Thread Safety in the C++ Standard Library](#)

mask_array Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

An internal, auxiliary template class that supports objects that are subsets of parent valarrays, specified with a Boolean expression, by providing operations between the subset arrays.

Syntax

Remarks

The class describes an object that stores a reference to an object `va` of class `valarray<Type>`, along with an object `ba` of class `valarray<bool>`, which describes the sequence of elements to select from the `valarray<Type>` object.

You construct a `mask_array<Type>` object only by writing an expression of the form `va[ba]`. The member functions of class `mask_array` then behave like the corresponding function signatures defined for `valarray<Type>`, except that only the sequence of selected elements is affected.

The sequence consists of at most `ba.size` elements. An element J is included only if `ba[J]` is true. Thus, there are as many elements in the sequence as there are true elements in `ba`. If `I` is the index of the lowest true element in `ba`, then `va[I]` is element zero in the selected sequence.

Example

```
// mask_array.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> va ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        va [ i ] = i;
    for ( i = 1 ; i < 10 ; i += 2 )
        va [ i ] = -1;

    cout << "The initial operand valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;

    // Use masked subsets to assign a value of 10
    // to all elements greater than 3 in value
    va [va > 3 ] = 10;
    cout << "The modified operand valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;
}
```

Output

```
The initial operand valarray is: (0 -1 2 -1 4 -1 6 -1 8 -1).  
The modified operand valarray is: (0 -1 2 -1 10 -1 10 -1 10 -1).
```

Requirements

Header: <valarray>

Namespace: std

[Thread Safety in the C++ Standard Library](#)

slice Class

10/31/2018 • 6 minutes to read • [Edit Online](#)

A utility class to valarray that is used to define one-dimensional subsets of a parent valarray. If a valarray is regarded as a two-dimensional matrix with all elements in an array, then the slice extracts a vector in one dimension out of the two-dimensional array.

Remarks

The class stores the parameters that characterize an object of type `slice_array`. The subset of a valarray is indirectly constructed when an object of class slice appears as an argument for an object of class `valarray<Type>`. The stored values that specify the subset selected from the parent valarray include:

- A starting index in the valarray.
- A total length, or number of elements in the slice.
- A stride, or distance between subsequent indices of elements in the valarray.

If the set defined by a slice is the subset of a constant valarray, then the slice is a new valarray. If the set defined by a slice is the subset of a nonconstant valarray, then the slice has reference semantics to the original valarray. The evaluation mechanism for nonconstant valarrays saves time and memory.

Operations on valarrays are guaranteed only if the source and destination subsets defined by the slices are distinct and all indices are valid.

Constructors

CONSTRUCTOR	DESCRIPTION
<code>slice</code>	Defines a subset of a <code>valarray</code> that consists of a number of elements that are an equal distance apart and that start at a specified element.

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>size</code>	Finds the number of elements in a slice of a <code>valarray</code> .
<code>start</code>	Finds the starting index of a slice of a <code>valarray</code> .
<code>stride</code>	Finds the distance between elements in a slice of a <code>valarray</code> .

Requirements

Header: `<valarray>`

Namespace: `std`

`slice::size`

Finds the number of elements in a slice of a valarray.

```
size_t size() const;
```

Return Value

The number of elements in a slice of a valarray.

Example

```
// slice_size.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    size_t sizeVA, sizeVAR;

    valarray<int> va ( 20 ), vaResult;
    for ( i = 0 ; i < 20 ; i += 1 )
        va [ i ] = i+1;

    cout << "The operand valarray va is:\n ( ";
    for ( i = 0 ; i < 20 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;

    sizeVA = va.size ( );
    cout << "The size of the valarray is: "
        << sizeVA << "." << endl << endl;

    slice vaSlice ( 3 , 6 , 3 );
    vaResult = va [ vaSlice ];

    cout << "The slice of valarray va is vaResult = "
        << "va[slice( 3, 6, 3)] =\n ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vaResult [ i ] << " ";
    cout << ")." << endl;

    sizeVAR = vaSlice.size ( );
    cout << "The size of slice vaSlice is: "
        << sizeVAR << "." << endl;
}
```

```
The operand valarray va is:
( 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 ).
The size of the valarray is: 20.

The slice of valarray va is vaResult = va[slice( 3, 6, 3)] =
( 4 7 10 13 16 19 ).
The size of slice vaSlice is: 6.
```

slice::slice

Defines a subset of a valarray that consists of a number of elements that are an equal distance apart and that start at a specified element.

```

slice();

slice(
    size_t _StartIndex,
    size_t _Len,
    size_t stride);

```

Parameters

_StartIndex

The valarray index of the first element in the subset.

_Len

The number of elements in the subset.

stride

The distance between elements in the subset.

Return Value

The default constructor stores zeros for the starting index, total length, and stride. The second constructor stores *_StartIndex* for the starting index, *_Len* for the total length, and *stride* for the stride.

Remarks

The stride may be negative.

Example

```

// slice_ctor.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> va ( 20 ), vaResult;
    for ( i = 0 ; i < 20 ; i+=1 )
        va [ i ] = 2 * ( i + 1 );

    cout << "The operand valarray va is:\n( ";
    for ( i = 0 ; i < 20 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;

    slice vaSlice ( 1 , 7 , 3 );
    vaResult = va [ vaSlice ];

    cout << "\nThe slice of valarray va is vaResult:"
        << "\nva[slice( 1, 7, 3)] = ( ";
    for ( i = 0 ; i < 7 ; i++ )
        cout << vaResult [ i ] << " ";
    cout << ")." << endl;
}

```

The operand valarray va is:
(2 4 6 8 10 12 14 16 18 20 22 24 26 28 30 32 34 36 38 40).

The slice of valarray va is vaResult:
va[slice(1, 7, 3)] = (4 10 16 22 28 34 40).

slice::start

Finds the starting index of a slice of a valarray.

```
size_t start() const;
```

Return Value

The starting index of a slice of a valarray.

Example

```
// slice_start.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    size_t startVAR;

    valarray<int> va ( 20 ), vaResult;
    for ( i = 0 ; i < 20 ; i += 1 )
        va [ i ] = i+1;

    cout << "The operand valarray va is:\n ( ";
    for ( i = 0 ; i < 20 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;

    slice vaSlice ( 3 , 6 , 3 );
    vaResult = va [ vaSlice ];

    cout << "The slice of valarray va is vaResult = "
        << "va[slice( 3, 6, 3)] =\n ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vaResult [ i ] << " ";
    cout << ")." << endl;

    startVAR = vaSlice.start ( );
    cout << "The start index of slice vaSlice is: "
        << startVAR << "." << endl;
}
```

```
The operand valarray va is:
( 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 ).
The slice of valarray va is vaResult = va[slice( 3, 6, 3)] =
( 4 7 10 13 16 19 ).
The start index of slice vaSlice is: 3.
```

slice::stride

Finds the distance between elements in a slice of a valarray.

```
size_t stride() const;
```

Return Value

The distance between elements in a slice of a valarray.

Example

```
// slice_stride.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    size_t strideVAR;

    valarray<int> va ( 20 ), vaResult;
    for ( i = 0 ; i < 20 ; i += 1 )
        va [ i ] = 3 * ( i + 1 );

    cout << "The operand valarray va is:\n ( ";
    for ( i = 0 ; i < 20 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;

    slice vaSlice ( 4 , 5 , 3 );
    vaResult = va [ vaSlice ];

    cout << "The slice of valarray va is vaResult = "
        << "va[slice( 4, 5, 3)] =\n ( ";
    for ( i = 0 ; i < 5 ; i++ )
        cout << vaResult [ i ] << " ";
    cout << ")." << endl;

    strideVAR = vaSlice.stride ( );
    cout << "The stride of slice vaSlice is: "
        << strideVAR << "." << endl;
}
```

```
The operand valarray va is:
( 3 6 9 12 15 18 21 24 27 30 33 36 39 42 45 48 51 54 57 60 ).
The slice of valarray va is vaResult = va[slice( 4, 5, 3)] =
( 15 24 33 42 51 ).
The stride of slice vaSlice is: 3.
```

slice_array Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

An internal, auxiliary template class that supports slice objects by providing operations between subset arrays defined by the slice of a valarray.

Syntax

```
template <class Type>
class slice_array : public slice {
public:
    typedef Type value_type;
    void operator=(const valarray<Type>& x) const;
    void operator=(const Type& x) const;
    void operator*=(const valarray<Type>& x) const;
    void operator/=(const valarray<Type>& x) const;
    void operator%=(const valarray<Type>& x) const;
    void operator+=(const valarray<Type>& x) const;
    void operator-=(const valarray<Type>& x) const;
    void operator^=(const valarray<Type>& x) const;
    void operator&=(const valarray<Type>& x) const;
    void operator|=(const valarray<Type>& x) const;
    void operator<=(const valarray<Type>& x) const;
    void operator>=(const valarray<Type>& x) const;
    // The rest is private or implementation defined
}
```

Remarks

The class describes an object that stores a reference to an object of class `valarray<Type>`, along with an object of class `slice`, which describes the sequence of elements to select from the `valarray<Type>` object.

The template class is created indirectly by certain valarray operations and cannot be used directly in the program. An internal, auxiliary template class that is used by the slice subscript operator:

```
slice_array < Type> valarray < Type>::operator[] ( slice ).
```

You construct a `slice_array<Type>` object only by writing an expression of the form `va[s]`, for a slice `s` of valarray `va`. The member functions of class `slice_array` then behave like the corresponding function signatures defined for `valarray<Type>`, except that only the sequence of selected elements is affected. The sequence controlled by the `slice_array` is defined by the three parameters of the slice constructor, the index of the first element in the slice, the number of elements, and the distance between the elements. A `slice_array` cut from valarray `va` declared by `va[slice(2, 5, 3)]` selects elements with indices 2, 5, 8, 11, and 14 from `va`. The indices must be valid for the procedure to be valid.

Example

See the example for `slice::slice` for an example of how to declare and use a `slice_array`.

valarray Class

3/28/2019 • 43 minutes to read • [Edit Online](#)

The template class describes an object that controls a sequence of elements of type `Type` that are stored as an array, designed for performing high-speed mathematical operations, and optimized for computational performance.

Remarks

The class is a representation of the mathematical concept of an ordered set of values and the elements are numbered sequentially from zero. The class is described as a near container because it supports some, but not all, of the capabilities that first-class sequence containers, such as [vector](#), support. It differs from template class `vector` in two important ways:

- It defines numerous arithmetic operations between corresponding elements of `valarray<Type>` objects of the same type and length, such as $xarr = \cos(yarr) + \sin(zarr)$.
- It defines a variety of interesting ways to subscript a `valarray<Type>` object, by overloading `operator[]`.

An object of class `Type`:

- Has a public default constructor, destructor, copy constructor, and assignment operator, with conventional behavior.
- Defines the arithmetic operators and math functions, as needed, that are defined for the floating-point types, with conventional behavior.

In particular, no subtle differences may exist between copy construction and default construction followed by assignment. None of the operations on objects of class `Type` may throw exceptions.

Constructors

CONSTRUCTOR	DESCRIPTION
valarray	Constructs a <code>valarray</code> of a specific size or with elements of a specific value or as a copy of another <code>valarray</code> or subset of another <code>valarray</code> .

Typedefs

TYPE NAME	DESCRIPTION
value_type	A type that represents the type of element stored in a <code>valarray</code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
apply	Applies a specified function to each element of a <code>valarray</code> .

MEMBER FUNCTION	DESCRIPTION
<code>cshift</code>	Cyclically shifts all the elements in a <code>valarray</code> by a specified number of positions.
<code>free</code>	Frees the memory used by the <code>valarray</code> .
<code>max</code>	Finds the largest element in a <code>valarray</code> .
<code>min</code>	Finds the smallest element in a <code>valarray</code> .
<code>resize</code>	Changes the number of elements in a <code>valarray</code> to a specified number, adding or removing elements as required.
<code>shift</code>	Shifts all the elements in a <code>valarray</code> by a specified number of positions.
<code>size</code>	Finds the number of elements in a <code>valarray</code> .
<code>sum</code>	Determines the sum of all the elements in a <code>valarray</code> of nonzero length.
<code>swap</code>	

Operators

OPERATOR	DESCRIPTION
<code>operator!</code>	A unary operator that obtains the logical <code>NOT</code> values of each element in a <code>valarray</code> .
<code>operator% =</code>	Obtains the remainder of dividing the elements of an array element-wise either by a specified <code>valarray</code> or by a value of the element type.
<code>operator& =</code>	Obtains the bitwise <code>AND</code> of elements in an array either with the corresponding elements in a specified <code>valarray</code> or with a value of the element type.
<code>operator>> =</code>	Right-shifts the bits for each element of a <code>valarray</code> operand a specified number of positions or by an element-wise amount specified by a second <code>valarray</code> .
<code>operator<< =</code>	Left-shifts the bits for each element of a <code>valarray</code> operand a specified number of positions or by an element-wise amount specified by a second <code>valarray</code> .
<code>operator* =</code>	Multiplies the elements of a specified <code>valarray</code> or a value of the element type, element-wise, to an operand <code>valarray</code> .
<code>operator+</code>	A unary operator that applies a plus to each element in a <code>valarray</code> .

OPERATOR	DESCRIPTION
<code>operator+=</code>	Adds the elements of a specified <code>valarray</code> or a value of the element type, element-wise, to an operand <code>valarray</code> .
<code>operator-</code>	A unary operator that applies a minus to each element in a <code>valarray</code> .
<code>operator-=</code>	Subtracts the elements of a specified <code>valarray</code> or a value of the element type, element-wise, from an operand <code>valarray</code> .
<code>operator/=</code>	Divides an operand <code>valarray</code> element-wise by the elements of a specified <code>valarray</code> or a value of the element type.
<code>operator=</code>	Assigns elements to a <code>valarray</code> whose values are specified either directly or as part of some other <code>valarray</code> or by a <code>slice_array</code> , <code>gslice_array</code> , <code>mask_array</code> , or <code>indirect_array</code> .
<code>operator[]</code>	Returns a reference to an element or its value at specified index or a specified subset.
<code>operator^=</code>	Obtains the element-wise exclusive logical or operator (<code>XOR</code>) of an array with either a specified <code>valarray</code> or a value of the element type.
<code>operator =</code>	Obtains the bitwise <code>OR</code> of elements in an array either with the corresponding elements in a specified <code>valarray</code> or with a value of the element type.
<code>operator~</code>	A unary operator that obtains the bitwise <code>NOT</code> values of each element in a <code>valarray</code> .

Requirements

Header: `<valarray>`

Namespace: `std`

`valarray::apply`

Applies a specified function to each element of a `valarray`.

```
valarray<Type> apply(Type _Func(Type)) const;

valarray<Type> apply(Type _Func(constType&)) const;
```

Parameters

`_Func(Type)`

The function object to be applied to each element of the operand `valarray`.

`_Func(const Type&)`

The function object for `const` to be applied to each element of the operand `valarray`.

Return Value

A valarray whose elements have had `_Func` applied element-wise to the elements of the operand valarray.

Remarks

The member function returns an object of class `valarray<Type>`, of length `size`, each of whose elements `i` is `_Func((*this)[i])`.

Example

```
// valarray_apply.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

using namespace std;

int __cdecl MyApplyFunc( int n )
{
    return n*2;
}

int main( int argc, char* argv[] )
{
    valarray<int> vaR(10), vaApplied(10);
    int i;

    for ( i = 0; i < 10; i += 3 )
        vaR[i] = i;

    for ( i = 1; i < 10; i += 3 )
        vaR[i] = 0;

    for ( i = 2; i < 10; i += 3 )
        vaR[i] = -i;

    cout << "The initial Right valarray is: (" ;
    for ( i=0; i < 10; ++i )
        cout << " " << vaR[i];
    cout << " )" << endl;

    vaApplied = vaR.apply( MyApplyFunc );

    cout << "The element-by-element result of "
        << "applying MyApplyFunc to vaR is the\nvalarray: ( ";
    for ( i = 0; i < 10; ++i )
        cout << " " << vaApplied[i];
    cout << " )" << endl;
}
/* Output:
The initial Right valarray is: ( 0 0 -2 3 0 -5 6 0 -8 9 )
The element-by-element result of applying MyApplyFunc to vaR is the
valarray: ( 0 0 -4 6 0 -10 12 0 -16 18 )
*/
```

valarray::cshift

Cyclically shifts all the elements in a valarray by a specified number of positions.

```
valarray<Type> cshift(int count) const;
```

Parameters

count

The number of places the elements are to be shifted forward.

Return Value

A new valarray in which all the elements have been moved *count* positions cyclically toward the front of the valarray, left with respect to their positions in the operand valarray.

Remarks

A positive value of *count* shifts the elements cyclically left *count* places.

A negative value of *count* shifts the elements cyclically right *count* places.

Example

```
// valarray_cshift.cpp
// compile with: /EHsc

#include <valarray>
#include <iostream>

int main()
{
    using namespace std;
    int i;

    valarray<int> va1(10), va2(10);
    for (i = 0; i < 10; i+=1)
        va1[i] = i;
    for (i = 0; i < 10; i+=1)
        va2[i] = 10 - i;

    cout << "The operand valarray va1 is: (";
    for (i = 0; i < 10; i++)
        cout << " " << va1[i];
    cout << ")" << endl;

    // A positive parameter shifts elements right
    va1 = va1.cshift(4);
    cout << "The cyclically shifted valarray va1 is:\nva1.cshift (4) = (";
    for (i = 0; i < 10; i++)
        cout << " " << va1[i];
    cout << ")" << endl;

    cout << "The operand valarray va2 is: (";
    for (i = 0; i < 10; i++)
        cout << " " << va2[i];
    cout << ")" << endl;

    // A negative parameter shifts elements left
    va2 = va2.cshift(-4);
    cout << "The cyclically shifted valarray va2 is:\nva2.shift (-4) = (";
    for (i = 0; i < 10; i++)
        cout << " " << va2[i];
    cout << ")" << endl;
}

/* Output:
The operand valarray va1 is: ( 0 1 2 3 4 5 6 7 8 9)
The cyclically shifted valarray va1 is:
va1.cshift (4) = ( 4 5 6 7 8 9 0 1 2 3)
The operand valarray va2 is: ( 10 9 8 7 6 5 4 3 2 1)
The cyclically shifted valarray va2 is:
va2.shift (-4) = ( 4 3 2 1 10 9 8 7 6 5)
*/
```

valarray::free

Frees the memory used by the valarray.

```
void free();
```

Remarks

This nonstandard function is equivalent to assigning an empty valarray. For example:

```
valarray<T> v;  
v = valarray<T>();  
  
// equivalent to v.free()
```

valarray::max

Finds the largest element in a valarray.

```
Type max() const;
```

Return Value

The maximum value of the elements in the operand valarray.

Remarks

The member function compares values by applying **operator<** or **operator>** between pairs of elements of class `Type`, for which operators must be provided for the element `Type`.

Example

```
// valarray_max.cpp  
// compile with: /EHsc  
#include <valarray>  
#include <iostream>  
  
int main( )  
{  
    using namespace std;  
    int i, MaxValue;  
  
    valarray<int> vaR ( 10 );  
    for ( i = 0 ; i < 10 ; i += 3 )  
        vaR [ i ] = i;  
    for ( i = 1 ; i < 10 ; i += 3 )  
        vaR [ i ] = 2*i - 1;  
    for ( i = 2 ; i < 10 ; i += 3 )  
        vaR [ i ] = 10 - i;  
  
    cout << "The operand valarray is: ( ";  
    for ( i = 0 ; i < 10 ; i++ )  
        cout << vaR [ i ] << " ";  
    cout << ")." << endl;  
  
    MaxValue = vaR.max ( );  
    cout << "The largest element in the valarray is: "  
        << MaxValue << "." << endl;  
}  
/* Output:  
The operand valarray is: ( 0 1 8 3 7 5 6 13 2 9 ).  
The largest element in the valarray is: 13.  
*/
```

valarray::min

Finds the smallest element in a valarray.

```
Type min() const;
```

Return Value

The minimum value of the elements in the operand valarray.

Remarks

The member function compares values by applying **operator<** or **operator>** between pairs of elements of class `Type`, for which operators must be provided for the element `Type`.

Example

```
// valarray_min.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i, MinValue;

    valarray<int> vaR ( 10 );
    for ( i = 0 ; i < 10 ; i += 3 )
        vaR [ i ] = -i;
    for ( i = 1 ; i < 10 ; i += 3 )
        vaR [ i ] = 2*i;
    for ( i = 2 ; i < 10 ; i += 3 )
        vaR [ i ] = 5 - i;

    cout << "The operand valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    MinValue = vaR.min ( );
    cout << "The smallest element in the valarray is: "
        << MinValue << "." << endl;
}
/* Output:
The operand valarray is: ( 0 2 3 -3 8 0 -6 14 -3 -9 ).
The smallest element in the valarray is: -9.
*/
```

valarray::operator!

A unary operator that obtains the logical **NOT** values of each element in a valarray.

```
valarray<bool> operator!() const;
```

Return Value

The valarray of Boolean values that are the negation of the element values of the operand valarray.

Remarks

The logical operation **NOT** negates the elements because it converts all zeros into ones and regards all nonzero

values as ones and converts them into zeros. The returned valarray of Boolean values is of the same size as the operand valarray.

There is also a bitwise **NOT** `valarray::operator~` that negates on the level of individual bits within the binary representation of **char** and **int** elements of a valarray.

Example

```
// valarray_op_lognot.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> val ( 10 );
    valarray<bool> vaNOT ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        val [ i ] = 0;
    for ( i = 1 ; i < 10 ; i += 2 )
        val [ i ] = i-1;

    cout << "The initial valarray is: ( ";
    for (i = 0 ; i < 10 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    vaNOT = !val;
    cout << "The element-by-element result of "
        << "the logical NOT operator! is the"
        << endl << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaNOT [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial valarray is: ( 0 0 0 2 0 4 0 6 0 8 ).
The element-by-element result of the logical NOT operator! is the
valarray: ( 1 1 1 0 1 0 1 0 1 0 ).
*/
```

valarray::operator%=

Obtains the remainder of dividing the elements of an array element-wise either by a specified valarray or by a value of the element type.

```
valarray<Type>& operator%=(const valarray<Type>& right);

valarray<Type>& operator%=(const Type& right);
```

Parameters

right

The valarray or value of an element type identical to that of the operand valarray that is to divide, element-wise, the operand valarray.

Return Value

A valarray whose elements are the remainder from the element-wise division of the operand valarray by *right*

Example

```
// valarray_class_op_rem.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> val ( 6 ), vaR ( 6 );
    for ( i = 0 ; i < 6 ; i += 2 )
        val [ i ] = 53;
    for ( i = 1 ; i < 6 ; i += 2 )
        val [ i ] = -67;
    for ( i = 0 ; i < 6 ; i++ )
        vaR [ i ] = 3*i+1;

    cout << "The initial valarray is: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial right valarray is: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    val %= vaR;
    cout << "The remainders from the element-by-element "
        << "division is the"
        << endl << "valarray: ( ";
    for ( i = 0 ; i < 6 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial valarray is: ( 53 -67 53 -67 53 -67 ).
The initial right valarray is: ( 1 4 7 10 13 16 ).
The remainders from the element-by-element division is the
valarray: ( 0 -3 4 -7 1 -3 ).
*/
```

valarray::operator&=

Obtains the bitwise **AND** of elements in an array either with the corresponding elements in a specified valarray or with a value of the element type.

```
valarray<Type>& operator&=(const valarray<Type>& right);

valarray<Type>& operator&=(const Type& right);
```

Parameters

right

The valarray or value of an element type identical to that of the operand valarray that is to be combined, element-wise, by the logical **AND** with the operand valarray.

Return Value

A valarray whose elements are the element-wise logical **AND** of the operand valarray by *right*

Remarks

A bitwise operation can only be used to manipulate bits in **char** and **int** data types and variants and not on **float**, **double**, **longdouble**, **void**, **bool**, or other, more complex data types.

The bitwise AND has the same truth table as the logical `AND` but applies to the data type on the level of the individual bits. Given bits $b1$ and $b2$, $b1$ `AND` $b2$ is **true** if both bits are true; **false** if at least one is false.

Example

```
// valarray_class_op_bitand.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> val ( 10 ), vaR ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        val [ i ] = 0;
    for ( i = 1 ; i < 10 ; i += 2 )
        val [ i ] = i-1;
    for ( i = 0 ; i < 10 ; i++ )
        vaR [ i ] = i;

    cout << "The initial valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    val &= vaR;
    cout << "The element-by-element result of "
        << "the logical AND operator&= is the"
        << endl << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial valarray is: ( 0 0 0 2 0 4 0 6 0 8 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 8 9 ).
The element-by-element result of the logical AND operator&= is the
valarray: ( 0 0 0 2 0 4 0 6 0 8 ).
*/
```

valarray::operator>>=

Right-shifts the bits for each element of a valarray operand a specified number of positions or by an element-wise amount specified by a second valarray.

```
valarray<Type>& operator>>=(const valarray<Type>& right);

valarray<Type>& operator>>=(const Type& right);
```

Parameters

right

The value indicating the amount of right shift or valarray whose elements indicate the element-wise amount of right shift.

Return Value

A valarray whose elements have been shifted right the amount specified in *right*.

Remarks

Signed numbers have their signs preserved.

Example

```
// valarray_class_op_rs.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 8 ), vaR ( 8 );
    for ( i = 0 ; i < 8 ; i += 2 )
        vaL [ i ] = 64;
    for ( i = 1 ; i < 8 ; i += 2 )
        vaL [ i ] = -64;
    for ( i = 0 ; i < 8 ; i++ )
        vaR [ i ] = i;

    cout << "The initial operand valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The right valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaL >>= vaR;
    cout << "The element-by-element result of "
        << "the right shift is the"
        << endl << "valarray: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;
}

/* Output:
The initial operand valarray is: ( 64 -64 64 -64 64 -64 64 -64 ).
The right valarray is: ( 0 1 2 3 4 5 6 7 ).
The element-by-element result of the right shift is the
valarray: ( 64 -32 16 -8 4 -2 1 -1 ).
*/
```

valarray::operator<<=

Left-shifts the bits for each element of a valarray operand a specified number of positions or by an element-wise amount specified by a second valarray.

```
valarray<Type>& operator<<=(const valarray<Type>& right);
```

```
valarray<Type>& operator<<=(const Type& right);
```

Parameters

right

The value indicating the amount of left shift or valarray whose elements indicate the element-wise amount of left shift.

Return Value

A valarray whose elements have been shifted left the amount specified in *right*.

Remarks

Signed numbers have their signs preserved.

Example

```
// valarray_class_op_ls.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> val ( 8 ), vaR ( 8 );
    for ( i = 0 ; i < 8 ; i += 2 )
        val [ i ] = 1;
    for ( i = 1 ; i < 8 ; i += 2 )
        val [ i ] = -1;
    for ( i = 0 ; i < 8 ; i++ )
        vaR [ i ] = i;

    cout << "The initial operand valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    cout << "The right valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    val <<= vaR;
    cout << "The element-by-element result of "
        << "the left shift"
        << endl << "on the operand array is the valarray:"
        << endl << "( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;
}

/* Output:
The initial operand valarray is: ( 1 -1 1 -1 1 -1 1 -1 ).
The right valarray is: ( 0 1 2 3 4 5 6 7 ).
The element-by-element result of the left shift
on the operand array is the valarray:
( 1 -2 4 -8 16 -32 64 -128 ).
*/
```

valarray::operator*=

Multiplies the elements of a specified valarray or a value of the element type, element-wise, to an operand valarray.

```
valarray<Type>& operator*=(const valarray<Type>& right);

valarray<Type>& operator*=(const Type& right);
```

Parameters

right

The valarray or value of an element type identical to that of the operand valarray that is to multiply, element-wise, the operand valarray.

Return Value

A valarray whose elements are the element-wise product of the operand valarray and *right*.

Example

```
// valarray_op_emult.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> val ( 8 ), vaR ( 8 );
    for ( i = 0 ; i < 8 ; i += 2 )
        val [ i ] = 2;
    for ( i = 1 ; i < 8 ; i += 2 )
        val [ i ] = -1;
    for ( i = 0 ; i < 8 ; i++ )
        vaR [ i ] = i;

    cout << "The initial valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    val *= vaR;
    cout << "The element-by-element result of "
        << "the multiplication is the"
        << endl << "valarray: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;
}

/* Output:
The initial valarray is: ( 2 -1 2 -1 2 -1 2 -1 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 ).
The element-by-element result of the multiplication is the
valarray: ( 0 -1 4 -3 8 -5 12 -7 ).
*/
```

valarray::operator+

A unary operator that applies a plus to each element in a valarray.

```
valarray<Type> operator+() const;
```

Return Value

A valarray whose elements are plus those of the operand array.

Example

```
// valarray_op_eplus.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> val ( 10 );
    valarray<int> vaPLUS ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        val [ i ] = -i;
    for ( i = 1 ; i < 10 ; i += 2 )
        val [ i ] = i-1;

    cout << "The initial valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    vaPLUS = +val;
    cout << "The element-by-element result of "
        << "the operator+ is the"
        << endl << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaPLUS [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial valarray is: ( 0 0 -2 2 -4 4 -6 6 -8 8 ).
The element-by-element result of the operator+ is the
valarray: ( 0 0 -2 2 -4 4 -6 6 -8 8 ).
*/
```

valarray::operator+=

Adds the elements of a specified valarray or a value of the element type, element-wise, to an operand valarray.

```
valarray<Type>& operator+=(const valarray<Type>& right);

valarray<Type>& operator+=(const Type& right);
```

Parameters

right

The valarray or value of an element type identical to that of the operand valarray that is to be added, element-wise, to the operand valarray.

Return Value

A valarray whose elements are the element-wise sum of the operand valarray and *right*.

Example

```
// valarray_op_eadd.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> val ( 8 ), vaR ( 8 );
    for ( i = 0 ; i < 8 ; i += 2 )
        val [ i ] = 2;
    for ( i = 1 ; i < 8 ; i += 2 )
        val [ i ] = -1;
    for ( i = 0 ; i < 8 ; i++ )
        vaR [ i ] = i;

    cout << "The initial valarray is: ( ";
    for (i = 0 ; i < 8 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial  right valarray is: ( ";
    for (i = 0 ; i < 8 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    val += vaR;
    cout << "The element-by-element result of "
        << "the sum is the"
        << endl << "valarray: ( ";
    for (i = 0 ; i < 8 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial valarray is: ( 2 -1 2 -1 2 -1 2 -1 ).
The initial  right valarray is: ( 0 1 2 3 4 5 6 7 ).
The element-by-element result of the sum is the
valarray: ( 2 0 4 2 6 4 8 6 ).
*/
```

valarray::operator-

A unary operator that applies a minus to each element in a valarray.

```
valarray<Type> operator-() const;
```

Return Value

A valarray whose elements are minus those of the operand array.

Example

```

// valarray_op_eminus.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> val ( 10 );
    valarray<int> vaMINUS ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        val [ i ] = -i;
    for ( i = 1 ; i < 10 ; i += 2 )
        val [ i ] = i-1;

    cout << "The initial valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    vaMINUS = -val;
    cout << "The element-by-element result of "
        << "the operator+ is the"
        << endl << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaMINUS [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial valarray is: ( 0 0 -2 2 -4 4 -6 6 -8 8 ).
The element-by-element result of the operator+ is the
valarray: ( 0 0 2 -2 4 -4 6 -6 8 -8 ).
*/

```

valarray::operator-=

Subtracts the elements of a specified valarray or a value of the element type, element-wise, from an operand valarray.

```

valarray<Type>& operator-=(const valarray<Type>& right);

valarray<Type>& operator-=(const Type& right);

```

Parameters

right

The valarray or value of an element type identical to that of the operand valarray that is to be subtracted, element-wise, from the operand valarray.

Return Value

A valarray whose elements are the element-wise difference of the operand valarray and *right*.

Example

```

// valarray_op_esub.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> val ( 8 ), vaR ( 8 );
    for ( i = 0 ; i < 8 ; i += 2 )
        val [ i ] = 10;
    for ( i = 1 ; i < 8 ; i += 2 )
        val [ i ] = 0;
    for ( i = 0 ; i < 8 ; i++ )
        vaR [ i ] = i;

    cout << "The initial valarray is: ( ";
    for (i = 0 ; i < 8 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial  right valarray is: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    val -= vaR;
    cout << "The element-by-element result of "
        << "the difference is the"
        << endl << "valarray: ( ";
    for ( i = 0 ; i < 8 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial valarray is: ( 10 0 10 0 10 0 10 0 ).
The initial  right valarray is: ( 0 1 2 3 4 5 6 7 ).
The element-by-element result of the difference is the
valarray: ( 10 -1 8 -3 6 -5 4 -7 ).
*/

```

valarray::operator/=

Divides an operand valarray element-wise by the elements of a specified valarray or a value of the element type.

```

valarray<Type>& operator/=(const valarray<Type>& right);

valarray<Type>& operator/=(const Type& right);

```

Parameters

right

The valarray or value of an element type identical to that of the operand valarray that is to be divided, element-wise, into the operand valarray.

Return Value

A valarray whose elements are the element-wise quotient of the operand valarray divided by *right*.

Example

```

// valarray_op_ediv.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<double> val ( 6 ), vaR ( 6 );
    for ( i = 0 ; i < 6 ; i += 2 )
        val [ i ] = 100;
    for ( i = 1 ; i < 6 ; i += 2 )
        val [ i ] = -100;
    for ( i = 0 ; i < 6 ; i++ )
        vaR [ i ] = 2*i;

    cout << "The initial valarray is: ( ";
    for (i = 0 ; i < 6 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for (i = 0 ; i < 6 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    val /= vaR;
    cout << "The element-by-element result of "
        << "the quotient is the"
        << endl << "valarray: ( ";
    for (i = 0 ; i < 6 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial valarray is: ( 100 -100 100 -100 100 -100 ).
The initial Right valarray is: ( 0 2 4 6 8 10 ).
The element-by-element result of the quotient is the
valarray: ( inf -50 25 -16.6667 12.5 -10 ).
*/

```

valarray::operator=

Assigns elements to a valarray whose values are specified either directly or as part of some other valarray or by a slice_array, gslice_array, mask_array, or indirect_array.

```

valarray<Type>& operator=(const valarray<Type>& right);

valarray<Type>& operator=(valarray<Type>&& right);

valarray<Type>& operator=(const Type& val);

valarray<Type>& operator=(const slice_array<Type>& _Slicearray);

valarray<Type>& operator=(const gslice_array<Type>& _Gslicearray);

valarray<Type>& operator=(const mask_array<Type>& _Maskarray);

valarray<Type>& operator=(const indirect_array<Type>& _Indarray);

```

Parameters

right

The valarray to be copied into the operand valarray.

val

The value to be assigned to the elements of the operand valarray.

_Slicearray

The slice_array to be copied into the operand valarray.

_Gslicearray

The gslice_array to be copied into the operand valarray.

_Maskarray

The mask_array to be copied into the operand valarray.

_Indarray

The indirect_array to be copied into the operand valarray.

Return Value

The first member operator replaces the controlled sequence with a copy of the sequence controlled by *right*.

The second member operator is the same as the first, but with an [Rvalue Reference Declarator: &&](#).

The third member operator replaces each element of the controlled sequence with a copy of *val*.

The remaining member operators replace those elements of the controlled sequence selected by their arguments, which are generated only by [operator\[\]](#).

If the value of a member in the replacement controlled sequence depends on a member in the initial controlled sequence, the result is undefined.

Remarks

If the length of the controlled sequence changes, the result is generally undefined. In this implementation, however, the effect is merely to invalidate any pointers or references to elements in the controlled sequence.

Example

```

// valarray_op_assign.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> va ( 10 ), vaR ( 10 );
    for ( i = 0 ; i < 10 ; i += 1 )
        va [ i ] = i;
    for ( i = 0 ; i < 10 ; i+=1 )
        vaR [ i ] = 10 - i;

    cout << "The operand valarray va is:";
    for ( i = 0 ; i < 10 ; i++ )
        cout << " " << va [ i ];
    cout << endl;

    cout << "The operand valarray vaR is:";
    for ( i = 0 ; i < 10 ; i++ )
        cout << " " << vaR [ i ];
    cout << endl;

    // Assigning vaR to va with the first member function
    va = vaR;
    cout << "The reassigned valarray va is:";
    for ( i = 0 ; i < 10 ; i++ )
        cout << " " << va [ i ];
    cout << endl;

    // Assigning elements of value 10 to va
    // with the second member function
    va = 10;
    cout << "The reassigned valarray va is:";
    for ( i = 0 ; i < 10 ; i++ )
        cout << " " << va [ i ];
    cout << endl;
}
/* Output:
The operand valarray va is: 0 1 2 3 4 5 6 7 8 9
The operand valarray vaR is: 10 9 8 7 6 5 4 3 2 1
The reassigned valarray va is: 10 9 8 7 6 5 4 3 2 1
The reassigned valarray va is: 10 10 10 10 10 10 10 10 10 10
*/

```

valarray::operator[]

Returns a reference to an element or its value at specified index or a specified subset.

```

Type& operator[](size_t _Off);

slice_array<Type> operator[](slice _Slicearray);

gslice_array<Type> operator[](const gslice& _Gslicearray);

mask_array<Type> operator[](const valarray<bool>& _Boolarray);

indirect_array<Type> operator[](const valarray<size_t>& _Indarray);

Type operator[](size_t _Off) const;

valarray<Type> operator[](slice _Slice) const;

valarray<Type> operator[](const gslice& _Gslicearray) const;

valarray<Type> operator[](const valarray<bool>& _Boolarray) const;

valarray<Type> operator[](const valarray<size_t>& _Indarray) const;

```

Parameters

_Off

The index of the element to be assigned a value.

_Slicearray

A slice_array of a valarray that specifies a subset to be selected or returned to a new valarray.

_Gslicearray

A gslice_array of a valarray that specifies a subset to be selected or returned to a new valarray.

_Boolarray

A bool_array of a valarray that specifies a subset to be selected or returned to a new valarray.

_Indarray

An indirect_array of a valarray that specifies a subset to be selected or returned to a new valarray.

Return Value

A reference to an element or its value at specified index or a specified subset.

Remarks

The member operator is overloaded to provide several ways to select sequences of elements from among those controlled by ***this**. The first group of five member operators work in conjunction with various overloads of [operator=](#) (and other assigning operators) to allow selective replacement (slicing) of the controlled sequence. The selected elements must exist.

When compiled by using [_ITERATOR_DEBUG_LEVEL](#) defined as 1 or 2, a runtime error occurs if you attempt to access an element outside the bounds of the valarray. See [Checked Iterators](#) for more information.

Example

See the examples for [slice::slice](#) and [gslice::gslice](#) for an example of how to declare and use the operator.

valarray::operator^=

Obtains the element-wise exclusive logical or operator (**XOR**) of an array with either a specified valarray or a value of the element type.

```
valarray<Type>& operator|=(const valarray<Type>& right);
```

```
valarray<Type>& operator|=(const Type& right);
```

Parameters

right

The valarray or value of an element type identical to that of the operand valarray that is to be combined, element-wise, by the exclusive logical **XOR** with the operand valarray.

Return Value

A valarray whose elements are the element-wise, exclusive logical **XOR** of the operand valarray and *right*.

Remarks

The exclusive logical or, referred to as **XOR**, has the following semantics: Given elements *e1* and *e2*, *e1 XOR e2* is **true** if exactly one of the elements is true; **false** if both elements are false or if both elements are true.

Example

```

// valarray_op_exor.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = 1;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = 0;
    for ( i = 0 ; i < 10 ; i += 3 )
        vaR [ i ] = i;
    for ( i = 1 ; i < 10 ; i += 3 )
        vaR [ i ] = i-1;
    for ( i = 2 ; i < 10 ; i += 3 )
        vaR [ i ] = i-1;

    cout << "The initial operand valarray is: ( ";
        for (i = 0 ; i < 10 ; i++ )
            cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The  right valarray is: ( ";
        for ( i = 0 ; i < 10 ; i++ )
            cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaL ^= vaR;
    cout << "The element-by-element result of "
        << "the bitwise XOR operator^= is the"
        << endl << "valarray: ( ";
        for (i = 0 ; i < 10 ; i++ )
            cout << vaL [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The initial operand valarray is: ( 1 0 1 0 1 0 1 0 1 0 ).
The  right valarray is: ( 0 0 1 3 3 4 6 6 7 9 ).
The element-by-element result of the bitwise XOR operator^= is the
valarray: ( 1 0 0 3 2 4 7 6 6 9 ).
*/

```

valarray::operator|=

Obtains the bitwise **OR** of elements in an array either with the corresponding elements in a specified valarray or with a value of the element type.

```

valarray<Type>& operator|=(const valarray<Type>& right);

valarray<Type>& operator|=(const Type& right);

```

Parameters

right

The valarray or value of an element type identical to that of the operand valarray that is to be combined, element-wise, by the bitwise **OR** with the operand valarray.

Return Value

A valarray whose elements are the element-wise bitwise `OR` of the operand valarray by *right*.

Remarks

A bitwise operation can only be used to manipulate bits in **char** and **int** data types and variants and not on **float**, **double**, **longdouble**, **void**, **bool**, or other, more complex data types.

The bitwise `OR` has the same truth table as the logical `OR` but applies to the data type on the level of the individual bits. Given bits *b1* and *b2*, *b1 OR b2* is **true** if at least one of the bits is true; **false** if both bits are false.

Example

```
// valarray_class_op_bitor.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> val ( 10 ), vaR ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        val [ i ] = 1;
    for ( i = 1 ; i < 10 ; i += 2 )
        val [ i ] = 0;
    for ( i = 0 ; i < 10 ; i += 3 )
        vaR [ i ] = i;
    for ( i = 1 ; i < 10 ; i += 3 )
        vaR [ i ] = i-1;
    for ( i = 2 ; i < 10 ; i += 3 )
        vaR [ i ] = i-1;

    cout << "The initial operand valarray is:"
         << endl << "( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;

    cout << "The right valarray is:"
         << endl << "( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    val |= vaR;
    cout << "The element-by-element result of "
         << "the logical OR"
         << endl << "operator|= is the valarray:"
         << endl << "( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << val [ i ] << " ";
    cout << ")." << endl;
}

/* Output:
The initial operand valarray is:
( 1 0 1 0 1 0 1 0 1 0 ).
The right valarray is:
( 0 0 1 3 3 4 6 6 7 9 ).
The element-by-element result of the logical OR
operator|= is the valarray:
( 1 0 1 3 3 4 7 6 7 9 ).
*/
```

valarray::operator~

A unary operator that obtains the bitwise `NOT` values of each element in a valarray.

```
valarray<Type> operator~() const;
```

Return Value

The valarray of Boolean values that are the bitwise `NOT` of the element values of the operand valarray.

Remarks

A bitwise operation can only be used to manipulate bits in **char** and **int** data types and variants and not on **float**, **double**, **longdouble**, **void**, **bool** or other, more complex data types.

The bitwise `NOT` has the same truth table as the logical `NOT` but applies to the data type on the level of the individual bits. Given bit b , $\sim b$ is true if b is false and false if b is true. The logical **NOToperator!** applies on an element level, counting all nonzero values as **true**, and the result is a valarray of Boolean values. The bitwise `NOToperator~`, by contrast, can result in a valarray of values other than 0 or 1, depending on outcome of the bitwise operation.

Example

```
// valarray_op_bitnot.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<unsigned short int> val1 ( 10 );
    valarray<unsigned short int> vaNOT1 ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        val1 [ i ] = i;
    for ( i = 1 ; i < 10 ; i += 2 )
        val1 [ i ] = 5*i;

    cout << "The initial valarray <unsigned short int> is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << val1 [ i ] << " ";
    cout << ")." << endl;

    vaNOT1 = ~val1;
    cout << "The element-by-element result of "
        << "the bitwise NOT operator~ is the"
        << endl << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaNOT1 [ i ] << " ";
    cout << ")." << endl << endl;

    valarray<int> val2 ( 10 );
    valarray<int> vaNOT2 ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        val2 [ i ] = i;
    for ( i = 1 ; i < 10 ; i += 2 )
        val2 [ i ] = -2 * i;

    cout << "The initial valarray <int> is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << val2 [ i ] << " ";
    cout << ")." << endl;
```

```

vaNOT2 = ~vaL2;
cout << "The element-by-element result of "
    << "the bitwise NOT operator~ is the"
    << endl << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaNOT2 [ i ] << " ";
cout << ")." << endl;

// The negative numbers are represented using
// the two's complement approach, so adding one
// to the flipped bits returns the negative elements
vaNOT2 = vaNOT2 + 1;
cout << "The element-by-element result of "
    << "adding one"
    << endl << "is the negative of the "
    << "original elements the"
    << endl << "valarray: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaNOT2 [ i ] << " ";
cout << ")." << endl;
}

/* Output:
The initial valarray <unsigned short int> is: ( 0 5 2 15 4 25 6 35 8 45 ).
The element-by-element result of the bitwise NOT operator~ is the
valarray: ( 65535 65530 65533 65520 65531 65510 65529 65500 65527 65490 ).

The initial valarray <int> is: ( 0 -2 2 -6 4 -10 6 -14 8 -18 ).
The element-by-element result of the bitwise NOT operator~ is the
valarray: ( -1 1 -3 5 -5 9 -7 13 -9 17 ).
The element-by-element result of adding one
is the negative of the original elements the
valarray: ( 0 2 -2 6 -4 10 -6 14 -8 18 ).
*/

```

valarray::resize

Changes the number of elements in a valarray to a specified number.

```

void resize(
    size_t _Newsize);

void resize(
    size_t _Newsize,
    const Type val);

```

Parameters

_Newsize

The number of elements in the resized valarray.

val

The value to be given to the elements of the resized valarray.

Remarks

The first member function initializes elements with their default constructor.

Any pointers or references to elements in the controlled sequence are invalidated.

Example

The following example demonstrates the use of the valarray::resize member function.

```
// valarray_resize.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main()
{
    using namespace std;
    int i;
    size_t size1, sizeNew;

    valarray<int> va1(10);
    for (i = 0; i < 10; i+=1)
        va1[i] = i;

    cout << "The valarray contains ( ";
    for (i = 0; i < 10; i++)
        cout << va1[i] << " ";
    cout << ")." << endl;

    size1 = va1.size();
    cout << "The number of elements in the valarray is: "
        << size1 << "." << endl << endl;

    va1.resize(15, 10);

    cout << "The valarray contains ( ";
    for (i = 0; i < 15; i++)
        cout << va1[i] << " ";
    cout << ")." << endl;
    sizeNew = va1.size();
    cout << "The number of elements in the resized valarray is: "
        << sizeNew << "." << endl << endl;
}
```

```
The valarray contains ( 0 1 2 3 4 5 6 7 8 9 ).
The number of elements in the valarray is: 10.
```

```
The valarray contains ( 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10 ).
The number of elements in the resized valarray is: 15.
```

valarray::shift

Shifts all the elements in a valarray by a specified number of places.

```
valarray<Type> shift(int count) const;
```

Parameters

count

The number of places the elements are to be shifted forward.

Return Value

A new valarray in which all the elements have been moved *count* positions toward the front of the valarray, left with respect to their positions in the operand valarray.

Remarks

A positive value of *count* shifts the elements left *count* places, with zero fill.

A negative value of *count* shifts the elements right *count* places, with zero fill.

Example

```
// valarray_shift.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> va1 ( 10 ), va2 ( 10 );
    for ( i = 0 ; i < 10 ; i += 1 )
        va1 [ i ] = i;
    for ( i = 0 ; i < 10 ; i += 1 )
        va2 [ i ] = 10 - i;

    cout << "The operand valarray va1(10) is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va1 [ i ] << " ";
    cout << ")." << endl;

    // A positive parameter shifts elements left
    va1 = va1.shift ( 4 );
    cout << "The shifted valarray va1 is: va1.shift (4) = ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va1 [ i ] << " ";
    cout << ")." << endl;

    cout << "The operand valarray va2(10) is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va2 [ i ] << " ";
    cout << ")." << endl;

    // A negative parameter shifts elements right
    va2 = va2.shift ( - 4 );
    cout << "The shifted valarray va2 is: va2.shift (-4) = ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va2 [ i ] << " ";
    cout << ")." << endl;
}
/* Output:
The operand valarray va1(10) is: ( 0 1 2 3 4 5 6 7 8 9 ).
The shifted valarray va1 is: va1.shift (4) = ( 4 5 6 7 8 9 0 0 0 0 ).
The operand valarray va2(10) is: ( 10 9 8 7 6 5 4 3 2 1 ).
The shifted valarray va2 is: va2.shift (-4) = ( 0 0 0 0 10 9 8 7 6 5 ).
*/
```

valarray::size

Finds the number of elements in a valarray.

```
size_t size() const;
```

Return Value

The number of elements in the operand valarray.

Example

The following example demonstrates the use of the valarray::size member function.

```

// valarray_size.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main()
{
    using namespace std;
    int i;
    size_t size1, size2;

    valarray<int> va1(10), va2(12);
    for (i = 0; i < 10; i += 1)
        va1[i] = i;
    for (i = 0; i < 10; i += 1)
        va2[i] = i;

    cout << "The operand valarray va1(10) is: ( ";
    for (i = 0; i < 10; i++)
        cout << va1[i] << " ";
    cout << ")." << endl;

    size1 = va1.size();
    cout << "The number of elements in the valarray va1 is: va1.size = "
        << size1 << "." << endl << endl;

    cout << "The operand valarray va2(12) is: ( ";
    for (i = 0; i < 10; i++)
        cout << va2[i] << " ";
    cout << ")." << endl;

    size2 = va2.size();
    cout << "The number of elements in the valarray va2 is: va2.size = "
        << size2 << "." << endl << endl;

    // Initializing two more elements to va2
    va2[10] = 10;
    va2[11] = 11;
    cout << "After initializing two more elements,\n"
        << "the operand valarray va2(12) is now: ( ";
    for (i = 0; i < 12; i++)
        cout << va2[i] << " ";
    cout << ")." << endl;
    cout << "The number of elements in the valarray va2 is still: "
        << size2 << "." << endl;
}

```

```

The operand valarray va1(10) is: ( 0 1 2 3 4 5 6 7 8 9 ).
The number of elements in the valarray va1 is: va1.size = 10.

```

```

The operand valarray va2(12) is: ( 0 1 2 3 4 5 6 7 8 9 ).
The number of elements in the valarray va2 is: va2.size = 12.

```

```

After initializing two more elements,
the operand valarray va2(12) is now: ( 0 1 2 3 4 5 6 7 8 9 10 11 ).
The number of elements in the valarray va2 is still: 12.

```

valarray::sum

Determines the sum of all the elements in a valarray of nonzero length.

```
Type sum() const;
```

Return Value

The sum of the elements of the operand valarray.

Remarks

If the length is greater than one, the member function adds values to the sum by applying `operator+=` between pairs of elements of class `Type`, which operator, consequently, needs be provided for elements of type `Type`.

Example

```
// valarray_sum.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    int sumva = 0;

    valarray<int> va ( 10 );
    for ( i = 0 ; i < 10 ; i+=1 )
        va [ i ] = i;

    cout << "The operand valarray va (10) is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;

    sumva = va.sum ( );
    cout << "The sum of elements in the valarray is: "
        << sumva << "." << endl;
}
/* Output:
The operand valarray va (10) is: ( 0 1 2 3 4 5 6 7 8 9 ).
The sum of elements in the valarray is: 45.
*/
```

valarray::swap

Exchanges the elements of two `valarray`s.

```
void swap(valarray& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	A <code>valarray</code> providing the elements to be swapped.

Remarks

The member function swaps the controlled sequences between `*this` and *right*. It does so in constant time, it throws no exceptions, and it invalidates no references, pointers, or iterators that designate elements in the two controlled sequences.

valarray::valarray

Constructs a valarray of a specific size or with elements of a specific value or as a copy of another valarray or

subset of another valarray.

```
valarray();

explicit valarray(
    size_t Count);

valarray(
    const Type& Val,
    size_t Count);

valarray(
    const Type* Ptr,
    size_t Count);

valarray(
    const valarray<Type>& Right);

valarray(
    const slice_array<Type>& SliceArray);

valarray(
    const gslice_array<Type>& GsliceArray);

valarray(
    const mask_array<Type>& MaskArray);

valarray(
    const indirect_array<Type>& IndArray);

valarray(
    valarray<Type>&& Right);

valarray(
    initializer_list<Type> IList);
```

Parameters

Count

The number of elements to be in the valarray.

Val

The value to be used in initializing the elements in the valarray.

Ptr

Pointer to the values to be used to initialize the elements in the valarray.

Right

An existing valarray to initialize the new valarray.

SliceArray

A slice_array whose element values are to be used in initializing the elements of the valarray being constructed.

GsliceArray

A gslice_array whose element values are to be used in initializing the elements of the valarray being constructed.

MaskArray

A mask_array whose element values are to be used in initializing the elements of the valarray being constructed.

IndArray

An indirect_array whose element values are to be used in initializing the elements of the valarray being constructed.

IList

The `initializer_list` containing the elements to copy.

Remarks

The first (default) constructor initializes the object to an empty array. The next three constructors each initialize the object to an array of *Count* elements as follows:

- For explicit `valarray(size_t Count)`, each element is initialized with the default constructor.
- For `valarray(const Type& Val, Count)`, each element is initialized with *Val*.
- For `valarray(const Type* Ptr, Count)`, the element at position *I* is initialized with `Ptr[I]`.

Each remaining constructor initializes the object to a `valarray<Type>` object determined by the subset specified in the argument.

The last constructor is the same as the next to last, but with an [Rvalue Reference Declarator](#): `&&`.

Example

```
// valarray_ctor.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main()
{
    using namespace std;
    int i;

    // The second member function
    valarray<int> va(10);
    for (auto i : va){
        va[i] = 2 * (i + 1);
    }

    cout << "The operand valarray va is:\n";
    for (auto i : va) {
        cout << " " << va[i];
    }
    cout << " )" << endl;

    slice Slice(2, 4, 3);

    // The fifth member function
    valarray<int> vaSlice = va[Slice];

    cout << "The new valarray initialized from the slice is vaSlice =\n"
        << "va[slice( 2, 4, 3)] = (" ;
    for (int i = 0; i < 3; i++) {
        cout << " " << vaSlice[i];
    }
    cout << " )" << endl;

    valarray<int> va2{{ 1, 2, 3, 4 }};
    for (auto& v : va2) {
        cout << v << " ";
    }
    cout << endl;
}
```

```
The operand valarray va is:
( 0 2 2 2 2 2 2 2 2 )
The new valarray initialized from the slice is vaSlice =
va[slice( 2, 4, 3)] = ( 0 0 0 )
1 2 3 4
```

valarray::value_type

A type that represents the type of element stored in a valarray.

```
typedef Type value_type;
```

Remarks

The type is a synonym for the template parameter `Type`.

Example

```
// valarray_value_type.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;
    valarray<int> va ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        va [ i ] = i;
    for ( i = 1 ; i < 10 ; i += 2 )
        va [ i ] = -1;

    cout << "The initial operand valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;

    // value_type declaration and initialization:
    valarray<int>::value_type Right = 10;

    cout << "The decalared value_type Right is: "
        << Right << endl;
    va *= Right;
    cout << "The resulting valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << va [ i ] << " ";
    cout << ")." << endl;
}

/* Output:
The initial operand valarray is: ( 0 -1 2 -1 4 -1 6 -1 8 -1 ).
The decalared value_type Right is: 10
The resulting valarray is: ( 0 -10 20 -10 40 -10 60 -10 80 -10 ).
*/

valarray<bool> Class

10/31/2018 • 2 minutes to read • [Edit Online](#)

A specialized version of the template class **valarray<Type>** to elements of type **bool**.

Syntax

```
class valarray<bool>
```

Example

```
// valarray_bool.cpp
// compile with: /EHsc
#include <valarray>
#include <iostream>

int main( )
{
    using namespace std;
    int i;

    valarray<int> vaL ( 10 ), vaR ( 10 );
    valarray<bool> vaBool ( 10 );
    for ( i = 0 ; i < 10 ; i += 2 )
        vaL [ i ] = -i;
    for ( i = 1 ; i < 10 ; i += 2 )
        vaL [ i ] = i;
    for ( i = 0 ; i < 10 ; i++ )
        vaR [ i ] = i;

    cout << "The initial Left valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaL [ i ] << " ";
    cout << ")." << endl;

    cout << "The initial Right valarray is: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaR [ i ] << " ";
    cout << ")." << endl;

    vaBool = ( vaL < vaR );
    cout << "The result of the less-than comparison "
    << "test is the\nvalarray<bool>: ( ";
    for ( i = 0 ; i < 10 ; i++ )
        cout << vaBool [ i ] << " ";
    cout << ")." << endl;
}

/* Output:
The initial Left valarray is: ( 0 1 -2 3 -4 5 -6 7 -8 9 ).
The initial Right valarray is: ( 0 1 2 3 4 5 6 7 8 9 ).
The result of the less-than comparison test is the
valarray<bool>: ( 0 0 1 0 1 0 1 0 1 0 ).

[valarray Class](#)

[Thread Safety in the C++ Standard Library](#)

<vector>

10/31/2018 • 2 minutes to read • [Edit Online](#)

Defines the container template class `vector` and several supporting templates.

The `vector` is a container that organizes elements of a given type in a linear sequence. It enables fast random access to any element, and dynamic additions and removals to and from the sequence. The `vector` is the preferred container for a sequence when random-access performance is at a premium.

For more information about the class `vector`, see [vector Class](#). For information about the specialization `vector<bool>`, see [vector<bool> Class](#).

Syntax

```

namespace std {
template <class Type, class Allocator>
class vector;
template <class Allocator>
class vector<bool>;

template <class Allocator>
struct hash<vector<bool, Allocator>>;

// TEMPLATE FUNCTIONS
template <class Type, class Allocator>
bool operator== (
    const vector<Type, Allocator>& left,
    const vector<Type, Allocator>& right);

template <class Type, class Allocator>
bool operator!= (
    const vector<Type, Allocator>& left,
    const vector<Type, Allocator>& right);

template <class Type, class Allocator>
bool operator< (
    const vector<Type, Allocator>& left,
    const vector<Type, Allocator>& right);

template <class Type, class Allocator>
bool operator> (
    const vector<Type, Allocator>& left,
    const vector<Type, Allocator>& right);

template <class Type, class Allocator>
bool operator<= (
    const vector<Type, Allocator>& left,
    const vector<Type, Allocator>& right);

template <class Type, class Allocator>
bool operator>= (
    const vector<Type, Allocator>& left,
    const vector<Type, Allocator>& right);

template <class Type, class Allocator>
void swap (
    vector<Type, Allocator>& left,
    vector<Type, Allocator>& right);

} // namespace std

```

Parameters

Type

The template parameter for the type of data stored in the vector.

Allocator

The template parameter for the stored allocator object responsible for memory allocation and deallocation.

left

The first (left) vector in a compare operation

right

The second (right) vector in a compare operation.

Operators

OPERATOR	DESCRIPTION
<code>operator!=</code>	Tests if the vector object on the left side of the operator is not equal to the vector object on the right side.
<code>operator<</code>	Tests if the vector object on the left side of the operator is less than the vector object on the right side.
<code>operator<=</code>	Tests if the vector object on the left side of the operator is less than or equal to the vector object on the right side.
<code>operator==</code>	Tests if the vector object on the left side of the operator is equal to the vector object on the right side.
<code>operator></code>	Tests if the vector object on the left side of the operator is greater than the vector object on the right side.
<code>operator>=</code>	Tests if the vector object on the left side of the operator is greater than or equal to the vector object on the right side.

Classes

CLASS	DESCRIPTION
<code>vector</code> Class	A template class of sequence containers that arrange elements of a given type in a linear arrangement and allow fast random access to any element.

Specializations

<code>vector<bool></code> Class	A full specialization of the template class <code>vector</code> for elements of type <code>bool</code> with an allocator for the underlying type used by the specialization.
---------------------------------------	--

Requirements

Header: `<vector>`

Namespace: `std`

vector Class

12/14/2018 • 36 minutes to read • [Edit Online](#)

The C++ Standard Library vector class is a template class of sequence containers that arrange elements of a given type in a linear arrangement and allow fast random access to any element. They should be the preferred container for a sequence when random-access performance is at a premium.

Syntax

```
template <class Type, class Allocator = allocator<Type>>
class vector
```

Parameters

Type

The element data type to be stored in the vector

Allocator

The type that represents the stored allocator object that encapsulates details about the vector's allocation and deallocation of memory. This argument is optional and the default value is `allocator<Type>`.

Remarks

Vectors allow constant time insertions and deletions at the end of the sequence. Inserting or deleting elements in the middle of a vector requires linear time. The performance of the [deque Class](#) container is superior with respect to insertions and deletions at the beginning and end of a sequence. The [list Class](#) container is superior with respect to insertions and deletions at any location within a sequence.

Vector reallocation occurs when a member function must increase the sequence contained in the vector object beyond its current storage capacity. Other insertions and erasures may alter various storage addresses within the sequence. In all such cases, iterators or references that point at altered portions of the sequence become invalid. If no reallocation happens, only iterators and references before the insertion/deletion point remain valid.

The [vector<bool> Class](#) is a full specialization of the template class vector for elements of type bool with an allocator for the underlying type used by the specialization.

The [vector<bool> reference Class](#) is a nested class whose objects are able to provide references to elements (single bits) within a vector<bool> object.

Members

Constructors

CONSTRUCTOR	DESCRIPTION
vector	Constructs a vector of a specific size or with elements of a specific value or with a specific <code>allocator</code> or as a copy of some other vector.

Typedefs

TYPE NAME	DESCRIPTION
<code>allocator_type</code>	A type that represents the <code>allocator</code> class for the vector object.
<code>const_iterator</code>	A type that provides a random-access iterator that can read a const element in a vector.
<code>const_pointer</code>	A type that provides a pointer to a const element in a vector.
<code>const_reference</code>	A type that provides a reference to a const element stored in a vector for reading and performing const operations.
<code>const_reverse_iterator</code>	A type that provides a random-access iterator that can read any const element in the vector.
<code>difference_type</code>	A type that provides the difference between the addresses of two elements in a vector.
<code>iterator</code>	A type that provides a random-access iterator that can read or modify any element in a vector.
<code>pointer</code>	A type that provides a pointer to an element in a vector.
<code>reference</code>	A type that provides a reference to an element stored in a vector.
<code>reverse_iterator</code>	A type that provides a random-access iterator that can read or modify any element in a reversed vector.
<code>size_type</code>	A type that counts the number of elements in a vector.
<code>value_type</code>	A type that represents the data type stored in a vector.

Member Functions

MEMBER FUNCTION	DESCRIPTION
<code>assign</code>	Erases a vector and copies the specified elements to the empty vector.
<code>at</code>	Returns a reference to the element at a specified location in the vector.
<code>back</code>	Returns a reference to the last element of the vector.
<code>begin</code>	Returns a random-access iterator to the first element in the vector.
<code>capacity</code>	Returns the number of elements that the vector could contain without allocating more storage.
<code>cbegin</code>	Returns a random-access const iterator to the first element in the vector.

MEMBER FUNCTION	DESCRIPTION
<code>cend</code>	Returns a random-access const iterator that points just beyond the end of the vector.
<code>crbegin</code>	Returns a const iterator to the first element in a reversed vector.
<code>crend</code>	Returns a const iterator to the end of a reversed vector.
<code>clear</code>	Erases the elements of the vector.
<code>data</code>	Returns a pointer to the first element in the vector.
<code>emplace</code>	Inserts an element constructed in place into the vector at a specified position.
<code>emplace_back</code>	Adds an element constructed in place to the end of the vector.
<code>empty</code>	Tests if the vector container is empty.
<code>end</code>	Returns a random-access iterator that points to the end of the vector.
<code>erase</code>	Removes an element or a range of elements in a vector from specified positions.
<code>front</code>	Returns a reference to the first element in a vector.
<code>get_allocator</code>	Returns an object to the <code>allocator</code> class used by a vector.
<code>insert</code>	Inserts an element or a number of elements into the vector at a specified position.
<code>max_size</code>	Returns the maximum length of the vector.
<code>pop_back</code>	Deletes the element at the end of the vector.
<code>push_back</code>	Add an element to the end of the vector.
<code>rbegin</code>	Returns an iterator to the first element in a reversed vector.
<code>rend</code>	Returns an iterator to the end of a reversed vector.
<code>reserve</code>	Reserves a minimum length of storage for a vector object.
<code>resize</code>	Specifies a new size for a vector.
<code>shrink_to_fit</code>	Discards excess capacity.
<code>size</code>	Returns the number of elements in the vector.

MEMBER FUNCTION	DESCRIPTION
swap	Exchanges the elements of two vectors.

Operators

OPERATOR	DESCRIPTION
operator[]	Returns a reference to the vector element at a specified position.
operator=	Replaces the elements of the vector with a copy of another vector.

Requirements

Header: <vector>

Namespace: std

vector::allocator_type

A type that represents the allocator class for the vector object.

```
typedef Allocator allocator_type;
```

Remarks

`allocator_type` is a synonym for the template parameter `Allocator`.

Example

See the example for [get_allocator](#) for an example that uses `allocator_type`.

vector::assign

Erases a vector and copies the specified elements to the empty vector.

```
void assign(size_type Count, const Type& Val);
void assign(initializer_list<Type> Ilist);

template <class InputIterator>
void assign(InputIterator First, InputIterator Last);
```

Parameters

First

Position of the first element in the range of elements to be copied.

Last

Position of the first element beyond the range of elements to be copied.

Count

The number of copies of an element being inserted into the vector.

Val

The value of the element being inserted into the vector.

//List

The initializer_list containing the elements to insert.

Remarks

After erasing any existing elements in a vector, assign either inserts a specified range of elements from the original vector into a vector or inserts copies of a new element of a specified value into a vector.

Example

```
/ vector_assign.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main()
{
    using namespace std;
    vector<int> v1, v2, v3;

    v1.push_back(10);
    v1.push_back(20);
    v1.push_back(30);
    v1.push_back(40);
    v1.push_back(50);

    cout << "v1 = ";
    for (auto& v : v1){
        cout << v << " ";
    }
    cout << endl;

    v2.assign(v1.begin(), v1.end());
    cout << "v2 = ";
    for (auto& v : v2){
        cout << v << " ";
    }
    cout << endl;

    v3.assign(7, 4);
    cout << "v3 = ";
    for (auto& v : v3){
        cout << v << " ";
    }
    cout << endl;

    v3.assign({ 5, 6, 7 });
    for (auto& v : v3){
        cout << v << " ";
    }
    cout << endl;
}
```

vector::at

Returns a reference to the element at a specified location in the vector.

```
reference at(size_type _Pos);

const_reference at(size_type _Pos) const;
```

Parameters

_Pos

The subscript or position number of the element to reference in the vector.

Return Value

A reference to the element subscripted in the argument. If `_off` is greater than the size of the vector, `at` throws an exception.

Remarks

If the return value of `at` is assigned to a `const_reference`, the vector object cannot be modified. If the return value of `at` is assigned to a `reference`, the vector object can be modified.

Example

```
// vector_at.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector <int> v1;

    v1.push_back( 10 );
    v1.push_back( 20 );

    const int &i = v1.at( 0 );
    int &j = v1.at( 1 );
    cout << "The first element is " << i << endl;
    cout << "The second element is " << j << endl;
}
```

```
The first element is 10
The second element is 20
```

vector::back

Returns a reference to the last element of the vector.

```
reference back();

const_reference back() const;
```

Return Value

The last element of the vector. If the vector is empty, the return value is undefined.

Remarks

If the return value of `back` is assigned to a `const_reference`, the vector object cannot be modified. If the return value of `back` is assigned to a `reference`, the vector object can be modified.

When compiled by using `_ITERATOR_DEBUG_LEVEL` defined as 1 or 2, a runtime error occurs if you attempt to access an element in an empty vector. See [Checked Iterators](#) for more information.

Example

```

// vector_back.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main() {
    using namespace std;
    vector<int> v1;

    v1.push_back( 10 );
    v1.push_back( 11 );

    int& i = v1.back( );
    const int& ii = v1.front( );

    cout << "The last integer of v1 is " << i << endl;
    i--;
    cout << "The next-to-last integer of v1 is " << ii << endl;
}

```

vector::begin

Returns a random-access iterator to the first element in the vector.

```

const_iterator begin() const;

iterator begin();

```

Return Value

A random-access iterator addressing the first element in the `vector` or to the location succeeding an empty `vector`. You should always compare the value returned with `vector::end` to ensure it is valid.

Remarks

If the return value of `begin` is assigned to a `vector::const_iterator`, the `vector` object cannot be modified. If the return value of `begin` is assigned to an `vector::iterator`, the `vector` object can be modified.

Example

```

// vector_begin.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main()
{
    using namespace std;
    vector<int> c1;
    vector<int>::iterator c1_Iter;
    vector<int>::const_iterator c1_cIter;

    c1.push_back(1);
    c1.push_back(2);

    cout << "The vector c1 contains elements:";
    c1_Iter = c1.begin();
    for (; c1_Iter != c1.end(); c1_Iter++)
    {
        cout << " " << *c1_Iter;
    }
    cout << endl;

    cout << "The vector c1 now contains elements:";
    c1_Iter = c1.begin();
    *c1_Iter = 20;
    for (; c1_Iter != c1.end(); c1_Iter++)
    {
        cout << " " << *c1_Iter;
    }
    cout << endl;

    // The following line would be an error because iterator is const
    // *c1_cIter = 200;
}

```

```

The vector c1 contains elements: 1 2
The vector c1 now contains elements: 20 2

```

vector::capacity

Returns the number of elements that the vector could contain without allocating more storage.

```
size_type capacity() const;
```

Return Value

The current length of storage allocated for the vector.

Remarks

The member function [resize](#) will be more efficient if sufficient memory is allocated to accommodate it. Use the member function [reserve](#) to specify the amount of memory allocated.

Example

```
// vector_capacity.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector <int> v1;

    v1.push_back( 1 );
    cout << "The length of storage allocated is "
         << v1.capacity( ) << "." << endl;

    v1.push_back( 2 );
    cout << "The length of storage allocated is now "
         << v1.capacity( ) << "." << endl;
}
```

```
The length of storage allocated is 1.
The length of storage allocated is now 2.
```

vector::cbegin

Returns a **const** iterator that addresses the first element in the range.

```
const_iterator cbegin() const;
```

Return Value

A **const** random-access iterator that points at the first element of the range, or the location just beyond the end of an empty range (for an empty range, `cbegin() == cend()`).

Remarks

With the return value of `cbegin`, the elements in the range cannot be modified.

You can use this member function in place of the `begin()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the [auto](#) type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non- **const**) container of any kind that supports `begin()` and `cbegin()`.

```
auto i1 = Container.begin();
// i1 is Container<T>::iterator
auto i2 = Container.cbegin();

// i2 is Container<T>::const_iterator
```

vector::cend

Returns a **const** iterator that addresses the location just beyond the last element in a range.

```
const_iterator cend() const;
```

Return Value

A **const** random-access iterator that points just beyond the end of the range.

Remarks

`cend` is used to test whether an iterator has passed the end of its range.

You can use this member function in place of the `end()` member function to guarantee that the return value is `const_iterator`. Typically, it's used in conjunction with the `auto` type deduction keyword, as shown in the following example. In the example, consider `Container` to be a modifiable (non-**const**) container of any kind that supports `end()` and `cend()`.

```
auto i1 = Container.end();
// i1 is Container<T>::iterator
auto i2 = Container.cend();

// i2 is Container<T>::const_iterator
```

The value returned by `cend` should not be dereferenced.

vector::clear

Erases the elements of the vector.

```
void clear();
```

Example

```
// vector_clear.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;

    v1.push_back( 10 );
    v1.push_back( 20 );
    v1.push_back( 30 );

    cout << "The size of v1 is " << v1.size( ) << endl;
    v1.clear( );
    cout << "The size of v1 after clearing is " << v1.size( ) << endl;
}
```

```
The size of v1 is 3
The size of v1 after clearing is 0
```

vector::const_iterator

A type that provides a random-access iterator that can read a **const** element in a vector.

```
typedef implementation-defined const_iterator;
```

Remarks

A type `const_iterator` cannot be used to modify the value of an element.

Example

See the example for [back](#) for an example that uses `const_iterator`.

vector::const_pointer

A type that provides a pointer to a **const** element in a vector.

```
typedef typename Allocator::const_pointer const_pointer;
```

Remarks

A type `const_pointer` cannot be used to modify the value of an element.

An [iterator](#) is more commonly used to access a vector element.

vector::const_reference

A type that provides a reference to a **const** element stored in a vector for reading and performing **const** operations.

```
typedef typename Allocator::const_reference const_reference;
```

Remarks

A type `const_reference` cannot be used to modify the value of an element.

Example

```
// vector_const_ref.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;

    v1.push_back( 10 );
    v1.push_back( 20 );

    const vector<int> v2 = v1;
    const int &i = v2.front( );
    const int &j = v2.back( );
    cout << "The first element is " << i << endl;
    cout << "The second element is " << j << endl;

    // The following line would cause an error as v2 is const
    // v2.push_back( 30 );
}
```

```
The first element is 10
The second element is 20
```

vector::const_reverse_iterator

A type that provides a random-access iterator that can read any **const** element in the vector.

```
typedef std::reverse_iterator<const_iterator> const_reverse_iterator;
```

Remarks

A type `const_reverse_iterator` cannot modify the value of an element and is used to iterate through the vector in reverse.

Example

See [rbegin](#) for an example of how to declare and use an iterator.

vector::crbegin

Returns a const iterator to the first element in a reversed vector.

```
const_reverse_iterator crbegin() const;
```

Return Value

A const reverse random-access iterator addressing the first element in a reversed [vector](#) or addressing what had been the last element in the unreversed `vector`.

Remarks

With the return value of `crbegin`, the `vector` object cannot be modified.

Example

```
// vector_crbegin.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator v1_Iter;
    vector<int>::const_reverse_iterator v1_rIter;

    v1.push_back( 1 );
    v1.push_back( 2 );

    v1_Iter = v1.begin( );
    cout << "The first element of vector is "
         << *v1_Iter << "." << endl;

    v1_rIter = v1.crbegin( );
    cout << "The first element of the reversed vector is "
         << *v1_rIter << "." << endl;
}
```

```
The first element of vector is 1.
The first element of the reversed vector is 2.
```

vector::crend

Returns a const iterator that addresses the location succeeding the last element in a reversed vector.

```
const_reverse_iterator crend() const;
```

Return Value

A const reverse random-access iterator that addresses the location succeeding the last element in a reversed **vector** (the location that had preceded the first element in the unreversed **vector**).

Remarks

crend is used with a reversed **vector** just as **vector::cend** is used with a **vector**.

With the return value of **crend** (suitably decremented), the **vector** object cannot be modified.

crend can be used to test to whether a reverse iterator has reached the end of its **vector**.

The value returned by **crend** should not be dereferenced.

Example

```
// vector_crend.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::const_reverse_iterator v1_rIter;

    v1.push_back( 1 );
    v1.push_back( 2 );

    for ( v1_rIter = v1.rbegin( ) ; v1_rIter != v1.rend( ) ; v1_rIter++ )
        cout << *v1_rIter << endl;
}
```

```
2
1
```

vector::data

Returns a pointer to the first element in the vector.

```
const_pointer data() const;

pointer data();
```

Return Value

A pointer to the first element in the **vector** or to the location succeeding an empty **vector**.

Example

```

// vector_data.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main()
{
    using namespace std;
    vector<int> c1;
    vector<int>::pointer c1_ptr;
    vector<int>::const_pointer c1_cPtr;

    c1.push_back(1);
    c1.push_back(2);

    cout << "The vector c1 contains elements:";
    c1_cPtr = c1.data();
    for (size_t n = c1.size(); 0 < n; --n, c1_cPtr++)
    {
        cout << " " << *c1_cPtr;
    }
    cout << endl;

    cout << "The vector c1 now contains elements:";
    c1_ptr = c1.data();
    *c1_ptr = 20;
    for (size_t n = c1.size(); 0 < n; --n, c1_ptr++)
    {
        cout << " " << *c1_ptr;
    }
    cout << endl;
}

```

```

The vector c1 contains elements: 1 2
The vector c1 now contains elements: 20 2

```

vector::difference_type

A type that provides the difference between two iterators that refer to elements within the same vector.

```
typedef typename Allocator::difference_type difference_type;
```

Remarks

A `difference_type` can also be described as the number of elements between two pointers, because a pointer to an element contains its address.

An [iterator](#) is more commonly used to access a vector element.

Example

```

// vector_diff_type.cpp
// compile with: /EHsc
#include <iostream>
#include <vector>
#include <algorithm>

int main( )
{
    using namespace std;

    vector<int> c1;
    vector<int>::iterator c1_Iter, c2_Iter;

    c1.push_back( 30 );
    c1.push_back( 20 );
    c1.push_back( 30 );
    c1.push_back( 10 );
    c1.push_back( 30 );
    c1.push_back( 20 );

    c1_Iter = c1.begin( );
    c2_Iter = c1.end( );

    vector<int>::difference_type df_typ1, df_typ2, df_typ3;

    df_typ1 = count( c1_Iter, c2_Iter, 10 );
    df_typ2 = count( c1_Iter, c2_Iter, 20 );
    df_typ3 = count( c1_Iter, c2_Iter, 30 );
    cout << "The number '10' is in c1 collection " << df_typ1 << " times.\n";
    cout << "The number '20' is in c1 collection " << df_typ2 << " times.\n";
    cout << "The number '30' is in c1 collection " << df_typ3 << " times.\n";
}

```

```

The number '10' is in c1 collection 1 times.
The number '20' is in c1 collection 2 times.
The number '30' is in c1 collection 3 times.

```

vector::emplace

Inserts an element constructed in place into the vector at a specified position.

```

iterator emplace(
    const_iterator _Where,
    Type&& val);

```

Parameters

PARAMETER	DESCRIPTION
<i>_Where</i>	The position in the vector where the first element is inserted.
<i>val</i>	The value of the element being inserted into the <code>vector</code> .

Return Value

The function returns an iterator that points to the position where the new element was inserted into the `vector`.

Remarks

Any insertion operation can be expensive, see [vector Class](#) for a discussion of `vector` performance.

Example

```
// vector_emplace.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter;

    v1.push_back( 10 );
    v1.push_back( 20 );
    v1.push_back( 30 );

    cout << "v1 =" ;
    for ( Iter = v1.begin( ) ; Iter != v1.end( ) ; Iter++ )
        cout << " " << *Iter;
    cout << endl;

    // initialize a vector of vectors by moving v1
    vector< vector<int> > vv1;

    vv1.emplace( vv1.begin(), move( v1 ) );
    if ( vv1.size( ) != 0 && vv1[0].size( ) != 0 )
    {
        cout << "vv1[0] =";
        for (Iter = vv1[0].begin( ); Iter != vv1[0].end( ); Iter++ )
            cout << " " << *Iter;
        cout << endl;
    }
}
```

```
v1 = 10 20 30
vv1[0] = 10 20 30
```

vector::emplace_back

Adds an element constructed in place to the end of the vector.

```
template <class... Types>
void emplace_back(Types&&... _Args);
```

Parameters

PARAMETER	DESCRIPTION
<i>_Args</i>	Constructor arguments. The function infers which constructor overload to invoke based on the arguments provided.

Example

```
#include <vector>
struct obj
{
    obj(int, double) {}
};

int main()
{
    std::vector<obj> v;
    v.emplace_back(1, 3.14); // obj is created in place in the vector
}
```

vector::empty

Tests if the vector is empty.

```
bool empty() const;
```

Return Value

true if the vector is empty; **false** if the vector is not empty.

Example

```
// vector_empty.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;

    v1.push_back( 10 );

    if ( v1.empty( ) )
        cout << "The vector is empty." << endl;
    else
        cout << "The vector is not empty." << endl;
}
```

```
The vector is not empty.
```

vector::end

Returns the past-the-end iterator.

```
iterator end();

const_iterator end() const;
```

Return Value

The past-the-end iterator for the vector. If the vector is empty, `vector::end() == vector::begin()`.

Remarks

If the return value of `end` is assigned to a variable of type `const_iterator`, the vector object cannot be modified. If the return value of `end` is assigned to a variable of type `iterator`, the vector object can be modified.

Example

```
// vector_end.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>
int main( )
{
    using namespace std;
    vector <int> v1;
    vector <int>::iterator v1_Iter;

    v1.push_back( 1 );
    v1.push_back( 2 );

    for ( v1_Iter = v1.begin( ) ; v1_Iter != v1.end( ) ; v1_Iter++ )
        cout << *v1_Iter << endl;
}
```

```
1
2
```

vector::erase

Removes an element or a range of elements in a vector from specified positions.

```
iterator erase(
    const_iterator _Where);

iterator erase(
    const_iterator first,
    const_iterator last);
```

Parameters

PARAMETER	DESCRIPTION
<i>_Where</i>	Position of the element to be removed from the vector.
<i>first</i>	Position of the first element removed from the vector.
<i>last</i>	Position just beyond the last element removed from the vector.

Return Value

An iterator that designates the first element remaining beyond any elements removed, or a pointer to the end of the vector if no such element exists.

Example

```

// vector_erase.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter;

    v1.push_back( 10 );
    v1.push_back( 20 );
    v1.push_back( 30 );
    v1.push_back( 40 );
    v1.push_back( 50 );

    cout << "v1 =" ;
    for ( Iter = v1.begin( ) ; Iter != v1.end( ) ; Iter++ )
        cout << " " << *Iter;
    cout << endl;

    v1.erase( v1.begin( ) );
    cout << "v1 =";
    for ( Iter = v1.begin( ) ; Iter != v1.end( ) ; Iter++ )
        cout << " " << *Iter;
    cout << endl;

    v1.erase( v1.begin( ) + 1, v1.begin( ) + 3 );
    cout << "v1 =";
    for ( Iter = v1.begin( ) ; Iter != v1.end( ) ; Iter++ )
        cout << " " << *Iter;
    cout << endl;
}

```

```

v1 = 10 20 30 40 50
v1 = 20 30 40 50
v1 = 20 50

```

vector::front

Returns a reference to the first element in a vector.

```

reference front();

const_reference front() const;

```

Return Value

A reference to the first element in the vector object. If the vector is empty, the return is undefined.

Remarks

If the return value of `front` is assigned to a `const_reference`, the vector object cannot be modified. If the return value of `front` is assigned to a **reference**, the vector object can be modified.

When compiled by using `_ITERATOR_DEBUG_LEVEL` defined as 1 or 2, a runtime error occurs if you attempt to access an element in an empty vector. See [Checked Iterators](#) for more information.

Example

```

// vector_front.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;

    v1.push_back( 10 );
    v1.push_back( 11 );

    int& i = v1.front( );
    const int& ii = v1.front( );

    cout << "The first integer of v1 is "<< i << endl;
    // by incrementing i, we move the front reference to the second element
    i++;
    cout << "Now, the first integer of v1 is "<< i << endl;
}

```

vector::get_allocator

Returns a copy of the allocator object used to construct the vector.

```
Allocator get_allocator() const;
```

Return Value

The allocator used by the vector.

Remarks

Allocators for the vector class specify how the class manages storage. The default allocators supplied with C++ Standard Library container classes are sufficient for most programming needs. Writing and using your own allocator class is an advanced C++ topic.

Example

```

// vector_get_allocator.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    // The following lines declare objects that use the default allocator.
    vector<int> v1;
    vector<int, allocator<int> > v2 = vector<int, allocator<int> >(allocator<int>( ) ) ;

    // v3 will use the same allocator class as v1
    vector<int> v3( v1.get_allocator( ) );

    vector<int>::allocator_type xvec = v3.get_allocator( );
    // You can now call functions on the allocator class used by vec
}

```

vector::insert

Inserts an element or a number of elements or a range of elements into the vector at a specified position.

```
iterator insert(
    const_iterator _Where,
    const Type& val);

iterator insert(
    const_iterator _Where,
    Type&& val);

void insert(
    const_iterator _Where,
    size_type count,
    const Type& val);

template <class InputIterator>
void insert(
    const_iterator _Where,
    InputIterator first,
    InputIterator last);
```

Parameters

PARAMETER	DESCRIPTION
<i>_Where</i>	The position in the vector where the first element is inserted.
<i>val</i>	The value of the element being inserted into the vector.
<i>count</i>	The number of elements being inserted into the vector.
<i>first</i>	The position of the first element in the range of elements to be copied.
<i>last</i>	The position of the first element beyond the range of elements to be copied.

Return Value

The first two `insert` functions return an iterator that points to the position where the new element was inserted into the vector.

Remarks

As a precondition, *first* and *last* must not be iterators into the vector, or the behavior is undefined. Any insertion operation can be expensive, see [vector Class](#) for a discussion of `vector` performance.

Example

```

// vector_insert.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator Iter;

    v1.push_back( 10 );
    v1.push_back( 20 );
    v1.push_back( 30 );

    cout << "v1 =" ;
    for ( Iter = v1.begin( ) ; Iter != v1.end( ) ; Iter++ )
        cout << " " << *Iter;
    cout << endl;

    v1.insert( v1.begin( ) + 1, 40 );
    cout << "v1 =";
    for ( Iter = v1.begin( ) ; Iter != v1.end( ) ; Iter++ )
        cout << " " << *Iter;
    cout << endl;
    v1.insert( v1.begin( ) + 2, 4, 50 );

    cout << "v1 =";
    for ( Iter = v1.begin( ) ; Iter != v1.end( ) ; Iter++ )
        cout << " " << *Iter;
    cout << endl;

    const auto v2 = v1;
    v1.insert( v1.begin( )+1, v2.begin( )+2, v2.begin( )+4 );
    cout << "v1 =";
    for (Iter = v1.begin( ); Iter != v1.end( ); Iter++ )
        cout << " " << *Iter;
    cout << endl;

    // initialize a vector of vectors by moving v1
    vector< vector<int> > vv1;

    vv1.insert( vv1.begin(), move( v1 ) );
    if ( vv1.size( ) != 0 && vv1[0].size( ) != 0 )
    {
        cout << "vv1[0] =";
        for (Iter = vv1[0].begin( ); Iter != vv1[0].end( ); Iter++ )
            cout << " " << *Iter;
        cout << endl;
    }
}

```

```

v1 = 10 20 30
v1 = 10 40 20 30
v1 = 10 40 50 50 50 50 20 30
v1 = 10 50 50 40 50 50 50 50 20 30
vv1[0] = 10 50 50 40 50 50 50 50 20 30

```

vector::iterator

A type that provides a random-access iterator that can read or modify any element in a vector.

```
typedef implementation-defined iterator;
```

Remarks

A type **iterator** can be used to modify the value of an element.

Example

See the example for [begin](#).

vector::max_size

Returns the maximum length of the vector.

```
size_type max_size() const;
```

Return Value

The maximum possible length of the vector.

Example

```
// vector_max_size.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector <int> v1;
    vector <int>::size_type i;

    i = v1.max_size( );
    cout << "The maximum possible length of the vector is " << i << "." << endl;
}
```

vector::operator[]

Returns a reference to the vector element at a specified position.

```
reference operator[](size_type Pos);

const_reference operator[](size_type Pos) const;
```

Parameters

PARAMETER	DESCRIPTION
<i>Pos</i>	The position of the vector element.

Return Value

If the position specified is greater than or equal to the size of the container, the result is undefined.

Remarks

If the return value of `operator[]` is assigned to a `const_reference`, the vector object cannot be modified. If the return value of `operator[]` is assigned to a reference, the vector object can be modified.

When compiled by using `_ITERATOR_DEBUG_LEVEL` defined as 1 or 2, a runtime error occurs if you attempt to access an element outside the bounds of the vector. See [Checked Iterators](#) for more information.

Example

```
// vector_op_ref.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector <int> v1;

    v1.push_back( 10 );
    v1.push_back( 20 );

    int& i = v1[1];
    cout << "The second integer of v1 is " << i << endl;
}
```

vector::operator=

Replaces the elements of the vector with a copy of another vector.

```
vector& operator=(const vector& right);

vector& operator=(vector&& right);
```

Parameters

PARAMETER	DESCRIPTION
<i>right</i>	The vector being copied into the <code>vector</code> .

Remarks

After erasing any existing elements in a `vector`, `operator=` either copies or moves the contents of *right* into the `vector`.

Example

```

// vector_operator_as.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1, v2, v3;
    vector<int>::iterator iter;

    v1.push_back(10);
    v1.push_back(20);
    v1.push_back(30);
    v1.push_back(40);
    v1.push_back(50);

    cout << "v1 = " ;
    for (iter = v1.begin(); iter != v1.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    v2 = v1;
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;

    // move v1 into v2
    v2.clear();
    v2 = move(v1);
    cout << "v2 = ";
    for (iter = v2.begin(); iter != v2.end(); iter++)
        cout << *iter << " ";
    cout << endl;
}

```

vector::pointer

A type that provides a pointer to an element in a vector.

```
typedef typename Allocator::pointer pointer;
```

Remarks

A type **pointer** can be used to modify the value of an element.

Example

```
// vector_pointer.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v;
    v.push_back( 11 );
    v.push_back( 22 );

    vector<int>::pointer ptr = &v[0];
    cout << *ptr << endl;
    ptr++;
    cout << *ptr << endl;
    *ptr = 44;
    cout << *ptr << endl;
}
```

```
11
22
44
```

vector::pop_back

Deletes the element at the end of the vector.

```
void pop_back();
```

Remarks

For a code example, see [vector::push_back\(\)](#).

vector::push_back

Adds an element to the end of the vector.

```
void push_back(const T& Val);

void push_back(T&& Val);
```

Parameters

Val

The value to assign to the element added to the end of the vector.

Example

```

// compile with: /EHsc /W4
#include <vector>
#include <iostream>

using namespace std;

template <typename T> void print_elem(const T& t) {
    cout << "(" << t << ") ";
}

template <typename T> void print_collection(const T& t) {
    cout << " " << t.size() << " elements: ";

    for (const auto& p : t) {
        print_elem(p);
    }
    cout << endl;
}

int main()
{
    vector<int> v;
    for (int i = 0; i < 10; ++i) {
        v.push_back(10 + i);
    }

    cout << "vector data: " << endl;
    print_collection(v);

    // pop_back() until it's empty, printing the last element as we go
    while (v.begin() != v.end()) {
        cout << "v.back(): "; print_elem(v.back()); cout << endl;
        v.pop_back();
    }
}

```

vector::rbegin

Returns an iterator to the first element in a reversed vector.

```

reverse_iterator rbegin();
const_reverse_iterator rbegin() const;

```

Return Value

A reverse random-access iterator addressing the first element in a reversed vector or addressing what had been the last element in the unreversed vector.

Remarks

If the return value of `rbegin` is assigned to a `const_reverse_iterator`, the vector object cannot be modified. If the return value of `rbegin` is assigned to a `reverse_iterator`, the vector object can be modified.

Example

```
// vector_rbegin.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::iterator v1_Iter;
    vector<int>::reverse_iterator v1_rIter;

    v1.push_back( 1 );
    v1.push_back( 2 );

    v1_Iter = v1.begin( );
    cout << "The first element of vector is "
         << *v1_Iter << "." << endl;

    v1_rIter = v1.rbegin( );
    cout << "The first element of the reversed vector is "
         << *v1_rIter << "." << endl;
}
```

```
The first element of vector is 1.
The first element of the reversed vector is 2.
```

vector::reference

A type that provides a reference to an element stored in a vector.

```
typedef typename Allocator::reference reference;
```

Example

See [at](#) for an example of how to use **reference** in the vector class.

vector::rend

Returns an iterator that addresses the location succeeding the last element in a reversed vector.

```
const_reverse_iterator rend() const;
reverse_iterator rend();
```

Return Value

A reverse random-access iterator that addresses the location succeeding the last element in a reversed vector (the location that had preceded the first element in the unreversed vector).

Remarks

`rend` is used with a reversed vector just as [end](#) is used with a vector.

If the return value of `rend` is assigned to a `const_reverse_iterator`, then the vector object cannot be modified. If the return value of `rend` is assigned to a `reverse_iterator`, then the vector object can be modified.

`rend` can be used to test to whether a reverse iterator has reached the end of its vector.

The value returned by `rend` should not be dereferenced.

Example

```
// vector_rend.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::reverse_iterator v1_rIter;

    v1.push_back( 1 );
    v1.push_back( 2 );

    for ( v1_rIter = v1.rbegin( ) ; v1_rIter != v1.rend( ) ; v1_rIter++ )
        cout << *v1_rIter << endl;
}
```

```
2
1
```

vector::reserve

Reserves a minimum length of storage for a vector object, allocating space if necessary.

```
void reserve(size_type count);
```

Parameters

count

The minimum length of storage to be allocated for the vector.

Example

```
// vector_reserve.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    //vector<int>::iterator Iter;

    v1.push_back( 1 );
    cout << "Current capacity of v1 = "
        << v1.capacity( ) << endl;
    v1.reserve( 20 );
    cout << "Current capacity of v1 = "
        << v1.capacity( ) << endl;
}
```

```
Current capacity of v1 = 1
Current capacity of v1 = 20
```

vector::resize

Specifies a new size for a vector.

```
void resize(size_type Newsize);
void resize(size_type Newsize, Type Val);
```

Parameters

Newsize

The new size of the vector.

Val

The initialization value of new elements added to the vector if the new size is larger than the original size. If the value is omitted, the new objects use their default constructor.

Remarks

If the container's size is less than the requested size, *Newsize*, elements are added to the vector until it reaches the requested size. If the container's size is larger than the requested size, the elements closest to the end of the container are deleted until the container reaches the size *Newsize*. If the present size of the container is the same as the requested size, no action is taken.

[size](#) reflects the current size of the vector.

Example

```
// vectorsizing.cpp
// compile with: /EHsc /W4
// Illustrates vector::reserve, vector::max_size,
// vector::resize, vector::resize, and vector::capacity.
//
// Functions:
//
//   vector::max_size - Returns maximum number of elements vector could
//                       hold.
//
//   vector::capacity - Returns number of elements for which memory has
//                       been allocated.
//
//   vector::size - Returns number of elements in the vector.
//
//   vector::resize - Reallocates memory for vector, preserves its
//                     contents if new size is larger than existing size.
//
//   vector::reserve - Allocates elements for vector to ensure a minimum
//                       size, preserving its contents if the new size is
//                       larger than existing size.
//
//   vector::push_back - Appends (inserts) an element to the end of a
//                        vector, allocating memory for it if necessary.
//
// //////////////////////////////////////

// The debugger cannot handle symbols more than 255 characters long.
// The C++ Standard Library often creates symbols longer than that.
// The warning can be disabled:
// #pragma warning(disable:4786)
```

```

#include <iostream>
#include <vector>
#include <string>

using namespace std;

template <typename C> void print(const string& s, const C& c) {
    cout << s;

    for (const auto& e : c) {
        cout << e << " ";
    }
    cout << endl;
}

void printvstats(const vector<int>& v) {
    cout << "    the vector's size is: " << v.size() << endl;
    cout << "    the vector's capacity is: " << v.capacity() << endl;
    cout << "    the vector's maximum size is: " << v.max_size() << endl;
}

int main()
{
    // declare a vector that begins with 0 elements.
    vector<int> v;

    // Show statistics about vector.
    cout << endl << "After declaring an empty vector:" << endl;
    printvstats(v);
    print("    the vector's contents: ", v);

    // Add one element to the end of the vector.
    v.push_back(-1);
    cout << endl << "After adding an element:" << endl;
    printvstats(v);
    print("    the vector's contents: ", v);

    for (int i = 1; i < 10; ++i) {
        v.push_back(i);
    }
    cout << endl << "After adding 10 elements:" << endl;
    printvstats(v);
    print("    the vector's contents: ", v);

    v.resize(6);
    cout << endl << "After resizing to 6 elements without an initialization value:" << endl;
    printvstats(v);
    print("    the vector's contents: ", v);

    v.resize(9, 999);
    cout << endl << "After resizing to 9 elements with an initialization value of 999:" << endl;
    printvstats(v);
    print("    the vector's contents: ", v);

    v.resize(12);
    cout << endl << "After resizing to 12 elements without an initialization value:" << endl;
    printvstats(v);
    print("    the vector's contents: ", v);

    // Ensure there's room for at least 1000 elements.
    v.reserve(1000);
    cout << endl << "After vector::reserve(1000):" << endl;
    printvstats(v);

    // Ensure there's room for at least 2000 elements.
    v.resize(2000);
    cout << endl << "After vector::resize(2000):" << endl;
    printvstats(v);
}

```

vector::reverse_iterator

A type that provides a random-access iterator that can read or modify any element in a reversed vector.

```
typedef std::reverse_iterator<iterator> reverse_iterator;
```

Remarks

A type `reverse_iterator` is used to iterate through the vector in reverse.

Example

See the example for [rbegin](#).

vector::shrink_to_fit

Discards excess capacity.

```
void shrink_to_fit();
```

Example

```
// vector_shrink_to_fit.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    //vector<int>::iterator Iter;

    v1.push_back( 1 );
    cout << "Current capacity of v1 = "
         << v1.capacity( ) << endl;
    v1.reserve( 20 );
    cout << "Current capacity of v1 = "
         << v1.capacity( ) << endl;
    v1.shrink_to_fit();
    cout << "Current capacity of v1 = "
         << v1.capacity( ) << endl;
}
```

```
Current capacity of v1 = 1
Current capacity of v1 = 20
Current capacity of v1 = 1
```

vector::size

Returns the number of elements in the vector.

```
size_type size() const;
```

Return Value

The current length of the vector.

Example

```
// vector_size.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1;
    vector<int>::size_type i;

    v1.push_back( 1 );
    i = v1.size( );
    cout << "Vector length is " << i << "." << endl;

    v1.push_back( 2 );
    i = v1.size( );
    cout << "Vector length is now " << i << "." << endl;
}
```

```
Vector length is 1.
Vector length is now 2.
```

vector::size_type

A type that counts the number of elements in a vector.

```
typedef typename Allocator::size_type size_type;
```

Example

See the example for [capacity](#).

vector::swap

Exchanges the elements of two vectors.

```
void swap(
    vector<Type, Allocator>& right);

friend void swap(
    vector<Type, Allocator>& left,
    vector<Type, Allocator>& right);
```

Parameters

right

A vector providing the elements to be swapped, or a vector whose elements are to be exchanged with those of the vector *left*.

left

A vector whose elements are to be exchanged with those of the vector *right*.

Example

```

// vector_swap.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int> v1, v2;

    v1.push_back( 1 );
    v1.push_back( 2 );
    v1.push_back( 3 );

    v2.push_back( 10 );
    v2.push_back( 20 );

    cout << "The number of elements in v1 = " << v1.size( ) << endl;
    cout << "The number of elements in v2 = " << v2.size( ) << endl;
    cout << endl;

    v1.swap( v2 );

    cout << "The number of elements in v1 = " << v1.size( ) << endl;
    cout << "The number of elements in v2 = " << v2.size( ) << endl;
}

```

```

The number of elements in v1 = 3
The number of elements in v2 = 2

The number of elements in v1 = 2
The number of elements in v2 = 3

```

vector::value_type

A type that represents the data type stored in a vector.

```
typedef typename Allocator::value_type value_type;
```

Remarks

`value_type` is a synonym for the template parameter `Type`.

Example

```

// vector_value_type.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;
    vector<int>::value_type AnInt;
    AnInt = 44;
    cout << AnInt << endl;
}

```

vector::vector

Constructs a vector of a specific size or with elements of a specific value or with a specific allocator or as a copy of all or part of some other vector.

```
vector();
explicit vector(const Allocator& Al);
explicit vector(size_type Count);
vector(size_type Count, const Type& Val);
vector(size_type Count, const Type& Val, const Allocator& Al);

vector(const vector& Right);
vector(vector&& Right);
vector(initializer_list<Type> IList, const _Allocator& Al);

template <class InputIterator>
vector(InputIterator First, InputIterator Last);
template <class InputIterator>
vector(InputIterator First, InputIterator Last, const Allocator& Al);
```

Parameters

PARAMETER	DESCRIPTION
<i>Al</i>	The allocator class to use with this object. get_allocator returns the allocator class for the object.
<i>Count</i>	The number of elements in the constructed vector.
<i>Val</i>	The value of the elements in the constructed vector.
<i>Right</i>	The vector of which the constructed vector is to be a copy.
<i>First</i>	Position of the first element in the range of elements to be copied.
<i>Last</i>	Position of the first element beyond the range of elements to be copied.
<i>IList</i>	The initializer_list containing the elmeents to copy.

Remarks

All constructors store an allocator object (*Al*) and initialize the vector.

The first two constructors specify an empty initial vector. The second explicitly specifies the allocator type (*Al*) to be used.

The third constructor specifies a repetition of a specified number (*Count*) of elements of the default value for class `Type`.

The fourth and fifth constructors specify a repetition of (*Count*) elements of value *Val*.

The sixth constructor specifies a copy of the vector *Right*.

The seventh constructor moves the vector *Right*.

The eighth constructor uses an initializer_list to specify the elements.

The ninth and tenth constructors copy the range [`First` , `Last`) of a vector.

Example

```
// vector_ctor.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main()
{
    using namespace std;
    vector<int>::iterator v1_Iter, v2_Iter, v3_Iter, v4_Iter, v5_Iter, v6_Iter;

    // Create an empty vector v0
    vector<int> v0;

    // Create a vector v1 with 3 elements of default value 0
    vector<int> v1(3);

    // Create a vector v2 with 5 elements of value 2
    vector<int> v2(5, 2);

    // Create a vector v3 with 3 elements of value 1 and with the allocator
    // of vector v2
    vector<int> v3(3, 1, v2.get_allocator());

    // Create a copy, vector v4, of vector v2
    vector<int> v4(v2);

    // Create a new temporary vector for demonstrating copying ranges
    vector<int> v5(5);
    for (auto i : v5) {
        v5[i] = i;
    }

    // Create a vector v6 by copying the range v5[ first, last)
    vector<int> v6(v5.begin() + 1, v5.begin() + 3);

    cout << "v1 =";
    for (auto& v : v1){
        cout << " " << v;
    }
    cout << endl;

    cout << "v2 =";
    for (auto& v : v2){
        cout << " " << v;
    }
    cout << endl;

    cout << "v3 =";
    for (auto& v : v3){
        cout << " " << v;
    }
    cout << endl;
    cout << "v4 =";
    for (auto& v : v4){
        cout << " " << v;
    }
    cout << endl;

    cout << "v5 =";
    for (auto& v : v5){
        cout << " " << v;
    }
    cout << endl;

    cout << "v6 =";
    for (auto& v : v6){
```

```

        cout << " " << v;
    }
    cout << endl;

    // Move vector v2 to vector v7
    vector<int> v7(move(v2));
    vector<int>::iterator v7_Iter;

    cout << "v7 =";
    for (auto& v : v7){
        cout << " " << v;
    }
    cout << endl;

    vector<int> v8{ { 1, 2, 3, 4 } };
    for (auto& v : v8){
        cout << " " << v ;
    }
    cout << endl;
}

```

vector<bool> Class

11/9/2018 • 7 minutes to read • [Edit Online](#)

The `vector<bool>` class is a partial specialization of `vector` for elements of type **bool**. It has an allocator for the underlying type that's used by the specialization, which provides space optimization by storing one **bool** value per bit.

Syntax

```
template <class Allocator = allocator<bool>>
class vector<bool, Allocator>
```

Remarks

This class template specialization behaves like `vector`, except for the differences explained in this article.

Operations that deal with the **bool** type correspond to values in the container storage.

`allocator_traits::construct` is not used to construct these values.

Typedefs

TYPE NAME	DESCRIPTION
<code>const_pointer</code>	A typedef to a <code>const_iterator</code> that can serve as a constant pointer to a Boolean element of the <code>vector<bool></code> .
<code>const_reference</code>	A typedef for bool . After initialization, it does not observe updates to the original value.
<code>pointer</code>	A typedef to an <code>iterator</code> that can serve as a pointer to a Boolean element of the <code>vector<bool></code> .

Member functions

MEMBER FUNCTION	DESCRIPTION
<code>flip</code>	Reverses all bits in the <code>vector<bool></code> .
<code>swap</code>	Exchanges the elements of two <code>vector<bool></code> s.
<code>operator[]</code>	Returns a simulated reference to the <code>vector<bool></code> element at a specified position.
<code>at</code>	Functions the same as the unspecialized <code>vector::at</code> function, except that it uses the proxy class <code>vector<bool>::reference</code> . Also see <code>operator[]</code> .
<code>front</code>	Functions the same as the unspecialized <code>vector::front</code> function, except that it uses the proxy class <code>vector<bool>::reference</code> . Also see <code>operator[]</code> .

MEMBER FUNCTION	DESCRIPTION
<code>back</code>	Functions the same as the unspecialized <code>vector::back</code> function, except that it uses the proxy class <code>vector<bool>::reference</code> . Also see <code>operator[]</code> .

Proxy Class

<code>vector<bool>::reference</code> Class	A class that acts as a proxy to simulate <code>bool&</code> behavior, and whose objects can provide references to elements (single bits) within a <code>vector<bool></code> object.
--	---

Requirements

Header: `<vector>`

Namespace: `std`

`vector<bool>::const_pointer`

A type that describes an object that can serve as a constant pointer to a Boolean element of the sequence contained by the `vector<bool>` object.

```
typedef const_iterator const_pointer;
```

`vector<bool>::const_reference`

A type that describes an object that can serve as a constant reference to a Boolean element of the sequence contained by the `vector<bool>` object.

```
typedef bool const_reference;
```

Remarks

For more information and code examples, see `vector<bool>::reference::operator=`.

`vector<bool>::flip`

Reverses all bits in a `vector<bool>`.

```
void flip();
```

Example

```

// vector_bool_flip.cpp
// compile with: /EHsc /W4
#include <vector>
#include <iostream>

int main()
{
    using namespace std;
    cout << boolalpha; // format output for subsequent code

    vector<bool> vb = { true, false, false, true, true };
    cout << "The vector is:" << endl << "    ";
    for (const auto& b : vb) {
        cout << b << " ";
    }
    cout << endl;

    vb.flip();

    cout << "The flipped vector is:" << endl << "    ";
    for (const auto& b : vb) {
        cout << b << " ";
    }
    cout << endl;
}

```

vector<bool>::operator[]

Returns a simulated reference to the `vector<bool>` element at a specified position.

```

vector<bool>::reference operator[](size_type Pos);

vector<&bool&>::const_reference operator[](size_type Pos) const;

```

Parameters

PARAMETER	DESCRIPTION
<i>Pos</i>	The position of the <code>vector<bool></code> element.

Return Value

A `vector<bool>::reference` or `vector<bool>::const_reference` object that contains the value of the indexed element.

If the position specified is greater than or equal to the size of the container, the result is undefined.

Remarks

If you compile with `_ITERATOR_DEBUG_LEVEL` set, a run-time error occurs if you attempt to access an element outside the bounds of the vector. For more information, see [Checked Iterators](#).

Example

This code example shows the correct use of `vector<bool>::operator[]` and two common coding mistakes, which are commented out. These mistakes cause errors because the address of the `vector<bool>::reference` object that `vector<bool>::operator[]` returns cannot be taken.

```

// cl.exe /EHsc /nologo /W4 /MTd
#include <vector>
#include <iostream>

int main()
{
    using namespace std;
    cout << boolalpha;
    vector<bool> vb;

    vb.push_back(true);
    vb.push_back(false);

    //    bool* pb = &vb[1]; // conversion error - do not use
    //    bool& refb = vb[1]; // conversion error - do not use
    bool hold = vb[1];
    cout << "The second element of vb is " << vb[1] << endl;
    cout << "The held value from the second element of vb is " << hold << endl;

    // Note this doesn't modify hold.
    vb[1] = true;
    cout << "The second element of vb is " << vb[1] << endl;
    cout << "The held value from the second element of vb is " << hold << endl;
}

```

vector<bool>::pointer

A type that describes an object that can serve as a pointer to a Boolean element of the sequence contained by the `vector<bool>` object.

```
typedef iterator pointer;
```

vector<bool>::reference Class

The `vector<bool>::reference` class is a proxy class provided by the [vector<bool> Class](#) to simulate `bool&`.

Remarks

A simulated reference is required because C++ does not natively allow direct references to bits. `vector<bool>` uses only one bit per element, which can be referenced by using this proxy class. However, the reference simulation is not complete because certain assignments are not valid. For example, because the address of the `vector<bool>::reference` object cannot be taken, the following code that uses [vector<bool>::operator\[\]](#) is not correct:

```

vector<bool> vb;
//...
bool* pb = &vb[1]; // conversion error - do not use
bool& refb = vb[1]; // conversion error - do not use

```

vector<bool>::reference::flip

Inverts the Boolean value of a referenced [vector<bool>](#) element.

```
void flip();
```

Example

```
// vector_bool_ref_flip.cpp
// compile with: /EHsc /W4
#include <vector>
#include <iostream>

int main()
{
    using namespace std;
    cout << boolalpha;

    vector<bool> vb = { true, false, false, true, true };

    cout << "The vector is: " << endl << "    ";
    for (const auto& b : vb) {
        cout << b << " ";
    }
    cout << endl;

    vector<bool>::reference vbref = vb.front();
    vbref.flip();

    cout << "The vector with first element flipped is: " << endl << "    ";
    for (const auto& b : vb) {
        cout << b << " ";
    }
    cout << endl;
}
```

```
The vector is:
true false false true true
The vector with first element flipped is:
false false false true true
```

vector<bool>::reference::operator bool

Provides an implicit conversion from `vector<bool>::reference` to **bool**.

```
operator bool() const;
```

Return Value

The Boolean value of the element of the vector<bool> object.

Remarks

The `vector<bool>` object cannot be modified by this operator.

vector<bool>::reference::operator=

Assigns a Boolean value to a bit, or the value held by a referenced element to a bit.

```
reference& operator=(const reference& Right);
reference& operator=(bool Val);
```

Parameters

Right

The element reference whose value is to be assigned to the bit.

Val

The Boolean value to be assigned to the bit.

Example

```

// vector_bool_ref_op_assign.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>
#include <string>

using namespace std;

template <typename C> void print(const string& s, const C& c) {
    cout << s;

    for (const auto& e : c) {
        cout << e << " ";
    }

    cout << endl;
}

int main()
{
    cout << boolalpha;

    vector<bool> vb = { true, false, false, true, true };

    print("The vector is: ", vb);

    // Invoke vector<bool>::reference::operator=()
    vector<bool>::reference refelem1 = vb[0];
    vector<bool>::reference refelem2 = vb[1];
    vector<bool>::reference refelem3 = vb[2];

    bool b1 = refelem1;
    bool b2 = refelem2;
    bool b3 = refelem3;
    cout << "The original value of the 1st element stored in a bool: " << b1 << endl;
    cout << "The original value of the 2nd element stored in a bool: " << b2 << endl;
    cout << "The original value of the 3rd element stored in a bool: " << b3 << endl;
    cout << endl;

    refelem2 = refelem1;

    print("The vector after assigning refelem1 to refelem2 is now: ", vb);

    refelem3 = true;

    print("The vector after assigning false to refelem1 is now: ", vb);

    // The initial values are still stored in the bool variables and remained unchanged
    cout << "The original value of the 1st element still stored in a bool: " << b1 << endl;
    cout << "The original value of the 2nd element still stored in a bool: " << b2 << endl;
    cout << "The original value of the 3rd element still stored in a bool: " << b3 << endl;
    cout << endl;
}

```

```

The vector is: true false false true true
The original value of the 1st element stored in a bool: true
The original value of the 2nd element stored in a bool: false
The original value of the 3rd element stored in a bool: false

The vector after assigning refelem1 to refelem2 is now: true true false true true
The vector after assigning false to refelem1 is now: true true true true true
The original value of the 1st element still stored in a bool: true
The original value of the 2nd element still stored in a bool: false
The original value of the 3rd element still stored in a bool: false

```

vector<bool>::swap

Static member function that exchanges two elements of Boolean vectors (`vector<bool>`) by using the proxy class [vector<bool>::reference](#).

```
static void swap(  
    reference Left,  
    reference Right);
```

Parameters

Left

The element to be exchanged with the *Right* element.

Right

The element to be exchanged with the *Left* element.

Remarks

This overload supports the special proxy requirements of `vector<bool>`. [vector::swap](#) has the same functionality as the single-argument overload of `vector<bool>::swap()`.

vector<bool>::reference::flip

11/9/2018 • 2 minutes to read • [Edit Online](#)

Inverts the Boolean value of a referenced `vector<bool>` element.

Syntax

```
void flip();
```

Example

```
// vector_bool_ref_flip.cpp
// compile with: /EHsc /W4
#include <vector>
#include <iostream>

int main()
{
    using namespace std;
    cout << boolalpha;

    vector<bool> vb = { true, false, false, true, true };

    cout << "The vector is: " << endl << "    ";
    for (const auto& b : vb) {
        cout << b << " ";
    }
    cout << endl;

    vector<bool>::reference vbref = vb.front();
    vbref.flip();

    cout << "The vector with first element flipped is: " << endl << "    ";
    for (const auto& b : vb) {
        cout << b << " ";
    }
    cout << endl;
}
```

Output

```
The vector is:
true false false true true
The vector with first element flipped is:
false false false true true
```

Requirements

Header: <vector>

Namespace: std

[vector<bool>::reference Class](#)
[C++ Standard Library Reference](#)

vector<bool>::reference::operator=

11/9/2018 • 2 minutes to read • [Edit Online](#)

Assigns a Boolean value to a bit, or the value held by a referenced element to a bit.

Syntax

```
reference& operator=(const reference& Right);  
  
reference& operator=(bool Val);
```

Parameters

Right

The element reference whose value is to be assigned to the bit.

Val

The Boolean value to be assigned to the bit.

Example

```

// vector_bool_ref_op_assign.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>
#include <string>

using namespace std;

template <typename C> void print(const string& s, const C& c) {
    cout << s;

    for (const auto& e : c) {
        cout << e << " ";
    }

    cout << endl;
}

int main()
{
    cout << boolalpha;

    vector<bool> vb = { true, false, false, true, true };

    print("The vector is: ", vb);

    // Invoke vector<bool>::reference::operator=()
    vector<bool>::reference refelem1 = vb[0];
    vector<bool>::reference refelem2 = vb[1];
    vector<bool>::reference refelem3 = vb[2];

    bool b1 = refelem1;
    bool b2 = refelem2;
    bool b3 = refelem3;
    cout << "The original value of the 1st element stored in a bool: " << b1 << endl;
    cout << "The original value of the 2nd element stored in a bool: " << b2 << endl;
    cout << "The original value of the 3rd element stored in a bool: " << b3 << endl;
    cout << endl;

    refelem2 = refelem1;

    print("The vector after assigning refelem1 to refelem2 is now: ", vb);

    refelem3 = true;

    print("The vector after assigning false to refelem1 is now: ", vb);

    // The initial values are still stored in the bool variables and remained unchanged
    cout << "The original value of the 1st element still stored in a bool: " << b1 << endl;
    cout << "The original value of the 2nd element still stored in a bool: " << b2 << endl;
    cout << "The original value of the 3rd element still stored in a bool: " << b3 << endl;
    cout << endl;
}

```

Output

```
The vector is: true false false true true
The original value of the 1st element stored in a bool: true
The original value of the 2nd element stored in a bool: false
The original value of the 3rd element stored in a bool: false

The vector after assigning refelem1 to refelem2 is now: true true false true true
The vector after assigning false to refelem1 is now: true true true true true
The original value of the 1st element still stored in a bool: true
The original value of the 2nd element still stored in a bool: false
The original value of the 3rd element still stored in a bool: false
```

Requirements

[vector<bool>::reference Class](#)

[C++ Standard Library Reference](#)

<vector> functions

10/31/2018 • 2 minutes to read • [Edit Online](#)

swap

Exchanges the elements of two vectors.

```
template <class Type, class Allocator>
void swap(vector<Type, Allocator>& left, vector<Type, Allocator>& right);
```

Parameters

right

The vector providing the elements to be swapped, or the vector whose elements are to be exchanged with those of the vector *left*.

left

The vector whose elements are to be exchanged with those of the vector *right*.

Remarks

The template function is an algorithm specialized on the container class `vector` to execute the member function `left.vector::swap (right)`. These are instances of the partial ordering of function templates by the compiler. When template functions are overloaded in such a way that the match of the template with the function call is not unique, then the compiler will select the most specialized version of the template function. The general version of the template function, **template < class T> void swap(T&, T&)**, in the algorithm class works by assignment and is a slow operation. The specialized version in each container is much faster as it can work with the internal representation of the container class.

Example

See the code example for member function `vector::swap` for an example that uses the template version of `swap`.

<vector> operators

10/31/2018 • 4 minutes to read • [Edit Online](#)

<code>operator!=</code>	<code>operator></code>	<code>operator>=</code>
<code>operator<</code>	<code>operator<=</code>	<code>operator==</code>

operator!=

Tests if the object on the left side of the operator is not equal to the object on the right side.

```
bool operator!=(const vector<Type, Allocator>& left, const vector<Type, Allocator>& right);
```

Parameters

left

An object of type `vector`.

right

An object of type `vector`.

Return Value

true if the vectors are not equal; **false** if the vectors are equal.

Remarks

Two vectors are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// vector_op_ne.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    vector<int> v1, v2;
    v1.push_back( 1 );
    v2.push_back( 2 );

    if ( v1 != v2 )
        cout << "Vectors not equal." << endl;
    else
        cout << "Vectors equal." << endl;
}
```

Vectors not equal.

operator<

Tests if the object on the left side of the operator is less than the object on the right side.

```
bool operator<(const vector<Type, Allocator>& left, const vector<Type, Allocator>& right);
```

Parameters

left

An object of type `vector`.

right

An object of type `vector`.

Return Value

true if the vector on the left side of the operator is less than the vector on the right side of the operator; otherwise **false**.

Example

```
// vector_op_lt.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    vector <int> v1, v2;
    v1.push_back( 1 );
    v1.push_back( 2 );
    v1.push_back( 4 );

    v2.push_back( 1 );
    v2.push_back( 3 );

    if ( v1 < v2 )
        cout << "Vector v1 is less than vector v2." << endl;
    else
        cout << "Vector v1 is not less than vector v2." << endl;
}
```

```
Vector v1 is less than vector v2.
```

operator<=

Tests if the object on the left side of the operator is less than or equal to the object on the right side.

```
bool operator<=(const vector<Type, Allocator>& left, const vector<Type, Allocator>& right);
```

Parameters

left

An object of type `vector`.

right

An object of type `vector`.

Return Value

true if the vector on the left side of the operator is less than or equal to the vector on the right side of the operator; otherwise **false**.

Example

```
// vector_op_le.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    vector <int> v1, v2;
    v1.push_back( 1 );
    v1.push_back( 2 );
    v1.push_back( 4 );

    v2.push_back( 1 );
    v2.push_back( 3 );

    if ( v1 <= v2 )
        cout << "Vector v1 is less than or equal to vector v2." << endl;
    else
        cout << "Vector v1 is greater than vector v2." << endl;
}
```

Vector v1 is less than or equal to vector v2.

operator==

Tests if the object on the left side of the operator is equal to the object on the right side.

```
bool operator==(const vector<Type, Allocator>& left, const vector<Type, Allocator>& right);
```

Parameters

left

An object of type `vector`.

right

An object of type `vector`.

Return Value

true if the vector on the left side of the operator is equal to the vector on the right side of the operator; otherwise **false**.

Remarks

Two vectors are equal if they have the same number of elements and their respective elements have the same values. Otherwise, they are unequal.

Example

```
// vector_op_eq.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    vector<int> v1, v2;
    v1.push_back( 1 );
    v2.push_back( 1 );

    if ( v1 == v2 )
        cout << "Vectors equal." << endl;
    else
        cout << "Vectors not equal." << endl;
}
```

Vectors equal.

operator>

Tests if the object on the left side of the operator is greater than the object on the right side.

```
bool operator>(const vector<Type, Allocator>& left, const vector<Type, Allocator>& right);
```

Parameters

left

An object of type `vector`.

right

An object of type `vector`.

Return Value

true if the vector on the left side of the operator is greater than the vector on the right side of the operator; otherwise **false**.

Example

```
// vector_op_gt.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    vector <int> v1, v2;
    v1.push_back( 1 );
    v1.push_back( 3 );
    v1.push_back( 1 );

    v2.push_back( 1 );
    v2.push_back( 2 );
    v2.push_back( 2 );

    if ( v1 > v2 )
        cout << "Vector v1 is greater than vector v2." << endl;
    else
        cout << "Vector v1 is not greater than vector v2." << endl;
}
```

Vector v1 is greater than vector v2.

operator>=

Tests if the object on the left side of the operator is greater than or equal to the object on the right side.

```
bool operator>=(const vector<Type, Allocator>& left, const vector<Type, Allocator>& right);
```

Parameters

left

An object of type `vector`.

right

An object of type `vector`.

Return Value

true if the vector on the left side of the operator is greater than or equal to the vector on the right side of the vector; otherwise **false**.

Example

```
// vector_op_ge.cpp
// compile with: /EHsc
#include <vector>
#include <iostream>

int main( )
{
    using namespace std;

    vector<int> v1, v2;
    v1.push_back( 1 );
    v1.push_back( 3 );
    v1.push_back( 1 );

    v2.push_back( 1 );
    v2.push_back( 2 );
    v2.push_back( 2 );

    if ( v1 >= v2 )
        cout << "Vector v1 is greater than or equal to vector v2." << endl;
    else
        cout << "Vector v1 is less than vector v2." << endl;
}
```

Vector v1 is greater than or equal to vector v2.

C++ Standard Library Overview

10/31/2018 • 2 minutes to read • [Edit Online](#)

All C++ library entities are declared or defined in one or more standard headers. This implementation includes two additional headers, `<hash_map>` and `<hash_set>`, that are not required by the C++ Standard. For a complete list of headers that this implementation supports, see [Header Files Reference](#).

A freestanding implementation of the C++ library provides only a subset of these headers:

<code><cstddef></code>	<code><cstdlib></code> (declaring at least the functions <code>abort</code> , <code>atexit</code> , and <code>exit</code>)
<code><exception></code>	<code><limits></code>
<code><new></code>	<code><cstdarg></code>

The C++ library headers have two broader subdivisions:

- [iostreams](#) conventions.
- [C++ Standard Library Reference](#) conventions.

This section contains the following sections:

[C++ Standard Library](#)

Using C++ Library Headers

10/31/2018 • 2 minutes to read • [Edit Online](#)

You include the contents of a standard header by naming it in an include directive.

```
#include <iostream> // include I/O facilities
```

You can include the standard headers in any order, a standard header more than once, or two or more standard headers that define the same macro or the same type. Do not include a standard header within a declaration. Do not define macros that have the same names as keywords before you include a standard header.

A C++ library header includes any other C++ library headers it needs to define needed types. (Always include explicitly any C++ library headers needed in a translation unit, however, lest you guess wrong about its actual dependencies.) A Standard C header never includes another standard header. A standard header declares or defines only the entities described for it in this document.

Every function in the library is declared in a standard header. Unlike in Standard C, the standard header never provides a masking macro with the same name as the function that masks the function declaration and achieves the same effect. For more information on masking macros, see [C++ Library Conventions](#).

All names other than **operator delete** and **operator new** in the C++ library headers are defined in the `std` namespace, or in a namespace nested within the `std` namespace. You refer to the name `cin`, for example, as `std::cin`. Note, however, that macro names are not subject to namespace qualification, so you always write `__STD_COMPLEX` without a namespace qualifier.

In some translation environments, including a C++ library header may hoist external names declared in the `std` namespace into the global namespace as well, with individual **using** declarations for each of the names. Otherwise, the header does *not* introduce any library names into the current namespace.

The C++ Standard requires that the C Standard headers declare all external names in namespace `std`, then hoist them into the global namespace with individual **using** declarations for each of the names. But in some translation environments the C Standard headers include no namespace declarations, declaring all names directly in the global namespace. Thus, the most portable way to deal with namespaces is to follow two rules:

- To assuredly declare in namespace `std` an external name that is traditionally declared in `<stdlib.h>`, for example, include the header `<cstdlib>`. Know that the name might also be declared in the global namespace.
- To assuredly declare in the global namespace an external name declared in `<stdlib.h>`, include the header `<stdlib.h>` directly. Know that the name might also be declared in namespace `std`.

Thus, if you want to call `std::abort` to cause abnormal termination, you should include `<cstdlib>`. If you want to call `abort`, you should include `<stdlib.h>`.

Alternatively, you can write the declaration:

```
using namespace std;
```

which brings all library names into the current namespace. If you write this declaration immediately after all include directives, you hoist the names into the global namespace. You can subsequently ignore namespace considerations in the remainder of the translation unit. You also avoid most differences across different translation

environments.

Unless specifically indicated otherwise, you may not define names in the `std` namespace, or in a namespace nested within the `std` namespace, within your program.

C++ Library Conventions

10/31/2018 • 2 minutes to read • [Edit Online](#)

The C++ library obeys much the same conventions as the Standard C Library, plus a few more outlined here.

An implementation has certain latitude in how it declares types and functions in the C++ library:

- Names of functions in the Standard C library may have either extern "C++" or extern "C" linkage. Include the appropriate Standard C header rather than declare a library entity inline.
- A member function name in a library class may have additional function signatures over those listed in this document. You can be sure that a function call described here behaves as expected, but you cannot reliably take the address of a library member function. (The type may not be what you expect.)
- A library class may have undocumented (nonvirtual) base classes. A class documented as derived from another class may, in fact, be derived from that class through other undocumented classes.
- A type defined as a synonym for some integer type may be the same as one of several different integer types.
- A bitmask type can be implemented as either an integer type or an enumeration. In either case, you can perform bitwise operations (such as `AND` and `OR`) on values of the same bitmask type. The elements `A` and `B` of a bitmask type are nonzero values such that `A & B` is zero.
- A library function that has no exception specification can throw an arbitrary exception, unless its definition clearly restricts such a possibility.

On the other hand, there are some restrictions:

- The Standard C Library uses no masking macros. Only specific function signatures are reserved, not the names of the functions themselves.
- A library function name outside a class will not have additional, undocumented, function signatures. You can reliably take its address.
- Base classes and member functions described as virtual are assuredly virtual, while those described as nonvirtual are assuredly nonvirtual.
- Two types defined by the C++ library are always different unless this document explicitly suggests otherwise.
- Functions supplied by the library, including the default versions of replaceable functions, can throw *at most* those exceptions listed in any exception specification. No destructors supplied by the library throw exceptions. Functions in the Standard C Library may propagate an exception, as when `qsort` calls a comparison function that throws an exception, but they do not otherwise throw exceptions.

[Thread Safety in the C++ Standard Library](#)

C++ Program Startup and Termination

10/31/2018 • 2 minutes to read • [Edit Online](#)

A C++ program performs the same operations as a C program does at program startup and at program termination, plus a few more outlined here.

Before the target environment calls the function `main`, and after it stores any constant initial values you specify in all objects that have static duration, the program executes any remaining constructors for such static objects. The order of execution is not specified between translation units, but you can nevertheless assume that some [iostreams](#) objects are properly initialized for use by these static constructors. These control text streams are:

- `cin` — for standard input.
- `cout` — for standard output.
- `cerr` — for unbuffered standard error output.
- `clog` — for buffered standard error output.

You can also use these objects within the destructors called for static objects, during program termination.

As with C, returning from `main` or calling `exit` calls all functions registered with `atexit` in reverse order of registry. An exception thrown from such a registered function calls `terminate`.

Safe Libraries: C++ Standard Library

5/7/2019 • 2 minutes to read • [Edit Online](#)

Several enhancements have been made to the libraries that ship with Microsoft C++, including the C++ Standard Library, to make them more secure.

Several methods in the C++ Standard Library have been identified as potentially unsafe because they could lead to a buffer overrun or other code defect. The use of these methods is discouraged, and new, more secure methods have been created to replace them. These new methods all end in `_s`.

Several enhancements have also been made to make iterators and algorithms more secure. For more information, see [Checked Iterators](#), [Debug Iterator Support](#) and `_ITERATOR_DEBUG_LEVEL`.

Remarks

The following table lists the C++ Standard Library methods that are potentially unsafe, as well as their safer equivalent:

POTENTIALLY UNSAFE METHOD	SAFER EQUIVALENT
<code>copy</code>	<code>basic_string::_Copy_s</code>
<code>copy</code>	<code>char_traits::_Copy_s</code>

If you call any one of the potentially unsafe methods above, or if you use iterators incorrectly, the compiler will generate [Compiler Warning \(level 3\) C4996](#). For information on how to disable these warnings, see `_SCL_SECURE_NO_WARNINGS`.

[C++ Standard Library Overview](#)

_ITERATOR_DEBUG_LEVEL

10/31/2018 • 2 minutes to read • [Edit Online](#)

The `_ITERATOR_DEBUG_LEVEL` macro controls whether [checked iterators](#) and [debug iterator support](#) are enabled. This macro supersedes and combines the functionality of the older `_SECURE_SCL` and `_HAS_ITERATOR_DEBUGGING` macros.

Macro Values

The following table summarizes the possible values for the `_ITERATOR_DEBUG_LEVEL` macro.

COMPILATION MODE	MACRO VALUE	DESCRIPTION
Debug		
	0	Disables checked iterators and disables iterator debugging.
	1	Enables checked iterators and disables iterator debugging.
	2 (Default)	Enables iterator debugging; checked iterators are not relevant.
Release		
	0 (Default)	Disables checked iterators.
	1	Enables checked iterators; iterator debugging is not relevant.

In release mode, the compiler generates an error if you specify `_ITERATOR_DEBUG_LEVEL` as 2.

Remarks

The `_ITERATOR_DEBUG_LEVEL` macro controls whether [checked iterators](#) are enabled, and in Debug mode, whether [debug iterator support](#) is enabled. If `_ITERATOR_DEBUG_LEVEL` is defined as 1 or 2, checked iterators ensure that the bounds of your containers are not overwritten. If `_ITERATOR_DEBUG_LEVEL` is 0, iterators are not checked. When `_ITERATOR_DEBUG_LEVEL` is defined as 1, any unsafe iterator use causes a runtime error and the program is terminated. When `_ITERATOR_DEBUG_LEVEL` is defined as 2, unsafe iterator use causes an assert and a runtime error dialog that lets you break into the debugger.

Because the `_ITERATOR_DEBUG_LEVEL` macro supports similar functionality to the `_SECURE_SCL` and `_HAS_ITERATOR_DEBUGGING` macros, you may be uncertain which macro and macro value to use in a particular situation. To prevent confusion, we recommend that you use only the `_ITERATOR_DEBUG_LEVEL` macro. This table describes the equivalent `_ITERATOR_DEBUG_LEVEL` macro value to use for various values of `_SECURE_SCL` and `_HAS_ITERATOR_DEBUGGING` in existing code.

<code>_ITERATOR_DEBUG_LEVEL</code>	<code>_SECURE_SCL</code>	<code>_HAS_ITERATOR_DEBUGGING</code>
0 (Release default)	0 (disabled)	0 (disabled)
1	1 (enabled)	0 (disabled)
2 (Debug default)	(not relevant)	1 (enabled in Debug mode)

For information on how to disable warnings about checked iterators, see [_SCL_SECURE_NO_WARNINGS](#).

Example

To specify a value for the `_ITERATOR_DEBUG_LEVEL` macro, use a [/D](#) compiler option to define it on the command line, or use `#define` before the C++ Standard Library headers are included in your source files. For example, on the command line, to compile *sample.cpp* in debug mode and to use debug iterator support, you can specify the `_ITERATOR_DEBUG_LEVEL` macro definition:

```
c1 /EHsc /Zi /MDd /D_ITERATOR_DEBUG_LEVEL=1 sample.cpp
```

In a source file, specify the macro before any standard library headers that define iterators.

```
// sample.cpp

#define _ITERATOR_DEBUG_LEVEL 1

#include <vector>

// ...
```

[Checked Iterators](#)

[Debug Iterator Support](#)

[Safe Libraries: C++ Standard Library](#)

_SCL_SECURE_NO_WARNINGS

10/31/2018 • 2 minutes to read • [Edit Online](#)

Calling any of the potentially unsafe methods in the C++ Standard Library results in [Compiler Warning \(level 3\) C4996](#). To disable this warning, define the macro `_SCL_SECURE_NO_WARNINGS` in your code:

```
#define _SCL_SECURE_NO_WARNINGS
```

If you use precompiled headers, put this directive in your precompiled header file before you include any C runtime library or standard library headers. If you put it in an individual source code file before you include the precompiled header file, it is ignored by the compiler.

Remarks

Other ways to disable warning C4996 include:

- Using the `/D` ([Preprocessor Definitions](#)) compiler option:

```
cl /D_SCL_SECURE_NO_WARNINGS [other compiler options] myfile.cpp
```

- Using the `/w` compiler option:

```
cl /wd4996 [other compiler options] myfile.cpp
```

- Using the `#pragma warning` directive:

```
#pragma warning(disable:4996)
```

Also, you can manually change the level of warning C4996 with the `/w<l><n>` compiler option. For example, to set warning C4996 to level 4:

```
cl /w44996 [other compiler options] myfile.cpp
```

For more information, see [/w](#), [/W0](#), [/W1](#), [/W2](#), [/W3](#), [/W4](#), [/w1](#), [/w2](#), [/w3](#), [/w4](#), [/Wall](#), [/wd](#), [/we](#), [/wo](#), [/Wv](#), [/WX](#) ([Warning Level](#)).

[Safe Libraries: C++ Standard Library](#)

Checked Iterators

11/9/2018 • 5 minutes to read • [Edit Online](#)

Checked iterators ensure that the bounds of your container are not overwritten. Checked iterators apply to both release builds and debug builds. For more information about how to use debug iterators when you compile in debug mode, see [Debug Iterator Support](#).

Remarks

For information about how to disable warnings that are generated by checked iterators, see [_SCL_SECURE_NO_WARNINGS](#).

You can use the [_ITERATOR_DEBUG_LEVEL](#) preprocessor macro to enable or disable the checked iterators feature. If [_ITERATOR_DEBUG_LEVEL](#) is defined as 1 or 2, unsafe use of iterators causes a runtime error and the program is terminated. If defined as 0, checked iterators are disabled. By default, the value for [_ITERATOR_DEBUG_LEVEL](#) is 0 for release builds and 2 for debug builds.

IMPORTANT

Older documentation and source code may refer to the [_SECURE_SCL](#) macro. Use [_ITERATOR_DEBUG_LEVEL](#) to control [_SECURE_SCL](#). For more information, see [_ITERATOR_DEBUG_LEVEL](#).

When [_ITERATOR_DEBUG_LEVEL](#) is defined as 1 or 2, these iterator checks are performed:

- All standard iterators (for example, [vector::iterator](#)) are checked.
- If an output iterator is a checked iterator, calls to standard library functions such as [std::copy](#) get checked behavior.
- If an output iterator is an unchecked iterator, calls to standard library functions cause compiler warnings.
- The following functions generate a runtime error if there is an access that is outside the bounds of the container:

basic_string::operator[]	bitset::operator[]	back	front
deque::operator[]	back	front	back
front	vector::operator[]	back	front

When [_ITERATOR_DEBUG_LEVEL](#) is defined as 0:

- All standard iterators are unchecked. Iterators can move beyond the container boundaries, which leads to undefined behavior.
- If an output iterator is a checked iterator, calls to standard library functions such as `std::copy` get checked behavior.
- If an output iterator is an unchecked iterator, calls to standard library functions get unchecked behavior.

A checked iterator refers to an iterator that calls `invalid_parameter_handler` if you attempt to move past the boundaries of the container. For more information about `invalid_parameter_handler`, see [Parameter Validation](#).

The iterator adaptors that support checked iterators are [checked_array_iterator Class](#) and [unchecked_array_iterator Class](#).

Example

When you compile by using `_ITERATOR_DEBUG_LEVEL` set to 1 or 2, a runtime error will occur if you attempt to access an element that is outside the bounds of the container by using the indexing operator of certain classes.

```
// checked_iterators_1.cpp
// cl.exe /Zi /MDd /EHsc /W4

#define _ITERATOR_DEBUG_LEVEL 1

#include <vector>
#include <iostream>

using namespace std;

int main()
{
    vector<int> v;
    v.push_back(67);

    int i = v[0];
    cout << i << endl;

    i = v[1]; //triggers invalid parameter handler
}
```

This program prints "67" then pops up an assertion failure dialog box with additional information about the failure.

Example

Similarly, when you compile by using `_ITERATOR_DEBUG_LEVEL` set to 1 or 2, a runtime error will occur if you attempt to access an element by using `front` or `back` in container classes when the container is empty.

```
// checked_iterators_2.cpp
// cl.exe /Zi /MDd /EHsc /W4
#define _ITERATOR_DEBUG_LEVEL 1

#include <vector>
#include <iostream>

using namespace std;

int main()
{
    vector<int> v;

    int& i = v.front(); // triggers invalid parameter handler
}
```

This program pops up an assertion failure dialog box with additional information about the failure.

Example

The following code demonstrates various iterator use-case scenarios with comments about each. By default, `_ITERATOR_DEBUG_LEVEL` is set to 2 in Debug builds, and to 0 in Retail builds.

```
// checked_iterators_3.cpp
// cl.exe /MTd /EHsc /W4

#include <algorithm>
#include <array>
#include <iostream>
#include <iterator>
#include <numeric>
#include <string>
#include <vector>

using namespace std;

template <typename C>
void print(const string& s, const C& c)
{
    cout << s;

    for (const auto& e : c) {
        cout << e << " ";
    }

    cout << endl;
}

int main()
{
    vector<int> v(16);
    iota(v.begin(), v.end(), 0);
    print("v: ", v);

    // OK: vector::iterator is checked in debug mode
    // (i.e. an overrun causes a debug assertion)
    vector<int> v2(16);
    transform(v.begin(), v.end(), v2.begin(), [](int n) { return n * 2; });
    print("v2: ", v2);

    // OK: back_insert_iterator is marked as checked in debug mode
    // (i.e. an overrun is impossible)
    vector<int> v3;
    transform(v.begin(), v.end(), back_inserter(v3), [](int n) { return n * 3; });
    print("v3: ", v3);

    // OK: array::iterator is checked in debug mode
    // (i.e. an overrun causes a debug assertion)
    array<int, 16> a4;
    transform(v.begin(), v.end(), a4.begin(), [](int n) { return n * 4; });
    print("a4: ", a4);

    // OK: Raw arrays are checked in debug mode
    // (an overrun causes a debug assertion)
    // NOTE: This applies only when raw arrays are given to C++ Standard Library algorithms!
    int a5[16];
    transform(v.begin(), v.end(), a5, [](int n) { return n * 5; });
    print("a5: ", a5);

    // WARNING C4996: Pointers cannot be checked in debug mode
    // (an overrun causes undefined behavior)
    int a6[16];
    int * p6 = a6;
    transform(v.begin(), v.end(), p6, [](int n) { return n * 6; });
    print("a6: ", a6);
}
```

```

// OK: stdext::checked_array_iterator is checked in debug mode
// (an overrun causes a debug assertion)
int a7[16];
int * p7 = a7;
transform(v.begin(), v.end(), stdext::make_checked_array_iterator(p7, 16), [](int n) { return
n * 7; });
print("a7: ", a7);

// WARNING SILENCED: stdext::unchecked_array_iterator is marked as checked in debug mode
// (it performs no checking, so an overrun causes undefined behavior)
int a8[16];
int * p8 = a8;
transform(v.begin(), v.end(), stdext::make_unchecked_array_iterator(p8), [](int n) { return n
* 8; });
print("a8: ", a8);
}

```

When you compile this code by using `cl.exe /EHsc /W4 /MTd checked_iterators_3.cpp` the compiler emits a warning, but compiles without error into an executable:

```

algorithm(1026) : warning C4996: 'std::_Transform1': Function call with parameters
that may be unsafe - this call relies on the caller to check that the passed values
are correct. To disable this warning, use -D_SCL_SECURE_NO_WARNINGS. See documentation
on how to use Visual C++ 'Checked Iterators'

```

When run at the command line, the executable generates this output:

```

v: 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
v2: 0 2 4 6 8 10 12 14 16 18 20 22 24 26 28 30
v3: 0 3 6 9 12 15 18 21 24 27 30 33 36 39 42 45
a4: 0 4 8 12 16 20 24 28 32 36 40 44 48 52 56 60
a5: 0 5 10 15 20 25 30 35 40 45 50 55 60 65 70 75
a6: 0 6 12 18 24 30 36 42 48 54 60 66 72 78 84 90
a7: 0 7 14 21 28 35 42 49 56 63 70 77 84 91 98 105
a8: 0 8 16 24 32 40 48 56 64 72 80 88 96 104 112 120

```

[C++ Standard Library Overview](#)

[Debug Iterator Support](#)

_SECURE_SCL

10/31/2018 • 2 minutes to read • [Edit Online](#)

Superseded by [_ITERATOR_DEBUG_LEVEL](#), this macro defines whether [Checked Iterators](#) are enabled. By default, checked iterators are enabled in Debug builds, and disabled in Retail builds.

IMPORTANT

Direct use of the `_SECURE_SCL` macro is deprecated. Instead, use `_ITERATOR_DEBUG_LEVEL` to control checked iterator settings. For more information, see [_ITERATOR_DEBUG_LEVEL](#).

Remarks

When checked iterators are enabled, unsafe iterator use causes a runtime error and the program is terminated. To enable checked iterators, set `_ITERATOR_DEBUG_LEVEL` to 1 or 2. This is equivalent to a `_SECURE_SCL` setting of 1, or enabled:

```
#define _ITERATOR_DEBUG_LEVEL 1
```

To disable checked iterators, set `_ITERATOR_DEBUG_LEVEL` to 0. This is equivalent to a `_SECURE_SCL` setting of 0, or disabled:

```
#define _ITERATOR_DEBUG_LEVEL 0
```

For information on how to disable warnings about checked iterators, see [_SCL_SECURE_NO_WARNINGS](#).

See also

[_ITERATOR_DEBUG_LEVEL](#)

[Checked Iterators](#)

[Debug Iterator Support](#)

[Safe Libraries: C++ Standard Library](#)

Debug Iterator Support

3/21/2019 • 3 minutes to read • [Edit Online](#)

The Visual C++ run-time library detects incorrect iterator use, and asserts and displays a dialog box at run time. To enable debug iterator support, you must use debug versions of the C++ Standard Library and C Runtime Library to compile your program. For more information, see [CRT Library Features](#). For information about how to use checked iterators, see [Checked Iterators](#).

The C++ standard describes how member functions might cause iterators to a container to become invalid. Two examples are:

- Erasing an element from a container causes iterators to the element to become invalid.
- Increasing the size of a [vector](#) by using push or insert causes iterators into the `vector` to become invalid.

Invalid iterators

If you compile this sample program in debug mode, at run time it asserts and terminates.

```
// iterator_debugging_0.cpp
// compile by using /EHsc /MDd
#include <vector>
#include <iostream>

int main() {
    std::vector<int> v {10, 15, 20};
    std::vector<int>::iterator i = v.begin();
    ++i;

    std::vector<int>::iterator j = v.end();
    --j;

    std::cout << *j << '\n';

    v.insert(i,25);

    std::cout << *j << '\n'; // Using an old iterator after an insert
}
```

Using _ITERATOR_DEBUG_LEVEL

You can use the preprocessor macro `_ITERATOR_DEBUG_LEVEL` to turn off the iterator debugging feature in a debug build. This program does not assert, but still triggers undefined behavior.

```
// iterator_debugging_1.cpp
// compile by using: /EHsc /MDd
#define _ITERATOR_DEBUG_LEVEL 0
#include <vector>
#include <iostream>

int main() {
    std::vector<int> v {10, 15, 20};

    std::vector<int>::iterator i = v.begin();
    ++i;

    std::vector<int>::iterator j = v.end();
    --j;

    std::cout << *j << '\n';

    v.insert(i,25);

    std::cout << *j << '\n'; // Using an old iterator after an insert
}
```

```
20
-572662307
```

Unitialized iterators

An assert also occurs if you attempt to use an iterator before it is initialized, as shown here:

```
// iterator_debugging_2.cpp
// compile by using: /EHsc /MDd
#include <string>
using namespace std;

int main() {
    string::iterator i1, i2;
    if (i1 == i2)
        ;
}
```

Incompatible iterators

The following code example causes an assertion because the two iterators to the [for_each](#) algorithm are incompatible. Algorithms check to determine whether the iterators that are supplied to them reference the same container.

```

// iterator_debugging_3.cpp
// compile by using /EHsc /MDd
#include <algorithm>
#include <vector>
using namespace std;

int main()
{
    vector<int> v1 {10, 20};
    vector<int> v2 {10, 20};

    // The next line asserts because v1 and v2 are
    // incompatible.
    for_each(v1.begin(), v2.end(), [] (int& elem) { elem *= 2; } );
}

```

Notice that this example uses the lambda expression `[] (int& elem) { elem *= 2; }` instead of a functor. Although this choice has no bearing on the assert failure—a similar functor would cause the same failure—lambdas are a very useful way to accomplish compact function object tasks. For more information about lambda expressions, see [Lambda Expressions](#).

Iterators going out of scope

Debug iterator checks also cause an iterator variable that's declared in a **for** loop to be out of scope when the **for** loop scope ends.

```

// iterator_debugging_4.cpp
// compile by using: /EHsc /MDd
#include <vector>
#include <iostream>
int main() {
    std::vector<int> v {10, 15, 20};

    for (std::vector<int>::iterator i = v.begin(); i != v.end(); ++i)
        ; // do nothing
    --i; // C2065
}

```

Destructors for debug iterators

Debug iterators have non-trivial destructors. If a destructor does not run but the object's memory is freed, access violations and data corruption might occur. Consider this example:

```
// iterator_debugging_5.cpp
// compile by using: /EHsc /MDd
#include <vector>
struct base {
    // TO FIX: uncomment the next line
    // virtual ~base() {}
};

struct derived : base {
    std::vector<int>::iterator m_iter;
    derived( std::vector<int>::iterator iter ) : m_iter( iter ) {}
    ~derived() {}
};

int main() {
    std::vector<int> vect( 10 );
    base * pb = new derived( vect.begin() );
    delete pb; // doesn't call ~derived()
               // access violation
}
```

_HAS_ITERATOR_DEBUGGING

10/31/2018 • 2 minutes to read • [Edit Online](#)

Superseded by [_ITERATOR_DEBUG_LEVEL](#), this macro defines whether the iterator debugging feature is enabled in a debug build. By default, iterator debugging is enabled in Debug builds and disabled in Retail builds. For more information, see [Debug Iterator Support](#).

IMPORTANT

Direct use of the `_HAS_ITERATOR_DEBUGGING` macro is deprecated. Instead, use `_ITERATOR_DEBUG_LEVEL` to control iterator debug settings. For more information, see [_ITERATOR_DEBUG_LEVEL](#).

Remarks

To enable iterator debugging in debug builds, set `_ITERATOR_DEBUG_LEVEL` to 2. This is equivalent to a `_HAS_ITERATOR_DEBUGGING` setting of 1, or enabled:

```
#define _ITERATOR_DEBUG_LEVEL 2
```

`_ITERATOR_DEBUG_LEVEL` cannot be set to 2 (and `_HAS_ITERATOR_DEBUGGING` cannot be set to 1) in retail builds.

To disable debug iterators in debug builds, set `_ITERATOR_DEBUG_LEVEL` to 0 or 1. This is equivalent to a `_HAS_ITERATOR_DEBUGGING` setting of 0, or disabled:

```
#define _ITERATOR_DEBUG_LEVEL 0
```

[Safe Libraries: C++ Standard Library](#)

Thread Safety in the C++ Standard Library

10/31/2018 • 2 minutes to read • [Edit Online](#)

The following thread safety rules apply to all classes in the C++ Standard Library—this includes `shared_ptr`, as described below. Stronger guarantees are sometimes provided—for example, the standard iostream objects, as described below, and types specifically intended for multithreading, like those in `<atomic>`.

An object is thread-safe for reading from multiple threads. For example, given an object A, it is safe to read A from thread 1 and from thread 2 simultaneously.

If an object is being written to by one thread, then all reads and writes to that object on the same or other threads must be protected. For example, given an object A, if thread 1 is writing to A, then thread 2 must be prevented from reading from or writing to A.

It is safe to read and write to one instance of a type even if another thread is reading or writing to a different instance of the same type. For example, given objects A and B of the same type, it is safe when A is being written in thread 1 and B is being read in thread 2.

shared_ptr

Multiple threads can simultaneously read and write different `shared_ptr` objects, even when the objects are copies that share ownership.

iostream

The standard iostream objects `cin`, `cout`, `cerr`, `clog`, `wcin`, `wcout`, `wcerr`, and `wclog` follow the same rules as the other classes, with this exception: it is safe to write to an object from multiple threads. For example, thread 1 can write to `cout` at the same time as thread 2. However, this can cause the output from the two threads to be intermixed.

NOTE

Reading from a stream buffer is not considered to be a read operation. Instead it is considered to be a write operation because the state of the class is changed.

[C++ Standard Library Overview](#)

stdext Namespace

3/11/2019 • 2 minutes to read • [Edit Online](#)

Members of the `<hash_map>` and `<hash_set>` header files are not currently part of the ISO C++ standard. Therefore, these types and members have been moved from the `std` namespace to namespace `stdext`, to remain conformant with the C++ standard.

When compiling with `/Ze`, which is the default, the compiler warns on the use of `std` for members of the `<hash_map>` and `<hash_set>` header files. To disable the warning, use the `warning` pragma.

To have the compiler generate an error for the use of `std` for members of the `<hash_map>` and `<hash_set>` header files with `/Ze`, add the following directive before you `#include` any C++ Standard Library header files.

```
#define _DEFINE_DEPRECATED_HASH_CLASSES 0
```

When compiling with `/Za`, the compiler generates an error.

[C++ Standard Library Overview](#)

C++ Standard Library Containers

11/9/2018 • 7 minutes to read • [Edit Online](#)

The Standard Library provides various type-safe containers for storing collections of related objects. The containers are class templates; when you declare a container variable, you specify the type of the elements that the container will hold. Containers can be constructed with initializer lists. They have member functions for adding and removing elements and performing other operations.

You iterate over the elements in a container, and access the individual elements by using [iterators](#). You can use iterators explicitly by using their member functions and operators as well as global functions. You can also use them implicitly, for example by using a range-for loop. Iterators for all C++ Standard Library containers have a common interface but each container defines its own specialized iterators.

Containers can be divided into three categories: sequence containers, associative containers, and container adapters.

Sequence Containers

Sequence containers maintain the ordering of inserted elements that you specify.

A `vector` container behaves like an array, but can automatically grow as required. It is random access and contiguously stored, and length is highly flexible. For these reasons and more, `vector` is the preferred sequence container for most applications. When in doubt as to what kind of sequence container to use, start by using a vector! For more information, see [vector Class](#).

An `array` container has some of the strengths of `vector`, but the length is not as flexible. For more information, see [array Class](#).

A `deque` (double-ended queue) container allows for fast insertions and deletions at the beginning and end of the container. It shares the random-access and flexible-length advantages of `vector`, but is not contiguous. For more information, see [deque Class](#).

A `list` container is a doubly linked list that enables bidirectional access, fast insertions, and fast deletions anywhere in the container, but you cannot randomly access an element in the container. For more information, see [list Class](#).

A `forward_list` container is a singly linked list—the forward-access version of `list`. For more information, see [forward_list Class](#).

Associative Containers

In associative containers, elements are inserted in a pre-defined order—for example, as sorted ascending. Unordered associative containers are also available. The associative containers can be grouped into two subsets: maps and sets.

A `map`, sometimes referred to as a dictionary, consists of a key/value pair. The key is used to order the sequence, and the value is associated with that key. For example, a `map` might contain keys that represent every unique word in a text and corresponding values that represent the number of times that each word appears in the text. The unordered version of `map` is `unordered_map`. For more information, see [map Class](#) and [unordered_map Class](#).

A `set` is just an ascending container of unique elements—the value is also the key. The unordered version of

`set` is `unordered_set`. For more information, see [set Class](#) and [unordered_set Class](#).

Both `map` and `set` only allow one instance of a key or element to be inserted into the container. If multiple instances of elements are required, use `multimap` or `multiset`. The unordered versions are `unordered_multimap` and `unordered_multiset`. For more information, see [multimap Class](#), [unordered_multimap Class](#), [multiset Class](#), and [unordered_multiset Class](#).

Ordered maps and sets support bi-directional iterators, and their unordered counterparts support forward iterators. For more information, see [Iterators](#).

Heterogeneous Lookup in Associative Containers (C++14)

The ordered associative containers (`map`, `multimap`, `set` and `multiset`) now support heterogeneous lookup, which means that you are no longer required to pass the exact same object type as the key or element in member functions such as `find()` and `lower_bound()`. Instead, you can pass any type for which an overloaded `operator<` is defined that enables comparison to the key type.

Heterogeneous lookup is enabled on an opt-in basis when you specify the `std::less<>` or `std::greater<>` "diamond functor" comparator when declaring the container variable, as shown here:

```
std::set<BigObject, std::less<>> myNewSet;
```

If you use the default comparator, then the container behaves exactly as it did in C++11 and earlier.

The following example shows how to overload `operator<` in order to enable users of a `std::set` to do lookups simply by passing in a small string that can be compared to each object's `BigObject::id` member.

```

#include <set>
#include <string>
#include <iostream>
#include <functional>

using namespace std;

class BigObject
{
public:
    string id;
    explicit BigObject(const string& s) : id(s) {}
    bool operator< (const BigObject& other) const
    {
        return this->id < other.id;
    }

    // Other members....
};

inline bool operator<(const string& otherId, const BigObject& obj)
{
    return otherId < obj.id;
}

inline bool operator<(const BigObject& obj, const string& otherId)
{
    return obj.id < otherId;
}

int main()
{
    // Use C++14 brace-init syntax to invoke BigObject(string).
    // The s suffix invokes string ctor. It is a C++14 user-defined
    // literal defined in <string>
    BigObject b1{ "42F"s };
    BigObject b2{ "52F"s };
    BigObject b3{ "62F"s };
    set<BigObject, less<>> myNewSet; // C++14
    myNewSet.insert(b1);
    myNewSet.insert(b2);
    myNewSet.insert(b3);
    auto it = myNewSet.find(string("62F"));
    if (it != myNewSet.end())
        cout << "myNewSet element = " << it->id << endl;
    else
        cout << "element not found " << endl;

    // Keep console open in debug mode:
    cout << endl << "Press Enter to exit.";
    string s;
    getline(cin, s);
    return 0;
}

//Output: myNewSet element = 62F

```

The following member functions in map, multimap, set and multiset have been overloaded to support heterogeneous lookup:

1. find
2. count
3. lower_bound

4. `upper_bound`

5. `equal_range`

Container Adapters

A container adapter is a variation of a sequence or associative container that restricts the interface for simplicity and clarity. Container adapters do not support iterators.

A `queue` container follows FIFO (first in, first out) semantics. The first element *pushed*—that is, inserted into the queue—is the first to be *popped*—that is, removed from the queue. For more information, see [queue Class](#).

A `priority_queue` container is organized such that the element that has the highest value is always first in the queue. For more information, see [priority_queue Class](#).

A `stack` container follows LIFO (last in, first out) semantics. The last element pushed on the stack is the first element popped. For more information, see [stack Class](#).

Because container adapters do not support iterators, they cannot be used with the C++ Standard Library algorithms. For more information, see [Algorithms](#).

Requirements for Container Elements

In general, elements inserted into a C++ Standard Library container can be of just about any object type if they are copyable. Movable-only elements—for example, those such as `vector<unique_ptr<T>>` that are created by using `unique_ptr<>` will work as long as you don't call member functions that attempt to copy them.

The destructor is not permitted to throw an exception.

Ordered associative containers—described earlier in this article—must have a public comparison operator defined. (By default, the operator is `operator<`, but even types that don't work with `operator<` are supported.

Some operations on containers might also require a public default constructor and a public equivalence operator. For example, the unordered associative containers require support for equality and hashing.

Accessing Container Elements

The elements of containers are accessed by using iterators. For more information, see [Iterators](#).

NOTE

You can also use [range-based for loops](#) to iterate over C++ Standard Library collections.

Comparing containers

All containers overload the `operator==` for comparing two containers of the same type that have the same element type. You can use `==` to compare a `vector<string>` to another `vector<string>`, but you cannot use it to compare a `vector<string>` to a `list<string>` or a `vector<string>` to a `vector<char*>`. In C++98/03 you can use [std::equal](#) or [std::mismatch](#) to compare dissimilar container types and/or element types. In C++11 you can also use [std::is_permutation](#). But in all these cases the functions assume that the containers are the same length. If the second range is shorter than the first, then undefined behavior results. If the second range is longer, results can still be incorrect because the comparison never continues past the end of the first range.

Comparing dissimilar containers (C++14)

In C++14 and later, you can compare dissimilar containers and/or dissimilar elements types by using one of the `std::equal`, `std::mismatch`, or `std::is_permutation` function overloads that take two complete ranges.

These overloads enable you to compare containers with different lengths. These overloads are much less susceptible to user error, and are optimized to return false in constant time when containers of dissimilar lengths are compared. Therefore, we recommend you use these overloads unless (1) you have a very clear reason not to, or (2) you are using a [std::list](#) container, which does not benefit from the dual-range optimizations.

NOTE

This topic is in the Microsoft C++ documentation as a nonfunctional example of containers used in the C++ Standard Library. For more information, see [C++ Standard Library Containers](#).

Describes an object that controls a varying-length sequence of elements, typically of type `Ty`. The sequence is stored in different ways, depending on the actual container.

A container constructor or member function may find occasion to call the constructor **`Ty(const Ty&)`** or the function **`Ty::operator=(const Ty&)`**. If such a call throws an exception, the container object is obliged to maintain its integrity, and to rethrow any exception it catches. You can safely swap, assign to, erase, or destroy a container object after it throws one of these exceptions. In general, however, you cannot otherwise predict the state of the sequence controlled by the container object.

A few additional caveats:

- If the expression `~Ty` throws an exception, the resulting state of the container object is undefined.
- If the container stores an allocator object `al`, and `al` throws an exception other than as a result of a call to `al.allocate`, the resulting state of the container object is undefined.
- If the container stores a function object `comp`, to determine how to order the controlled sequence, and `comp` throws an exception of any kind, the resulting state of the container object is undefined.

The container classes defined by C++ Standard Library satisfy several additional requirements, as described in the following paragraphs.

Container template class `list` provides deterministic, and useful, behavior even in the presence of the exceptions described above. For example, if an exception is thrown during the insertion of one or more elements, the container is left unaltered and the exception is rethrown.

For *all* the container classes defined by C++ Standard Library, if an exception is thrown during calls to the following member functions, `insert`, `push_back`, or `push_front`, the container is left unaltered and the exception is rethrown.

For *all* the container classes defined by C++ Standard Library, no exception is thrown during calls to the following member functions: `pop_back`, `pop_front`.

The member function `erase` throws an exception only if a copy operation (assignment or copy construction) throws an exception.

Moreover, no exception is thrown while copying an iterator returned by a member function.

The member function `swap` makes additional promises for *all* container classes defined by C++ Standard Library:

- The member function throws an exception only if the container stores an allocator object `al`, and `al` throws an exception when copied.
- References, pointers, and iterators that designate elements of the controlled sequences being swapped remain valid.

An object of a container class defined by C++ Standard Library allocates and frees storage for the sequence it controls through a stored object of type `Alloc`, which is typically a template parameter. Such an allocator object must have the same external interface as an object of class `allocator<Ty>`. In particular, `Alloc` must be the same type as `Alloc::rebind<value_type>::other`.

For *all* container classes defined by C++ Standard Library, the member function `Alloc get_allocator const;` returns a copy of the stored allocator object. Note that the stored allocator object is *not* copied when the container object is assigned. All constructors initialize the value stored in `allocator`, to `Alloc` if the constructor contains no allocator parameter.

According to the C++ Standard, a container class defined by the C++ Standard Library can assume that:

- All objects of class `Alloc` compare equal.
- Type `Alloc::const_pointer` is the same as `const Ty *`.
- Type `Alloc::const_reference` is the same as `const Ty&`.
- Type `Alloc::pointer` is the same as `Ty *`.
- Type `Alloc::reference` is the same as `Ty&`.

In this implementation, however, containers do not make such simplifying assumptions. Thus, they work properly with allocator objects that are more ambitious:

- All objects of class `Alloc` does not need to compare equal. (You can maintain multiple pools of storage.)
- Type `Alloc::const_pointer` does not need to be the same as `const Ty *`. (A const pointer can be a class.)
- Type `Alloc::pointer` does not need to be the same as `Ty *`. (A pointer can be a class.)

Reference

Typedefs

const_iterator	Describes an object that can serve as a constant iterator for the controlled sequence.
const_reference	Describes an object that can serve as a constant reference to an element of the controlled sequence.
const_reverse_iterator	Describes an object that can serve as a constant reverse iterator for the controlled sequence.
difference_type	Describes an object that can represent the difference between the addresses of any two elements in the controlled sequence.
iterator	Describes an object that can serve as an iterator for the controlled sequence.
reference	Describes an object that can serve as a reference to an element of the controlled sequence.
reverse_iterator	Describes an object that can serve as a reverse iterator for the controlled sequence.
size_type	Describes an object that can represent the length of any controlled sequence.
value_type	Acts a synonym for the template parameter <code>Ty</code> .

Member Functions

begin	Returns an iterator that points at the first element of the sequence (or just beyond the end of an empty sequence).
clear	Calls erase(begin, end) .
empty	Returns true for an empty controlled sequence.

--	--

end	Returns an iterator that points just beyond the end of the sequence.
erase	Erases an element.
max_size	Returns the length of the longest sequence that the object can control, in constant time regardless of the length of the controlled sequence.
rbegin	Returns a reverse iterator that points just beyond the end of the controlled sequence, designating the beginning of the reverse sequence.
rend	The member function returns a reverse iterator that points at the first element of the sequence (or just beyond the end of an empty sequence), designating the end of the reverse sequence.
size	Returns the length of the controlled sequence, in constant time regardless of the length of the controlled sequence.
swap	

Sample Container Typedefs

Container Class::clear

5/7/2019 • 2 minutes to read • [Edit Online](#)

NOTE

This topic is in the Microsoft C++ documentation as a nonfunctional example of containers used in the C++ Standard Library. For more information, see [C++ Standard Library Containers](#).

Calls [erase\(begin, end\)](#).

Syntax

```
void clear();
```

See also

[Sample Container Class](#)

Container Class::empty

5/7/2019 • 2 minutes to read • [Edit Online](#)

NOTE

This topic is in the Microsoft C++ documentation as a nonfunctional example of containers used in the C++ Standard Library. For more information, see [C++ Standard Library Containers](#).

Returns **true** for an empty controlled sequence.

Syntax

```
bool empty() const;
```

See also

[Sample Container Class](#)

Container Class::end

5/7/2019 • 2 minutes to read • [Edit Online](#)

NOTE

This topic is in the Microsoft C++ documentation as a nonfunctional example of containers used in the C++ Standard Library. For more information, see [C++ Standard Library Containers](#).

Returns an iterator that points just beyond the end of the sequence.

Syntax

```
const_iterator end() const;  
  
iterator end();
```

See also

[Sample Container Class](#)

Container Class::erase

5/7/2019 • 2 minutes to read • [Edit Online](#)

NOTE

This topic is in the Microsoft C++ documentation as a nonfunctional example of containers used in the C++ Standard Library. For more information, see [C++ Standard Library Containers](#).

Erases an element.

Syntax

```
iterator erase(  
    iterator _Where);  
  
iterator erase(  
    iterator first,  
    iterator last);
```

Remarks

The first member function removes the element of the controlled sequence pointed to by *_Where*. The second member function removes the elements of the controlled sequence in the range [*first*, *last*). Both return an iterator that designates the first element remaining beyond any elements removed, or [end](#) if no such element exists.

The member functions throw an exception only if a copy operation throws an exception.

Container Class::max_size

5/7/2019 • 2 minutes to read • [Edit Online](#)

NOTE

This topic is in the Microsoft C++ documentation as a nonfunctional example of containers used in the C++ Standard Library. For more information, see [C++ Standard Library Containers](#).

Returns the length of the longest sequence that the object can control, in constant time regardless of the length of the controlled sequence.

Syntax

```
size_type max_size() const;
```

See also

[Sample Container Class](#)

Container Class::rbegin

5/7/2019 • 2 minutes to read • [Edit Online](#)

NOTE

This topic is in the Microsoft C++ documentation as a nonfunctional example of containers used in the C++ Standard Library. For more information, see [C++ Standard Library Containers](#).

Returns a reverse iterator that points just beyond the end of the controlled sequence, designating the beginning of the reverse sequence.

Syntax

```
const_reverse_iterator rbegin() const;  
  
reverse_iterator rbegin();
```

See also

[Sample Container Class](#)

Container Class::rend

5/7/2019 • 2 minutes to read • [Edit Online](#)

NOTE

This topic is in the Microsoft C++ documentation as a nonfunctional example of containers used in the C++ Standard Library. For more information, see [C++ Standard Library Containers](#).

The member function returns a reverse iterator that points at the first element of the sequence (or just beyond the end of an empty sequence), designating the end of the reverse sequence.

Syntax

```
const_reverse_iterator rend() const;  
reverse_iterator rend();
```

See also

[Sample Container Class](#)

Container Class::size

5/7/2019 • 2 minutes to read • [Edit Online](#)

NOTE

This topic is in the Microsoft C++ documentation as a nonfunctional example of containers used in the C++ Standard Library. For more information, see [C++ Standard Library Containers](#).

Returns the length of the controlled sequence, in constant time regardless of the length of the controlled sequence.

Syntax

```
size_type size() const;
```

See also

[Sample Container Class](#)

Container Class::swap

5/7/2019 • 2 minutes to read • [Edit Online](#)

NOTE

This topic is in the Microsoft C++ documentation as a nonfunctional example of containers used in the C++ Standard Library. For more information, see [C++ Standard Library Containers](#).

Swaps the controlled sequences between ***this** and its argument.

Syntax

```
void swap(Container& right);
```

Remarks

If ***this.get_allocator == right.get_allocator**, it does a swap in constant time. Otherwise, it performs a number of element assignments and constructor calls proportional to the number of elements in the two controlled sequences.

Iterators

5/7/2019 • 4 minutes to read • [Edit Online](#)

An iterator is an object that can iterate over elements in a C++ Standard Library container and provide access to individual elements. The C++ Standard Library containers all provide iterators so that algorithms can access their elements in a standard way without having to be concerned with the type of container the elements are stored in.

You can use iterators explicitly using member and global functions such as `begin()` and `end()` and operators such as `++` and `--` to move forward or backward. You can also use iterators implicitly with a range-for loop or (for some iterator types) the subscript operator `[]`.

In the C++ Standard Library, the beginning of a sequence or range is the first element. The end of a sequence or range is always defined as one past the last element. The global functions `begin` and `end` return iterators to a specified container. The typical explicit iterator loop over all elements in a container looks like this:

```
vector<int> vec{ 0,1,2,3,4 };
for (auto it = begin(vec); it != end(vec); it++)
{
    // Access element using dereference operator
    cout << *it << " ";
}
```

The same thing can be accomplished more simply with a range-for loop:

```
for (auto num : vec)
{
    // no dereference operator
    cout << num << " ";
}
```

There are five categories of iterators. In order of increasing power, the categories are:

- **Output.** An *output iterator* `x` can iterate forward over a sequence by using the `++` operator, and can write an element only once, by using the `*` operator.
- **Input.** An *input iterator* `x` can iterate forward over a sequence by using the `++` operator, and can read an element any number of times by using the `*` operator. You can compare input iterators by using the `++` and `!=` operators. After you increment any copy of an input iterator, none of the other copies can safely be compared, dereferenced, or incremented thereafter.
- **Forward.** A *forward iterator* `x` can iterate forward over a sequence using the `++` operator and can read any element or write non-const elements any number of times by using the `*` operator. You can access element members by using the `->` operator and compare forward iterators by using the `==` and `!=` operators. You can make multiple copies of a forward iterator, each of which can be dereferenced and incremented independently. A forward iterator that is initialized without reference to any container is called a *null forward iterator*. Null forward iterators always compare equal.
- **Bidirectional.** A *bidirectional iterator* `x` can take the place of a forward iterator. You can, however, also decrement a bidirectional iterator, as in `--x`, `x--`, or `(v = *x--)`. You can access element members and compare bidirectional iterators in the same way as forward iterators.
- **Random access.** A *random-access iterator* `x` can take the place of a bidirectional iterator. With a random access iterator you can use the subscript operator `[]` to access elements. You can use the `+`, `-`, `+=` and `-=`

operators to move forward or backward a specified number of elements and to calculate the distance between iterators. You can compare bidirectional iterators by using `==`, `!=`, `<`, `>`, `<=`, and `>=`.

All iterators can be assigned or copied. They are assumed to be lightweight objects and are often passed and returned by value, not by reference. Note also that none of the operations previously described can throw an exception when performed on a valid iterator.

The hierarchy of iterator categories can be summarized by showing three sequences. For write-only access to a sequence, you can use any of:

```
output iterator
-> forward iterator
-> bidirectional iterator
-> random-access iterator
```

The right arrow means "can be replaced by." Any algorithm that calls for an output iterator should work nicely with a forward iterator, for example, but *not* the other way around.

For read-only access to a sequence, you can use any of:

```
input iterator
-> forward iterator
-> bidirectional iterator
-> random-access iterator
```

An input iterator is the weakest of all categories, in this case.

Finally, for read/write access to a sequence, you can use any of:

```
forward iterator
-> bidirectional iterator
-> random-access iterator
```

An object pointer can always serve as a random-access iterator, so it can serve as any category of iterator if it supports the proper read/write access to the sequence it designates.

An iterator `Iterator` other than an object pointer must also define the member types required by the specialization `iterator_traits<Iterator>`. Note that these requirements can be met by deriving `Iterator` from the public base class `iterator`.

It is important to understand the promises and limitations of each iterator category to see how iterators are used by containers and algorithms in the C++ Standard Library.

NOTE

You can avoid using iterators explicitly by using range-for loops. For more information, see [Range-based for statement](#).

Microsoft C++ now offers checked iterators and debug iterators to ensure that you do not overwrite the bounds of your container. For more information, see [Checked Iterators](#) and [Debug Iterator Support](#).

[Thread Safety in the C++ Standard Library](#)

Algorithms

10/31/2018 • 4 minutes to read • [Edit Online](#)

Algorithms are a fundamental part of the C++ Standard Library. Algorithms do not work with containers themselves but rather with iterators. Therefore, the same algorithm can be used by most if not all of the C++ Standard Library containers. This section discusses the conventions and terminology of the C++ Standard Library algorithms.

Remarks

The descriptions of the algorithm template functions employ several shorthand phrases:

- The phrase "in the range $[A, B)$ " means the sequence of zero or more discrete values beginning with A up to but not including B . A range is valid only if B is reachable from A ; you can store A in an object N ($N = A$), increment the object zero or more times ($++N$), and have the object compare equal to B after a finite number of increments ($N == B$).
- The phrase "each N in the range $[A, B)$ " means that N begins with the value A and is incremented zero or more times until it equals the value B . The case $N == B$ is not in the range.
- The phrase "the lowest value of N in the range $[A, B)$ such that X " means that the condition X is determined for each N in the range $[A, B)$ until the condition X is met.
- The phrase "the highest value of N in the range $[A, B)$ such that X " means that X is determined for each N in the range $[A, B)$. The function stores in K a copy of N each time the condition X is met. If any such store occurs, the function replaces the final value of N , which equals B , with the value of K . For a bidirectional or random-access iterator, however, it can also mean that N begins with the highest value in the range and is decremented over the range until the condition X is met.
- Expressions such as $X - Y$, where X and Y can be iterators other than random-access iterators, are intended in the mathematical sense. The function does not necessarily evaluate operator $-$ if it must determine such a value. The same is also true for expressions such as $X + N$ and $X - N$, where N is an integer type.

Several algorithms make use of a predicate that performs a pairwise comparison, such as with `operator==`, to yield a **bool** result. The predicate function `operator==`, or any replacement for it, must not alter either of its operands. It must yield the same **bool** result every time it is evaluated, and it must yield the same result if a copy of either operand is substituted for the operand.

Several algorithms make use of a predicate that must impose a strict weak ordering on pairs of elements from a sequence. For the predicate $pred(X, Y)$:

- Strict means that $pred(X, X)$ is false.
- Weak means that X and Y have an equivalent ordering if $!pred(X, Y) \ \&\& \ !pred(Y, X)$ ($X == Y$ does not need to be defined).
- Ordering means that $pred(X, Y) \ \&\& \ pred(Y, Z)$ implies $pred(X, Z)$.

Some of these algorithms implicitly use the predicate $X < Y$. Other predicates that typically satisfy the strict weak ordering requirement are $X > Y$, `less`(X, Y), and `greater`(X, Y). Note, however, that predicates such as $X <= Y$ and $X >= Y$ do not satisfy this requirement.

A sequence of elements designated by iterators in the range $[First, Last)$ is a sequence ordered by operator $<$ if, for each N in the range $[0, Last - First)$ and for each M in the range $(N, Last - First)$ the predicate $!(*(First + M) < *(First + N))$ is false.

+ N) is true. (Note that the elements are sorted in ascending order.) The predicate function `operator<`, or any replacement for it, must not alter either of its operands. It must yield the same **bool** result every time it is evaluated, and it must yield the same result if a copy of either operand is substituted for the operand. Moreover, it must impose a strict weak ordering on the operands it compares.

A sequence of elements designated by iterators in the range `[First, Last)` is a heap ordered by `operator<` if, for each N in the range `[1, Last - First)` the predicate `!(*First < *(First + N))` is true. (The first element is the largest.) Its internal structure is otherwise known only to the template functions `make_heap`, `pop_heap`, and `push_heap`. As with an ordered sequence, the predicate function `operator<`, or any replacement for it, must not alter either of its operands, and it must impose a strict weak ordering on the operands it compares. It must yield the same **bool** result every time it is evaluated, and it must yield the same result if a copy of either operand is substituted for the operand.

The C++ Standard Library algorithms are located in the `<algorithm>` and `<numeric>` header files.

Allocators

10/31/2018 • 3 minutes to read • [Edit Online](#)

Allocators are used by the C++ Standard Library to handle the allocation and deallocation of elements stored in containers. All C++ Standard Library containers except `std::array` have a template parameter of type `allocator<Type>`, where `Type` represents the type of the container element. For example, the vector class is declared as follows:

```
template <
    class Type,
    class Allocator = allocator<Type>
>
class vector
```

The C++ Standard Library provides a default implementation for an allocator. In C++11 and later, the default allocator is updated to expose a smaller interface; the new allocator is called a *minimal allocator*. In particular, the minimal allocator's `construct()` member supports move semantics, which can greatly improve performance. In most cases, this default allocator should be sufficient. In C++11 all the Standard Library types and functions that take an allocator type parameter support the minimal allocator interface, including `std::function`, `shared_ptr`, `allocate_shared()`, and `basic_string`. For more information on the default allocator, see [allocator Class](#).

Writing Your Own Allocator (C++11)

The default allocator uses **new** and **delete** to allocate and deallocate memory. If you want to use a different method of memory allocation, such as using shared memory, then you must create your own allocator. If you are targeting C++11 and you need to write a new custom allocator, make it a minimal allocator if possible. Even if you have already implemented an old-style allocator, consider modifying it to be a *minimal allocator* in order to take advantage of the more efficient `construct()` method that will be provided for you automatically.

A minimal allocator requires much less boilerplate and enable you to focus on the `allocate` and `deallocate` member functions which do all of the work. When creating a minimal allocator, do not implement any members except the ones shown in the example below:

1. a converting copy constructor (see example)
2. `operator==`
3. `operator!=`
4. `allocate`
5. `deallocate`

The C++11 default `construct()` member that will be provided for you does perfect forwarding and enables move semantics; it is much more efficient in many cases than the older version.

WARNING

At compile time, the C++ Standard Library uses the `allocator_traits` class to detect which members you have explicitly provided and provides a default implementation for any members that are not present. Do not interfere with this mechanism by providing a specialization of `allocator_traits` for your allocator!

The following example shows a minimal implementation of an allocator that uses `malloc` and `free`. Note the use of the new exception type `std::bad_array_new_length` which is thrown if the array size is less than zero or greater than the maximum allowed size.

```
#pragma once
#include <stdlib.h> //size_t, malloc, free
#include <new> // bad_alloc, bad_array_new_length
#include <memory>
template <class T>
struct Mallocator
{
    typedef T value_type;
    Mallocator() noexcept {} //default ctor not required by C++ Standard Library

    // A converting copy constructor:
    template<class U> Mallocator(const Mallocator<U>&) noexcept {}
    template<class U> bool operator==(const Mallocator<U>&) const noexcept
    {
        return true;
    }
    template<class U> bool operator!=(const Mallocator<U>&) const noexcept
    {
        return false;
    }
    T* allocate(const size_t n) const;
    void deallocate(T* const p, size_t) const noexcept;
};

template <class T>
T* Mallocator<T>::allocate(const size_t n) const
{
    if (n == 0)
    {
        return nullptr;
    }
    if (n > static_cast<size_t>(-1) / sizeof(T))
    {
        throw std::bad_array_new_length();
    }
    void* const pv = malloc(n * sizeof(T));
    if (!pv) { throw std::bad_alloc(); }
    return static_cast<T*>(pv);
}

template<class T>
void Mallocator<T>::deallocate(T * const p, size_t) const noexcept
{
    free(p);
}
```

Writing Your Own Allocator (C++03)

In C++03, any allocator used with C++ Standard Library containers must implement the following type definitions:

<code>const_pointer</code>	<code>rebind</code>
<code>const_reference</code>	<code>reference</code>
<code>difference_type</code>	<code>size_type</code>
<code>pointer</code>	<code>value_type</code>

In addition, any allocator used with C++ Standard Library containers must implement the following methods:

Constructor	<code>deallocate</code>
Copy constructor	<code>destroy</code>
Destructor	<code>max_size</code>
<code>address</code>	<code>operator==</code>
<code>allocate</code>	<code>operator!=</code>
<code>construct</code>	

For more information on these type definitions and methods, see [allocator Class](#).

[C++ Standard Library Reference](#)

Function Objects in the C++ Standard Library

3/18/2019 • 2 minutes to read • [Edit Online](#)

A *function object*, or *functor*, is any type that implements `operator()`. This operator is referred to as the *call operator* or sometimes the *application operator*. The C++ Standard Library uses function objects primarily as sorting criteria for containers and in algorithms.

Function objects provide two main advantages over a straight function call. The first is that a function object can contain state. The second is that a function object is a type and therefore can be used as a template parameter.

Creating a Function Object

To create a function object, create a type and implement `operator()`, such as:

```
class Functor
{
public:
    int operator()(int a, int b)
    {
        return a < b;
    }
};

int main()
{
    Functor f;
    int a = 5;
    int b = 7;
    int ans = f(a, b);
}
```

The last line of the `main` function shows how you call the function object. This call looks like a call to a function, but it's actually calling `operator()` of the `Functor` type. This similarity between calling a function object and a function is how the term function object came about.

Function Objects and Containers

The C++ Standard Library contains several function objects in the `<functional>` header file. One use of these function objects is as a sorting criterion for containers. For example, the `set` container is declared as follows:

```
template <class Key,
          class Traits=less<Key>,
          class Allocator=allocator<Key>>
class set
```

The second template argument is the function object `less`. This function object returns **true** if the first parameter is less than the second parameter. Since some containers sort their elements, the container needs a way of comparing two elements. The comparison is done by using the function object. You can define your own sorting criteria for containers by creating a function object and specifying it in the template list for the container.

Function Objects and Algorithms

Another use of functional objects is in algorithms. For example, the `remove_if` algorithm is declared as follows:

```
template <class ForwardIterator, class Predicate>
ForwardIterator remove_if(
    ForwardIterator first,
    ForwardIterator last,
    Predicate pred);
```

The last argument to `remove_if` is a function object that returns a boolean value (a *predicate*). If the result of the function object is **true**, then the element is removed from the container being accessed by the iterators `first` and `last`. You can use any of the function objects declared in the [<functional>](#) header for the argument `pred` or you can create your own.

What a Stream Is

10/31/2018 • 2 minutes to read • [Edit Online](#)

Like C, C++ does not have built-in input/output capability. All C++ compilers, however, come bundled with a systematic, object-oriented I/O package, known as the `iostream` classes. The stream is the central concept of the `iostream` classes. You can think of a stream object as a smart file that acts as a source and destination for bytes. A stream's characteristics are determined by its class and by customized insertion and extraction operators.

Through device drivers, the disk operating system deals with the keyboard, screen, printer, and communication ports as extended files. The `iostream` classes interact with these extended files. Built-in classes support reading from and writing to memory with syntax identical to that for disk I/O, which makes it easy to derive stream classes.

In This Section

[Input/Output Alternatives](#)

See also

[iostream Programming](#)

Input/Output Alternatives

5/7/2019 • 2 minutes to read • [Edit Online](#)

The Microsoft C++ compiler provides several alternatives for I/O programming:

- C run-time library direct, unbuffered I/O.
- ANSI C run-time library stream I/O.
- Console and port direct I/O.
- Microsoft Foundation Class Library.
- Microsoft C++ Standard Library.

The `iostream` classes are useful for buffered, formatted text I/O. They are also useful for unbuffered or binary I/O if you need a C++ programming interface and decide not to use the Microsoft Foundation Class (MFC) library. The `iostream` classes are an object-oriented I/O alternative to the C run-time functions.

You can use `iostream` classes with the Microsoft Windows operating system. String and file streams work without restrictions, but the character-mode stream objects `cin`, `cout`, `cerr`, and `clog` are inconsistent with the Windows graphical user interface. You can also derive custom stream classes that interact directly with the Windows environment.

See also

[What a Stream Is](#)

Output Streams

10/31/2018 • 2 minutes to read • [Edit Online](#)

An output stream object is a destination for bytes. The three most important output stream classes are `ostream`, `ofstream`, and `ostringstream`.

The `ostream` class, through the derived class `basic_ostream`, supports the predefined stream objects:

- `cout` standard output
- `cerr` standard error with limited buffering
- `clog` similar to `cerr` but with full buffering

Objects are rarely constructed from `ostream`; predefined objects are generally used. In some cases, you can reassign predefined objects after program startup. The `ostream` class, which can be configured for buffered or unbuffered operation, is best suited to sequential text-mode output. All functionality of the base class, `ios`, is included in `ostream`. If you construct an object of class `ostream`, you must specify a `streambuf` object to the constructor.

The `ofstream` class supports disk file output. If you need an output-only disk, construct an object of class `ofstream`. You can specify whether `ofstream` objects accept binary or text-mode data when constructing the `ofstream` object or when calling the `open` member function of the object. Many formatting options and member functions apply to `ofstream` objects, and all functionality of the base classes `ios` and `ostream` is included.

If you specify a filename in the constructor, that file is automatically opened when the object is constructed. Otherwise, you can use the `open` member function after invoking the default constructor.

Like the run-time function `sprintf_s`, the `ostringstream` class supports output to in-memory strings. To create a string in memory by using I/O stream formatting, construct an object of class `ostringstream`.

Constructing Output Stream Objects

10/31/2018 • 2 minutes to read • [Edit Online](#)

If you use only the predefined `cout`, `cerr`, or `clog` objects, you do not need to construct an output stream. You must use constructors for:

- [Output File Stream Constructors](#)
- [Output String Stream Constructors](#)

Output File Stream Constructors

You can construct an output file stream in one of two ways:

- Use the default constructor, and then call the `open` member function.

```
ofstream myFile; // Static or on the stack
myFile.open("filename");

ofstream* pmyFile = new ofstream; // On the heap
pmyFile->open("filename");
```

- Specify a filename and mode flags in the constructor call.

```
ofstream myFile("filename", ios_base::out);
```

Output String Stream Constructors

To construct an output string stream, you can use `ostringstream` in the following way:

```
using namespace std;
// ...
ostringstream myString;
myString << "this is a test" << ends;

string sp = myString.str(); // Obtain string
cout << sp << endl;
```

The `ends` "manipulator" adds the necessary terminating null character to the string.

See also

[Output Streams](#)

Using Insertion Operators and Controlling Format

10/31/2018 • 5 minutes to read • [Edit Online](#)

This topic shows how to control format and how to create insertion operators for your own classes. The insertion (<<) operator, which is preprogrammed for all standard C++ data types, sends bytes to an output stream object. Insertion operators work with predefined "manipulators," which are elements that change the default format of integer arguments.

You can control the format with the following options:

- [Output Width](#)
- [Alignment](#)
- [Precision](#)
- [Radix](#)

Output Width

To align output, you specify the output width for each item by placing the `setw` manipulator in the stream or by calling the `width` member function. This example right-aligns the values in a column at least 10 characters wide:

```
// output_width.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main( )
{
    double values[] = { 1.23, 35.36, 653.7, 4358.24 };
    for( int i = 0; i < 4; i++ )
    {
        cout.width(10);
        cout << values[i] << '\n';
    }
}
```

```
    1.23
   35.36
  653.7
4358.24
```

Leading blanks are added to any value fewer than 10 characters wide.

To pad a field, use the `fill` member function, which sets the value of the padding character for fields that have a specified width. The default is a blank. To pad the column of numbers with asterisks, modify the previous **for** loop as follows:

```
for (int i = 0; i < 4; i++)
{
    cout.width(10);
    cout.fill('*');
    cout << values[i] << endl;
}
```

The `endl` manipulator replaces the newline character (`'\n'`). The output looks like this:

```
*****1.23
*****35.36
*****653.7
***4358.24
```

To specify widths for data elements in the same line, use the `setw` manipulator:

```
// setw.cpp
// compile with: /EHsc
#include <iostream>
#include <iomanip>
using namespace std;

int main( )
{
    double values[] = { 1.23, 35.36, 653.7, 4358.24 };
    char *names[] = { "Zoot", "Jimmy", "Al", "Stan" };
    for( int i = 0; i < 4; i++ )
        cout << setw( 7 ) << names[i]
            << setw( 10 ) << values[i] << endl;
}
```

The `width` member function is declared in `<iostream>`. If you use `setw` or any other manipulator with arguments, you must include `<iomanip>`. In the output, strings are printed in a field of width 6 and integers in a field of width 10:

```

Zoot      1.23
Jimmy     35.36
  Al      653.7
Stan    4358.24
```

Neither `setw` nor `width` truncates values. If formatted output exceeds the width, the entire value prints, subject to the stream's precision setting. Both `setw` and `width` affect the following field only. Field width reverts to its default behavior (the necessary width) after one field has been printed. However, the other stream format options remain in effect until changed.

Alignment

Output streams default to right-aligned text. To left-align the names in the previous example and right-align the numbers, replace the **for** loop as follows:

```
for (int i = 0; i < 4; i++)
    cout << setiosflags(ios::left)
        << setw(6) << names[i]
        << resetiosflags(ios::left)
        << setw(10) << values[i] << endl;
```

The output looks like this:

```
Zoot      1.23
Jimmy     35.36
Al        653.7
Stan     4358.24
```

The left-align flag is set by using the `setiosflags` manipulator with the `left` enumerator. This enumerator is defined in the `ios` class, so its reference must include the `ios::` prefix. The `resetiosflags` manipulator turns off the left-align flag. Unlike `width` and `setw`, the effect of `setiosflags` and `resetiosflags` is permanent.

Precision

The default value for floating-point precision is six. For example, the number 3466.9768 prints as 3466.98. To change the way this value prints, use the `setprecision` manipulator. The manipulator has two flags: `fixed` and `scientific`. If `fixed` is set, the number prints as 3466.976800. If `scientific` is set, it prints as 3.4669773+003.

To display the floating-point numbers shown in [Alignment](#) with one significant digit, replace the **for** loop as follows:

```
for (int i = 0; i <4; i++)
    cout << setiosflags(ios::left)
          << setw(6)
          << names[i]
          << resetiosflags(ios::left)
          << setw(10)
          << setprecision(1)
          << values[i]
          << endl;
```

The program prints this list:

```
Zoot      1
Jimmy     4e+01
Al        7e+02
Stan     4e+03
```

To eliminate scientific notation, insert this statement before the **for** loop:

```
cout << setiosflags(ios::fixed);
```

With fixed notation, the program prints with one digit after the decimal point.

```
Zoot      1.2
Jimmy     35.4
Al        653.7
Stan     4358.2
```

If you change the `ios::fixed` flag to `ios::scientific`, the program prints this:

```
Zoot      1.2e+00
Jimmy     3.5e+01
Al        6.5e+02
Stan     4.4e+03
```

Again, the program prints one digit after the decimal point. If either `ios::fixed` or `ios::scientific` is set, the precision value determines the number of digits after the decimal point. If neither flag is set, the precision value determines the total number of significant digits. The `resetiosflags` manipulator clears these flags.

Radix

The `dec`, `oct`, and `hex` manipulators set the default radix for input and output. For example, if you insert the `hex` manipulator into the output stream, the object correctly translates the internal data representation of integers into a hexadecimal output format. The numbers are displayed with digits a through f in lower case if the [uppercase](#) flag is clear (the default); otherwise, they are displayed in upper case. The default radix is `dec` (decimal).

Quoted strings (C++14)

When you insert a string into a stream, you can easily retrieve the same string back by calling the `stringstream::str()` member function. However, if you want to use the extraction operator to insert the stream into a new string at a later point, you may get an unexpected result because the `>>` operator by default will stop when it encounters the first whitespace character.

```
std::stringstream ss;
std::string inserted = "This is a sentence.";
std::string extracted;

ss << inserted;
ss >> extracted;

std::cout << inserted;    // This is a sentence.
std::cout << extracted;   // This
```

This behavior can be overcome manually, but to make string round-tripping more convenient, C++14 adds the `std::quoted` stream manipulator in `<iomanip>`. Upon insertion, `quoted()` surrounds the string with a delimiter (double quote `' '` by default) and upon extraction manipulates the stream to extract all characters until the final delimiter is encountered. Any embedded quotes are escaped with an escape character (`'\\'` by default).

The delimiters are present only in the stream object; they are not present in the extracted string but they are present in the string returned by [basic_stringstream::str](#).

The whitespace behavior of the insertion and extraction operations is independent of how a string is represented in code, so the `quoted` operator is useful regardless of whether the input string is a raw string literal or a regular string. The input string, whatever its format, can have embedded quotes, line breaks, tabs, and so on and all these will be preserved by the `quoted()` manipulator.

For more information and full code examples, see [quoted](#).

Output File Stream Member Functions

10/31/2018 • 3 minutes to read • [Edit Online](#)

Output stream member functions have three types: those that are equivalent to manipulators, those that perform unformatted write operations, and those that otherwise modify the stream state and have no equivalent manipulator or insertion operator. For sequential, formatted output, you might use only insertion operators and manipulators. For random-access binary disk output, you use other member functions, with or without insertion operators.

The open Function for Output Streams

To use an output file stream ([ofstream](#)), you must associate that stream with a specific disk file in the constructor or the `open` function. If you use the `open` function, you can reuse the same stream object with a series of files. In either case, the arguments describing the file are the same.

When you open the file associated with an output stream, you generally specify an `open_mode` flag. You can combine these flags, which are defined as enumerators in the `ios` class, with the bitwise OR (`|`) operator. See [ios_base::openmode](#) for a list of the enumerators.

Three common output stream situations involve mode options:

- Creating a file. If the file already exists, the old version is deleted.

```
ostream ofile("FILENAME");  
// Default is ios::out  
  
ofstream ofile("FILENAME", ios::out);  
// Equivalent to above
```

- Appending records to an existing file or creating one if it does not exist.

```
ofstream ofile("FILENAME", ios::app);
```

- Opening two files, one at a time, on the same stream.

```
ofstream ofile();  
ofile.open("FILE1", ios::in);  
// Do some output  
ofile.close();    // FILE1 closed  
ofile.open("FILE2", ios::in);  
// Do some more output  
ofile.close();    // FILE2 closed  
// When ofile goes out of scope it is destroyed.
```

The put

The **put** function writes one character to the output stream. The following two statements are the same by default, but the second is affected by the stream's format arguments:

```
cout.put('A');

// Exactly one character written
cout <<'A'; // Format arguments 'width' and 'fill' apply
```

The write

The `write` function writes a block of memory to an output file stream. The length argument specifies the number of bytes written. This example creates an output file stream and writes the binary value of the `Date` structure to it:

```
// write_function.cpp
// compile with: /EHsc
#include <fstream>
using namespace std;

struct Date
{
    int mo, da, yr;
};

int main( )
{
    Date dt = { 6, 10, 92 };
    ofstream tfile( "date.dat" , ios::binary );
    tfile.write( (char *) &dt, sizeof dt );
}
```

The `write` function does not stop when it reaches a null character, so the complete class structure is written. The function takes two arguments: a **char** pointer and a count of characters to write. Note the required cast to **char*** before the address of the structure object.

The seekp and tellp Functions

An output file stream keeps an internal pointer that points to the position where data is to be written next. The `seekp` member function sets this pointer and thus provides random-access disk file output. The `tellp` member function returns the file position. For examples that use the input stream equivalents to `seekp` and `tellp`, see [The seekg and tellg Functions](#).

The close Function for Output Streams

The `close` member function closes the disk file associated with an output file stream. The file must be closed to complete all disk output. If necessary, the `ofstream` destructor closes the file for you, but you can use the `close` function if you need to open another file for the same stream object.

The output stream destructor automatically closes a stream's file only if the constructor or the `open` member function opened the file. If you pass the constructor a file descriptor for an already-open file or use the `attach` member function, you must close the file explicitly.

Error Processing Functions

Use these member functions to test for errors while writing to a stream:

FUNCTION	RETURN VALUE
<code>bad</code>	Returns true if there is an unrecoverable error.

FUNCTION	RETURN VALUE
<code>fail</code>	Returns true if there is an unrecoverable error or an "expected" condition, such as a conversion error, or if the file is not found. Processing can often resume after a call to <code>clear</code> with a zero argument.
<code>good</code>	Returns true if there is no error condition (unrecoverable or otherwise) and the end-of-file flag is not set.
<code>eof</code>	Returns true on the end-of-file condition.
<code>clear</code>	Sets the internal error state. If called with the default arguments, it clears all error bits.
<code>[rdstate](basic-ios-class.md#rdstate)</code>	Returns the current error state.

The **!** operator is overloaded to perform the same function as the `fail` function. Thus the expression:

```
if(!cout)...
```

is equivalent to:

```
if(cout.fail())...
```

The **void*()** operator is overloaded to be the opposite of the **!** operator; thus the expression:

```
if(cout)...
```

is equal to:

```
if(!cout.fail())...
```

The **void*()** operator is not equivalent to `good` because it does not test for the end of file.

[Output Streams](#)

Effects of Buffering

10/31/2018 • 2 minutes to read • [Edit Online](#)

The following example shows the effects of buffering. You might expect the program to print `please wait`, wait 5 seconds, and then proceed. It will not necessarily work this way, however, because the output is buffered.

```
// effects_buffering.cpp
// compile with: /EHsc
#include <iostream>
#include <time.h>
using namespace std;

int main( )
{
    time_t tm = time( NULL ) + 5;
    cout << "Please wait...";
    while ( time( NULL ) < tm )
        ;
    cout << "\nAll done" << endl;
}
```

To make the program work logically, the `cout` object must empty itself when the message is to appear. To flush an `ostream` object, send it the `flush` manipulator:

```
cout <<"Please wait..." <<flush;
```

This step flushes the buffer, ensuring the message prints before the wait. You can also use the `endl` manipulator, which flushes the buffer and outputs a carriage return-linefeed, or you can use the `cin` object. This object (with the `cerr` or `clog` objects) is usually tied to the `cout` object. Thus, any use of `cin` (or of the `cerr` or `clog` objects) flushes the `cout` object.

[Output Streams](#)

Binary Output Files

10/31/2018 • 2 minutes to read • [Edit Online](#)

Streams were originally designed for text, so the default output mode is text. In text mode, the newline character (hexadecimal 10) expands to a carriage return-linefeed (16-bit only). The expansion can cause problems, as shown here:

```
// binary_output_files.cpp
// compile with: /EHsc
#include <fstream>
using namespace std;
int iarray[2] = { 99, 10 };
int main( )
{
    ofstream os( "test.dat" );
    os.write( (char *) iarray, sizeof( iarray ) );
}
```

You might expect this program to output the byte sequence { 99, 0, 10, 0 }; instead, it outputs { 99, 0, 13, 10, 0 }, which causes problems for a program expecting binary input. If you need true binary output, in which characters are written untranslated, you could specify binary output by using the [ofstream](#) constructor openmode argument:

```
// binary_output_files2.cpp
// compile with: /EHsc
#include <fstream>
using namespace std;
int iarray[2] = { 99, 10 };

int main()
{
    ofstream ofs ( "test.dat", ios_base::binary );

    // Exactly 8 bytes written
    ofs.write( (char*)&iarray[0], sizeof(int)*2 );
}
```

Overloading the << Operator for Your Own Classes

10/31/2018 • 2 minutes to read • [Edit Online](#)

Output streams use the insertion (`<<`) operator for standard types. You can also overload the `<<` operator for your own classes.

Example

The `write` function example showed the use of a `Date` structure. A date is an ideal candidate for a C++ class in which the data members (month, day, and year) are hidden from view. An output stream is the logical destination for displaying such a structure. This code displays a date using the `cout` object:

```
Date dt(1, 2, 92);

cout << dt;
```

To get `cout` to accept a `Date` object after the insertion operator, overload the insertion operator to recognize an `ostream` object on the left and a `Date` on the right. The overloaded `<<` operator function must then be declared as a friend of class `Date` so it can access the private data within a `Date` object.

```
// overload_date.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

class Date
{
    int mo, da, yr;
public:
    Date(int m, int d, int y)
    {
        mo = m; da = d; yr = y;
    }
    friend ostream& operator<<(ostream& os, const Date& dt);
};

ostream& operator<<(ostream& os, const Date& dt)
{
    os << dt.mo << '/' << dt.da << '/' << dt.yr;
    return os;
}

int main()
{
    Date dt(5, 6, 92);
    cout << dt;
}
```

```
5/6/92
```

Remarks

The overloaded operator returns a reference to the original `ostream` object, which means you can combine

insertions:

```
cout <<"The date is" <<dt <<flush;
```

Writing Your Own Manipulators Without Arguments

10/31/2018 • 2 minutes to read • [Edit Online](#)

Writing manipulators that do not use arguments requires neither class derivation nor use of complex macros. Suppose your printer requires the pair <ESC>[to enter bold mode. You can insert this pair directly into the stream:

```
cout << "regular " << '\033' << '[' << "boldface" << endl;
```

Or you can define the `bold` manipulator, which inserts the characters:

```
ostream& bold(ostream& os) {  
    return os << '\033' << '[';  
}  
cout << "regular " << bold << "boldface" << endl;
```

The globally defined `bold` function takes an `ostream` reference argument and returns the `ostream` reference. It is not a member function or a friend because it does not need access to any private class elements. The `bold` function connects to the stream because the stream's `<<` operator is overloaded to accept that type of function, using a declaration that looks something like this:

```
_Myt& operator<<(ios_base& (__cdecl *_Pfn)(ios_base&))  
{  
    // call ios_base manipulator  
    (*_Pfn)(*(ios_base *)this);  
  
    return (*this);  
}
```

You can use this feature to extend other overloaded operators. In this case, it is incidental that `bold` inserts characters into the stream. The function is called when it is inserted into the stream, not necessarily when the adjacent characters are printed. Thus, printing could be delayed because of the stream's buffering.

[Output Streams](#)

Input Streams

10/31/2018 • 2 minutes to read • [Edit Online](#)

An input stream object is a source of bytes. The three most important input stream classes are `istream`, `ifstream`, and `istringstream`.

The `istream` class is best used for sequential text-mode input. You can configure objects of class `istream` for buffered or unbuffered operation. All functionality of the base class, `ios`, is included in `istream`. You will rarely construct objects from class `istream`. Instead, you will generally use the predefined `cin` object, which is actually an object of class `ostream`. In some cases, you can assign `cin` to other stream objects after program startup.

The `ifstream` class supports disk file input. If you need an input-only disk file, construct an object of class `ifstream`. You can specify binary or text-mode data. If you specify a filename in the constructor, the file is automatically opened when the object is constructed. Otherwise, you can use the `open` function after invoking the default constructor. Many formatting options and member functions apply to `ifstream` objects. All functionality of the base classes `ios` and `istream` is included in `ifstream`.

Like the library function `sscanf_s`, the `istringstream` class supports input from in-memory strings. To extract data from a character array that has a null terminator, allocate and initialize the string, then construct an object of class `istringstream`.

[iostream Programming](#)

Constructing Input Stream Objects

10/31/2018 • 2 minutes to read • [Edit Online](#)

If you use only the `cin` object, you do not need to construct an input stream. You must construct an input stream if you use:

- [Input File Stream Constructors](#)
- [Input String Stream Constructors](#)

Input File Stream Constructors

There are two ways to create an input file stream:

- Use the **void** argument constructor, then call the `open` member function:

```
ifstream myFile; // On the stack
myFile.open("filename");

ifstream* pmyFile = new ifstream; // On the heap
pmyFile->open("filename");
```

- Specify a filename and mode flags in the constructor invocation, thereby opening the file during the construction process:

```
ifstream myFile("filename");
```

Input String Stream Constructors

Input string stream constructors require the address of preallocated, preinitialized storage:

```
string s("123.45");

double amt;
istringstream myString(s);

//istringstream myString("123.45") also works
myString >> amt; // amt contains 123.45
```

[Input Streams](#)

Using Extraction Operators

10/31/2018 • 2 minutes to read • [Edit Online](#)

The extraction operator (`>>`), which is preprogrammed for all standard C++ data types, is the easiest way to get bytes from an input stream object.

Formatted text input extraction operators depend on white space to separate incoming data values. This is inconvenient when a text field contains multiple words or when commas separate numbers. In such a case, one alternative is to use the unformatted input member function `istream::getline` to read a block of text with white space included, then parse the block with special functions. Another method is to derive an input stream class with a member function such as `GetNextToken`, which can call `istream` members to extract and format character data.

See also

[Input Streams](#)

Testing for Extraction Errors

10/31/2018 • 2 minutes to read • [Edit Online](#)

Output error processing functions, discussed in [Error Processing Functions](#), apply to input streams. Testing for errors during extraction is important. Consider this statement:

```
cin >> n;
```

If `n` is a signed integer, a value greater than 32,767 (the maximum allowed value, or `MAX_INT`) sets the stream's `fail` bit, and the `cin` object becomes unusable. All subsequent extractions result in an immediate return with no value stored.

See also

[Input Streams](#)

Input Stream Manipulators

10/31/2018 • 2 minutes to read • [Edit Online](#)

Many manipulators, such as [setprecision](#), are defined for the `ios` class and thus apply to input streams. Few manipulators, however, actually affect input stream objects. Of those that do, the most important are the radix manipulators, `dec`, `oct`, and `hex`, which determine the conversion base used with numbers from the input stream.

On extraction, the `hex` manipulator enables processing of various input formats. For example, `c`, `C`, `0xc`, `0xC`, `0Xc`, and `0XC` are all interpreted as the decimal integer 12. Any character other than 0 through 9, A through F, a through f, `x`, and `X` terminates the numeric conversion. Thus the sequence `"124n5"` is converted to the number 124 with the [basic_ios::fail](#) bit set.

See also

[Input Streams](#)

Input Stream Member Functions

10/31/2018 • 4 minutes to read • [Edit Online](#)

Input stream member functions are used for disk input. The member functions include:

- [The open Function for Input Streams](#)
- [The get](#)
- [The getline](#)
- [The read](#)
- [The seekg and tellg Functions](#)
- [The close Function for Input Streams](#)

The open Function for Input Streams

If you are using an input file stream (ifstream), you must associate that stream with a specific disk file. You can do this in the constructor, or you can use the `open` function. In either case, the arguments are the same.

You generally specify an `ios_base::openmode` flag when you open the file associated with an input stream (the default mode is `ios::in`). For a list of the `open_mode` flags, see [The open](#). The flags can be combined with the bitwise OR (`|`) operator.

To read a file, first use the `fail` member function to determine whether it exists:

```
istream ifile("FILENAME");

if (ifile.fail())
    // The file does not exist ...
```

The get

The unformatted `get` member function works like the `>>` operator with two exceptions. First, the `get` function includes white-space characters, whereas the extractor excludes white space when the `skipws` flag is set (the default). Second, the `get` function is less likely to cause a tied output stream (`cout`, for example) to be flushed.

A variation of the `get` function specifies a buffer address and the maximum number of characters to read. This is useful for limiting the number of characters sent to a specific variable, as this example shows:

```
// io_get_function.cpp
// compile with: /EHsc
// Type up to 24 characters and a terminating character.
// Any remaining characters can be extracted later.
#include <iostream>
using namespace std;

int main()
{
    char line[25];
    cout << " Type a line terminated by carriage return\n>";
    cin.get( line, 25 );
    cout << line << endl;
}
```

Input

1234

Sample Output

1234

The getline

The `getline` member function is similar to the `get` function. Both functions allow a third argument that specifies the terminating character for input. The default value is the newline character. Both functions reserve one character for the required terminating character. However, `get` leaves the terminating character in the stream and `getline` removes the terminating character.

The following example specifies a terminating character for the input stream:

```
// getline_func.cpp
// compile with: /EHsc
#include <iostream>
using namespace std;

int main( )
{
    char line[100];
    cout << " Type a line terminated by 't'" << endl;
    cin.getline( line, 100, 't' );
    cout << line;
}
```

Input

test

The read

The `read` member function reads bytes from a file to a specified area of memory. The length argument determines the number of bytes read. If you do not include that argument, reading stops when the physical end of file is reached or, in the case of a text-mode file, when an embedded `EOF` character is read.

This example reads a binary record from a payroll file into a structure:

```

#include <fstream>
#include <iostream>
using namespace std;

int main()
{
    struct
    {
        double salary;
        char name[23];
    } employee;

    ifstream is( "payroll" );
    if( is ) { // ios::operator void*()
        is.read( (char *) &employee, sizeof( employee ) );
        cout << employee.name << ' ' << employee.salary << endl;
    }
    else {
        cout << "ERROR: Cannot open file 'payroll'." << endl;
    }
}

```

The program assumes that the data records are formatted exactly as specified by the structure with no terminating carriage-return or linefeed characters.

The seekg and tellg Functions

Input file streams keep an internal pointer to the position in the file where data is to be read next. You set this pointer with the `seekg` function, as shown here:

```

#include <iostream>
#include <fstream>
using namespace std;

int main( )
{
    char ch;

    ifstream tfile( "payroll" );
    if( tfile ) {
        tfile.seekg( 8 ); // Seek 8 bytes in (past salary)
        while ( tfile.good() ) { // EOF or failure stops the reading
            tfile.get( ch );
            if( !ch ) break; // quit on null
            cout << ch;
        }
    }
    else {
        cout << "ERROR: Cannot open file 'payroll'." << endl;
    }
}

```

To use `seekg` to implement record-oriented data management systems, multiply the fixed-length record size by the record number to obtain the byte position relative to the end of the file, and then use the `get` object to read the record.

The `tellg` member function returns the current file position for reading. This value is of type `streampos`, a `typedef` defined in `<iostream>`. The following example reads a file and displays messages showing the positions of spaces.

```

#include <fstream>
#include <iostream>
using namespace std;

int main( )
{
    char ch;
    ifstream tfile( "payroll" );
    if( tfile ) {
        while ( tfile.good( ) ) {
            streampos here = tfile.tellg();
            tfile.get( ch );
            if ( ch == ' ' )
                cout << "\nPosition " << here << " is a space";
        }
    }
    else {
        cout << "ERROR: Cannot open file 'payroll'." << endl;
    }
}

```

The close Function for Input Streams

The `close` member function closes the disk file associated with an input file stream and frees the operating system file handle. The `ifstream` destructor closes the file for you, but you can use the `close` function if you need to open another file for the same stream object.

See also

[Input Streams](#)

Overloading the >> Operator for Your Own Classes

10/31/2018 • 2 minutes to read • [Edit Online](#)

Input streams use the extraction (`>>`) operator for the standard types. You can write similar extraction operators for your own types; your success depends on using white space precisely.

Here is an example of an extraction operator for the `Date` class presented earlier:

```
istream& operator>> (istream& is, Date& dt)
{
    is>> dt.mo>> dt.da>> dt.yr;
    return is;
}
```

Input/Output Streams

10/31/2018 • 2 minutes to read • [Edit Online](#)

`basic_istream`, which is defined in the header file `<istream>`, is the class template for objects that handle both input and output character-based I/O streams.

There are two typedefs that define character-specific specializations of `basic_istream` and can help make code easier to read: `istream` (not to be confused with the header file `<istream>`) is an I/O stream that is based on `basic_istream<char>`; `wistream` is an I/O stream that is based on `basic_istream<wchar_t>`.

For more information, see [basic_istream Class](#), [istream](#), and [wistream](#).

Deriving from `basic_istream` is the class template `basic_fstream`, which is used to stream character data to and from files.

There also are typedefs that provide character-specific specializations of `basic_fstream`. They are `fstream`, which is a file I/O stream that is based on **char**, and `wfstream`, which is a file I/O stream that is based on **wchar_t**. For more information, see [basic_fstream Class](#), [fstream](#), and [wfstream](#). Using these typedefs requires the inclusion of the header file `<fstream>`.

NOTE

When a `basic_fstream` object is used to perform file I/O, although the underlying buffer contains separately designated positions for reading and writing, the current input and current output positions are tied together, and therefore, reading some data moves the output position.

The class template `basic_stringstream` and its common specialization, `stringstream`, are often used to work with I/O stream objects to insert and extract character data. For more information, see [basic_stringstream Class](#).

iostreams Conventions

10/31/2018 • 2 minutes to read • [Edit Online](#)

The iostreams headers support conversions between text and encoded forms, and input and output to external files:

<fstream>	<iomanip>
<ios>	<iosfwd>
<iostream>	<istream>
<ostream>	<sstream>
<streambuf>	<strstream>

The simplest use of iostreams requires only that you include the header [<iostream>](#). You can then extract values from [cin](#) or [wcin](#) to read the standard input. The rules for doing so are outlined in the description of the class [basic_istream Class](#). You can also insert values to [cout](#) or [wcout](#) to write the standard output. The rules for doing so are outlined in the description of the class [basic_ostream Class](#). Format control common to both extractors and insertors is managed by the class [basic_ios Class](#). Manipulating this format information in the guise of extracting and inserting objects is the province of several manipulators.

You can perform the same iostreams operations on files that you open by name, using the classes declared in [<fstream>](#). To convert between iostreams and objects of class [basic_string Class](#), use the classes declared in [<sstream>](#). To do the same with C strings, use the classes declared in [<strstream>](#).

The remaining headers provide support services, typically of direct interest to only the most advanced users of the iostreams classes.

Output Stream Manipulators with One Argument (int or long)

10/31/2018 • 2 minutes to read • [Edit Online](#)

The `iostream` class library provides a set of macros for creating parameterized manipulators. Manipulators with a single **int** or **long** argument are a special case. To create an output stream manipulator that accepts a single **int** or **long** argument (like `setw`), you must use the `_Smanip` macro, which is defined in `<iomanip>`. This example defines a `fillblank` manipulator that inserts a specified number of blanks into the stream:

Example

```
// output_stream_manip.cpp
// compile with: /GR /EHsc
#include <iostream>
#include <iomanip>
using namespace std;

void fb( ios_base& os, int l )
{
    ostream *pos = dynamic_cast<ostream*>(&os);
    if (pos)
    {
        for( int i=0; i < l; i++ )
            (*pos) << ' ';
    };
}

_Smanip<int>
__cdecl fillblank(int no)
{
    return (_Smanip<int>(&fb, no));
}

int main( )
{
    cout << "10 blanks follow" << fillblank( 10 ) << ".\n";
}
```

[Custom Manipulators with Arguments](#)

Other One-Argument Output Stream Manipulators

10/31/2018 • 2 minutes to read • [Edit Online](#)

The following example uses a class `money`, which is a **long** type. The `setpic` manipulator attaches a formatting "picture" string to the class that can be used by the overloaded stream insertion operator of the class `money`. The picture string is stored as a static variable in the `money` class rather than as data member of a stream class, so you do not have to derive a new output stream class.

Example

```

// one_arg_output.cpp
// compile with: /GR /EHsc
#include <iostream>
#include <iomanip>
#include <string>
using namespace std;

typedef char* charp;

class money
{
private:
    long value;
    static char *szCurrentPic;
public:
    money( long val ) { value = val; }
    friend ostream& operator << ( ostream& os, money m ) {
        // A more complete function would merge the picture
        // with the value rather than simply appending it
        os << m.value << '[' << money::szCurrentPic << ']' ;
        return os;
    }
    static void setpic( char* szPic ) {
        money::szCurrentPic = new char[strlen( szPic ) + 1];
        strcpy_s( money::szCurrentPic, strlen( szPic ) + 1, szPic );
    }
};

char *money::szCurrentPic; // Static pointer to picture

void fb( ios_base& os, char * somename )
{
    money::setpic(somename);
    /*
    ostream *pos = dynamic_cast<ostream*>(&os);
    if (pos)
    {
        for( int i=0; i < 1; i++ )
            (*pos) << ' ';
    }
    */
}

_Smanip<charp>
__cdecl setpic(char * somename)
{
    return (_Smanip<charp>(&fb, somename));
}

int main( )
{
    money amt = (long)35235.22;
    cout << setiosflags( ios::fixed );
    cout << setpic( "###,###,###.##" ) << "amount = " << amt << endl;
}

```

[Custom Manipulators with Arguments](#)

Regular Expressions (C++)

5/7/2019 • 24 minutes to read • [Edit Online](#)

The C++ standard library supports multiple regular expression grammars. This topic discusses the grammar variations available when using regular expressions.

Regular Expression Grammar

The regular expression grammar to use is specified by the use of one of the

`std::regex_constants::syntax_option_type` enumeration values. These regular expression grammars are defined in `std::regex_constants`:

- `ECMAScript`: This is closest to the grammar used by JavaScript and the .NET languages.
- `basic`: The POSIX basic regular expressions or BRE.
- `extended`: The POSIX extended regular expressions or ERE.
- `awk`: This is `extended`, but it has additional escapes for non-printing characters.
- `grep`: This is `basic`, but it also allows newline (`'\n'`) characters to separate alternations.
- `egrep`: This is `extended`, but it also allows newline characters to separate alternations.

By default, if no grammar is specified, `ECMAScript` is assumed. Only one grammar may be specified.

In addition to the grammar, several flags can be applied:

- `icase`: Ignore case when matching.
- `nosubs`: Ignore marked matches (that is, expressions in parentheses); no substitutions are stored.
- `optimize`: Make matching faster, at the possible expense of greater construction time.
- `collate`: Use locale-sensitive collation sequences (for example, ranges of the form `"[a-z]"`).

Zero or more flags may be combined with the grammar to specify the regular expression engine behavior. If only flags are specified, `ECMAScript` is assumed as the grammar.

Element

An element can be one of the following things:

- An *ordinary character* that matches the same character in the target sequence.
- A *wildcard character* `'.'` that matches any character in the target sequence except a newline.
- A *bracket expression* of the form `"[expr]"`, which matches a character or a collation element in the target sequence that is also in the set defined by the expression `expr`, or of the form `"[^ expr]"`, which matches a character or a collation element in the target sequence that is not in the set defined by the expression `expr`.

The expression `expr` can contain any combination of the following things:

- An individual character. Adds that character to the set defined by `expr`.
- A *character range* of the form `"ch1 - ch2"`. Adds the characters that are represented by values in the closed range `[ch1 , ch2]` to the set defined by `expr`.
- A *character class* of the form `"[: name :]"`. Adds the characters in the named class to the set defined by `expr`.

- An *equivalence class* of the form "[= `elt` =]". Adds the collating elements that are equivalent to `elt` to the set defined by `expr`.
- A *collating symbol* of the form "[. `elt` .]". Adds the collation element `elt` to the set defined by `expr`.
- An *anchor*. Anchor '^' matches the beginning of the target sequence; anchor '\$' matches the end of the target sequence.

A *capture group* of the form "(*subexpression*)", or "\ (*subexpression* \)" in `basic` and `grep`, which matches the sequence of characters in the target sequence that is matched by the pattern between the delimiters.

- An *identity escape* of the form "\ `k`", which matches the character `k` in the target sequence.

Examples:

- "a" matches the target sequence "a" but does not match the target sequences "B", "b", or "c".
- "." matches all the target sequences "a", "B", "b", and "c".
- "[b-z]" matches the target sequences "b" and "c" but does not match the target sequences "a" or "B".
- "[:lower:]" matches the target sequences "a", "b", and "c" but does not match the target sequence "B".
- "(a)" matches the target sequence "a" and associates capture group 1 with the subsequence "a", but does not match the target sequences "B", "b", or "c".

In `ECMAScript`, `basic`, and `grep`, an element can also be a *back reference* of the form "\ `dd`", where `dd` represents a decimal value N that matches a sequence of characters in the target sequence that is the same as the sequence of characters that is matched by the Nth *capture group*. For example, "(a)\1" matches the target sequence "aa" because the first (and only) capture group matches the initial sequence "a" and then the \1 matches the final sequence "a".

In `ECMAScript`, an element can also be one of the following things:

- A *non-capture group* of the form "(?: *subexpression*)". Matches the sequence of characters in the target sequence that is matched by the pattern between the delimiters.
- A limited *file format escape* of the form "\f", "\n", "\r", "\t", or "\v". These match a form feed, newline, carriage return, horizontal tab, and vertical tab, respectively, in the target sequence.
- A *positive assert* of the form "(= *subexpression*)". Matches the sequence of characters in the target sequence that is matched by the pattern between the delimiters, but does not change the match position in the target sequence.
- A *negative assert* of the form "(! *subexpression*)". Matches any sequence of characters in the target sequence that does not match the pattern between the delimiters, and does not change the match position in the target sequence.
- A *hexadecimal escape sequence* of the form "\x `hh`". Matches a character in the target sequence that is represented by the two hexadecimal digits `hh`.
- A *unicode escape sequence* of the form "\u `hhhh`". Matches a character in the target sequence that is represented by the four hexadecimal digits `hhhh`.
- A *control escape sequence* of the form "\c `k`". Matches the control character that is named by the character `k`.
- A *word boundary assert* of the form "\b". Matches when the current position in the target sequence is immediately after a *word boundary*.

- A *negative word boundary assert* of the form `"\B"`. Matches when the current position in the target sequence is not immediately after a *word boundary*.
- A *dsw character escape* of the form `"\d"`, `"\D"`, `"\s"`, `"\S"`, `"\w"`, `"\W"`. Provides a short name for a character class.

Examples:

- `"(?:a)"` matches the target sequence `"a"`, but `"(?:a)\1"` is invalid because there is no capture group 1.
- `"(=a)a"` matches the target sequence `"a"`. The positive assert matches the initial sequence `"a"` in the target sequence and the final `"a"` in the regular expression matches the initial sequence `"a"` in the target sequence.
- `"(!a)a"` does not match the target sequence `"a"`.
- `"a\b."` matches the target sequence `"a~"`, but does not match the target sequence `"ab"`.
- `"a\B."` matches the target sequence `"ab"`, but does not match the target sequence `"a~"`.

In `awk`, an element can also be one of the following things:

- A *file format escape* of the form `"\\"`, `"\a"`, `"\b"`, `"\f"`, `"\n"`, `"\r"`, `"\t"`, or `"\v"`. These match a backslash, alert, backspace, form feed, newline, carriage return, horizontal tab, and vertical tab, respectively, in the target sequence.
- An *octal escape sequence* of the form `"\ooo"`. Matches a character in the target sequence whose representation is the value represented by the one, two, or three octal digits `ooo`.

Repetition

Any element other than a *positive assert*, a *negative assert*, or an *anchor* can be followed by a repetition count. The most general kind of repetition count takes the form `"{min, max}"`, or `"{\min, max}"` in `basic` and `grep`. An element that is followed by this form of repetition count matches at least `min` successive occurrences and no more than `max` successive occurrences of a sequence that matches the element. For example, `"a{2,3}"` matches the target sequence `"aa"` and the target sequence `"aaa"`, but not the target sequence `"a"` or the target sequence `"aaaa"`.

A repetition count can also take one of the following forms:

- `"{min}"`, or `"{\min}"` in `basic` and `grep`. Equivalent to `"{min, min}"`.
- `"{min,}"`, or `"{\min,}"` in `basic` and `grep`. Equivalent to `"{min, unbounded}"`.
- `"*"`. Equivalent to `"{0, unbounded}"`.

Examples:

- `"a{2}"` matches the target sequence `"aa"` but not the target sequence `"a"` or the target sequence `"aaa"`.
- `"a{2,}"` matches the target sequence `"aa"`, the target sequence `"aaa"`, and so on, but does not match the target sequence `"a"`.
- `"a*"` matches the target sequence `""`, the target sequence `"a"`, the target sequence `"aa"`, and so on.

For all grammars except `basic` and `grep`, a repetition count can also take one of the following forms:

- `"?"`. Equivalent to `"{0,1}"`.
- `"+"`. Equivalent to `"{1, unbounded}"`.

Examples:

- `"a?"` matches the target sequence `""` and the target sequence `"a"`, but not the target sequence `"aa"`.

- "a+" matches the target sequence "a", the target sequence "aa", and so on, but not the target sequence "".

In `ECMAScript`, all the forms of repetition count can be followed by the character '?', which designates a *non-greedy repetition*.

Concatenation

Regular expression elements, with or without *repetition counts*, can be concatenated to form longer regular expressions. The resulting expression matches a target sequence that is a concatenation of the sequences that are matched by the individual elements. For example, "a{2,3}b" matches the target sequence "aab" and the target sequence "aaab", but does not match the target sequence "ab" or the target sequence "aaaab".

Alternation

In all regular expression grammars except `basic` and `grep`, a concatenated regular expression can be followed by the character '|' and another concatenated regular expression. Any number of concatenated regular expressions can be combined in this manner. The resulting expression matches any target sequence that matches one or more of the concatenated regular expressions.

When more than one of the concatenated regular expressions matches the target sequence, `ECMAScript` chooses the first of the concatenated regular expressions that matches the sequence as the match (*first match*); the other regular expression grammars choose the one that achieves the *longest match*. For example, "ab|cd" matches the target sequence "ab" and the target sequence "cd", but does not match the target sequence "abd" or the target sequence "acd".

In `grep` and `egrep`, a newline character ('\n') can be used to separate alternations.

Subexpression

In `basic` and `grep`, a subexpression is a concatenation. In the other regular expression grammars, a subexpression is an alternation.

Grammar Summary

The following table summarizes the features that are available in the various regular expression grammars:

ELEMENT	BASIC	EXTENDED	ECMASCRIPT	GREP	EGREP	AWK
alternation using ' '		+	+		+	+
alternation using '\n'				+	+	
anchor	+	+	+	+	+	+
back reference	+		+	+		
bracket expression	+	+	+	+	+	+
capture group using "()"		+	+		+	+
capture group using "\(\\""	+			+		

ELEMENT	BASIC	EXTENDED	ECMASCRIPT	GREP	EGREP	AWK
control escape sequence			+			
dsw character escape			+			
file format escape			+			+
hexadecimal escape sequence			+			
identity escape	+	+	+	+	+	+
negative assert			+			
negative word boundary assert			+			
non-capture group			+			
non-greedy repetition			+			
octal escape sequence						+
ordinary character	+	+	+	+	+	+
positive assert			+			
repetition using "{}"		+	+		+	+
repetition using "\\{}"	+			+		
repetition using '*'	+	+	+	+	+	+
repetition using '?' and '+'		+	+		+	+
unicode escape sequence			+			

ELEMENT	BASIC	EXTENDED	ECMASCRIPT	GREP	EGREP	AWK
wildcard character	+	+	+	+	+	+
word boundary assert			+			

Semantic Details

Anchor

An anchor matches a position in the target string, not a character. A '^' matches the beginning of the target string, and a '\$' matches the end of the target string.

Back Reference

A back reference is a backslash that is followed by a decimal value N. It matches the contents of the Nth *capture group*. The value of N must not be more than the number of capture groups that precede the back reference. In `basic` and `grep`, the value of N is determined by the decimal digit that follows the backslash. In `ECMAScript`, the value of N is determined by all the decimal digits that immediately follow the backslash. Therefore, in `basic` and `grep`, the value of N is never more than 9, even if the regular expression has more than nine capture groups. In `ECMAScript`, the value of N is unbounded.

Examples:

- `"((a+)(b+))(c+)\3"` matches the target sequence `"aabbbcbbb"`. The back reference `"\3"` matches the text in the third capture group, that is, the `"(b+)"`. It does not match the target sequence `"aabbbcb"`.
- `"(a)\2"` is not valid.
- `"(b((((((((a))))))))))\10"` has different meanings in `basic` and in `ECMAScript`. In `basic` the back reference is `"\1"`. The back reference matches the contents of the first capture group (that is, the one that begins with `"(b"` and ends with the final `)"` and comes before the back reference), and the final `'0'` matches the ordinary character `'0'`. In `ECMAScript`, the back reference is `"\10"`. It matches the tenth capture group, that is, the innermost one.

Bracket Expression

A bracket expression defines a set of characters and *collating elements*. When the bracket expression begins with the character '^' the match succeeds if no elements in the set match the current character in the target sequence. Otherwise, the match succeeds if any one of the elements in the set matches the current character in the target sequence.

The set of characters can be defined by listing any combination of *individual characters*, *character ranges*, *character classes*, *equivalence classes*, and *collating symbols*.

Capture Group

A capture group marks its contents as a single unit in the regular expression grammar and labels the target text that matches its contents. The label that is associated with each capture group is a number, which is determined by counting the opening parentheses that mark capture groups up to and including the opening parenthesis that marks the current capture group. In this implementation, the maximum number of capture groups is 31.

Examples:

- `"ab+"` matches the target sequence `"abb"`, but does not match the target sequence `"abab"`.
- `"(ab)+"` does not match the target sequence `"abb"`, but matches the target sequence `"abab"`.

- `"((a+)(b+))(c+)"` matches the target sequence "aabbbc" and associates capture group 1 with the subsequence "aabbb", capture group 2 with the subsequence "aa", capture group 3 with "bbb", and capture group 4 with the subsequence "c".

Character Class

A character class in a bracket expression adds all the characters in the named class to the character set that is defined by the bracket expression. To create a character class, use `"[:"` followed by the name of the class followed by `"]"`. Internally, names of character classes are recognized by calling `id = traits.lookup_classname`. A character `ch` belongs to such a class if `traits.isctype(ch, id)` returns true. The default `regex_traits` template supports the class names in the following table.

CLASS NAME	DESCRIPTION
"alnum"	lowercase letters, uppercase letters, and digits
"alpha"	lowercase letters and uppercase letters
"blank"	space or tab
"cntrl"	the <i>file format escape</i> characters
"digit"	digits
"graph"	lowercase letters, uppercase letters, digits, and punctuation
"lower"	lowercase letters
"print"	lowercase letters, uppercase letters, digits, punctuation, and space
"punct"	punctuation
"space"	space
"upper"	uppercase characters
"xdigit"	digits, 'a', 'b', 'c', 'd', 'e', 'f', 'A', 'B', 'C', 'D', 'E', 'F'
"d"	same as digit
"s"	same as space
"w"	same as alnum

Character Range

A character range in a bracket expression adds all the characters in the range to the character set that is defined by the bracket expression. To create a character range, put the character `'-'` between the first and last characters in the range. Doing this puts into the set all characters that have a numeric value that is more than or equal to the numeric value of the first character, and less than or equal to the numeric value of the last character. Notice that this set of added characters depends on the platform-specific representation of characters. If the character `'-'` occurs at the beginning or the end of a bracket expression, or as the first or last character of a character range, it represents itself.

Examples:

- "[0-7]" represents the set of characters { '0', '1', '2', '3', '4', '5', '6', '7' }. It matches the target sequences "0", "1", and so on, but not "a".
- On systems that use the ASCII character encoding, "[h-k]" represents the set of characters { 'h', 'i', 'j', 'k' }. It matches the target sequences "h", "i", and so on, but not "\x8A" or "0".
- On systems that use the EBCDIC character encoding, "[h-k]" represents the set of characters { 'h', 'i', '\x8A', '\x8B', '\x8C', '\x8D', '\x8E', '\x8F', '\x90', 'j', 'k' } ('h' is encoded as 0x88 and 'k' is encoded as 0x92). It matches the target sequences "h", "i", "\x8A", and so on, but not "0".
- "[-0-24]" represents the set of characters { '-', '0', '1', '2', '4' }.
- "[0-2-]" represents the set of characters { '0', '1', '2', '-' }.
- On systems that use the ASCII character encoding, "[+--]" represents the set of characters { '+', '-', '-' }.

However, when locale-sensitive ranges are used, the characters in a range are determined by the collation rules for the locale. Characters that collate after the first character in the definition of the range and before the last character in the definition of the range are in the set. The two end characters are also in the set.

Collating Element

A collating element is a multi-character sequence that is treated as a single character.

Collating Symbol

A collating symbol in a bracket expression adds a *collating element* to the set that is defined by the bracket expression. To create a collating symbol, use "[" followed by the collating element followed by "."].

Control Escape Sequence

A control escape sequence is a backslash followed by the letter 'c' followed by one of the letters 'a' through 'z' or 'A' through 'Z'. It matches the ASCII control character that is named by that letter. For example, "\ci" matches the target sequence "\x09", because <ctrl-i> has the value 0x09.

DSW Character Escape

A dsw character escape is a short name for a character class, as shown in the following table.

ESCAPE SEQUENCE	EQUIVALENT NAMED CLASS	DEFAULT NAMED CLASS
"\d"	"[[d:]]"	"[[digit:]]"
"\D"	"[^d:]"	"[^digit:]"
"\s"	"[[s:]]"	"[[space:]]"
"\S"	"[^s:]"	"[^space:]"
"\w"	"[[w:]]"	"[a-zA-Z0-9_]"*
"\W"	"[^w:]"	"[^a-zA-Z0-9_]"*

*ASCII character set

Equivalence Class

An equivalence class in a bracket expression adds all the characters and *collating elements* that are equivalent to the collating element in the equivalence class definition to the set that is defined by the bracket expression. To create an equivalence class, use "[=" followed by a collating element followed by "=]". Internally, two collating

elements `elt1` and `elt2` are equivalent if

```
traits.transform_primary(elt1.begin(), elt1.end()) == traits.transform_primary(elt2.begin(), elt2.end()) .
```

File Format Escape

A file format escape consists of the usual C language character escape sequences, `"\\", "\a", "\b", "\f", "\n", "\r", "\t", "\v"`. These have the usual meanings, that is, backslash, alert, backspace, form feed, newline, carriage return, horizontal tab, and vertical tab, respectively. In `ECMAScript`, `"\a"` and `"\b"` are not allowed. (`"\\"` is allowed, but it is an identity escape, not a file format escape).

Hexadecimal Escape Sequence

A hexadecimal escape sequence is a backslash followed by the letter 'x' followed by two hexadecimal digits (0-9a-fA-F). It matches a character in the target sequence that has the value that is specified by the two digits. For example, `"\x41"` matches the target sequence "A" when ASCII character encoding is used.

Identity Escape

An identity escape is a backslash followed by a single character. It matches that character. It is required when the character has a special meaning; by using the identity escape, the special meaning is removed. For example:

- `"a*"` matches the target sequence "aaa", but does not match the target sequence "a*".
- `"a\""` does not match the target sequence "aaa", but matches the target sequence "a*".

The set of characters that are allowed in an identity escape depends on the regular expression grammar, as shown in the following table.

GRAMMAR	ALLOWED IDENTITY ESCAPE CHARACTERS
<code>basic</code> , <code>grep</code>	{ <code>'(,), {, }, ^, \, *, ^, \$'</code> }
<code>extended</code> , <code>egrep</code>	{ <code>'(,), {, }, ^, \, *, ^, \$, +, ?, '</code> }
<code>awk</code>	<code>extended</code> plus <code>'" , /'</code> }
<code>ECMAScript</code>	All characters except those that can be part of an identifier. Typically, this includes letters, digits, <code>'\$, _'</code> , and unicode escape sequences. For more information, see the ECMAScript Language Specification.

Individual Character

An individual character in a bracket expression adds that character to the character set that is defined by the bracket expression. Anywhere in a bracket expression except at the beginning, a `'^'` represents itself.

Examples:

- `"[abc]"` matches the target sequences "a", "b", and "c", but not the sequence "d".
- `"[^abc]"` matches the target sequence "d", but not the target sequences "a", "b", or "c".
- `"[a^bc]"` matches the target sequences "a", "b", "c", and "^", but not the target sequence "d".

In all regular expression grammars except `ECMAScript`, if a `']'` is the first character that follows the opening `'['` or is the first character that follows an initial `'^'`, it represents itself.

Examples:

- `"[a]"` is invalid because there is no `']'` to end the bracket expression.
- `"[]abc]"` matches the target sequences "a", "b", "c", and "]", but not the target sequence "d".

- "[^]abc]" matches the target sequence "d", but not the target sequences "a", "b", "c", or "]"

In `ECMAScript`, use `\]` to represent the character `]` in a bracket expression.

Examples:

- "[a]" matches the target sequence "a" because the bracket expression is empty.
- "[\]abc]" matches the target sequences "a", "b", "c", and "]" but not the target sequence "d".

Negative Assert

A negative assert matches anything but its contents. It does not consume any characters in the target sequence. For example, `!(aa)(a*)` matches the target sequence "a" and associates capture group 1 with the subsequence "a". It does not match the target sequence "aa" or the target sequence "aaa".

Negative Word Boundary Assert

A negative word boundary assert matches if the current position in the target string is not immediately after a *word boundary*.

Non-capture Group

A non-capture group marks its contents as a single unit in the regular expression grammar, but does not label the target text. For example, `(a)(?:b)*(c)` matches the target text "abbc" and associates capture group 1 with the subsequence "a" and capture group 2 with the subsequence "c".

Non-greedy Repetition

A non-greedy repetition consumes the shortest subsequence of the target sequence that matches the pattern. A greedy repetition consumes the longest. For example, `(a+)(a*b)` matches the target sequence "aaab". When a non-greedy repetition is used, it associates capture group 1 with the subsequence "a" at the beginning of the target sequence and capture group 2 with the subsequence "aab" at the end of the target sequence. When a greedy match is used, it associates capture group 1 with the subsequence "aaa" and capture group 2 with the subsequence "b".

Octal Escape Sequence

An octal escape sequence is a backslash followed by one, two, or three octal digits (0-7). It matches a character in the target sequence that has the value that is specified by those digits. If all the digits are '0', the sequence is invalid. For example, `\101` matches the target sequence "A" when ASCII character encoding is used.

Ordinary Character

An ordinary character is any valid character that does not have a special meaning in the current grammar.

In `ECMAScript`, the following characters have special meanings:

- `^ $ \ . * + ? () [] { } |`

In `basic` and `grep`, the following characters have special meanings:

- `.[\`

Also in `basic` and `grep`, the following characters have special meanings when they are used in a particular context:

- `*` has a special meaning in all cases except when it is the first character in a regular expression or the first character that follows an initial `^` in a regular expression, or when it is the first character of a capture group or the first character that follows an initial `^` in a capture group.
- `^` has a special meaning when it is the first character of a regular expression.
- `$` has a special meaning when it is the last character of a regular expression.

In `extended`, `egrep`, and `awk`, the following characters have special meanings:

- `.[\(*+?{|`

Also in `extended`, `egrep`, and `awk`, the following characters have special meanings when they are used in a particular context.

- `'` has a special meaning when it matches a preceding `'`.
- `^` has a special meaning when it is the first character of a regular expression.
- `$` has a special meaning when it is the last character of a regular expression.

An ordinary character matches the same character in the target sequence. By default, this means that the match succeeds if the two characters are represented by the same value. In a case-insensitive match, two characters `ch0` and `ch1` match if `traits.translate_nocase(ch0) == traits.translate_nocase(ch1)`. In a locale-sensitive match, two characters `ch0` and `ch1` match if `traits.translate(ch0) == traits.translate(ch1)`.

Positive Assert

A positive assert matches its contents, but does not consume any characters in the target sequence.

Examples:

- `"(=aa)(a*)"` matches the target sequence "aaaa" and associates capture group 1 with the subsequence "aaaa".
- `"(aa)(a*)"` matches the target sequence "aaaa" and associates capture group 1 with the subsequence "aa" at the beginning of the target sequence and capture group 2 with the subsequence "aa" at the end of the target sequence.
- `"(=aa)(a)|(a)"` matches the target sequence "a" and associates capture group 1 with an empty sequence (because the positive assert failed) and capture group 2 with the subsequence "a". It also matches the target sequence "aa" and associates capture group 1 with the subsequence "aa" and capture group 2 with an empty sequence.

Unicode Escape Sequence

A unicode escape sequence is a backslash followed by the letter 'u' followed by four hexadecimal digits (0-9a-fA-F). It matches a character in the target sequence that has the value that is specified by the four digits. For example, `"\u0041"` matches the target sequence "A" when ASCII character encoding is used.

Wildcard Character

A wildcard character matches any character in the target expression except a newline.

Word Boundary

A word boundary occurs in the following situations:

- The current character is at the beginning of the target sequence and is one of the word characters `A-Za-z0-9_.`
- The current character position is past the end of the target sequence and the last character in the target sequence is one of the word characters.
- The current character is one of the word characters and the preceding character is not.
- The current character is not one of the word characters and the preceding character is.

Word Boundary Assert

A word boundary assert matches when the current position in the target string is immediately after a *word boundary*.

Matching and Searching

For a regular expression to match a target sequence, the entire regular expression must match the entire target sequence. For example, the regular expression "bcd" matches the target sequence "bcd" but does not match the target sequence "abcd" nor the target sequence "bcde".

For a regular expression search to succeed, there must be a subsequence somewhere in the target sequence that matches the regular expression. The search typically finds the left-most matching subsequence.

Examples:

- A search for the regular expression "bcd" in the target sequence "bcd" succeeds and matches the entire sequence. The same search in the target sequence "abcd" also succeeds and matches the last three characters. The same search in the target sequence "bcde" also succeeds and matches the first three characters.
- A search for the regular expression "bcd" in the target sequence "bcdbcd" succeeds and matches the first three characters.

If there is more than one subsequence that matches at some location in the target sequence, there are two ways to choose the matching pattern. *First match* chooses the subsequence that was found first when the regular expression is matched. *Longest match* chooses the longest subsequence from the ones that match at that location. If there is more than one subsequence that has the maximal length, longest match chooses the one that was found first. For example, when first match is used, a search for the regular expression "b|bc" in the target sequence "abcd" matches the subsequence "b" because the left-hand term of the alternation matches that subsequence; therefore, first match does not try the right-hand term of the alternation. When longest match is used, the same search matches "bc" because "bc" is longer than "b".

A partial match succeeds if the match reaches the end of the target sequence without failing, even if it has not reached the end of the regular expression. Therefore, after a partial match succeeds, appending characters to the target sequence could cause a later partial match to fail. However, after a partial match fails, appending characters to the target sequence cannot cause a later partial match to succeed. For example, with a partial match, "ab" matches the target sequence "a" but not "ac".

Format Flags

ECMAScript FORMAT RULES	SED FORMAT RULES	REPLACEMENT TEXT
"\$&"	"&"	The character sequence that matches the entire regular expression (<code>[match[0].first, match[0].second)</code>)
"\$"		"\$"
	"\&"	"&"
"\$`" (dollar sign followed by back quote)		The character sequence that precedes the subsequence that matches the regular expression (<code>[match.prefix().first, match.prefix().second)</code>)

ECMAScript Format Rules	SED Format Rules	Replacement Text
"\$" (dollar sign followed by forward quote)		<p>The character sequence that follows the subsequence that matches the regular expression (</p> <pre>[match.suffix().first, match.suffix().second]</pre> <p>)</p>
"\$n"	"\n"	<p>The character sequence that matches the capture group at position <code>n</code>, where <code>n</code> is a number between 0 and 9 (</p> <pre>[match[n].first, match[n].second]</pre> <p>)</p>
	"\\n"	"\n"
"\$nn"		<p>The character sequence that matches the capture group at position <code>nn</code>, where <code>nn</code> is a number between 10 and 99 (</p> <pre>[match[nn].first, match[nn].second]</pre> <p>)</p>

File System Navigation

10/31/2018 • 5 minutes to read • [Edit Online](#)

The `<filesystem>` header implements the C++ File System Technical Specification ISO/IEC TS 18822:2015 (Final draft: [ISO/IEC JTC 1/SC 22/WG 21 N4100](#)) and has types and functions that enable you to write platform-independent code for navigating the file system. Because it is cross-platform, it contains APIs that are not relevant for Windows systems. For example, this means that `is_fifo(const path&)` always returns **false** on Windows.

Overview

Use the `<filesystem>` APIs for the following tasks:

- iterate over files and directories under a specified path
- get information about files including the time created, size, extension, and root directory
- compose, decompose, and compare paths
- create, copy and delete directories
- copy and delete files

For more information about File IO using the Standard Library, see [iostream Programming](#).

Paths

Constructing and composing paths

Paths in Windows (since XP) are stored natively in Unicode. The `path` class automatically performs all necessary string conversions. It accepts arguments of both wide and narrow character arrays, as well as `std::string` and `std::wstring` types formatted as UTF8 or UTF16. The `path` class also automatically normalizes path separators. You can use a single forward slash as a directory separator in constructor arguments. This enables you to use the same strings to store paths in both Windows and UNIX environments:

```
path pathToDisplay(L"/FileSystemTest/SubDir3");    // OK!
path pathToDisplay2(L"\\FileSystemTest\\SubDir3"); // Still OK as always
path pathToDisplay3(LR"(\FileSystemTest\SubDir3)"); // Raw string literals are OK, too.
```

To concatenate two paths, you can use the overloaded `/` and `/=` operators, which are analogous to the `+` and `+=` operators on `std::string` and `std::wstring`. The `path` object will conveniently supply the separators if you don't.

```
path myRoot("C:/FileSystemTest"); // no trailing separator, no problem!
myRoot /= path("SubDirRoot");     // C:/FileSystemTest/SubDirRoot
```

Examining paths

The `path` class has several methods that return information about various parts of the path itself, as distinct from the file system entity it might refer to. You can get the root, the relative path, the file name, the file extension, and more. You can iterate over a path object to examine all the folders in the hierarchy. The following example shows how to iterate over a path (not the directory it refers to), and to retrieve information about its parts.

```

// filesystem_path_example.cpp
// compile by using: /EHsc
#include <string>
#include <iostream>
#include <sstream>
#include <filesystem>

using namespace std;
using namespace std::experimental::filesystem;

wstring DisplayPathInfo()
{
    // This path may or may not refer to an existing file. We are
    // examining this path string, not file system objects.
    path pathToDisplay(L"C:/FileSystemTest/SubDir3/SubDirLevel2/File2.txt ");

    wstringstream wos;
    int i = 0;
    wos << L"Displaying path info for: " << pathToDisplay << endl;
    for (path::iterator itr = pathToDisplay.begin(); itr != pathToDisplay.end(); ++itr)
    {
        wos << L"path part: " << i++ << L" = " << *itr << endl;
    }

    wos << L"root_name() = " << pathToDisplay.root_name() << endl
        << L"root_path() = " << pathToDisplay.root_path() << endl
        << L"relative_path() = " << pathToDisplay.relative_path() << endl
        << L"parent_path() = " << pathToDisplay.parent_path() << endl
        << L"filename() = " << pathToDisplay.filename() << endl
        << L"stem() = " << pathToDisplay.stem() << endl
        << L"extension() = " << pathToDisplay.extension() << endl;

    return wos.str();
}

void main(int argc, char* argv[])
{
    wcout << DisplayPathInfo() << endl;
    // wcout << ComparePaths() << endl; // see following example
    wcout << endl << L"Press Enter to exit" << endl;
    wstring input;
    getline(wcin, input);
}

```

The code produces this output:

```

Displaying path info for: C:\FileSystemTest\SubDir3\SubDirLevel2\File2.txt
path part: 0 = C:
path part: 1 = \
path part: 2 = FileSystemTest
path part: 3 = SubDir3
path part: 4 = SubDirLevel2
path part: 5 = File2.txt
root_name() = C:
root_path() = C:\
relative_path() = FileSystemTest\SubDir3\SubDirLevel2\File2.txt
parent_path() = C:\FileSystemTest\SubDir3\SubDirLevel2
filename() = File2.txt
stem() = File2
extension() = .txt

```

Comparing paths

The `path` class overloads the same comparison operators as `std::string` and `std::wstring`. When you compare two paths, you are performing a string comparison after the separators have been normalized. If a

trailing slash (or backslash) is missing it is not added and affects the comparison. The following example demonstrates how path values compare:

```
wstring ComparePaths()
{
    path p0(L"C:/Documents");           // no trailing separator
    path p1(L"C:/Documents/");          // p0 < p1
    path p2(L"C:/Documents/2013/");     // p1 < p2
    path p3(L"C:/Documents/2013/Reports/"); // p2 < p3
    path p4(L"C:/Documents/2014/");     // p3 < p4
    path p5(L"D:/Documents/2013/Reports/"); // p4 < p5

    wstringstream wos;
    wos << boolalpha <<
        p0.wstring() << L" < " << p1.wstring() << L": " << (p0 < p1) << endl <<
        p1.wstring() << L" < " << p2.wstring() << L": " << (p1 < p2) << endl <<
        p2.wstring() << L" < " << p3.wstring() << L": " << (p2 < p3) << endl <<
        p3.wstring() << L" < " << p4.wstring() << L": " << (p3 < p4) << endl <<
        p4.wstring() << L" < " << p5.wstring() << L": " << (p4 < p5) << endl;
    return wos.str();
}
```

```
C:\Documents < C:\Documents\: true
C:\Documents\ < C:\Documents\2013\: true
C:\Documents\2013\ < C:\Documents\2013\Reports\: true
C:\Documents\2013\Reports\ < C:\Documents\2014\: true
C:\Documents\2014\ < D:\Documents\2013\Reports\: true
```

To run this code, paste it into the full example above before `main` and uncomment the line that calls it in main.

Converting between path and string types

A `path` object is implicitly convertible to `std::wstring` or `std::string`. This means you can pass a path to functions such as [wofstream::open](#), as shown in this example:

```

// filesystem_path_conversion.cpp
// compile by using: /EHsc
#include <string>
#include <iostream>
#include <fstream>
#include <filesystem>

using namespace std;
using namespace std::experimental::filesystem;

void main(int argc, char* argv[])
{
    wchar_t* p = L"C:/Users/Public/Documents";
    path filePath(p);

    filePath /= L"NewFile.txt";

    // Open, write to, and close the file.
    wofstream writeFile(filePath, ios::out); // implicit conversion
    writeFile << L"Lorem ipsum\nDolor sit amet";
    writeFile.close();

    // Open, read, and close the file.
    wifstream readFile;
    wstring line;
    readFile.open(filePath); // implicit conversions
    wcout << L"File " << filePath << L" contains:" << endl;
    while (readFile.good())
    {
        getline(readFile, line);
        wcout << line << endl;
    }
    readFile.close();

    wcout << endl << L"Press Enter to exit" << endl;
    wstring input;
    getline(wcin, input);
}

```

```

File C:\Users\Public\Documents\NewFile.txt contains:
Lorem ipsum
Dolor sit amet

Press Enter to exit

```

Iterating directories and files

The `<filesystem>` header provides the [directory_iterator](#) type to iterate over single directories, and the [recursive_directory_iterator](#) class to iterate recursively over a directory and its subdirectories. After you construct an iterator by passing it a `path` object, the iterator points to the first `directory_entry` in the path. Create the end iterator by calling the default constructor.

When iterating through a directory, there are several kinds of items you might encounter, including but not limited to directories, files, symbolic links, and socket files. The `directory_iterator` returns its items as [directory_entry](#) objects.
